

# SALTSTACK

## Salt Documentation

*Release 2015.5.10*

**SaltStack, Inc.**

April 18, 2016

<b>1</b>	<b>Introduction to Salt</b>	<b>1</b>
1.1	The 30 second summary . . . . .	1
1.2	Simplicity . . . . .	1
1.3	Parallel execution . . . . .	1
1.4	Building on proven technology . . . . .	2
1.5	Python client interface . . . . .	2
1.6	Fast, flexible, scalable . . . . .	2
1.7	Open . . . . .	2
1.8	Salt Community . . . . .	2
1.9	Mailing List . . . . .	2
1.10	IRC . . . . .	3
1.11	Follow on Github . . . . .	3
1.12	Blogs . . . . .	3
1.13	Example Salt States . . . . .	3
1.14	Follow on ohloh . . . . .	3
1.15	Other community links . . . . .	4
1.16	Hack the Source . . . . .	4
<b>2</b>	<b>Installation</b>	<b>5</b>
2.1	Quick Install . . . . .	5
2.2	Platform-specific Installation Instructions . . . . .	5
2.3	Dependencies . . . . .	26
2.4	Optional Dependencies . . . . .	27
2.5	Upgrading Salt . . . . .	27
<b>3</b>	<b>Tutorials</b>	<b>29</b>
3.1	Introduction . . . . .	29
3.2	Basics . . . . .	31
3.3	States . . . . .	40
3.4	Advanced Topics . . . . .	70
3.5	Salt Virt . . . . .	126
3.6	Halite . . . . .	131
3.7	LXC . . . . .	134
3.8	Using Salt at scale . . . . .	134
<b>4</b>	<b>Targeting Minions</b>	<b>139</b>
4.1	Matching the minion id . . . . .	139
4.2	Grains . . . . .	140

4.3	Targeting with Pillar . . . . .	144
4.4	Subnet/IP Address Matching . . . . .	144
4.5	Compound matchers . . . . .	144
4.6	Node groups . . . . .	145
4.7	Batch Size . . . . .	146
4.8	SECO Range . . . . .	146
<b>5</b>	<b>Storing Static Data in the Pillar . . . . .</b>	<b>149</b>
5.1	Declaring the Master Pillar . . . . .	149
5.2	Pillar namespace flattened . . . . .	150
5.3	Pillar Namespace Merges . . . . .	151
5.4	Including Other Pillars . . . . .	152
5.5	Viewing Minion Pillar . . . . .	152
5.6	Pillar ``get" Function . . . . .	152
5.7	Refreshing Pillar Data . . . . .	153
5.8	Set Pillar Data at the Command Line . . . . .	153
5.9	Master Config In Pillar . . . . .	153
5.10	Master Provided Pillar Error . . . . .	153
<b>6</b>	<b>Reactor System . . . . .</b>	<b>155</b>
6.1	Event System . . . . .	155
6.2	Mapping Events to Reactor SLS Files . . . . .	155
6.3	Fire an event . . . . .	156
6.4	Knowing what event is being fired . . . . .	156
6.5	Debugging the Reactor . . . . .	157
6.6	Understanding the Structure of Reactor Formulas . . . . .	157
6.7	A Complete Example . . . . .	160
6.8	Syncing Custom Types on Minion Start . . . . .	161
<b>7</b>	<b>The Salt Mine . . . . .</b>	<b>163</b>
7.1	Mine vs Grains . . . . .	163
7.2	Mine Functions . . . . .	163
7.3	Mine Interval . . . . .	164
7.4	Mine in Salt-SSH . . . . .	164
7.5	Example . . . . .	164
<b>8</b>	<b>External Authentication System . . . . .</b>	<b>167</b>
8.1	Access Control System . . . . .	167
8.2	Tokens . . . . .	168
8.3	OpenLDAP and similar systems . . . . .	168
8.4	Active Directory . . . . .	170
<b>9</b>	<b>Access Control System . . . . .</b>	<b>171</b>
<b>10</b>	<b>Job Management . . . . .</b>	<b>173</b>
10.1	The Minion proc System . . . . .	173
10.2	Functions in the saltutil Module . . . . .	173
10.3	The jobs Runner . . . . .	173
10.4	Scheduling Jobs . . . . .	174
10.5	States . . . . .	176
10.6	Highstates . . . . .	176
10.7	Runners . . . . .	177
10.8	Scheduler With Returner . . . . .	177
<b>11</b>	<b>Managing the Job Cache . . . . .</b>	<b>181</b>

11.1	Default Job Cache . . . . .	181
11.2	Additional Job Cache Options . . . . .	181
<b>12</b>	<b>Storing Job Results in an External System</b>	<b>183</b>
12.1	External Job Cache - Minion-Side Returner . . . . .	183
12.2	Master Job Cache - Master-Side Returner . . . . .	184
12.3	Configure an External or Master Job Cache . . . . .	184
<b>13</b>	<b>Storing Data in Other Databases</b>	<b>187</b>
13.1	SDB Configuration . . . . .	187
13.2	SDB URIs . . . . .	187
13.3	Writing SDB Modules . . . . .	188
<b>14</b>	<b>Salt Event System</b>	<b>189</b>
14.1	Event types . . . . .	189
14.2	Listening for Events . . . . .	193
14.3	Firing Events . . . . .	194
14.4	Firing Events from Python . . . . .	195
<b>15</b>	<b>Beacons</b>	<b>197</b>
15.1	Configuring Beacons . . . . .	197
15.2	Beacon Example . . . . .	198
15.3	Writing Beacon Plugins . . . . .	200
<b>16</b>	<b>Running Custom Master Processes</b>	<b>201</b>
16.1	Example Configuration . . . . .	201
16.2	Example Process Class . . . . .	201
<b>17</b>	<b>High Availability Features in Salt</b>	<b>203</b>
17.1	Multimaster . . . . .	203
17.2	Multimaster with Failover . . . . .	203
17.3	Syndic . . . . .	204
17.4	Syndic with Multimaster . . . . .	204
<b>18</b>	<b>Salt Syndic</b>	<b>205</b>
18.1	Configuring the Syndic . . . . .	205
18.2	Configuring the Syndic with Multimaster . . . . .	206
18.3	Running the Syndic . . . . .	206

## Introduction to Salt

---

We're not just talking about NaCl.

### 1.1 The 30 second summary

Salt is:

- a configuration management system, capable of maintaining remote nodes in defined states (for example, ensuring that specific packages are installed and specific services are running)
- a distributed remote execution system used to execute commands and query data on remote nodes, either individually or by arbitrary selection criteria

It was developed in order to bring the best solutions found in the world of remote execution together and make them better, faster, and more malleable. Salt accomplishes this through its ability to handle large loads of information, and not just dozens but hundreds and even thousands of individual servers quickly through a simple and manageable interface.

### 1.2 Simplicity

Providing versatility between massive scale deployments and smaller systems may seem daunting, but Salt is very simple to set up and maintain, regardless of the size of the project. The architecture of Salt is designed to work with any number of servers, from a handful of local network systems to international deployments across different data centers. The topology is a simple server/client model with the needed functionality built into a single set of daemons. While the default configuration will work with little to no modification, Salt can be fine tuned to meet specific needs.

### 1.3 Parallel execution

The core functions of Salt:

- enable commands to remote systems to be called in parallel rather than serially
- use a secure and encrypted protocol
- use the smallest and fastest network payloads possible
- provide a simple programming interface

Salt also introduces more granular controls to the realm of remote execution, allowing systems to be targeted not just by hostname, but also by system properties.

## 1.4 Building on proven technology

Salt takes advantage of a number of technologies and techniques. The networking layer is built with the excellent [ZeroMQ](#) networking library, so the Salt daemon includes a viable and transparent AMQ broker. Salt uses public keys for authentication with the master daemon, then uses faster [AES](#) encryption for payload communication; authentication and encryption are integral to Salt. Salt takes advantage of communication via [msgpack](#), enabling fast and light network traffic.

## 1.5 Python client interface

In order to allow for simple expansion, Salt execution routines can be written as plain Python modules. The data collected from Salt executions can be sent back to the master server, or to any arbitrary program. Salt can be called from a simple Python API, or from the command line, so that Salt can be used to execute one-off commands as well as operate as an integral part of a larger application.

## 1.6 Fast, flexible, scalable

The result is a system that can execute commands at high speed on target server groups ranging from one to very many servers. Salt is very fast, easy to set up, amazingly malleable and provides a single remote execution architecture that can manage the diverse requirements of any number of servers. The Salt infrastructure brings together the best of the remote execution world, amplifies its capabilities and expands its range, resulting in a system that is as versatile as it is practical, suitable for any network.

## 1.7 Open

Salt is developed under the [Apache 2.0 license](#), and can be used for open and proprietary projects. Please submit your expansions back to the Salt project so that we can all benefit together as Salt grows. Please feel free to sprinkle Salt around your systems and let the deliciousness come forth.

## 1.8 Salt Community

Join the Salt!

There are many ways to participate in and communicate with the Salt community.

Salt has an active IRC channel and a mailing list.

## 1.9 Mailing List

Join the [salt-users mailing list](#). It is the best place to ask questions about Salt and see whats going on with Salt development! The Salt mailing list is hosted by Google Groups. It is open to new members.

<https://groups.google.com/forum/#!forum/salt-users>

There is also a low-traffic list used to announce new releases called [salt-announce](#)

<https://groups.google.com/forum/#!forum/salt-announce>

## 1.10 IRC

The `#salt` IRC channel is hosted on the popular [Freenode](#) network. You can use the [Freenode webchat client](#) right from your browser.

Logs of the IRC channel activity are being collected courtesy of Moritz Lenz.

If you wish to discuss the development of Salt itself join us in `#salt-devel`.

## 1.11 Follow on Github

The Salt code is developed via Github. Follow Salt for constant updates on what is happening in Salt development:

<https://github.com/saltstack/salt>

## 1.12 Blogs

SaltStack Inc. keeps a [blog](#) with recent news and advancements:

<http://www.saltstack.com/blog/>

Thomas Hatch also shares news and thoughts on Salt and related projects in his personal blog [The Red45](#):

<http://red45.wordpress.com/>

## 1.13 Example Salt States

The official `salt-states` repository is: <https://github.com/saltstack/salt-states>

A few examples of salt states from the community:

- <https://github.com/blast-hardcheese/blast-salt-states>
- <https://github.com/kevingranade/kevingranade-salt-state>
- <https://github.com/uggedal/states>
- <https://github.com/mattmcclean/salt-openstack/tree/master/salt>
- <https://github.com/rentalita/ubuntu-setup/>
- <https://github.com/brutasse/states>
- <https://github.com/bclermont/states>
- <https://github.com/pcrews/salt-data>

## 1.14 Follow on ohloh

<https://www.ohloh.net/p/salt>

## 1.15 Other community links

- [Salt Stack Inc.](#)
- [Subreddit](#)

- [YouTube](#)
- [Facebook](#)
- [Twitter](#)
- [Wikipedia page](#)

## 1.16 Hack the Source

If you want to get involved with the development of source code or the documentation efforts, please review the [hacking section](#)!

---

## Installation

---

### See also:

Installing Salt for development and contributing to the project.

## 2.1 Quick Install

On most distributions, you can set up a **Salt Minion** with the [Salt Bootstrap](#).

## 2.2 Platform-specific Installation Instructions

These guides go into detail how to install Salt on a given platform.

### 2.2.1 Arch Linux

#### Installation

Salt (stable) is currently available via the Arch Linux Official repositories. There are currently `-git` packages available in the Arch User repositories (AUR) as well.

#### Stable Release

Install Salt stable releases from the Arch Linux Official repositories as follows:

```
pacman -S salt-zmq
```

To install Salt stable releases using the RAET protocol, use the following:

```
pacman -S salt-raet
```

#### Tracking develop

To install the bleeding edge version of Salt (**may include bugs!**), use the `-git` package. Installing the `-git` package as follows:

```
wget https://aur.archlinux.org/packages/sa/salt-git/salt-git.tar.gz
tar xf salt-git.tar.gz
cd salt-git/
makepkg -is
```

**Note:** yaourt

If a tool such as [Yaourt](#) is used, the dependencies will be gathered and built automatically.

The command to install salt using the yaourt tool is:

```
yaourt salt-git
```

---

## Post-installation tasks

### systemd

Activate the Salt Master and/or Minion via `systemctl` as follows:

```
systemctl enable salt-master.service
systemctl enable salt-minion.service
```

### Start the Master

Once you've completed all of these steps you're ready to start your Salt Master. You should be able to start your Salt Master now using the command seen here:

```
systemctl start salt-master
```

Now go to the [Configuring Salt](#) page.

## 2.2.2 Debian Installation

Currently the latest packages for Debian Old Stable, Stable, and Unstable (Squeeze, Wheezy, and Sid) are published in our ([saltstack.com](#)) Debian repository.

### Configure Apt

#### Squeeze (Old Stable)

For squeeze, you will need to enable the Debian backports repository as well as the [debian.saltstack.com](#) repository. To do so, add the following to `/etc/apt/sources.list` or a file in `/etc/apt/sources.list.d`:

```
deb http://debian.saltstack.com/debian squeeze-saltstack main
deb http://backports.debian.org/debian-backports squeeze-backports main contrib non-free
```

#### Wheezy (Stable)

For wheezy, the following line is needed in either `/etc/apt/sources.list` or a file in `/etc/apt/sources.list.d`:

```
deb http://debian.saltstack.com/debian wheezy-saltstack main
```

### Jessie (Testing)

For jessie, the following line is needed in either `/etc/apt/sources.list` or a file in `/etc/apt/sources.list.d`:

```
deb http://debian.saltstack.com/debian jessie-saltstack main
```

### Sid (Unstable)

For sid, the following line is needed in either `/etc/apt/sources.list` or a file in `/etc/apt/sources.list.d`:

```
deb http://debian.saltstack.com/debian unstable main
```

### Import the repository key.

You will need to import the key used for signing.

```
wget -q -O- "http://debian.saltstack.com/debian-salt-team-joehealy.gpg.key" | apt-key add -
```

**Note:** You can optionally verify the key integrity with `sha512sum` using the public key signature shown here. E.g:

```
echo "b702969447140d5553e31e9701be13ca11cc0a7ed5fe2b30acb8491567560ee62f834772b5095d735dfcecb2384a5c"
```

### Update the package database

```
apt-get update
```

### Install packages

Install the Salt master, minion, or syndic from the repository with the `apt-get` command. These examples each install one daemon, but more than one package name may be given at a time:

```
apt-get install salt-master
```

```
apt-get install salt-minion
```

```
apt-get install salt-syndic
```

### Post-installation tasks

Now, go to the [Configuring Salt](#) page.

### Notes

1. These packages will be backported from the packages intended to be uploaded into Debian unstable. This means that the packages will be built for unstable first and then backported over the next day or so.

2. These packages will be tracking the released versions of salt rather than maintaining a stable fixed feature set. If a fixed version is what you desire, then either pinning or manual installation may be more appropriate for you.
3. The version numbering and backporting process should provide clean upgrade paths between Debian versions.

If you have any questions regarding these, please email the mailing list or look for joeHH on IRC.

### 2.2.3 Fedora

Beginning with version 0.9.4, Salt has been available in the primary Fedora repositories and EPEL. It is installable using yum. Fedora will have more up to date versions of Salt than other members of the Red Hat family, which makes it a great place to help improve Salt!

**WARNING:** Fedora 19 comes with systemd 204. Systemd has known bugs fixed in later revisions that prevent the salt-master from starting reliably or opening the network connections that it needs to. It's not likely that a salt-master will start or run reliably on any distribution that uses systemd version 204 or earlier. Running salt-minions should be OK.

#### Installation

Salt can be installed using yum and is available in the standard Fedora repositories.

#### Stable Release

Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

```
yum install salt-master
yum install salt-minion
```

#### Installing from updates-testing

When a new Salt release is packaged, it is first admitted into the updates-testing repository, before being moved to the stable repo.

To install from updates-testing, use the enablerepo argument for yum:

```
yum --enablerepo=updates-testing install salt-master
yum --enablerepo=updates-testing install salt-minion
```

#### Installation Using pip

Since Salt is on PyPI, it can be installed using pip, though most users prefer to install using a package manager.

Installing from pip has a few additional requirements:

- Install the group 'Development Tools', `dnf groupinstall 'Development Tools'`
- Install the 'zeromq-devel' package if it fails on linking against that afterwards as well.

A pip install does not make the init scripts or the /etc/salt directory, and you will need to provide your own systemd service unit.

Installation from pip:

```
pip install salt
```

**Warning:** If installing from pip (or from source using `setup.py install`), be advised that the `yum-utils` package is needed for Salt to manage packages. Also, if the Python dependencies are not already installed, then you will need additional libraries/tools installed to build some of them. More information on this can be found [here](#).

## Post-installation tasks

### Master

To have the Master start automatically at boot time:

```
systemctl enable salt-master.service
```

To start the Master:

```
systemctl start salt-master.service
```

### Minion

To have the Minion start automatically at boot time:

```
systemctl enable salt-minion.service
```

To start the Minion:

```
systemctl start salt-minion.service
```

Now go to the [Configuring Salt](#) page.

## 2.2.4 FreeBSD

Salt was added to the FreeBSD ports tree Dec 26th, 2011 by Christer Edwards <[christer.edwards@gmail.com](mailto:christer.edwards@gmail.com)>. It has been tested on FreeBSD 7.4, 8.2, 9.0, and 9.1 releases.

Salt is dependent on the following additional ports. These will be installed as dependencies of the `sysutils/py-salt` port:

```
/devel/py-yaml  
/devel/py-pyzmq  
/devel/py-Jinja2  
/devel/py-msgpack  
/security/py-pycrypto  
/security/py-m2crypto
```

### Installation

On FreeBSD 10 and later, to install Salt from the FreeBSD pkgng repo, use the command:

```
pkg install py27-salt
```

On older versions of FreeBSD, to install Salt from the FreeBSD ports tree, use the command:

```
make -C /usr/ports/sysutils/py-salt install clean
```

### Post-installation tasks

#### Master

Copy the sample configuration file:

```
cp /usr/local/etc/salt/master.sample /usr/local/etc/salt/master
```

#### rc.conf

Activate the Salt Master in `/etc/rc.conf` or `/etc/rc.conf.local` and add:

```
+ salt_master_enable="YES"
```

#### Start the Master

Start the Salt Master as follows:

```
service salt_master start
```

#### Minion

Copy the sample configuration file:

```
cp /usr/local/etc/salt/minion.sample /usr/local/etc/salt/minion
```

#### rc.conf

Activate the Salt Minion in `/etc/rc.conf` or `/etc/rc.conf.local` and add:

```
+ salt_minion_enable="YES"  
+ salt_minion_paths="/bin:/sbin:/usr/bin:/usr/sbin:/usr/local/bin:/usr/local/sbin"
```

#### Start the Minion

Start the Salt Minion as follows:

```
service salt_minion start
```

Now go to the [Configuring Salt](#) page.

## 2.2.5 Gentoo

Salt can be easily installed on Gentoo via Portage:

```
emerge app-admin/salt
```

### Post-installation tasks

Now go to the [Configuring Salt](#) page.

## 2.2.6 OpenBSD

Salt was added to the OpenBSD ports tree on Aug 10th 2013. It has been tested on OpenBSD 5.5 onwards.

Salt is dependent on the following additional ports. These will be installed as dependencies of the `sysutils/salt` port:

```
devel/py-futures
devel/py-progressbar
net/py-msgpack
net/py-zmq
security/py-crypto
security/py-M2Crypto
textproc/py-MarkupSafe
textproc/py-yaml
www/py-jinja2
www/py-requests
www/py-tornado
```

### Installation

To install Salt from the OpenBSD pkg repo, use the command:

```
pkg_add salt
```

### Post-installation tasks

#### Master

To have the Master start automatically at boot time:

```
rcctl enable salt_master
```

To start the Master:

```
rcctl start salt_master
```

#### Minion

To have the Minion start automatically at boot time:

```
rcctl enable salt_minion
```

To start the Minion:

```
rcctl start salt_minion
```

Now go to the [Configuring Salt](#) page.

## 2.2.7 OS X

### Dependency Installation

It should be noted that Homebrew explicitly discourages the [use of sudo](#):

Homebrew is designed to work without using sudo. You can decide to use it but we strongly recommend not to do so. If you have used sudo and run into a bug then it is likely to be the cause. Please don't file a bug report unless you can reproduce it after reinstalling Homebrew from scratch without using sudo

So when using Homebrew, if you want support from the Homebrew community, install this way:

```
brew install saltstack
```

When using MacPorts, install this way:

```
sudo port install salt
```

When only using the OS X system's pip, install this way:

```
sudo pip install salt
```

### Salt-Master Customizations

To run salt-master on OS X, the root user maxfiles limit must be increased:

```
sudo launchctl limit maxfiles 4096 8192
```

And sudo add this configuration option to the /etc/salt/master file:

```
max_open_files: 8192
```

Now the salt-master should run without errors:

```
sudo salt-master --log-level=all
```

### Post-installation tasks

Now go to the [Configuring Salt](#) page.

## 2.2.8 RHEL / CentOS / Scientific Linux / Amazon Linux / Oracle Linux

### Installation from Repository

#### RHEL/CentOS 5

Due to the removal of some of Salt's dependencies from EPEL5, we have created a repository on [Fedora COPR](#). Moving forward, this will be the official means of installing Salt on RHEL5-based systems. Information on how to enable this repository can be found [here](#).

#### RHEL/CentOS 6 and 7, Scientific Linux, etc.

Beginning with version 0.9.4, Salt has been available in [EPEL](#). It is installable using yum. Salt should work properly with all mainstream derivatives of RHEL, including CentOS, Scientific Linux, Oracle Linux and Amazon Linux. Report any bugs or issues on the [issue tracker](#).

On RHEL6, the proper Jinja package `python-jinja2` was moved from EPEL to the ``RHEL Server Optional Channel``. Verify this repository is enabled before installing salt on RHEL6.

**Enabling EPEL** If the EPEL repository is not installed on your system, you can download the RPM from [here](#) for RHEL/CentOS 6 (or [here](#) for RHEL/CentOS 7) and install it using the following command:

```
rpm -Uvh epel-release-X-Y.rpm
```

Replace `epel-release-X-Y.rpm` with the appropriate filename.

**Installing Stable Release** Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

On the salt-master, run this:

```
yum install salt-master
```

On each salt-minion, run this:

```
yum install salt-minion
```

**Installing from `epel-testing`** When a new Salt release is packaged, it is first admitted into the `epel-testing` repository, before being moved to the stable repo.

To install from `epel-testing`, use the `enablerepo` argument for yum:

```
yum --enablerepo=epel-testing install salt-minion
```

## Installation Using pip

Since Salt is on [PyPI](#), it can be installed using pip, though most users prefer to install using RPMs (which can be installed from [EPEL](#)).

Installing from pip has a few additional requirements:

- Install the group 'Development Tools', `yum groupinstall 'Development Tools'`
- Install the `zeromq-devel` package if it fails on linking against that afterwards as well.

A pip install does not make the init scripts or the `/etc/salt` directory, and you will need to provide your own systemd service unit.

Installation from pip:

```
pip install salt
```

**Warning:** If installing from pip (or from source using `setup.py install`), be advised that the `yum-utils` package is needed for Salt to manage packages. Also, if the Python dependencies are not already installed, then you will need additional libraries/tools installed to build some of them. More information on this can be found [here](#).

## ZeroMQ 4

We recommend using ZeroMQ 4 where available. SaltStack provides ZeroMQ 4.0.4 and pyzmq 14.3.1 in a [COPR](#) repository. Instructions for adding this repository (as well as for upgrading ZeroMQ and pyzmq on existing minions) can be found [here](#).

If this repo is added *before* Salt is installed, then installing either `salt-master` or `salt-minion` will automatically pull in ZeroMQ 4.0.4, and additional states to upgrade ZeroMQ and pyzmq are unnecessary.

**Warning:** RHEL/CentOS 5 Users Using COPR repos on RHEL/CentOS 5 requires that the `python-hashlib` package be installed. Not having it present will result in checksum errors because YUM will not be able to process the SHA256 checksums used by COPR.

**Note:** For RHEL/CentOS 5 installations, if using the new repository to install Salt (as detailed [above](#)), then it is not necessary to enable the zeromq4 COPR, as the new EL5 repository includes ZeroMQ 4.

---

## Package Management

Salt's interface to `yum` makes heavy use of the `repoquery` utility, from the `yum-utils` package. This package will be installed as a dependency if salt is installed via EPEL. However, if salt has been installed using pip, or a host is being managed using salt-ssh, then as of version 2014.7.0 `yum-utils` will be installed automatically to satisfy this dependency.

### Post-installation tasks

#### Master

To have the Master start automatically at boot time:

```
chkconfig salt-master on
```

To start the Master:

```
service salt-master start
```

#### Minion

To have the Minion start automatically at boot time:

```
chkconfig salt-minion on
```

To start the Minion:

```
service salt-minion start
```

Now go to the [Configuring Salt](#) page.

## 2.2.9 Solaris

Salt was added to the OpenCSW package repository in September of 2012 by Romeo Theriault <[romeot@hawaii.edu](mailto:romeot@hawaii.edu)> at version 0.10.2 of Salt. It has mainly been tested on Solaris 10 (sparc), though it is built for and has been tested minimally on Solaris 10 (x86), Solaris 9 (sparc/x86) and 11 (sparc/x86). (Please let me know if you're using it on these platforms!) Most of the testing has also just focused on the minion, though it has verified that the master starts up successfully on Solaris 10.

Comments and patches for better support on these platforms is very welcome.

As of version 0.10.4, Solaris is well supported under salt, with all of the following working well:

1. remote execution
2. grain detection
3. service control with SMF

4. `pkg` states with `pkgadd` and `pkgutil` modules
5. cron modules/states
6. user and group modules/states
7. shadow password management modules/states

Salt is dependent on the following additional packages. These will automatically be installed as dependencies of the `py_salt` package:

- `py_yaml`
- `py_pyzmq`
- `py_jinja2`
- `py_msgpack_python`
- `py_m2crypto`
- `py_crypto`
- `python`

## Installation

To install Salt from the OpenCSW package repository you first need to install `pkgutil` assuming you don't already have it installed:

On Solaris 10:

```
pkgadd -d http://get.opencsw.org/now
```

On Solaris 9:

```
wget http://mirror.opencsw.org/opencsw/pkgutil.pkg
pkgadd -d pkgutil.pkg all
```

Once `pkgutil` is installed you'll need to edit its config file `/etc/opt/csw/pkgutil.conf` to point it at the unstable catalog:

```
- #mirror=http://mirror.opencsw.org/opencsw/testing
+ mirror=http://mirror.opencsw.org/opencsw/unstable
```

OK, time to install salt.

```
# Update the catalog
root> /opt/csw/bin/pkgutil -U
# Install salt
root> /opt/csw/bin/pkgutil -i -y py_salt
```

## Minion Configuration

Now that salt is installed you can find its configuration files in `/etc/opt/csw/salt/`.

You'll want to edit the minion config file to set the name of your salt master server:

```
- #master: salt
+ master: your-salt-server
```

If you would like to use `pkgutil` as the default package provider for your Solaris minions, you can do so using the `providers` option in the minion config file.

You can now start the salt minion like so:

On Solaris 10:

```
svcadm enable salt-minion
```

On Solaris 9:

```
/etc/init.d/salt-minion start
```

You should now be able to log onto the salt master and check to see if the salt-minion key is awaiting acceptance:

```
salt-key -l un
```

Accept the key:

```
salt-key -a <your-salt-minion>
```

Run a simple test against the minion:

```
salt '<your-salt-minion>' test.ping
```

## Troubleshooting

Logs are in `/var/log/salt`

### 2.2.10 Ubuntu Installation

#### Add repository

The latest packages for Ubuntu are published in the saltstack PPA. If you have the `add-apt-repository` utility, you can add the repository and import the key in one step:

```
sudo add-apt-repository ppa:saltstack/salt
```

#### `add-apt-repository: command not found?`

The `add-apt-repository` command is not always present on Ubuntu systems. This can be fixed by installing `python-software-properties`:

```
sudo apt-get install python-software-properties
```

The following may be required as well:

```
sudo apt-get install software-properties-common
```

Note that since Ubuntu 12.10 (Raring Ringtail), `add-apt-repository` is found in the `software-properties-common` package, and is part of the base install. Thus, `add-apt-repository` should be able to be used out-of-the-box to add the PPA.

Alternately, manually add the repository and import the PPA key with these commands:

```
echo deb http://ppa.launchpad.net/saltstack/salt/ubuntu `lsb_release -sc` main | sudo tee /etc/apt/sources.list.d/saltstack.list && wget -q -O- "http://keyserver.ubuntu.com:11371/pks/lookup?op=get&search=0x4759FA960E27C0A6" | sudo apt-key add -
```

After adding the repository, update the package management database:

```
sudo apt-get update
```

### Install packages

Install the Salt master, minion, or syndic from the repository with the apt-get command. These examples each install one daemon, but more than one package name may be given at a time:

```
sudo apt-get install salt-master
```

```
sudo apt-get install salt-minion
```

```
sudo apt-get install salt-syndic
```

### ZeroMQ 4

ZeroMQ 4 is available by default for Ubuntu 14.04 and newer. However, for Ubuntu 12.04 LTS, starting with Salt version 2014.7.5, ZeroMQ 4 is included with the Salt installation package and nothing additional needs to be done.

### Post-installation tasks

Now go to the [Configuring Salt](#) page.

## 2.2.11 Windows

Salt has full support for running the Salt Minion on Windows.

There are no plans for the foreseeable future to develop a Salt Master on Windows. For now you must run your Salt Master on a supported operating system to control your Salt Minions on Windows.

Many of the standard Salt modules have been ported to work on Windows and many of the Salt States currently work on Windows, as well.

### Windows Installer

Salt Minion Windows installers can be found [here](#). The output of `md5sum <salt minion exe>` should match the contents of the corresponding md5 file.

**Latest stable build from the selected branch:**

[Earlier builds from supported branches](#)

[Archived builds from unsupported branches](#)

---

**Note:** The installation executable installs dependencies that the Salt minion requires.

---

The 64bit installer has been tested on Windows 7 64bit and Windows Server 2008R2 64bit. The 32bit installer has been tested on Windows 2003 Server 32bit. Please file a bug report on our GitHub repo if issues for other platforms are found.

The installer asks for 2 bits of information; the master hostname and the minion name. The installer will update the minion config with these options and then start the minion.

The *salt-minion* service will appear in the Windows Service Manager and can be started and stopped there or with the command line program *sc* like any other Windows service.

If the minion won't start, try installing the Microsoft Visual C++ 2008 x64 SP1 redistributable. Allow all Windows updates to run salt-minion smoothly.

### Silent Installer options

The installer can be run silently by providing the */S* option at the command line. The installer also accepts the following options for configuring the Salt Minion silently:

- */master=* A string value to set the IP address or host name of the master. Default value is `'salt'`
- */minion-name=* A string value to set the minion name. Default is `'hostname'`
- */start-service=* Either a 1 or 0. `'1'` will start the service, `'0'` will not. Default is to start the service after installation.

Here's an example of using the silent installer:

```
Salt-Minion-2015.5.6-Setup-amd64.exe /S /master=yoursaltmaster /minion-name=yourminionname /start-se
```

### Running the Salt Minion on Windows as an Unprivileged User

Notes: - These instructions were tested with Windows Server 2008 R2 - They are generalizable to any version of Windows that supports a salt-minion

#### A. Create the Unprivileged User that the Salt Minion will Run As

1. Click `Start`, `Control Panel`, `User Accounts`
2. Click `Add or remove user accounts`
3. Click `Create new account`
4. Enter `salt-user` (or a name of your preference) in the `New account name` field
5. Select the `Standard user` radio button
6. Click the `Create Account` button
7. Click on the newly created user account
8. Click the `Create a password` link
9. In the `New password` and `Confirm new password` fields, provide a password (e.g. `SuperSecretMinion-Password4Me!`)
10. In the `Type a password hint` field, provide appropriate text (e.g. `My Salt Password`)
11. Click the `Create password` button
12. Close the `Change an Account` window

### B. Add the New User to the Access Control List for the Salt Folder

1. In a File Explorer window, browse to the path where Salt is installed (the default path is C:\Salt)
2. Right-click on the "Salt" folder and select "Properties"
3. Click on the "Security" tab
4. Click the "Edit" button
5. Click the "Add" button
6. Type the name of your designated Salt user and click the "OK" button
7. Check the box to "Allow" the "Modify" permission
8. Click the "OK" button
9. Click the "OK" button to close the "Salt Properties" window

### C. Update the Windows Service User for the "salt-minion" Service

1. Click "Start", "Administrative Tools", "Services"
2. In the list of Services, Right-Click on "salt-minion" and select "Properties"
3. Click the "Log On" tab
4. Click the "This account" radio button
5. Provide the account credentials created in section A
6. Click the "OK" button
7. Click the "OK" button to the prompt confirming that the user "has been granted the Log On As A Service right"
8. Click the "OK" button to the prompt confirming that "The new logon name will not take effect until you stop and restart the service"
9. Right-Click on "salt-minion" and select "Stop"
10. Right-Click on "salt-minion" and select "Start"

## Setting up a Windows build environment

This document will explain how to set up a development environment for salt on Windows. The development environment allows you to work with the source code to customize or fix bugs. It will also allow you to build your own installation.

### The Easy Way

**Prerequisite Software** To do this the easy way you only need to install [Git for Windows](#).

### Create the Build Environment

1. Clone the [Salt-Windows-Dev](#) repo from github.  
Open a command line and type:

```
git clone https://github.com/saltstack/salt-windows-dev
```

## 2. Build the Python Environment

Go into the salt-windows-dev directory. Right-click the file named `dev_env.ps1` and select **Run with PowerShell**

If you get an error, you may need to change the execution policy.

Open a powershell window and type the following:

```
Set-ExecutionPolicy RemoteSigned
```

This will download and install Python with all the dependencies needed to develop and build salt.

## 3. Build the Salt Environment

Right-click on the file named `dev_env_salt.ps1` and select **Run with Powershell**

This will clone salt into `C:\Salt-Dev\salt` and set it to the 2015.5 branch. You could optionally run the command from a powershell window with a `-Version` switch to pull a different version. For example:

```
dev_env_salt.ps1 -Version '2014.7'
```

To view a list of available branches and tags, open a command prompt in your `C:\Salt-Dev\salt` directory and type:

```
git branch -a
git tag -n
```

## The Hard Way

**Prerequisite Software** Install the following software:

1. [Git for Windows](#)
2. [Nullsoft Installer](#)

Download the Prerequisite zip file for your CPU architecture from the SaltStack download site:

- [Salt32.zip](#)
- [Salt64.zip](#)

These files contain all software required to build and develop salt. Unzip the contents of the file to `C:\Salt-Dev\temp`.

## Create the Build Environment

### 1. Build the Python Environment

- Install Python:

Browse to the `C:\Salt-Dev\temp` directory and find the Python installation file for your CPU Architecture under the corresponding subfolder. Double-click the file to install python.

Make sure the following are in your **PATH** environment variable:

```
C:\Python27
C:\Python27\Scripts
```

- Install Pip

Open a command prompt and navigate to C:\Salt-Dev\temp Run the following command:

```
python get-pip.py
```

- Easy Install compiled binaries.

M2Crypto, PyCrypto, and PyWin32 need to be installed using Easy Install. Open a command prompt and navigate to C:\Salt-Dev\temp\<cpuarch>. Run the following commands:

```
easy_install -Z <M2Crypto file name>
easy_install -Z <PyCrypto file name>
easy_install -Z <PyWin32 file name>
```

**Note:** You can type the first part of the file name and then press the tab key to auto-complete the name of the file.

- Pip Install Additional Prerequisites

All remaining prerequisites need to be pip installed. These prerequisites are as follow:

- MarkupSafe
- Jinja
- MsgPack
- PSUtil
- PyYAML
- PyZMQ
- WMI
- Requests
- Certifi

Open a command prompt and navigate to C:\Salt-Dev\temp. Run the following commands:

```
pip install <cpuarch>\<MarkupSafe file name>
pip install <Jinja file name>
pip install <cpuarch>\<MsgPack file name>
pip install <cpuarch>\<psutil file name>
pip install <cpuarch>\<PyYAML file name>
pip install <cpuarch>\<pyzmq file name>
pip install <WMI file name>
pip install <requests file name>
pip install <certifi file name>
```

## 2. Build the Salt Environment

- Clone Salt

Open a command prompt and navigate to C:\Salt-Dev. Run the following command to clone salt:

```
git clone https://github.com/saltstack/salt
```

- Checkout Branch

Checkout the branch or tag of salt you want to work on or build. Open a command prompt and navigate to C:\Salt-Dev\salt. Get a list of available tags and branches by running the following commands:

```
git fetch --all
```

To view a list of available branches:

```
git branch -a
```

To view a list of available tags:

```
git tag -n
```

Checkout the branch or tag by typing the following command:

```
git checkout <branch/tag name>
```

- Clean the Environment

When switching between branches residual files can be left behind that will interfere with the functionality of salt. Therefore, after you check out the branch you want to work on, type the following commands to clean the salt environment:

## Developing with Salt

There are two ways to develop with salt. You can run salt's setup.py each time you make a change to source code or you can use the setup tools develop mode.

### Configure the Minion

Both methods require that the minion configuration be in the C:\salt directory. Copy the conf and var directories from C:\Salt-Dev\salt\pkg\ windows\builddenv to C:\salt. Now go into the C:\salt\conf directory and edit the file name minion (no extension). You need to configure the master and id parameters in this file. Edit the following lines:

```
master: <ip or name of your master>  
id: <name of your minion>
```

### Setup.py Method

Go into the C:\Salt-Dev\salt directory from a cmd prompt and type:

```
python setup.py install --force
```

This will install python into your python installation at C:\Python27. Everytime you make an edit to your source code, you'll have to stop the minion, run the setup, and start the minion.

To start the salt-minion go into C:\Python27\Scripts from a cmd prompt and type:

```
salt-minion
```

For debug mode type:

```
salt-minion -l debug
```

To stop the minion press Ctrl+C.

### Setup Tools Develop Mode (Preferred Method)

To use the Setup Tools Develop Mode go into `C:\Salt-Dev\salt` from a cmd prompt and type:

```
pip install -e .
```

This will install pointers to your source code that resides at `C:\Salt-Dev\salt`. When you edit your source code you only have to restart the minion.

### Build the windows installer

This is the method of building the installer as of version 2014.7.4.

### Clean the Environment

Make sure you don't have any leftover salt files from previous versions of salt in your Python directory.

1. Remove all files that start with salt in the `C:\Python27\Scripts` directory
2. Remove all files and directories that start with salt in the `C:\Python27\Lib\site-packages` directory

### Install Salt

Install salt using salt's setup.py. From the `C:\Salt-Dev\salt` directory type the following command:

```
python setup.py install --force
```

### Build the Installer

From cmd prompt go into the `C:\Salt-Dev\salt\pkg\windows` directory. Type the following command for the branch or tag of salt you're building:

```
BuildSalt.bat <branch or tag>
```

This will copy python with salt installed to the `buildev\bin` directory, make it portable, and then create the windows installer. The .exe for the windows installer will be placed in the `installer` directory.

### Testing the Salt minion

1. Create the directory `C:\salt` (if it doesn't exist already)
2. Copy the example `conf` and `var` directories from `pkg/windows/buildev/` into `C:\salt`
3. Edit `C:\salt\conf\minion`

```
master: ipaddress or hostname of your salt-master
```

4. Start the salt-minion

```
cd C:\Python27\Scripts
python salt-minion
```

5. On the salt-master accept the new minion's key

```
sudo salt-key -A
```

This accepts all unaccepted keys. If you're concerned about security just accept the key for this specific minion.

#### 6. Test that your minion is responding

On the salt-master run:

```
sudo salt '*' test.ping
```

You should get the following response: {'your minion hostname': True}

### Single command bootstrap script

On a 64 bit Windows host the following script makes an unattended install of salt, including all dependencies:

#### Not up to date.

This script is not up to date. Please use the installer found above

---

```
# (All in one line.)  
"PowerShell (New-Object System.Net.WebClient).DownloadFile('http://csa-net.dk/salt/bootstrap64.bat',
```

You can execute the above command remotely from a Linux host using winexe:

```
winexe -U "administrator" //fqdn "PowerShell (New-Object .....);"
```

For more info check <http://csa-net.dk/salt>

### Packages management under Windows 2003

On windows Server 2003, you need to install optional component "wmi windows installer provider" to have full list of installed packages. If you don't have this, salt-minion can't report some installed softwares.

## 2.2.12 SUSE Installation

With openSUSE 13.2, Salt 2014.1.11 is available in the primary repositories. The devel:language:python repo will have more up to date versions of salt, all package development will be done there.

### Installation

Salt can be installed using zypper and is available in the standard openSUSE repositories.

#### Stable Release

Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

```
zypper install salt-master  
zypper install salt-minion
```

## Post-installation tasks openSUSE

### Master

To have the Master start automatically at boot time:

```
systemctl enable salt-master.service
```

To start the Master:

```
systemctl start salt-master.service
```

### Minion

To have the Minion start automatically at boot time:

```
systemctl enable salt-minion.service
```

To start the Minion:

```
systemctl start salt-minion.service
```

## Post-installation tasks SLES

### Master

To have the Master start automatically at boot time:

```
chkconfig salt-master on
```

To start the Master:

```
rcsalt-master start
```

### Minion

To have the Minion start automatically at boot time:

```
chkconfig salt-minion on
```

To start the Minion:

```
rcsalt-minion start
```

## Unstable Release

### openSUSE

For openSUSE Factory run the following as root:

```
zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/openSUSE_Factory/devel:languages:python
zypper refresh
zypper install salt salt-minion salt-master
```

For openSUSE 13.2 run the following as root:

```
zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/openSUSE_13.2/devel:languages:python
zypper refresh
zypper install salt salt-minion salt-master
```

For openSUSE 13.1 run the following as root:

```
zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/openSUSE_13.1/devel:languages:python
zypper refresh
zypper install salt salt-minion salt-master
```

For bleeding edge python Factory run the following as root:

```
zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/bleeding_edge_python/devel:languages:python
zypper refresh
zypper install salt salt-minion salt-master
```

### Suse Linux Enterprise

For SLE 12 run the following as root:

```
zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/SLE_12/devel:languages:python
zypper refresh
zypper install salt salt-minion salt-master
```

For SLE 11 SP3 run the following as root:

```
zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/SLE_11_SP3/devel:languages:python
zypper refresh
zypper install salt salt-minion salt-master
```

For SLE 11 SP2 run the following as root:

```
zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/SLE_11_SP2/devel:languages:python
zypper refresh
zypper install salt salt-minion salt-master
```

Now go to the [Configuring Salt](#) page.

## 2.3 Dependencies

Salt should run on any Unix-like platform so long as the dependencies are met.

- [Python 2.6](#) >= 2.6 <3.0
- [msgpack-python](#) - High-performance message interchange format
- [YAML](#) - Python YAML bindings
- [Jinja2](#) - parsing Salt States (configurable in the master settings)
- [MarkupSafe](#) - Implements a XML/HTML/XHTML Markup safe string for Python
- [apache-libcloud](#) - Python lib for interacting with many of the popular cloud service providers using a unified API
- [Requests](#) - HTTP library

Depending on the chosen Salt transport, [ZeroMQ](#) or [RAET](#), dependencies vary:

- [ZeroMQ](#):
  - [ZeroMQ](#) >= 3.2.0
  - [pyzmq](#) >= 2.2.0 - ZeroMQ Python bindings

- [PyCrypto](#) - The Python cryptography toolkit
- [M2Crypto](#) - ``Me Too Crypto" - Python OpenSSL wrapper
- RAET:
  - [libnacl](#) - Python bindings to [libsodium](#)
  - [ioflo](#) - The flo programming interface raet and salt-raet is built on
  - [RAET](#) - The worlds most awesome UDP protocol

Salt defaults to the [ZeroMQ](#) transport, and the choice can be made at install time, for example:

```
python setup.py install --salt-transport=raet
```

This way, only the required dependencies are pulled by the setup script if need be.

If installing using pip, the `--salt-transport` install option can be provided like:

```
pip install --install-option="--salt-transport=raet" salt
```

## 2.4 Optional Dependencies

- [mako](#) - an optional parser for Salt States (configurable in the master settings)
- [gcc](#) - dynamic [Cython](#) module compiling

## 2.5 Upgrading Salt

When upgrading Salt, the master(s) should always be upgraded first. Backward compatibility for minions running newer versions of salt than their masters is not guaranteed.

Whenever possible, backward compatibility between new masters and old minions will be preserved. Generally, the only exception to this policy is in case of a security vulnerability.

## 3.1 Introduction

### 3.1.1 Salt Masterless Quickstart

Running a masterless salt-minion lets you use Salt's configuration management for a single machine without calling out to a Salt master on another machine.

Since the Salt minion contains such extensive functionality it can be useful to run it standalone. A standalone minion can be used to do a number of things:

- Stand up a master server via States (Salting a Salt Master)
- Use salt-call commands on a system without connectivity to a master
- Masterless States, run states entirely from files local to the minion

It is also useful for testing out state trees before deploying to a production setup.

#### Bootstrap Salt Minion

The `salt-bootstrap` script makes bootstrapping a server with Salt simple for any OS with a Bourne shell:

```
wget -O - https://bootstrap.saltstack.com | sudo sh
```

See the `salt-bootstrap` documentation for other one liners. When using `Vagrant` to test out salt, the `Vagrant salt provisioner` will provision the VM for you.

#### Telling Salt to Run Masterless

To instruct the minion to not look for a master, the `file_client` configuration option needs to be set in the minion configuration file. By default the `file_client` is set to `remote` so that the minion gathers file server and pillar data from the salt master. When setting the `file_client` option to `local` the minion is configured to not gather this data from the master.

```
file_client: local
```

Now the salt minion will not look for a master and will assume that the local system has all of the file and pillar resources.

---

**Note:** When running Salt in masterless mode, do not run the salt-minion daemon. Otherwise, it will attempt to

connect to a master and fail. The salt-call command stands on its own and does not need the salt-minion daemon.

---

## Create State Tree

Following the successful installation of a salt-minion, the next step is to create a state tree, which is where the SLS files that comprise the possible states of the minion are stored.

The following example walks through the steps necessary to create a state tree that ensures that the server has the Apache webserver installed.

---

**Note:** For a complete explanation on Salt States, see the [tutorial](#).

---

1. Create the top.sls file:

/srv/salt/top.sls:

```
base:
  '*':
    - webserver
```

2. Create the webserver state tree:

/srv/salt/webserver.sls:

```
apache:           # ID declaration
  pkg:            # state declaration
    - installed   # function declaration
```

---

**Note:** The apache package has different names on different platforms, for instance on Debian/Ubuntu it is apache2, on Fedora/RHEL it is httpd and on Arch it is apache

---

The only thing left is to provision our minion using salt-call.

## Salt-call

The salt-call command is used to run remote execution functions locally on a minion instead of executing them from the master. Normally the salt-call command checks into the master to retrieve file server and pillar data, but when running standalone salt-call needs to be instructed to not check the master for this data:

```
salt-call --local state.apply
```

The --local flag tells the salt-minion to look for the state tree in the local file system and not to contact a Salt Master for instructions.

To provide verbose output, use -l debug:

```
salt-call --local state.apply -l debug
```

The minion first examines the top.sls file and determines that it is a part of the group matched by \* glob and that the webserver SLS should be applied.

It then examines the webserver.sls file and finds the apache state, which installs the Apache package.

The minion should now have Apache installed, and the next step is to begin learning how to write [more complex states](#).

## 3.2 Basics

### 3.2.1 Standalone Minion

Since the Salt minion contains such extensive functionality it can be useful to run it standalone. A standalone minion can be used to do a number of things:

- Use salt-call commands on a system without connectivity to a master
- Masterless States, run states entirely from files local to the minion

---

**Note:** When running Salt in masterless mode, do not run the salt-minion daemon. Otherwise, it will attempt to connect to a master and fail. The salt-call command stands on its own and does not need the salt-minion daemon.

---

#### Telling Salt Call to Run Masterless

The salt-call command is used to run module functions locally on a minion instead of executing them from the master. Normally the salt-call command checks into the master to retrieve file server and pillar data, but when running standalone salt-call needs to be instructed to not check the master for this data. To instruct the minion to not look for a master when running salt-call the *file\_client* configuration option needs to be set. By default the *file\_client* is set to `remote` so that the minion knows that file server and pillar data are to be gathered from the master. When setting the *file\_client* option to `local` the minion is configured to not gather this data from the master.

```
file_client: local
```

Now the salt-call command will not look for a master and will assume that the local system has all of the file and pillar resources.

#### Running States Masterless

The state system can be easily run without a Salt master, with all needed files local to the minion. To do this the minion configuration file needs to be set up to know how to return `file_roots` information like the master. The `file_roots` setting defaults to `/srv/salt` for the base environment just like on the master:

```
file_roots:
  base:
    - /srv/salt
```

Now set up the Salt State Tree, top file, and SLS modules in the same way that they would be set up on a master. Now, with the *file\_client* option set to `local` and an available state tree then calls to functions in the state module will use the information in the `file_roots` on the minion instead of checking in with the master.

Remember that when creating a state tree on a minion there are no syntax or path changes needed, SLS modules written to be used from a master do not need to be modified in any way to work with a minion.

This makes it easy to "script" deployments with Salt states without having to set up a master, and allows for these SLS modules to be easily moved into a Salt master as the deployment grows.

The declared state can now be executed with:

```
salt-call state.apply
```

Or the salt-call command can be executed with the `--local` flag, this makes it unnecessary to change the configuration file:

```
salt-call state.apply --local
```

## External Pillars

*External pillars* are supported when running in masterless mode.

### 3.2.2 Opening the Firewall up for Salt

The Salt master communicates with the minions using an AES-encrypted ZeroMQ connection. These communications are done over TCP ports 4505 and 4506, which need to be accessible on the master only. This document outlines suggested firewall rules for allowing these incoming connections to the master.

---

**Note:** No firewall configuration needs to be done on Salt minions. These changes refer to the master only.

---

#### Fedora 18 and beyond / RHEL 7 / CentOS 7

Starting with Fedora 18 `Firewalld` is the tool that is used to dynamically manage the firewall rules on a host. It has support for IPv4/6 settings and the separation of runtime and permanent configurations. To interact with `Firewalld` use the command line client `firewall-cmd`.

**firewall-cmd example:**

```
firewall-cmd --permanent --zone=<zone> --add-port=4505-4506/tcp
```

Please choose the desired zone according to your setup. Don't forget to reload after you made your changes.

```
firewall-cmd --reload
```

#### RHEL 6 / CentOS 6

The `lokkit` command packaged with some Linux distributions makes opening iptables firewall ports very simple via the command line. Just be careful to not lock out access to the server by neglecting to open the ssh port.

**lokkit example:**

```
lokkit -p 22:tcp -p 4505:tcp -p 4506:tcp
```

The `system-config-firewall-tui` command provides a text-based interface to modifying the firewall.

**system-config-firewall-tui:**

```
system-config-firewall-tui
```

#### openSUSE

Salt installs firewall rules in `/etc/sysconfig/SuSEfirewall2.d/services/salt`. Enable with:

```
SuSEfirewall2 open
SuSEfirewall2 start
```

If you have an older package of Salt where the above configuration file is not included, the `SuSEfirewall2` command makes opening iptables firewall ports very simple via the command line.

#### SuSEfirewall example:

```
SuSEfirewall2 open EXT TCP 4505
SuSEfirewall2 open EXT TCP 4506
```

The firewall module in YaST2 provides a text-based interface to modifying the firewall.

#### YaST2:

```
yast2 firewall
```

### iptables

Different Linux distributions store their *iptables* (also known as *netfilter*) rules in different places, which makes it difficult to standardize firewall documentation. Included are some of the more common locations, but your mileage may vary.

#### Fedora / RHEL / CentOS:

```
/etc/sysconfig/iptables
```

#### Arch Linux:

```
/etc/iptables/iptables.rules
```

#### Debian

Follow these instructions: <https://wiki.debian.org/iptables>

Once you've found your firewall rules, you'll need to add the two lines below to allow traffic on `tcp/4505` and `tcp/4506`:

```
-A INPUT -m state --state new -m tcp -p tcp --dport 4505 -j ACCEPT
-A INPUT -m state --state new -m tcp -p tcp --dport 4506 -j ACCEPT
```

#### Ubuntu

Salt installs firewall rules in `/etc/ufw/applications.d/salt.ufw`. Enable with:

```
ufw allow salt
```

### pf.conf

The BSD-family of operating systems uses *packet filter* (*pf*). The following example describes the additions to `pf.conf` needed to access the Salt master.

```
pass in on $int_if proto tcp from any to $int_if port 4505
pass in on $int_if proto tcp from any to $int_if port 4506
```

Once these additions have been made to the `pf.conf` the rules will need to be reloaded. This can be done using the `pfctl` command.

```
pfctl -vf /etc/pf.conf
```

### 3.2.3 Whitelist communication to Master

There are situations where you want to selectively allow Minion traffic from specific hosts or networks into your Salt Master. The first scenario which comes to mind is to prevent unwanted traffic to your Master out of security concerns, but another scenario is to handle Minion upgrades when there are backwards incompatible changes between the installed Salt versions in your environment.

Here is an example *Linux iptables* ruleset to be set on the Master:

```
# Allow Minions from these networks
-I INPUT -s 10.1.2.0/24 -p tcp -m multiport --dports 4505,4506 -j ACCEPT
-I INPUT -s 10.1.3.0/24 -p tcp -m multiport --dports 4505,4506 -j ACCEPT
# Allow Salt to communicate with Master on the loopback interface
-A INPUT -i lo -p tcp -m multiport --dports 4505,4506 -j ACCEPT
# Reject everything else
-A INPUT -p tcp -m multiport --dports 4505,4506 -j REJECT
```

---

**Note:** The important thing to note here is that the `salt` command needs to communicate with the listening network socket of `salt-master` on the *loopback* interface. Without this you will see no outgoing Salt traffic from the master, even for a simple `salt '*' test.ping`, because the `salt` client never reached the `salt-master` to tell it to carry out the execution.

---

### 3.2.4 Using cron with Salt

The Salt Minion can initiate its own *highstate* using the `salt-call` command.

```
$ salt-call state.apply
```

This will cause the minion to check in with the master and ensure it is in the correct ``state``.

### 3.2.5 Use cron to initiate a highstate

If you would like the Salt Minion to regularly check in with the master you can use cron to run the `salt-call` command:

```
0 0 * * * salt-call state.apply
```

The above cron entry will run a *highstate* every day at midnight.

---

**Note:** When executing Salt using cron, keep in mind that the default `PATH` for cron may not include the path for any scripts or commands used by Salt, and it may be necessary to set the `PATH` accordingly in the crontab:

```
PATH=/bin:/sbin:/usr/bin:/usr/sbin:/usr/local/bin:/usr/local/sbin:/opt/bin
0 0 * * * salt-call state.apply
```

---

### 3.2.6 Remote execution tutorial

Before continuing make sure you have a working Salt installation by following the [installation](#) and the [configuration](#) instructions.

---

Stuck?

---

There are many ways to *get help from the Salt community* including our [mailing list](#) and our [IRC channel #salt](#).

---

## Order your minions around

Now that you have a *master* and at least one *minion* communicating with each other you can perform commands on the minion via the **salt** command. Salt calls are comprised of three main components:

```
salt '<target>' <function> [arguments]
```

See also:

[salt manpage](#)

### target

The target component allows you to filter which minions should run the following function. The default filter is a glob on the minion id. For example:

```
salt '*' test.ping
salt '*.example.org' test.ping
```

Targets can be based on minion system information using the Grains system:

```
salt -G 'os:Ubuntu' test.ping
```

See also:

[Grains system](#)

Targets can be filtered by regular expression:

```
salt -E 'virtmach[0-9]' test.ping
```

Targets can be explicitly specified in a list:

```
salt -L 'foo,bar,baz,quo' test.ping
```

Or Multiple target types can be combined in one command:

```
salt -C 'G@os:Ubuntu and webser* or E@database.*' test.ping
```

### function

A function is some functionality provided by a module. Salt ships with a large collection of available functions. List all available functions on your minions:

```
salt '*' sys.doc
```

Here are some examples:

Show all currently available minions:

```
salt '*' test.ping
```

Run an arbitrary shell command:

```
salt '*' cmd.run 'uname -a'
```

**See also:**

the full list of modules

**arguments**

Space-delimited arguments to the function:

```
salt '*' cmd.exec_code python 'import sys; print sys.version'
```

Optional, keyword arguments are also supported:

```
salt '*' pip.install salt timeout=5 upgrade=True
```

They are always in the form of `kwarg=argument`.

### 3.2.7 Pillar Walkthrough

---

**Note:** This walkthrough assumes that the reader has already completed the initial Salt [walkthrough](#).

---

Pillars are tree-like structures of data defined on the Salt Master and passed through to minions. They allow confidential, targeted data to be securely sent only to the relevant minion.

---

**Note:** Grains and Pillar are sometimes confused, just remember that Grains are data about a minion which is stored or generated from the minion. This is why information like the OS and CPU type are found in Grains. Pillar is information about a minion or many minions stored or generated on the Salt Master.

---

Pillar data is useful for:

**Highly Sensitive Data:** Information transferred via pillar is guaranteed to only be presented to the minions that are targeted, making Pillar suitable for managing security information, such as cryptographic keys and passwords.

**Minion Configuration:** Minion modules such as the execution modules, states, and returners can often be configured via data stored in pillar.

**Variables:** Variables which need to be assigned to specific minions or groups of minions can be defined in pillar and then accessed inside sls formulas and template files.

**Arbitrary Data:** Pillar can contain any basic data structure in dictionary format, so a key/value store can be defined making it easy to iterate over a group of values in sls formulas.

Pillar is therefore one of the most important systems when using Salt. This walkthrough is designed to get a simple Pillar up and running in a few minutes and then to dive into the capabilities of Pillar and where the data is available.

#### Setting Up Pillar

The pillar is already running in Salt by default. To see the minion's pillar data:

```
salt '*' pillar.items
```

---

**Note:** Prior to version 0.16.2, this function is named `pillar.data`. This function name is still supported for backwards compatibility.

---

By default the contents of the master configuration file are loaded into pillar for all minions. This enables the master configuration file to be used for global configuration of minions.

Similar to the state tree, the pillar is comprised of sls files and has a top file. The default location for the pillar is in `/srv/pillar`.

**Note:** The pillar location can be configured via the `pillar_roots` option inside the master configuration file. It must not be in a subdirectory of the state tree or `file_roots`. If the pillar is under `file_roots`, any pillar targeting can be bypassed by minions.

To start setting up the pillar, the `/srv/pillar` directory needs to be present:

```
mkdir /srv/pillar
```

Now create a simple top file, following the same format as the top file used for states:

```
/srv/pillar/top.sls:
```

```
base:
  '*':
    - data
```

This top file associates the `data.sls` file to all minions. Now the `/srv/pillar/data.sls` file needs to be populated:

```
/srv/pillar/data.sls:
```

```
info: some data
```

To ensure that the minions have the new pillar data, issue a command to them asking that they fetch their pillars from the master:

```
salt '*' saltutil.refresh_pillar
```

Now that the minions have the new pillar, it can be retrieved:

```
salt '*' pillar.items
```

The key `info` should now appear in the returned pillar data.

### More Complex Data

Unlike states, pillar files do not need to define **formulas**. This example sets up user data with a UID:

```
/srv/pillar/users/init.sls:
```

```
users:
  thatch: 1000
  shouse: 1001
  utahdave: 1002
  redbear: 1003
```

**Note:** The same directory lookups that exist in states exist in pillar, so the file `users/init.sls` can be referenced with `users` in the *top file*.

The top file will need to be updated to include this sls file:

```
/srv/pillar/top.sls:
```

```
base:
  '*':
    - data
    - users
```

Now the data will be available to the minions. To use the pillar data in a state, you can use Jinja:

/srv/salt/users/init.sls

```
{% for user, uid in pillar.get('users', {}).items() %}
{{user}}:
  user.present:
    - uid: {{uid}}
{% endfor %}
```

This approach allows for users to be safely defined in a pillar and then the user data is applied in an sls file.

### Parameterizing States With Pillar

Pillar data can be accessed in state files to customise behavior for each minion. All pillar (and grain) data applicable to each minion is substituted into the state files through templating before being run. Typical uses include setting directories appropriate for the minion and skipping states that don't apply.

A simple example is to set up a mapping of package names in pillar for separate Linux distributions:

/srv/pillar/pkg/init.sls:

```
pkgs:
  {% if grains['os_family'] == 'RedHat' %}
  apache: httpd
  vim: vim-enhanced
  {% elif grains['os_family'] == 'Debian' %}
  apache: apache2
  vim: vim
  {% elif grains['os'] == 'Arch' %}
  apache: apache
  vim: vim
  {% endif %}
```

The new pkg sls needs to be added to the top file:

/srv/pillar/top.sls:

```
base:
  '*':
    - data
    - users
    - pkg
```

Now the minions will auto map values based on respective operating systems inside of the pillar, so sls files can be safely parameterized:

/srv/salt/apache/init.sls:

```
apache:
  pkg.installed:
    - name: {{ pillar['pkgs']['apache'] }}
```

Or, if no pillar is available a default can be set as well:

**Note:** The function `pillar.get` used in this example was added to Salt in version 0.14.0

`/srv/salt/apache/init.sls:`

```
apache:
  pkg.installed:
    - name: {{ salt['pillar.get']('pkgs:apache', 'httpd') }}
```

In the above example, if the pillar value `pillar['pkgs']['apache']` is not set in the minion's pillar, then the default of `httpd` will be used.

**Note:** Under the hood, pillar is just a Python dict, so Python dict methods such as `get` and `items` can be used.

### Pillar Makes Simple States Grow Easily

One of the design goals of pillar is to make simple sls formulas easily grow into more flexible formulas without refactoring or complicating the states.

A simple formula:

`/srv/salt/edit/vim.sls:`

```
vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
    - mode: 644
    - user: root
    - group: root
    - require:
      - pkg: vim
```

Can be easily transformed into a powerful, parameterized formula:

`/srv/salt/edit/vim.sls:`

```
vim:
  pkg.installed:
    - name: {{ pillar['pkgs']['vim'] }}

/etc/vimrc:
  file.managed:
    - source: {{ pillar['vimrc'] }}
    - mode: 644
    - user: root
    - group: root
    - require:
      - pkg: vim
```

Where the `vimrc` source location can now be changed via pillar:

`/srv/pillar/edit/vim.sls:`

```
{% if grains['id'].startswith('dev') %}
vimrc: salt://edit/dev_vimrc
{% elif grains['id'].startswith('qa') %}
```

```
vimrc: salt://edit/qa_vimrc
{% else %}
vimrc: salt://edit/vimrc
{% endif %}
```

Ensuring that the right vimrc is sent out to the correct minions.

### Setting Pillar Data on the Command Line

Pillar data can be set on the command line when running `state.apply <salt.modules.state.apply_(>` like so:

```
salt '*' state.apply pillar='{"foo": "bar"}'
salt '*' state.apply my_sls_file pillar='{"hello": "world"}'
```

---

**Note:** If a key is passed on the command line that already exists on the minion, the key that is passed in will overwrite the entire value of that key, rather than merging only the specified value set via the command line.

---

The example below will swap the value for vim with telnet in the previously specified list, notice the nested pillar dict:

```
salt '*' state.apply edit.vim pillar='{"pkgs": {"vim": "telnet"}}'
```

---

**Note:** This will attempt to install telnet on your minions, feel free to uninstall the package or replace telnet value with anything else.

---

### More On Pillar

Pillar data is generated on the Salt master and securely distributed to minions. Salt is not restricted to the pillar sls files when defining the pillar but can retrieve data from external sources. This can be useful when information about an infrastructure is stored in a separate location.

Reference information on pillar and the external pillar interface can be found in the Salt documentation:

[Pillar](#)

## 3.3 States

### 3.3.1 How Do I Use Salt States?

Simplicity, Simplicity, Simplicity

Many of the most powerful and useful engineering solutions are founded on simple principles. Salt States strive to do just that: K.I.S.S. (Keep It Stupidly Simple)

The core of the Salt State system is the SLS, or SaLt State file. The SLS is a representation of the state in which a system should be in, and is set up to contain this data in a simple format. This is often called configuration management.

---

**Note:** This is just the beginning of using states, make sure to read up on pillar [Pillar](#) next.

---

## It is All Just Data

Before delving into the particulars, it will help to understand that the SLS file is just a data structure under the hood. While understanding that the SLS is just a data structure isn't critical for understanding and making use of Salt States, it should help bolster knowledge of where the real power is.

SLS files are therefore, in reality, just [dictionaries](#), [lists](#), [strings](#), and [numbers](#). By using this approach Salt can be much more flexible. As one writes more state files, it becomes clearer exactly what is being written. The result is a system that is easy to understand, yet grows with the needs of the admin or developer.

## The Top File

The example SLS files in the below sections can be assigned to hosts using a file called `top.sls`. This file is described in-depth [here](#).

## Default Data - YAML

By default Salt represents the SLS data in what is one of the simplest serialization formats available - [YAML](#).

A typical SLS file will often look like this in YAML:

---

**Note:** These demos use some generic service and package names, different distributions often use different names for packages and services. For instance *apache* should be replaced with *httpd* on a Red Hat system. Salt uses the name of the init script, systemd name, upstart name etc. based on what the underlying service management for the platform. To get a list of the available service names on a platform execute the `service.get_all` salt function.

Information on how to make states work with multiple distributions is later in the tutorial.

---

```
apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache
```

This SLS data will ensure that the package named `apache` is installed, and that the `apache` service is running. The components can be explained in a simple way.

The first line is the ID for a set of data, and it is called the ID Declaration. This ID sets the name of the thing that needs to be manipulated.

The second and third lines contain the state module function to be run, in the format `<state_module>.<function>`. The `pkg.installed` state module function ensures that a software package is installed via the system's native package manager. The `service.running` state module function ensures that a given system daemon is running.

Finally, on line five, is the word `require`. This is called a Requisite Statement, and it makes sure that the Apache service is only started after a successful installation of the `apache` package.

## Adding Configs and Users

When setting up a service like an Apache web server, many more components may need to be added. The Apache configuration file will most likely be managed, and a user and group may need to be set up.

```
apache:
  pkg.installed: []
  service.running:
    - watch:
      - pkg: apache
      - file: /etc/httpd/conf/httpd.conf
      - user: apache
  user.present:
    - uid: 87
    - gid: 87
    - home: /var/www/html
    - shell: /bin/nologin
    - require:
      - group: apache
  group.present:
    - gid: 87
    - require:
      - pkg: apache

/etc/httpd/conf/httpd.conf:
  file.managed:
    - source: salt://apache/httpd.conf
    - user: root
    - group: root
    - mode: 644
```

This SLS data greatly extends the first example, and includes a config file, a user, a group and new requisite statement: `watch`.

Adding more states is easy, since the new user and group states are under the Apache ID, the user and group will be the Apache user and group. The `require` statements will make sure that the user will only be made after the group, and that the group will be made only after the Apache package is installed.

Next, the `require` statement under `service` was changed to `watch`, and is now watching 3 states instead of just one. The `watch` statement does the same thing as `require`, making sure that the other states run before running the state with a `watch`, but it adds an extra component. The `watch` statement will run the state's watcher function for any changes to the watched states. So if the package was updated, the config file changed, or the user uid modified, then the service state's watcher will be run. The service state's watcher just restarts the service, so in this case, a change in the config file will also trigger a restart of the respective service.

### Moving Beyond a Single SLS

When setting up Salt States in a scalable manner, more than one SLS will need to be used. The above examples were in a single SLS file, but two or more SLS files can be combined to build out a State Tree. The above example also references a file with a strange source - `salt://apache/httpd.conf`. That file will need to be available as well.

The SLS files are laid out in a directory structure on the Salt master; an SLS is just a file and files to download are just files.

The Apache example would be laid out in the root of the Salt file server like this:

```
apache/init.sls
apache/httpd.conf
```

So the `httpd.conf` is just a file in the `apache` directory, and is referenced directly.

But when using more than one single SLS file, more components can be added to the toolkit. Consider this SSH example:

ssh/init.sls:

```
openssh-client:
  pkg.installed

/etc/ssh/ssh_config:
  file.managed:
    - user: root
    - group: root
    - mode: 644
    - source: salt://ssh/ssh_config
    - require:
      - pkg: openssh-client
```

ssh/server.sls:

```
include:
  - ssh

openssh-server:
  pkg.installed

sshd:
  service.running:
    - require:
      - pkg: openssh-client
      - pkg: openssh-server
      - file: /etc/ssh/banner
      - file: /etc/ssh/sshd_config

/etc/ssh/sshd_config:
  file.managed:
    - user: root
    - group: root
    - mode: 644
    - source: salt://ssh/sshd_config
    - require:
      - pkg: openssh-server

/etc/ssh/banner:
  file:
    - managed
    - user: root
    - group: root
    - mode: 644
    - source: salt://ssh/banner
    - require:
      - pkg: openssh-server
```

**Note:** Notice that we use two similar ways of denoting that a file is managed by Salt. In the `/etc/ssh/sshd_config` state section above, we use the `file.managed` state declaration whereas with the `/etc/ssh/banner` state section, we use the `file` state declaration and add a `managed` attribute to that state declaration. Both ways produce an identical result; the first way -- using `file.managed` -- is merely a shortcut.

Now our State Tree looks like this:

```
apache/init.sls
apache/httpd.conf
ssh/init.sls
ssh/server.sls
ssh/banner
ssh/ssh_config
ssh/sshd_config
```

This example now introduces the `include` statement. The include statement includes another SLS file so that components found in it can be required, watched or as will soon be demonstrated - extended.

The include statement allows for states to be cross linked. When an SLS has an include statement it is literally extended to include the contents of the included SLS files.

Note that some of the SLS files are called `init.sls`, while others are not. More info on what this means can be found in the [States Tutorial](#).

### Extending Included SLS Data

Sometimes SLS data needs to be extended. Perhaps the apache service needs to watch additional resources, or under certain circumstances a different file needs to be placed.

In these examples, the first will add a custom banner to ssh and the second will add more watchers to apache to include `mod_python`.

`ssh/custom-server.sls`:

```
include:
  - ssh.server

extend:
  /etc/ssh/banner:
    file:
      - source: salt://ssh/custom-banner
```

`python/mod_python.sls`:

```
include:
  - apache

extend:
  apache:
    service:
      - watch:
          - pkg: mod_python

mod_python:
  pkg.installed
```

The `custom-server.sls` file uses the `extend` statement to overwrite where the banner is being downloaded from, and therefore changing what file is being used to configure the banner.

In the new `mod_python` SLS the `mod_python` package is added, but more importantly the `apache` service was extended to also watch the `mod_python` package.

---

### Using extend with require or watch

The `extend` statement works differently for `require` or `watch`. It appends to, rather than replacing the requisite component.

## Understanding the Render System

Since SLS data is simply that (data), it does not need to be represented with YAML. Salt defaults to YAML because it is very straightforward and easy to learn and use. But the SLS files can be rendered from almost any imaginable medium, so long as a renderer module is provided.

The default rendering system is the `yaml_jinja` renderer. The `yaml_jinja` renderer will first pass the template through the `Jinja2` templating system, and then through the YAML parser. The benefit here is that full programming constructs are available when creating SLS files.

Other renderers available are `yaml_mako` and `yaml_wempy` which each use the `Mako` or `Wempy` templating system respectively rather than the `jinja` templating system, and more notably, the pure Python or `py`, `pydsl` & `pyobjects` renderers. The `py` renderer allows for SLS files to be written in pure Python, allowing for the utmost level of flexibility and power when preparing SLS data; while the `pydsl` renderer provides a flexible, domain-specific language for authoring SLS data in Python; and the `pyobjects` renderer gives you a ``Pythonic'' interface to building state data.

**Note:** The templating engines described above aren't just available in SLS files. They can also be used in `file.managed` states, making file management much more dynamic and flexible. Some examples for using templates in managed files can be found in the documentation for the `file states`, as well as the *MooseFS example* below.

## Getting to Know the Default - `yaml_jinja`

The default renderer - `yaml_jinja`, allows for use of the `jinja` templating system. A guide to the `Jinja` templating system can be found here: <http://jinja.pocoo.org/docs>

When working with renderers a few very useful bits of data are passed in. In the case of templating engine based renderers, three critical components are available, `salt`, `grains`, and `pillar`. The `salt` object allows for any Salt function to be called from within the template, and `grains` allows for the `Grains` to be accessed from within the template. A few examples:

`apache/init.sls:`

```
apache:
  pkg.installed:
    {% if grains['os'] == 'RedHat' %}
    - name: httpd
    {% endif %}
  service.running:
    {% if grains['os'] == 'RedHat' %}
    - name: httpd
    {% endif %}
    - watch:
      - pkg: apache
      - file: /etc/httpd/conf/httpd.conf
      - user: apache
  user.present:
    - uid: 87
    - gid: 87
    - home: /var/www/html
    - shell: /bin/nologin
    - require:
      - group: apache
  group.present:
```

```
- gid: 87
- require:
  - pkg: apache

/etc/httpd/conf/httpd.conf:
  file.managed:
    - source: salt://apache/httpd.conf
    - user: root
    - group: root
    - mode: 644
```

This example is simple. If the OS grain states that the operating system is Red Hat, then the name of the Apache package and service needs to be httpd. A more aggressive way to use Jinja can be found here, in a module to set up a MooseFS distributed filesystem chunkserver:

moosefs/chunk.sls:

```
include:
  - moosefs

{% for mnt in salt['cmd.run']('ls /dev/data/moose*').split() %}
/mnt/moose{{ mnt[-1] }}:
  mount.mounted:
    - device: {{ mnt }}
    - fstype: xfs
    - mkmnt: True
  file.directory:
    - user: mfs
    - group: mfs
    - require:
      - user: mfs
      - group: mfs
{% endfor %}

/etc/mfshdd.cfg:
  file.managed:
    - source: salt://moosefs/mfshdd.cfg
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - require:
      - pkg: mfs-chunkserver

/etc/mfschunkserver.cfg:
  file.managed:
    - source: salt://moosefs/mfschunkserver.cfg
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - require:
      - pkg: mfs-chunkserver

mfs-chunkserver:
  pkg.installed: []
mfschunkserver:
  service.running:
    - require:
```

```
{% for mnt in salt['cmd.run']('ls /dev/data/moose*') %}
  - mount: /mnt/moose{{ mnt[-1] }}
  - file: /mnt/moose{{ mnt[-1] }}
{% endfor %}
  - file: /etc/mfschunkserver.cfg
  - file: /etc/mfshdd.cfg
  - file: /var/lib/mfs
```

This example shows much more of the available power of Jinja. Multiple for loops are used to dynamically detect available hard drives and set them up to be mounted, and the `salt` object is used multiple times to call shell commands to gather data.

### Introducing the Python, PyDSL, and the Pyobjects Renderers

Sometimes the chosen default renderer might not have enough logical power to accomplish the needed task. When this happens, the Python renderer can be used. Normally a YAML renderer should be used for the majority of SLS files, but an SLS file set to use another renderer can be easily added to the tree.

This example shows a very basic Python SLS file:

python/django.sls:

```
#!/py
def run():
    '''
    Install the django package
    '''
    return {'include': ['python'],
            'django': {'pkg': ['installed']}}
```

This is a very simple example; the first line has an SLS shebang that tells Salt to not use the default renderer, but to use the `py` renderer. Then the `run` function is defined, the return value from the `run` function must be a Salt friendly data structure, or better known as a Salt [HighState data structure](#).

Alternatively, using the `pydsl` renderer, the above example can be written more succinctly as:

```
#!/pydsl
include('python', delayed=True)
state('django').pkg.installed()
```

The `pyobjects` renderer provides an `Pythonic` object based approach for building the state data. The above example could be written as:

```
#!/pyobjects
include('python')
Pkg.installed("django")
```

This Python examples would look like this if they were written in YAML:

```
include:
  - python

django:
  pkg.installed
```

This example clearly illustrates that; one, using the YAML renderer by default is a wise decision and two, unbridled power can be obtained where needed by using a pure Python SLS.

#### Running and debugging salt states.

Once the rules in an SLS are ready, they should be tested to ensure they work properly. To invoke these rules, simply execute `salt '*' state.apply` on the command line. If you get back only hostnames with a `:` after, but no return, chances are there is a problem with one or more of the sls files. On the minion, use the `salt-call` command to examine the output for errors:

```
salt-call state.apply -l debug
```

This should help troubleshoot the issue. The minion can also be started in the foreground in debug mode by running `salt-minion -l debug`.

#### Next Reading

With an understanding of states, the next recommendation is to become familiar with Salt's pillar interface:

[Pillar Walkthrough](#)

### 3.3.2 States tutorial, part 1 - Basic Usage

The purpose of this tutorial is to demonstrate how quickly you can configure a system to be managed by Salt States. For detailed information about the state system please refer to the full [states reference](#).

This tutorial will walk you through using Salt to configure a minion to run the Apache HTTP server and to ensure the server is running.

**Before continuing** make sure you have a working Salt installation by following the [installation](#) and the [configuration](#) instructions.

---

#### Stuck?

There are many ways to [get help from the Salt community](#) including our [mailing list](#) and our [IRC channel #salt](#).

---

#### Setting up the Salt State Tree

States are stored in text files on the master and transferred to the minions on demand via the master's File Server. The collection of state files make up the `State Tree`.

To start using a central state system in Salt, the Salt File Server must first be set up. Edit the master config file (`file_roots`) and uncomment the following lines:

```
file_roots:
  base:
    - /srv/salt
```

---

**Note:** If you are deploying on FreeBSD via ports, the `file_roots` path defaults to `/usr/local/etc/salt/states`.

---

Restart the Salt master in order to pick up this change:

```

pkill salt-master
salt-master -d

```

## Preparing the Top File

On the master, in the directory uncommented in the previous step, (`/srv/salt` by default), create a new file called `top.sls` and add the following:

```

base:
  '*':
    - webservice

```

The `top file` is separated into environments (discussed later). The default environment is `base`. Under the `base` environment a collection of minion matches is defined; for now simply specify all hosts (`*`).

## Targeting minions

The expressions can use any of the targeting mechanisms used by Salt – minions can be matched by glob, PCRE regular expression, or by `grains`. For example:

```

base:
  'G@os:Fedora':
    - match: grain
    - webservice

```

## Create an `sls` file

In the same directory as the `top file`, create a file named `webservice.sls`, containing the following:

```

apache:                # ID declaration
pkg:                   # state declaration
  - installed          # function declaration

```

The first line, called the *ID declaration*, is an arbitrary identifier. In this case it defines the name of the package to be installed.

**Note:** The package name for the Apache httpd web server may differ depending on OS or distro – for example, on Fedora it is `httpd` but on Debian/Ubuntu it is `apache2`.

The second line, called the *State declaration*, defines which of the Salt States we are using. In this example, we are using the `pkg state` to ensure that a given package is installed.

The third line, called the *Function declaration*, defines which function in the `pkg state` module to call.

## Renderers

States `sls` files can be written in many formats. Salt requires only a simple data structure and is not concerned with how that data structure is built. Templating languages and *DSLs* are a dime-a-dozen and everyone has a favorite.

Building the expected data structure is the job of Salt `renderers` and they are dead-simple to write.

In this tutorial we will be using `YAML` in `Jinja2` templates, which is the default format. The default can be changed by editing `renderer` in the master configuration file.

## Install the package

Next, let's run the state we created. Open a terminal on the master and run:

```
salt '*' state.apply
```

Our master is instructing all targeted minions to run `state.apply`. When this function is executed without any SLS targets, a minion will download the *top file* and attempt to match the expressions within it. When the minion does match an expression the modules listed for it will be downloaded, compiled, and executed.

**Note:** This action is referred to as a `highstate`, and can be run using the `state.highstate` function. However, to make the usage easier to understand (`highstate` is not necessarily an intuitive name), a `state.apply` function was added in version 2015.5.0, which when invoked without any SLS names will trigger a highstate. `state.highstate` still exists and can be used, but the documentation (as can be seen above) has been updated to reference `state.apply`, so keep the following in mind as you read the documentation:

- `state.apply` invoked without any SLS names will run `state.highstate`
- `state.apply` invoked with SLS names will run `state.sls`

Once completed, the minion will report back with a summary of all actions taken and all changes made.

**Warning:** If you have created *custom grain modules*, they will not be available in the top file until after the first *highstate*. To make custom grains available on a minion's first *highstate*, it is recommended to use *this example* to ensure that the custom grains are synced when the minion starts.

---

## SLS File Namespace

Note that in the *example* above, the SLS file `webserver.sls` was referred to simply as `webserver`. The namespace for SLS files follows a few simple rules:

1. The `.sls` is discarded (i.e. `webserver.sls` becomes `webserver`).
2. Subdirectories can be used for better organization.
  - (a) Each subdirectory is represented by a dot.
  - (b) `webserver/dev.sls` is referred to as `webserver.dev`.
3. A file called `init.sls` in a subdirectory is referred to by the path of the directory. So, `webserver/init.sls` is referred to as `webserver`.
4. If both `webserver.sls` and `webserver/init.sls` happen to exist, `webserver/init.sls` will be ignored and `webserver.sls` will be the file referred to as `webserver`.

---

## Troubleshooting Salt

If the expected output isn't seen, the following tips can help to narrow down the problem.

**Turn up logging** Salt can be quite chatty when you change the logging setting to debug:

```
salt-minion -l debug
```

**Run the minion in the foreground** By not starting the minion in daemon mode (`-d`) one can view any output from the minion as it works:

```
salt-minion
```

Increase the default timeout value when running **salt**. For example, to change the default timeout to 60 seconds:

```
salt -t 60
```

For best results, combine all three:

```
salt-minion -l debug      # On the minion
salt '*' state.apply -t 60 # On the master
```

### Next steps

This tutorial focused on getting a simple Salt States configuration working. [Part 2](#) will build on this example to cover more advanced `sls` syntax and will explore more of the states that ship with Salt.

### 3.3.3 States tutorial, part 2 - More Complex States, Requisites

**Note:** This tutorial builds on topics covered in [part 1](#). It is recommended that you begin there.

In the [last part](#) of the Salt States tutorial we covered the basics of installing a package. We will now modify our `webserver.sls` file to have requirements, and use even more Salt States.

#### Call multiple States

You can specify multiple *State declaration* under an *ID declaration*. For example, a quick modification to our `webserver.sls` to also start Apache if it is not running:

```
1 apache:
2   pkg.installed: []
3   service.running:
4     - require:
5       - pkg: apache
```

Try stopping Apache before running `state.apply` once again and observe the output.

**Note:** For those running RedhatOS derivatives (Centos, AWS), you will want to specify the service name to be `httpd`. More on state service here, [service state](#). With the example above, just add `name: httpd` above the require line and with the same spacing.

#### Require other states

We now have a working installation of Apache so let's add an HTML file to customize our website. It isn't exactly useful to have a website without a webserver so we don't want Salt to install our HTML file until Apache is installed and running. Include the following at the bottom of your `webserver/init.sls` file:

```
1 apache:
2   pkg.installed: []
3   service.running:
4     - require:
5       - pkg: apache
6
7 /var/www/index.html:      # ID declaration
8   file:                  # state declaration
```

```

9   - managed                               # function
10  - source: salt://webserver/index.html   # function arg
11  - require:                               # requisite declaration
12    - pkg: apache                         # requisite reference

```

**line 9** is the *ID declaration*. In this example it is the location we want to install our custom HTML file. (Note: the default location that Apache serves may differ from the above on your OS or distro. `/srv/www` could also be a likely place to look.)

**Line 10** the *State declaration*. This example uses the Salt *file state*.

**Line 11** is the *Function declaration*. The *managed function* will download a file from the master and install it in the location specified.

**Line 12** is a *Function arg declaration* which, in this example, passes the `source` argument to the *managed function*.

**Line 13** is a *Requisite declaration*.

**Line 14** is a *Requisite reference* which refers to a state and an ID. In this example, it is referring to the `ID declaration` from our example in [part 1](#). This declaration tells Salt not to install the HTML file until Apache is installed.

Next, create the `index.html` file and save it in the `webserver` directory:

```

<html>
  <head><title>Salt rocks</title></head>
  <body>
    <h1>This file brought to you by Salt</h1>
  </body>
</html>

```

Last, call `state.apply` again and the minion will fetch and execute the *highstate* as well as our HTML file from the master using Salt's File Server:

```
salt '*' state.apply
```

Verify that Apache is now serving your custom HTML.

## require vs. watch

There are two *Requisite declaration*, “require”, and “watch”. Not every state supports “watch”. The *service state* does support “watch” and will restart a service based on the watch condition.

For example, if you use Salt to install an Apache virtual host configuration file and want to restart Apache whenever that file is changed you could modify our Apache example from earlier as follows:

```

/etc/httpd/extra/httpd-vhosts.conf:
  file.managed:
    - source: salt://webserver/httpd-vhosts.conf

apache:
  pkg.installed: []
  service.running:
    - watch:
      - file: /etc/httpd/extra/httpd-vhosts.conf
    - require:
      - pkg: apache

```

If the `pkg` and `service` names differ on your OS or distro of choice you can specify each one separately using a *Name declaration* which explained in [Part 3](#).

## Next steps

In [part 3](#) we will discuss how to use includes, extends, and templating to make a more complete State Tree configuration.

### 3.3.4 States tutorial, part 3 - Templating, Includes, Extends

**Note:** This tutorial builds on topics covered in [part 1](#) and [part 2](#). It is recommended that you begin there.

This part of the tutorial will cover more advanced templating and configuration techniques for SLS files.

#### Templating SLS modules

SLS modules may require programming logic or inline execution. This is accomplished with module templating. The default module templating system used is Jinja2 and may be configured by changing the *renderer* value in the master config.

All states are passed through a templating system when they are initially read. To make use of the templating system, simply add some templating markup. An example of an sls module with templating markup may look like this:

```
{% for usr in ['moe','larry','curly'] %}
{{ usr }}:
  user.present
{% endfor %}
```

This templated sls file once generated will look like this:

```
moe:
  user.present
larry:
  user.present
curly:
  user.present
```

Here's a more complex example:

```
# Comments in yaml start with a hash symbol.
# Since jinja rendering occurs before yaml parsing, if you want to include jinja
# in the comments you may need to escape them using 'jinja' comments to prevent
# jinja from trying to render something which is not well-defined jinja.
# e.g.
# {# iterate over the Three Stooges using a {% for %}..{% endfor %} loop
# with the iterator variable {{ usr }} becoming the state ID. #}
{% for usr in 'moe','larry','curly' %}
{{ usr }}:
  group:
    - present
  user:
    - present
    - gid_from_name: True
    - require:
      - group: {{ usr }}
{% endfor %}
```

## Using Grains in SLS modules

Often times a state will need to behave differently on different systems. Salt grains objects are made available in the template context. The *grains* can be used from within sls modules:

```
apache:
  pkg.installed:
    {% if grains['os'] == 'RedHat' %}
    - name: httpd
    {% elif grains['os'] == 'Ubuntu' %}
    - name: apache2
    {% endif %}
```

## Using Environment Variables in SLS modules

You can use `salt['environ.get']('VARIABLE')` to use an environment variable in a Salt state.

```
MYENVVAR="world" salt-call state.template test.sls
```

Create a file with contents from an environment variable:

```
file.managed:
  - name: /tmp/hello
  - contents: {{ salt['environ.get']('MYENVVAR') }}
```

Error checking:

```
{% set myenvvar = salt['environ.get']('MYENVVAR') %}
{% if myenvvar %}

Create a file with contents from an environment variable:
  file.managed:
    - name: /tmp/hello
    - contents: {{ salt['environ.get']('MYENVVAR') }}

{% else %}

Fail - no environment passed in:
  test:
    A. fail_without_changes

{% endif %}
```

## Calling Salt modules from templates

All of the Salt modules loaded by the minion are available within the templating system. This allows data to be gathered in real time on the target system. It also allows for shell commands to be run easily from within the sls modules.

The Salt module functions are also made available in the template context as `salt`:

```
moe:
  user.present:
    - gid: {{ salt['file.group_to_gid']('some_group_that_exists') }}
```

Note that for the above example to work, `some_group_that_exists` must exist before the state file is processed by the templating engine.

Below is an example that uses the `network.hw_addr` function to retrieve the MAC address for `eth0`:

```
salt['network.hw_addr']('eth0')
```

### Advanced SLS module syntax

Lastly, we will cover some incredibly useful techniques for more complex State trees.

#### Include declaration

A previous example showed how to spread a Salt tree across several files. Similarly, `requisites` span multiple files by using an *Include declaration*. For example:

python/python-libs.sls:

```
python-dateutil:
  pkg.installed
```

python/django.sls:

```
include:
  - python.python-libs

django:
  pkg.installed:
    - require:
      - pkg: python-dateutil
```

#### Extend declaration

You can modify previous declarations by using an *Extend declaration*. For example the following modifies the Apache tree to also restart Apache when the `vhosts` file is changed:

apache/apache.sls:

```
apache:
  pkg.installed
```

apache/mywebsite.sls:

```
include:
  - apache.apache

extend:
  apache:
    service:
      - running
      - watch:
        - file: /etc/httpd/extra/httpd-vhosts.conf

/etc/httpd/extra/httpd-vhosts.conf:
  file.managed:
    - source: salt://apache/httpd-vhosts.conf
```

---

### Using extend with require or watch

The extend statement works differently for `require` or `watch`. It appends to, rather than replacing the requisite component.

---

#### Name declaration

You can override the *ID declaration* by using a *Name declaration*. For example, the previous example is a bit more maintainable if rewritten as follows:

apache/mywebsite.sls:

```
include:
  - apache.apache

extend:
  apache:
    service:
      - running
      - watch:
        - file: mywebsite

mywebsite:
  file.managed:
    - name: /etc/httpd/extra/httpd-vhosts.conf
    - source: salt://apache/httpd-vhosts.conf
```

#### Names declaration

Even more powerful is using a *Names declaration* to override the *ID declaration* for multiple states at once. This often can remove the need for looping in a template. For example, the first example in this tutorial can be rewritten without the loop:

```
stooges:
  user.present:
    - names:
      - moe
      - larry
      - curly
```

#### Next steps

In [part 4](#) we will discuss how to use salt's *file\_roots* to set up a workflow in which states can be ``promoted" from dev, to QA, to production.

### 3.3.5 States tutorial, part 4

---

**Note:** This tutorial builds on topics covered in [part 1](#), [part 2](#) and [part 3](#). It is recommended that you begin there.

---

This part of the tutorial will show how to use salt's *file\_roots* to set up a workflow in which states can be ``promoted" from dev, to QA, to production.

### Salt fileserver path inheritance

Salt's fileserver allows for more than one root directory per environment, like in the below example, which uses both a local directory and a secondary location shared to the salt master via NFS:

```
# In the master config file (/etc/salt/master)
file_roots:
  base:
    - /srv/salt
    - /mnt/salt-nfs/base
```

Salt's fileserver collapses the list of root directories into a single virtual environment containing all files from each root. If the same file exists at the same relative path in more than one root, then the top-most match ``wins". For example, if `/srv/salt/foo.txt` and `/mnt/salt-nfs/base/foo.txt` both exist, then `salt://foo.txt` will point to `/srv/salt/foo.txt`.

**Note:** When using multiple fileserver backends, the order in which they are listed in the `fileserver_backend` parameter also matters. If both `roots` and `git` backends contain a file with the same relative path, and `roots` appears before `git` in the `fileserver_backend` list, then the file in `roots` will ``win", and the file in `gitfs` will be ignored.

A more thorough explanation of how Salt's modular fileserver works can be found [here](#). We recommend reading this.

### Environment configuration

Configure a multiple-environment setup like so:

```
file_roots:
  base:
    - /srv/salt/prod
  qa:
    - /srv/salt/qa
    - /srv/salt/prod
  dev:
    - /srv/salt/dev
    - /srv/salt/qa
    - /srv/salt/prod
```

Given the path inheritance described above, files within `/srv/salt/prod` would be available in all environments. Files within `/srv/salt/qa` would be available in both `qa`, and `dev`. Finally, the files within `/srv/salt/dev` would only be available within the `dev` environment.

Based on the order in which the roots are defined, new files/states can be placed within `/srv/salt/dev`, and pushed out to the dev hosts for testing.

Those files/states can then be moved to the same relative path within `/srv/salt/qa`, and they are now available only in the `dev` and `qa` environments, allowing them to be pushed to QA hosts and tested.

Finally, if moved to the same relative path within `/srv/salt/prod`, the files are now available in all three environments.

### Practical Example

As an example, consider a simple website, installed to `/var/www/foobar.com`. Below is a top.sls that can be used to deploy the website:

/srv/salt/prod/top.sls:

```
base:
  'web*prod*':
    - webserver.foobarcom
qa:
  'web*qa*':
    - webserver.foobarcom
dev:
  'web*dev*':
    - webserver.foobarcom
```

Using pillar, roles can be assigned to the hosts:

/srv/pillar/top.sls:

```
base:
  'web*prod*':
    - webserver.prod
  'web*qa*':
    - webserver.qa
  'web*dev*':
    - webserver.dev
```

/srv/pillar/webserver/prod.sls:

```
webserver_role: prod
```

/srv/pillar/webserver/qa.sls:

```
webserver_role: qa
```

/srv/pillar/webserver/dev.sls:

```
webserver_role: dev
```

And finally, the SLS to deploy the website:

/srv/salt/prod/webserver/foobarcom.sls:

```
{% if pillar.get('webserver_role', '') %}
/var/www/foobarcom:
  file.recurse:
    - source: salt://webserver/src/foobarcom
    - env: {{ pillar['webserver_role'] }}
    - user: www
    - group: www
    - dir_mode: 755
    - file_mode: 644
{% endif %}
```

Given the above SLS, the source for the website should initially be placed in /srv/salt/dev/webserver/src/foobarcom.

First, let's deploy to dev. Given the configuration in the top file, this can be done using *state.apply*:

```
salt --pillar 'webserver_role:dev' state.apply
```

However, in the event that it is not desirable to apply all states configured in the top file (which could be likely in more complex setups), it is possible to apply just the states for the foobarcom website, by invoking *state.apply* with the desired SLS target as an argument:

```
salt --pillar 'webserver_role:dev' state.apply webserver.foobarcom
```

Once the site has been tested in dev, then the files can be moved from `/srv/salt/dev/webserver/src/foobarcom` to `/srv/salt/qa/webserver/src/foobarcom`, and deployed using the following:

```
salt --pillar 'webserver_role:qa' state.apply webserver.foobarcom
```

Finally, once the site has been tested in qa, then the files can be moved from `/srv/salt/qa/webserver/src/foobarcom` to `/srv/salt/prod/webserver/src/foobarcom`, and deployed using the following:

```
salt --pillar 'webserver_role:prod' state.apply webserver.foobarcom
```

Thanks to Salt's fileserver inheritance, even though the files have been moved to within `/srv/salt/prod`, they are still available from the same `salt://` URI in both the qa and dev environments.

### Continue Learning

The best way to continue learning about Salt States is to read through the [reference documentation](#) and to look through examples of existing state trees. Many pre-configured state trees can be found on Github in the [saltstack-formulas](#) collection of repositories.

If you have any questions, suggestions, or just want to chat with other people who are using Salt, we have a very [active community](#) and we'd love to hear from you.

In addition, by continuing to [part 5](#), you can learn about the powerful orchestration of which Salt is capable.

## 3.3.6 States Tutorial, Part 5 - Orchestration with Salt

---

**Note:** This tutorial builds on some of the topics covered in the earlier [States Walkthrough](#) pages. It is recommended to start with [Part 1](#) if you are not familiar with how to use states.

---

Orchestration is accomplished in salt primarily through the [Orchestrate Runner](#). Added in version 0.17.0, this Salt [Runner](#) can use the full suite of [requisites](#) available in states, and can also execute states/functions using salt-ssh. This runner replaces the [OverState](#).

### The Orchestrate Runner

New in version 0.17.0.

---

**Note:** Orchestrate Deprecates OverState

The Orchestrate Runner (originally called the state.sls runner) offers all the functionality of the OverState, but with some advantages:

- All [requisites](#) available in states can be used.
- The states/functions will also work on salt-ssh minions.

The Orchestrate Runner was added with the intent to eventually deprecate the OverState system, however the OverState will still be maintained until Salt Boron.

---

The orchestrate runner generalizes the Salt state system to a Salt master context. Whereas [state.apply](#) is currently and independently executed on each Salt minion, the [state.orchestrate](#) runner is executed on the

master, giving it a master-level view and control over requisites, such as state ordering and conditionals. This allows for inter minion requisites, like ordering the application of states on different minions that must not happen simultaneously, or for halting the state run on all minions if a minion fails one of its states.

If you want to setup a load balancer in front of a cluster of web servers, for example, you can ensure the load balancer is setup before the web servers or stop the state run altogether if one of the minions does not set up correctly.

`state.apply` allows you to statefully manage each minion and the `state.orchestrate` runner allows you to statefully manage your entire infrastructure.

### Executing the Orchestrate Runner

The Orchestrate Runner command format is the same as for the `state.sls` function, except that since it is a runner, it is executed with `salt-run` rather than `salt`. Assuming you have a state.sls file called `/srv/salt/orch/webserver.sls` the following command run on the master will apply the states defined in that file.

```
salt-run state.orchestrate orch.webserver
```

---

**Note:** `state.orch` is a synonym for `state.orchestrate`

---

Changed in version 2014.1.1: The runner function was renamed to `state.orchestrate` to avoid confusion with the `state.sls` remote execution function. In versions 0.17.0 through 2014.1.0, `state.sls` must be used.

### Examples

**Function** To execute a function, use `salt.function`:

```
# /srv/salt/orch/cleanfoo.sls
cmd.run:
  salt.function:
    - tgt: '*'
    - arg:
      - rm -rf /tmp/foo
```

```
salt-run state.orchestrate orch.cleanfoo
```

**State** To execute a state, use `salt.state`.

```
# /srv/salt/orch/webserver.sls
install_nginx:
  salt.state:
    - tgt: 'web*'
    - sls:
      - nginx
```

```
salt-run state.orchestrate orch.webserver
```

**Highstate** To run a `highstate`, set `highstate: True` in your state config:

```
# /srv/salt/orch/web_setup.sls
webserver_setup:
  salt.state:
```

```
- tgt: 'web*'
- highstate: True
```

```
salt-run state.orchestrate orch.web_setup
```

### More Complex Orchestration

Many states/functions can be configured in a single file, which when combined with the full suite of [requisites](#), can be used to easily configure complex orchestration tasks. Additionally, the states/functions will be executed in the order in which they are defined, unless prevented from doing so by any [requisites](#), as is the default in SLS files since 0.17.0.

```
cmd.run:
  salt.function:
    - tgt: 10.0.0.0/24
    - tgt_type: ipcidr
    - arg:
      - bootstrap

storage_setup:
  salt.state:
    - tgt: 'role:storage'
    - tgt_type: grain
    - sls: ceph
    - require:
      - salt: webserver_setup

webserver_setup:
  salt.state:
    - tgt: 'web*'
    - highstate: True
```

Given the above setup, the orchestration will be carried out as follows:

1. The shell command `bootstrap` will be executed on all minions in the 10.0.0.0/24 subnet.
2. A Highstate will be run on all minions whose ID starts with `web`, since the `storage_setup` state requires it.
3. Finally, the `ceph` SLS target will be executed on all minions which have a grain called `role` with a value of `storage`.

### The OverState System

**Warning:** The OverState runner is deprecated, and will be removed in the feature release of Salt codenamed Boron. (Three feature releases after 2014.7.0, which is codenamed Helium)

Often, servers need to be set up and configured in a specific order, and systems should only be set up if systems earlier in the sequence have been set up without any issues.

The OverState system can be used to orchestrate deployment in a smooth and reliable way across multiple systems in small to large environments.

## The OverState SLS

The OverState system is managed by an SLS file named `overstate.sls`, located in the root of a Salt fileserver environment.

The `overstate.sls` configures an unordered list of stages, each stage defines the minions on which to execute the state, and can define what sls files to run, execute a *highstate*, or run a function. Here's a sample `overstate.sls`:

```
mysql:
  match: 'db*'
  sls:
    - mysql.server
    - drbd
webservers:
  match: 'web*'
  require:
    - mysql
all:
  match: '*'
  require:
    - mysql
    - webservers
```

---

**Note:** The `match` argument uses *compound matching*

---

Given the above setup, the OverState will be carried out as follows:

1. The `mysql` stage will be executed first because it is required by the `webservers` and `all` stages. It will execute *state.apply* once for each of the two listed SLS targets. These states will be executed on all minions whose minion ID starts with `db`. This is the equivalent of running the following two commands from the CLI:

```
salt 'db*' state.apply mysql.server
salt 'db*' state.apply drbd
```

2. The `webservers` stage will then be executed, but only if the `mysql` stage executes without any failures. The `webservers` stage will trigger a *highstate* on all minions whose minion IDs start with `web`. This is the equivalent of running the following command from the CLI:

```
salt 'web*' state.apply
```

3. Finally, the `all` stage will execute, triggering a *highstate* all systems, if, and only if the `mysql` and `webservers` stages completed without any failures. This is the equivalent of running the following command from the CLI:

```
salt '*' state.apply
```

Any failure in the above steps would cause the requires to fail, preventing the dependent stages from executing.

## Using Functions with OverState

In the above example, you'll notice that the stages lacking an `sls` entry trigger a *highstate*. As mentioned earlier, it is also possible to execute other functions in a stage. This functionality was added in version 0.15.0.

Running a function is easy:

```
http:
  function:
    pkg.install:
      - httpd
```

The list of function arguments are defined after the declared function. So, the above stage would run `pkg.install http`. Requisites only function properly if the given function supports returning a custom return code.

### Executing an OverState

Since the OverState is a [Runner](#), it is executed using the `salt-run` command. The runner function for the OverState is `state.over`.

```
salt-run state.over
```

The function will by default look in the root of the `base` environment (as defined in `file_roots`) for a file called `overstate.sls`, and then execute the stages defined within that file.

Different environments and paths can be used as well, by adding them as positional arguments:

```
salt-run state.over dev /root/other-overstate.sls
```

The above would run an OverState using the `dev` files server environment, with the stages defined in `/root/other-overstate.sls`.

**Warning:** Since these are positional arguments, when defining the path to the overstate file the environment must also be specified, even if it is the `base` environment.

**Note:** Remember, `salt-run` is always executed on the master.

## 3.3.7 Syslog-ng usage

### Overview

Syslog\_ng state module is for generating syslog-ng configurations. You can do the following things:

- generate syslog-ng configuration from YAML,
- use non-YAML configuration,
- start, stop or reload syslog-ng.

There is also an execution module, which can check the syntax of the configuration, get the version and other information about syslog-ng.

### Configuration

Users can create syslog-ng configuration statements with the `syslog_ng.config` function. It requires a `name` and a `config` parameter. The `name` parameter determines the name of the generated statement and the `config` parameter holds a parsed YAML structure.

A statement can be declared in the following forms (both are equivalent):

```
source.s_localhost:
  syslog_ng.config:
    - config:
      - tcp:
        - ip: "127.0.0.1"
        - port: 1233
```

```
s_localhost:
  syslog_ng.config:
    - config:
      source:
        - tcp:
          - ip: "127.0.0.1"
          - port: 1233
```

The first one is called short form, because it needs less typing. Users can use lists and dictionaries to specify their configuration. The format is quite self describing and there are more examples [at the end](#examples) of this document.

### Quotation

The quotation can be tricky sometimes but here are some rules to follow:

- when a string meant to be "string" in the generated configuration, it should be like '"string"' in the YAML document
- similarly, users should write "'string'" to get 'string' in the generated configuration

### Full example

The following configuration is an example, how a complete syslog-ng configuration looks like:

```
# Set the location of the configuration file
set_location:
  module.run:
    - name: syslog_ng.set_config_file
    - m_name: "/home/tibi/install/syslog-ng/etc/syslog-ng.conf"

# The syslog-ng and syslog-ng-ctl binaries are here. You needn't use
# this method if these binaries can be found in a directory in your PATH.
set_bin_path:
  module.run:
    - name: syslog_ng.set_binary_path
    - m_name: "/home/tibi/install/syslog-ng/sbin"

# Writes the first lines into the config file, also erases its previous
# content
write_version:
  module.run:
    - name: syslog_ng.write_version
    - m_name: "3.6"

# There is a shorter form to set the above variables
set_variables:
  module.run:
    - name: syslog_ng.set_parameters
```

```

- version: "3.6"
- binary_path: "/home/tibi/install/syslog-ng/sbin"
- config_file: "/home/tibi/install/syslog-ng/etc/syslog-ng.conf"

# Some global options
options.global_options:
  syslog_ng.config:
    - config:
      - time_reap: 30
      - mark_freq: 10
      - keep_hostname: "yes"

source.s_localhost:
  syslog_ng.config:
    - config:
      - tcp:
        - ip: "127.0.0.1"
        - port: 1233

destination.d_log_server:
  syslog_ng.config:
    - config:
      - tcp:
        - "127.0.0.1"
        - port: 1234

log.l_log_to_central_server:
  syslog_ng.config:
    - config:
      - source: s_localhost
      - destination: d_log_server

some_comment:
  module.run:
    - name: syslog_ng.write_config
    - config: |
      # Multi line
      # comment

# An other mode to use comments or existing configuration snippets
config.other_comment_form:
  syslog_ng.config:
    - config: |
      # Multi line
      # comment

```

The `syslog_ng.reloaded` function can generate syslog-ng configuration from YAML. If the statement (source, destination, parser, etc.) has a name, this function uses the id as the name, otherwise (log statement) it's purpose is like a mandatory comment.

After execution this example the `syslog_ng` state will generate this file:

```

#Generated by Salt on 2014-08-18 00:11:11
@version: 3.6

options {
    time_reap(
        30

```

```
);
mark_freq(
    10
);
keep_hostname(
    yes
);
};

source s_localhost {
    tcp(
        ip(
            127.0.0.1
        ),
        port(
            1233
        )
    );
};

destination d_log_server {
    tcp(
        127.0.0.1,
        port(
            1234
        )
    );
};

log {
    source(
        s_localhost
    );
    destination(
        d_log_server
    );
};

# Multi line
# comment

# Multi line
# comment
```

Users can include arbitrary texts in the generated configuration with using the `config` statement (see the example above).

### Syslog\_ng module functions

You can use `syslog_ng.set_binary_path` to set the directory which contains the syslog-ng and syslog-ngctl binaries. If this directory is in your PATH, you don't need to use this function. There is also a `syslog_ng.set_config_file` function to set the location of the configuration file.

## Examples

### Simple source

```
source s_tail {
  file(
    "/var/log/apache/access.log",
    follow_freq(1),
    flags(no-parse, validate-utf8)
  );
};
```

```
s_tail:
  # Salt will call the source function of syslog_ng module
  syslog_ng.config:
    - config:
      source:
        - file:
          - file: '''/var/log/apache/access.log'''
          - follow_freq : 1
          - flags:
            - no-parse
            - validate-utf8
```

OR

```
s_tail:
  syslog_ng.config:
    - config:
      source:
        - file:
          - '''/var/log/apache/access.log'''
          - follow_freq : 1
          - flags:
            - no-parse
            - validate-utf8
```

OR

```
source.s_tail:
  syslog_ng.config:
    - config:
      - file:
        - '''/var/log/apache/access.log'''
        - follow_freq : 1
        - flags:
          - no-parse
          - validate-utf8
```

### Complex source

```
source s_gsoc2014 {
  tcp(
    ip("0.0.0.0"),
    port(1234),
    flags(no-parse)
```

```
);  
};
```

```
s_gsoc2014:  
  syslog_ng.config:  
    - config:  
      source:  
        - tcp:  
          - ip: 0.0.0.0  
          - port: 1234  
          - flags: no-parse
```

### Filter

```
filter f_json {  
  match(  
    "@json:"  
  );  
};
```

```
f_json:  
  syslog_ng.config:  
    - config:  
      filter:  
        - match:  
          - "'@json:'"
```

### Template

```
template t_demo_filetemplate {  
  template(  
    "$ISODATE $HOST $MSG "  
  );  
  template_escape(  
    no  
  );  
};
```

```
t_demo_filetemplate:  
  syslog_ng.config:  
    -config:  
      template:  
        - template:  
          - "$ISODATE $HOST $MSG\n"  
        - template_escape:  
          - "no"
```

### Rewrite

```
rewrite r_set_message_to_MESSAGE {  
  set(  
    "${.json.message}",
```

```

    value("$MESSAGE")
  );
};

```

```

r_set_message_to_MESSAGE:
  syslog_ng.config:
    - config:
      rewrite:
        - set:
          - "${.json.message}"
          - value : "$MESSAGE"

```

### Global options

```

options {
  time_reap(30);
  mark_freq(10);
  keep_hostname(yes);
};

```

```

global_options:
  syslog_ng.config:
    - config:
      options:
        - time_reap: 30
        - mark_freq: 10
        - keep_hostname: "yes"

```

### Log

```

log {
  source(s_gsoc2014);
  junction {
    channel {
      filter(f_json);
      parser(p_json);
      rewrite(r_set_json_tag);
      rewrite(r_set_message_to_MESSAGE);
      destination {
        file(
          "/tmp/json-input.log",
          template(t_gsoc2014)
        );
      };
    };
    flags(final);
  };
  channel {
    filter(f_not_json);
    parser {
      syslog-parser(
    );
  };
};
rewrite(r_set_syslog_tag);

```

```
    flags(final);
  };
};
destination {
  file(
    "/tmp/all.log",
    template(t_gsoc2014)
  );
};
};
```

```
l_gsoc2014:
  syslog_ng.config:
    - config:
      log:
        - source: s_gsoc2014
        - junction:
          - channel:
            - filter: f_json
            - parser: p_json
            - rewrite: r_set_json_tag
            - rewrite: r_set_message_to_MESSAGE
            - destination:
              - file:
                - "/tmp/json-input.log"
                - template: t_gsoc2014
            - flags: final
          - channel:
            - filter: f_not_json
            - parser:
              - syslog-parser: []
            - rewrite: r_set_syslog_tag
            - flags: final
        - destination:
          - file:
            - "/tmp/all.log"
            - template: t_gsoc2014
```

## 3.4 Advanced Topics

### 3.4.1 SaltStack Walk-through

---

**Note:** Welcome to SaltStack! I am excited that you are interested in Salt and starting down the path to better infrastructure management. I developed (and am continuing to develop) Salt with the goal of making the best software available to manage computers of almost any kind. I hope you enjoy working with Salt and that the software can solve your real world needs!

- Thomas S Hatch
  - Salt creator and Chief Developer
  - CTO of SaltStack, Inc.
-

## Getting Started

### What is Salt?

Salt is a different approach to infrastructure management, founded on the idea that high-speed communication with large numbers of systems can open up new capabilities. This approach makes Salt a powerful multitasking system that can solve many specific problems in an infrastructure.

The backbone of Salt is the remote execution engine, which creates a high-speed, secure and bi-directional communication net for groups of systems. On top of this communication system, Salt provides an extremely fast, flexible, and easy-to-use configuration management system called `Salt States`.

### Installing Salt

SaltStack has been made to be very easy to install and get started. The [installation documents](#) contain instructions for all supported platforms.

### Starting Salt

Salt functions on a master/minion topology. A master server acts as a central control bus for the clients, which are called `minions`. The minions connect back to the master.

**Setting Up the Salt Master** Turning on the Salt Master is easy -- just turn it on! The default configuration is suitable for the vast majority of installations. The Salt Master can be controlled by the local Linux/Unix service manager:

On Systemd based platforms (OpenSuse, Fedora):

```
systemctl start salt-master
```

On Upstart based systems (Ubuntu, older Fedora/RHEL):

```
service salt-master start
```

On SysV Init systems (Debian, Gentoo etc.):

```
/etc/init.d/salt-master start
```

Alternatively, the Master can be started directly on the command-line:

```
salt-master -d
```

The Salt Master can also be started in the foreground in debug mode, thus greatly increasing the command output:

```
salt-master -l debug
```

The Salt Master needs to bind to two TCP network ports on the system. These ports are 4505 and 4506. For more in depth information on firewalling these ports, the firewall tutorial is available [here](#).

### Setting up a Salt Minion

**Note:** The Salt Minion can operate with or without a Salt Master. This walk-through assumes that the minion will be connected to the master, for information on how to run a master-less minion please see the master-less quick-start guide:

[Masterless Minion Quickstart](#)

---

The Salt Minion only needs to be aware of one piece of information to run, the network location of the master.

By default the minion will look for the DNS name `salt` for the master, making the easiest approach to set internal DNS to resolve the name `salt` back to the Salt Master IP.

Otherwise, the minion configuration file will need to be edited so that the configuration option `master` points to the DNS name or the IP of the Salt Master:

---

**Note:** The default location of the configuration files is `/etc/salt`. Most platforms adhere to this convention, but platforms such as FreeBSD and Microsoft Windows place this file in different locations.

---

`/etc/salt/minion:`

```
master: saltmaster.example.com
```

Now that the master can be found, start the minion in the same way as the master; with the platform init system or via the command line directly:

As a daemon:

```
salt-minion -d
```

In the foreground in debug mode:

```
salt-minion -l debug
```

When the minion is started, it will generate an `id` value, unless it has been generated on a previous run and cached in the configuration directory, which is `/etc/salt` by default. This is the name by which the minion will attempt to authenticate to the master. The following steps are attempted, in order to try to find a value that is not `localhost`:

1. The Python function `socket.getfqdn()` is run
2. `/etc/hostname` is checked (non-Windows only)
3. `/etc/hosts` (`%WINDIR%\system32\drivers\etc\hosts` on Windows hosts) is checked for hostnames that map to anything within `127.0.0.0/8`.

If none of the above are able to produce an `id` which is not `localhost`, then a sorted list of IP addresses on the minion (excluding any within `127.0.0.0/8`) is inspected. The first publicly-routable IP address is used, if there is one. Otherwise, the first privately-routable IP address is used.

If all else fails, then `localhost` is used as a fallback.

---

**Note:** Overriding the `id`

The minion `id` can be manually specified using the `id` parameter in the minion config file. If this configuration value is specified, it will override all other sources for the `id`.

---

Now that the minion is started, it will generate cryptographic keys and attempt to connect to the master. The next step is to venture back to the master server and accept the new minion's public key.

**Using salt-key** Salt authenticates minions using public-key encryption and authentication. For a minion to start accepting commands from the master, the minion keys need to be accepted by the master.

The `salt-key` command is used to manage all of the keys on the master. To list the keys that are on the master:

```
salt-key -L
```

The keys that have been rejected, accepted, and pending acceptance are listed. The easiest way to accept the minion key is to accept all pending keys:

```
salt-key -A
```

**Note:** Keys should be verified! Print the master key fingerprint by running `salt-key -F master` on the Salt master. Copy the `master.pub` fingerprint from the Local Keys section, and then set this value as the `master_finger` in the minion configuration file. Restart the Salt minion.

On the master, run `salt-key -f minion-id` to print the fingerprint of the minion's public key that was received by the master. On the minion, run `salt-call key.finger --local` to print the fingerprint of the minion key.

On the master:

```
# salt-key -f foo.domain.com
Unaccepted Keys:
foo.domain.com: 39:f9:e4:8a:aa:74:8d:52:1a:ec:92:03:82:09:c8:f9
```

On the minion:

```
# salt-call key.finger --local
local:
  39:f9:e4:8a:aa:74:8d:52:1a:ec:92:03:82:09:c8:f9
```

If they match, approve the key with `salt-key -a foo.domain.com`.

**Sending the First Commands** Now that the minion is connected to the master and authenticated, the master can start to command the minion.

Salt commands allow for a vast set of functions to be executed and for specific minions and groups of minions to be targeted for execution.

The `salt` command is comprised of command options, target specification, the function to execute, and arguments to the function.

A simple command to start with looks like this:

```
salt '*' test.ping
```

The `*` is the target, which specifies all minions.

`test.ping` tells the minion to run the `test.ping` function.

In the case of `test.ping`, `test` refers to a [execution module](#). `ping` refers to the `ping` function contained in the aforementioned `test` module.

**Note:** Execution modules are the workhorses of Salt. They do the work on the system to perform various tasks, such as manipulating files and restarting services.

The result of running this command will be the master instructing all of the minions to execute `test.ping` in parallel and return the result.

This is not an actual ICMP ping, but rather a simple function which returns True. Using `test.ping` is a good way of confirming that a minion is connected.

**Note:** Each minion registers itself with a unique minion ID. This ID defaults to the minion's hostname, but can be explicitly defined in the minion config as well by using the `id` parameter.

Of course, there are hundreds of other modules that can be called just as `test.ping` can. For example, the following would return disk usage on all targeted minions:

```
salt '*' disk.usage
```

**Getting to Know the Functions** Salt comes with a vast library of functions available for execution, and Salt functions are self-documenting. To see what functions are available on the minions execute the `sys.doc` function:

```
salt '*' sys.doc
```

This will display a very large list of available functions and documentation on them.

---

**Note:** Module documentation is also available [on the web](#).

---

These functions cover everything from shelling out to package management to manipulating database servers. They comprise a powerful system management API which is the backbone to Salt configuration management and many other aspects of Salt.

---

**Note:** Salt comes with many plugin systems. The functions that are available via the `salt` command are called [Execution Modules](#).

---

**Helpful Functions to Know** The `cmd` module contains functions to shell out on minions, such as `cmd.run` and `cmd.run_all`:

```
salt '*' cmd.run 'ls -l /etc'
```

The `pkg` functions automatically map local system package managers to the same salt functions. This means that `pkg.install` will install packages via `yum` on Red Hat based systems, `apt` on Debian systems, etc.:

```
salt '*' pkg.install vim
```

---

**Note:** Some custom Linux spins and derivatives of other distributions are not properly detected by Salt. If the above command returns an error message saying that `pkg.install` is not available, then you may need to override the `pkg` provider. This process is explained [here](#).

---

The `network.interfaces` function will list all interfaces on a minion, along with their IP addresses, netmasks, MAC addresses, etc:

```
salt '*' network.interfaces
```

**Changing the Output Format** The default output format used for most Salt commands is called the `nested` outputter, but there are several other outputters that can be used to change the way the output is displayed. For instance, the `pprint` outputter can be used to display the return data using Python's `pprint` module:

```
root@saltmaster:~# salt myminion grains.item pythonpath --out=pprint
{'myminion': {'pythonpath': ['/usr/lib64/python2.7',
                             '/usr/lib/python2.7/plat-linux2',
                             '/usr/lib64/python2.7/lib-tk',
                             '/usr/lib/python2.7/lib-tk',
                             '/usr/lib/python2.7/site-packages',
                             '/usr/lib/python2.7/site-packages/gst-0.10',
                             '/usr/lib/python2.7/site-packages/gtk-2.0']}}}
```

The full list of Salt outputters, as well as example output, can be found [here](#).

**salt-call** The examples so far have described running commands from the Master using the `salt` command, but when troubleshooting it can be more beneficial to login to the minion directly and use `salt-call`.

Doing so allows you to see the minion log messages specific to the command you are running (which are *not* part of the return data you see when running the command from the Master using `salt`), making it unnecessary to tail the minion log. More information on `salt-call` and how to use it can be found [here](#).

**Grains** Salt uses a system called [Grains](#) to build up static data about minions. This data includes information about the operating system that is running, CPU architecture and much more. The grains system is used throughout Salt to deliver platform data to many components and to users.

Grains can also be statically set, this makes it easy to assign values to minions for grouping and managing.

A common practice is to assign grains to minions to specify what the role or roles a minion might be. These static grains can be set in the minion configuration file or via the `grains.setval` function.

**Targeting** Salt allows for minions to be targeted based on a wide range of criteria. The default targeting system uses globular expressions to match minions, hence if there are minions named `larry1`, `larry2`, `curly1`, and `curly2`, a glob of `larry*` will match `larry1` and `larry2`, and a glob of `*1` will match `larry1` and `curly1`.

Many other targeting systems can be used other than globs, these systems include:

**Regular Expressions** Target using PCRE-compliant regular expressions

**Grains** Target based on grains data: [Targeting with Grains](#)

**Pillar** Target based on pillar data: [Targeting with Pillar](#)

**IP** Target based on IP address/subnet/range

**Compound** Create logic to target based on multiple targets: [Targeting with Compound](#)

**Nodegroup** Target with nodegroups: [Targeting with Nodegroup](#)

The concepts of targets are used on the command line with Salt, but also function in many other areas as well, including the state system and the systems used for ACLs and user permissions.

**Passing in Arguments** Many of the functions available accept arguments which can be passed in on the command line:

```
salt '*' pkg.install vim
```

This example passes the argument `vim` to the `pkg.install` function. Since many functions can accept more complex input than just a string, the arguments are parsed through YAML, allowing for more complex data to be sent on the command line:

```
salt '*' test.echo 'foo: bar'
```

In this case Salt translates the string ``foo: bar'` into the dictionary ``{'foo': `bar}'`

---

**Note:** Any line that contains a newline will not be parsed by YAML.

---

## Salt States

Now that the basics are covered the time has come to evaluate States. Salt States, or the State System is the component of Salt made for configuration management.

The state system is already available with a basic Salt setup, no additional configuration is required. States can be set up immediately.

---

**Note:** Before diving into the state system, a brief overview of how states are constructed will make many of the concepts clearer. Salt states are based on data modeling and build on a low level data structure that is used to execute each state function. Then more logical layers are built on top of each other.

The high layers of the state system which this tutorial will cover consists of everything that needs to be known to use states, the two high layers covered here are the *sls* layer and the highest layer *highstate*.

Understanding the layers of data management in the State System will help with understanding states, but they never need to be used. Just as understanding how a compiler functions assists when learning a programming language, understanding what is going on under the hood of a configuration management system will also prove to be a valuable asset.

---

### The First SLS Formula

The state system is built on SLS formulas. These formulas are built out in files on Salt's file server. To make a very basic SLS formula open up a file under `/srv/salt` named `vim.sls`. The following state ensures that vim is installed on a system to which that state has been applied.

```
/srv/salt/vim.sls:
```

```
vim:
  pkg.installed
```

Now install vim on the minions by calling the SLS directly:

```
salt '*' state.apply vim
```

This command will invoke the state system and run the `vim` SLS.

Now, to beef up the vim SLS formula, a `vimrc` can be added:

```
/srv/salt/vim.sls:
```

```
vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
    - source: salt://vimrc
    - mode: 644
    - user: root
    - group: root
```

Now the desired `vimrc` needs to be copied into the Salt file server to `/srv/salt/vimrc`. In Salt, everything is a file, so no path redirection needs to be accounted for. The `vimrc` file is placed right next to the `vim.sls` file. The same command as above can be executed to all the vim SLS formulas and now include managing the file.

---

**Note:** Salt does not need to be restarted/reloaded or have the master manipulated in any way when changing SLS formulas. They are instantly available.

---

### Adding Some Depth

Obviously maintaining SLS formulas right in a single directory at the root of the file server will not scale out to reasonably sized deployments. This is why more depth is required. Start by making an `nginx` formula a better way, make an `nginx` subdirectory and add an `init.sls` file:

```
/srv/salt/nginx/init.sls:
```

```
nginx:
  pkg.installed: []
  service.running:
    - require:
      - pkg: nginx
```

A few concepts are introduced in this SLS formula.

First is the service statement which ensures that the `nginx` service is running.

Of course, the `nginx` service can't be started unless the package is installed -- hence the `require` statement which sets up a dependency between the two.

The `require` statement makes sure that the required component is executed before and that it results in success.

**Note:** The `require` option belongs to a family of options called *requisites*. Requisites are a powerful component of Salt States, for more information on how requisites work and what is available see: [Requisites](#)

Also evaluation ordering is available in Salt as well: [Ordering States](#)

This new `sls` formula has a special name -- `init.sls`. When an SLS formula is named `init.sls` it inherits the name of the directory path that contains it. This formula can be referenced via the following command:

```
salt '*' state.apply nginx
```

**Note:** `state.apply` is just another remote execution function, just like `test.ping` or `disk.usage`. It simply takes the name of an SLS file as an argument.

Now that subdirectories can be used, the `vim.sls` formula can be cleaned up. To make things more flexible, move the `vim.sls` and `vimrc` into a new subdirectory called `edit` and change the `vim.sls` file to reflect the change:

```
/srv/salt/edit/vim.sls:
```

```
vim:
  pkg.installed

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
    - mode: 644
    - user: root
    - group: root
```

Only the source path to the `vimrc` file has changed. Now the formula is referenced as `edit.vim` because it resides in the `edit` subdirectory. Now the `edit` subdirectory can contain formulas for `emacs`, `nano`, `joe` or any other editor that may need to be deployed.

### Next Reading

Two walk-throughs are specifically recommended at this point. First, a deeper run through States, followed by an explanation of Pillar.

1. [Starting States](#)
2. [Pillar Walkthrough](#)

An understanding of Pillar is extremely helpful in using States.

### Getting Deeper Into States

Two more in-depth States tutorials exist, which delve much more deeply into States functionality.

1. [How Do I Use Salt States?](#), covers much more to get off the ground with States.
2. The [States Tutorial](#) also provides a fantastic introduction.

These tutorials include much more in-depth information including templating SLS formulas etc.

### So Much More!

This concludes the initial Salt walk-through, but there are many more things still to learn! These documents will cover important core aspects of Salt:

- [Pillar](#)
- [Job Management](#)

A few more tutorials are also available:

- [Remote Execution Tutorial](#)
- [Standalone Minion](#)

This still is only scratching the surface, many components such as the reactor and event systems, extending Salt, modular components and more are not covered here. For an overview of all Salt features and documentation, look at the [Table of Contents](#).

## 3.4.2 MinionFS Backend Walkthrough

### Propagating Files

New in version 2014.1.0.

Sometimes, one might need to propagate files that are generated on a minion. Salt already has a feature to send files from a minion to the master.

### Enabling File Propagation

To enable propagation, the `file_recv` option needs to be set to `True`.

```
file_recv: True
```

These changes require a restart of the master, then new requests for the `salt://minion-id/` protocol will send files that are pushed by `cp.push` from `minion-id` to the master.

```
salt 'minion-id' cp.push /path/to/the/file
```

This command will store the file, including its full path, under `cachedir/master/minions/minion-id/files`. With the default `cachedir` the example file above would be stored as `/var/cache/salt/master/minions/minion-id/files/path/to/the/file`.

**Note:** This walkthrough assumes basic knowledge of Salt and `cp.push`. To get up to speed, check out the [walkthrough](#).

## MinionFS Backend

Since it is not a good idea to expose the whole `cachedir`, MinionFS should be used to send these files to other minions.

### Simple Configuration

To use the minionfs backend only two configuration changes are required on the master. The `fileserver_backend` option needs to contain a value of `minion` and `file_recv` needs to be set to true:

```
fileserver_backend:
  - roots
  - minion

file_recv: True
```

These changes require a restart of the master, then new requests for the `salt://minion-id/` protocol will send files that are pushed by `cp.push` from `minion-id` to the master.

**Note:** All of the files that are pushed to the master are going to be available to all of the minions. If this is not what you want, please remove `minion` from `fileserver_backend` in the master config file.

**Note:** Having directories with the same name as your minions in the root that can be accessed like `salt://minion-id/` might cause confusion.

## Commandline Example

Lets assume that we are going to generate SSH keys on a minion called `minion-source` and put the public part in `~/.ssh/authorized_keys` of root user of a minion called `minion-destination`.

First, lets make sure that `/root/.ssh` exists and has the right permissions:

```
[root@salt-master file]# salt '*' file.mkdir dir_path=/root/.ssh user=root group=root mode=700
minion-source:
  None
minion-destination:
  None
```

We create an RSA key pair without a passphrase <sup>\*0</sup>:

<sup>0</sup> Yes, that was the actual key on my server, but the server is already destroyed.

```
[root@salt-master file]# salt 'minion-source' cmd.run 'ssh-keygen -N "" -f /root/.ssh/id_rsa'
minion-source:
  Generating public/private rsa key pair.
  Your identification has been saved in /root/.ssh/id_rsa.
  Your public key has been saved in /root/.ssh/id_rsa.pub.
  The key fingerprint is:
  9b:cd:1c:b9:c2:93:8e:ad:a3:52:a0:8b:0a:cc:d4:9b root@minion-source
  The key's randomart image is:
  +--[ RSA 2048]-----+
  |
  |
  |   o      .
  |  oo   S o
  |=  +   . B o
  |o+ E   B =
  |+ .   .+ o
  |o   ...ooo
  +-----+

```

and we send the public part to the master to be available to all minions:

```
[root@salt-master file]# salt 'minion-source' cp.push /root/.ssh/id_rsa.pub
minion-source:
  True

```

now it can be seen by everyone:

```
[root@salt-master file]# salt 'minion-destination' cp.list_master_dirs
minion-destination:
  - .
  - etc
  - minion-source/root
  - minion-source/root/.ssh

```

Lets copy that as the only authorized key to minion-destination:

```
[root@salt-master file]# salt 'minion-destination' cp.get_file salt://minion-source/root/.ssh/id_rsa.pub
minion-destination:
  /root/.ssh/authorized_keys

```

Or we can use a more elegant and salty way to add an SSH key:

```
[root@salt-master file]# salt 'minion-destination' ssh.set_auth_key_from_file user=root source=salt://minion-source/root/.ssh/id_rsa.pub
minion-destination:
  new

```

### 3.4.3 Automatic Updates / Frozen Deployments

New in version 0.10.3.d.

Salt has support for the [Esky](#) application freezing and update tool. This tool allows one to build a complete zipfile out of the salt scripts and all their dependencies - including shared objects / DLLs.

## Getting Started

To build frozen applications, suitable build environment will be needed for each platform. You should probably set up a virtualenv in order to limit the scope of Q/A.

This process does work on Windows. Directions are available at <https://github.com/saltstack/salt-windows-install> for details on installing Salt in Windows. Only the 32-bit Python and dependencies have been tested, but they have been tested on 64-bit Windows.

Install `bbfreeze`, and then `esky` from PyPI in order to enable the `bdist_esky` command in `setup.py`. Salt itself must also be installed, in addition to its dependencies.

## Building and Freezing

Once you have your tools installed and the environment configured, use `setup.py` to prepare the distribution files.

```
python setup.py sdist
python setup.py bdist
```

Once the distribution files are in place, Esky can be used traverse the module tree and pack all the scripts up into a redistributable.

```
python setup.py bdist_esky
```

There will be an appropriately versioned `salt-VERSION.zip` in `dist/` if everything went smoothly.

## Windows

`C:\Python27\lib\site-packages\zmq` will need to be added to the PATH variable. This helps `bbfreeze` find the `zmq` DLL so it can pack it up.

## Using the Frozen Build

Unpack the zip file in the desired install location. Scripts like `salt-minion` and `salt-call` will be in the root of the zip file. The associated libraries and bootstrapping will be in the directories at the same level. (Check the [Esky](#) documentation for more information)

To support updating your minions in the wild, put the builds on a web server that the minions can reach. `salt.modules.saltutil.update()` will trigger an update and (optionally) a restart of the minion service under the new version.

## Troubleshooting

### A Windows minion isn't responding

The process dispatch on Windows is slower than it is on \*nix. It may be necessary to add `-t 15'` to salt commands to give minions plenty of time to return.

### Windows and the Visual Studio Redist

The Visual C++ 2008 32-bit redistributable will need to be installed on all Windows minions. Esky has an option to pack the library into the zipfile, but OpenSSL does not seem to acknowledge the new location. If a no

OPENSSL\_AppLink error appears on the console when trying to start a frozen minion, the redistributable is not installed.

### Mixed Linux environments and Yum

The Yum Python module doesn't appear to be available on any of the standard Python package mirrors. If RHEL/CentOS systems need to be supported, the frozen build should be created on that platform to support all the Linux nodes. Remember to build the virtualenv with `--system-site-packages` so that the yum module is included.

### Automatic (Python) module discovery

Automatic (Python) module discovery does not work with the late-loaded scheme that Salt uses for (Salt) modules. Any misbehaving modules will need to be explicitly added to the `freezer_includes` in Salt's `setup.py`. Always check the zipped application to make sure that the necessary modules were included.

## 3.4.4 Multi Master Tutorial

As of Salt 0.16.0, the ability to connect minions to multiple masters has been made available. The multi-master system allows for redundancy of Salt masters and facilitates multiple points of communication out to minions. When using a multi-master setup, all masters are running hot, and any active master can be used to send commands out to the minions.

---

**Note:** If you need failover capabilities with multiple masters, there is also a MultiMaster-PKI setup available, that uses a different topology [MultiMaster-PKI with Failover Tutorial](#)

---

In 0.16.0, the masters do not share any information, keys need to be accepted on both masters, and shared files need to be shared manually or use tools like the git fileserver backend to ensure that the `file_roots` are kept consistent.

### Summary of Steps

1. Create a redundant master server
2. Copy primary master key to redundant master
3. Start redundant master
4. Configure minions to connect to redundant master
5. Restart minions
6. Accept keys on redundant master

### Prepping a Redundant Master

The first task is to prepare the redundant master. If the redundant master is already running, stop it. There is only one requirement when preparing a redundant master, which is that masters share the same private key. When the first master was created, the master's identifying key pair was generated and placed in the master's `pkidir`. The default location of the master's key pair is `/etc/salt/pki/master/`. Take the private key, `master.pem`, and copy it to the same location on the redundant master. Do the same for the master's public key, `master.pub`. Assuming that no minions have yet been connected to the new redundant master, it is safe to delete any existing key in this location and replace it.

---

**Note:** There is no logical limit to the number of redundant masters that can be used.

---

Once the new key is in place, the redundant master can be safely started.

### Configure Minions

Since minions need to be master-aware, the new master needs to be added to the minion configurations. Simply update the minion configurations to list all connected masters:

```
master:
- saltmaster1.example.com
- saltmaster2.example.com
```

Now the minion can be safely restarted.

Now the minions will check into the original master and also check into the new redundant master. Both masters are first-class and have rights to the minions.

---

**Note:** Minions can automatically detect failed masters and attempt to reconnect to them quickly. To enable this functionality, set `master_alive_interval` in the minion config and specify a number of seconds to poll the masters for connection status.

If this option is not set, minions will still reconnect to failed masters but the first command sent after a master comes back up may be lost while the minion authenticates.

---

### Sharing Files Between Masters

Salt does not automatically share files between multiple masters. A number of files should be shared or sharing of these files should be strongly considered.

#### Minion Keys

Minion keys can be accepted the normal way using `salt-key` on both masters. Keys accepted, deleted, or rejected on one master will NOT be automatically managed on redundant masters; this needs to be taken care of by running `salt-key` on both masters or sharing the `/etc/salt/pki/master/{minions,minions_pre,minions_rejected}` directories between masters.

---

**Note:** While sharing the `/etc/salt/pki/master` directory will work, it is strongly discouraged, since allowing access to the `master.pem` key outside of Salt creates a *SERIOUS* security risk.

---

#### File\_Roots

The `file_roots` contents should be kept consistent between masters. Otherwise state runs will not always be consistent on minions since instructions managed by one master will not agree with other masters.

The recommended way to sync these is to use a fileserver backend like gitfs or to keep these files on shared storage.

## Pillar\_Roots

Pillar roots should be given the same considerations as *file\_roots*.

## Master Configurations

While reasons may exist to maintain separate master configurations, it is wise to remember that each master maintains independent control over minions. Therefore, access controls should be in sync between masters unless a valid reason otherwise exists to keep them inconsistent.

These access control options include but are not limited to:

- `external_auth`
- `client_acl`
- `peer`
- `peer_run`

### 3.4.5 Multi-Master-PKI Tutorial With Failover

This tutorial will explain, how to run a salt-environment where a single minion can have multiple masters and fail-over between them if its current master fails.

The individual steps are

- setup the master(s) to sign its auth-replies
- setup minion(s) to verify master-public-keys
- enable multiple masters on minion(s)
- enable master-check on minion(s)

Please note, that it is advised to have good knowledge of the salt- authentication and communication-process to understand this tutorial. All of the settings described here, go on top of the default authentication/communication process.

## Motivation

The default behaviour of a salt-minion is to connect to a master and accept the masters public key. With each publication, the master sends his public-key for the minion to check and if this public-key ever changes, the minion complains and exits. Practically this means, that there can only be a single master at any given time.

Would it not be much nicer, if the minion could have any number of masters (1:n) and jump to the next master if its current master died because of a network or hardware failure?

---

**Note:** There is also a MultiMaster-Tutorial with a different approach and topology than this one, that might also suite your needs or might even be better suited [Multi-Master Tutorial](#)

---

It is also desirable, to add some sort of authenticity-check to the very first public key a minion receives from a master. Currently a minions takes the first masters public key for granted.

## The Goal

Setup the master to sign the public key it sends to the minions and enable the minions to verify this signature for authenticity.

### Prepping the master to sign its public key

For signing to work, both master and minion must have the signing and/or verification settings enabled. If the master signs the public key but the minion does not verify it, the minion will complain and exit. The same happens, when the master does not sign but the minion tries to verify.

The easiest way to have the master sign its public key is to set

```
master_sign_pubkey: True
```

After restarting the salt-master service, the master will automatically generate a new key-pair

```
master_sign.pem
master_sign.pub
```

A custom name can be set for the signing key-pair by setting

```
master_sign_key_name: <name_without_suffix>
```

The master will then generate that key-pair upon restart and use it for creating the public keys signature attached to the auth-reply.

The computation is done for every auth-request of a minion. If many minions auth very often, it is advised to use `conf_master:master_pubkey_signature` and `conf_master:master_use_pubkey_signature` settings described below.

If multiple masters are in use and should sign their auth-replies, the signing key-pair `master_sign.*` has to be copied to each master. Otherwise a minion will fail to verify the masters public when connecting to a different master than it did initially. That is because the public keys signature was created with a different signing key-pair.

### Prepping the minion to verify received public keys

The minion must have the public key (and only that one!) available to be able to verify a signature it receives. That public key (defaults to `master_sign.pub`) must be copied from the master to the minions pki-directory.

```
/etc/salt/pki/minion/master_sign.pub
```

```
DO NOT COPY THE master_sign.pem FILE. IT MUST STAY ON THE MASTER AND ONLY THERE!
```

When that is done, enable the signature checking in the minions configuration

```
verify_master_pubkey_sign: True
```

and restart the minion. For the first try, the minion should be run in manual debug mode.

```
$ salt-minion -l debug
```

Upon connecting to the master, the following lines should appear on the output:

```
[DEBUG ] Attempting to authenticate with the Salt Master at 172.16.0.10
[DEBUG ] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBUG ] salt.crypt.verify_signature: Loading public key
[DEBUG ] salt.crypt.verify_signature: Verifying signature
```

```
[DEBUG ] Successfully verified signature of master public key with verification public key master_s
[INFO ] Received signed and verified master pubkey from master 172.16.0.10
[DEBUG ] Decrypting the current master AES key
```

If the signature verification fails, something went wrong and it will look like this

```
[DEBUG ] Attempting to authenticate with the Salt Master at 172.16.0.10
[DEBUG ] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBUG ] salt.crypt.verify_signature: Loading public key
[DEBUG ] salt.crypt.verify_signature: Verifying signature
[DEBUG ] Failed to verify signature of public key
[CRITICAL] The Salt Master server's public key did not authenticate!
```

In a case like this, it should be checked, that the verification pubkey (master\_sign.pub) on the minion is the same as the one on the master.

Once the verification is successful, the minion can be started in daemon mode again.

For the paranoid among us, its also possible to verify the publication whenever it is received from the master. That is, for every single auth-attempt which can be quite frequent. For example just the start of the minion will force the signature to be checked 6 times for various things like auth, mine, *highstate*, etc.

If that is desired, enable the setting

```
always_verify_signature: True
```

### Multiple Masters For A Minion

Configuring multiple masters on a minion is done by specifying two settings:

- a list of masters addresses
- what type of master is defined

```
master:
- 172.16.0.10
- 172.16.0.11
- 172.16.0.12
```

```
master_type: failover
```

This tells the minion that all the master above are available for it to connect to. When started with this configuration, it will try the master in the order they are defined. To randomize that order, set

```
master_shuffle: True
```

The master-list will then be shuffled before the first connection attempt.

The first master that accepts the minion, is used by the minion. If the master does not yet know the minion, that counts as accepted and the minion stays on that master.

For the minion to be able to detect if its still connected to its current master enable the check for it

```
master_alive_interval: <seconds>
```

If the loss of the connection is detected, the minion will temporarily remove the failed master from the list and try one of the other masters defined (again shuffled if that is enabled).

## Testing the setup

At least two running masters are needed to test the failover setup.

Both masters should be running and the minion should be running on the command line in debug mode

```
$ salt-minion -l debug
```

The minion will connect to the first master from its master list

```
[DEBUG ] Attempting to authenticate with the Salt Master at 172.16.0.10
[DEBUG ] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBUG ] salt.crypt.verify_signature: Loading public key
[DEBUG ] salt.crypt.verify_signature: Verifying signature
[DEBUG ] Successfully verified signature of master public key with verification public key master_s
[INFO ] Received signed and verified master pubkey from master 172.16.0.10
[DEBUG ] Decrypting the current master AES key
```

A test ping on the master the minion is currently connected to should be run to test connectivity.

If successful, that master should be turned off. A firewall-rule denying the minions packets will also do the trick.

Depending on the configured `conf_minion:master_alive_interval`, the minion will notice the loss of the connection and log it to its logfile.

```
[INFO ] Connection to master 172.16.0.10 lost
[INFO ] Trying to tune in to next master from master-list
```

The minion will then remove the current master from the list and try connecting to the next master

```
[INFO ] Removing possibly failed master 172.16.0.10 from list of masters
[WARNING ] Master ip address changed from 172.16.0.10 to 172.16.0.11
[DEBUG ] Attempting to authenticate with the Salt Master at 172.16.0.11
```

If everything is configured correctly, the new masters public key will be verified successfully

```
[DEBUG ] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBUG ] salt.crypt.verify_signature: Loading public key
[DEBUG ] salt.crypt.verify_signature: Verifying signature
[DEBUG ] Successfully verified signature of master public key with verification public key master_s
```

the authentication with the new master is successful

```
[INFO ] Received signed and verified master pubkey from master 172.16.0.11
[DEBUG ] Decrypting the current master AES key
[DEBUG ] Loaded minion key: /etc/salt/pki/minion/minion.pem
[INFO ] Authentication with master successful!
```

and the minion can be pinged again from its new master.

## Performance Tuning

With the setup described above, the master computes a signature for every auth-request of a minion. With many minions and many auth-requests, that can chew up quite a bit of CPU-Power.

To avoid that, the master can use a pre-created signature of its public-key. The signature is saved as a base64 encoded string which the master reads once when starting and attaches only that string to auth-replies.

Enabling this also gives paranoid users the possibility, to have the signing key-pair on a different system than the actual salt-master and create the public keys signature there. Probably on a system with more restrictive firewall rules, without internet access, less users, etc.

That signature can be created with

```
$ salt-key --gen-signature
```

This will create a default signature file in the master pki-directory

```
/etc/salt/pki/master/master_pubkey_signature
```

It is a simple text-file with the binary-signature converted to base64.

If no signing-pair is present yet, this will auto-create the signing pair and the signature file in one call

```
$ salt-key --gen-signature --auto-create
```

Telling the master to use the pre-created signature is done with

```
master_use_pubkey_signature: True
```

That requires the file `master\_pubkey\_signature` to be present in the masters pki-directory with the correct signature.

If the signature file is named differently, its name can be set with

```
master_pubkey_signature: <filename>
```

With many masters and many public-keys (default and signing), it is advised to use the salt-masters hostname for the signature-files name. Signatures can be easily confused because they do not provide any information about the key the signature was created from.

Verifying that everything works is done the same way as above.

### How the signing and verification works

The default key-pair of the salt-master is

```
/etc/salt/pki/master/master.pem  
/etc/salt/pki/master/master.pub
```

To be able to create a signature of a message (in this case a public-key), another key-pair has to be added to the setup. Its default name is:

```
master_sign.pem  
master_sign.pub
```

The combination of the master.\* and master\_sign.\* key-pairs give the possibility of generating signatures. The signature of a given message is unique and can be verified, if the public-key of the signing-key-pair is available to the recipient (the minion).

The signature of the masters public-key in master.pub is computed with

```
master_sign.pem  
master.pub  
M2Crypto.EVP.sign_update()
```

This results in a binary signature which is converted to base64 and attached to the auth-reply send to the minion.

With the signing-pairs public-key available to the minion, the attached signature can be verified with

```

master_sign.pub
master.pub
M2Cryptos EVP.verify_update().

```

When running multiple masters, either the signing key-pair has to be present on all of them, or the `master_pubkey_signature` has to be pre-computed for each master individually (because they all have different public-keys).

DO NOT PUT THE SAME `master.pub` ON ALL MASTERS FOR EASE OF USE.

### 3.4.6 Preseed Minion with Accepted Key

In some situations, it is not convenient to wait for a minion to start before accepting its key on the master. For instance, you may want the minion to bootstrap itself as soon as it comes online. You may also want to let your developers provision new development machines on the fly.

**See also:**

Many ways to preseed minion keys

Salt has other ways to generate and pre-accept minion keys in addition to the manual steps outlined below.

`salt-cloud` performs these same steps automatically when new cloud VMs are created (unless instructed not to).

`salt-api` exposes an HTTP call to Salt's REST API to *generate and download the new minion keys as a tarball*.

There is a general four step process to do this:

1. Generate the keys on the master:

```

root@saltmaster# salt-key --gen-keys=[key_name]

```

Pick a name for the key, such as the minion's id.

2. Add the public key to the accepted minion folder:

```

root@saltmaster# cp key_name.pub /etc/salt/pki/master/minions/[minion_id]

```

It is necessary that the public key file has the same name as your minion id. This is how Salt matches minions with their keys. Also note that the `pki` folder could be in a different location, depending on your OS or if specified in the master config file.

3. Distribute the minion keys.

There is no single method to get the keypair to your minion. The difficulty is finding a distribution method which is secure. For Amazon EC2 only, an AWS best practice is to use IAM Roles to pass credentials. (See blog post, <http://blogs.aws.amazon.com/security/post/Tx610S2MLVZWEA/Using-IAM-roles-to-distribute-non-AWS-credentials-to-your-EC2-instances> )

---

#### Security Warning

Since the minion key is already accepted on the master, distributing the private key poses a potential security risk. A malicious party will have access to your entire state tree and other sensitive data if they gain access to a preseeded minion key.

---

4. Preseed the Minion with the keys

You will want to place the minion keys before starting the `salt-minion` daemon:

```
/etc/salt/pki/minion/minion.pem
/etc/salt/pki/minion/minion.pub
```

Once in place, you should be able to start `salt-minion` and run `salt-call state.apply` or any other salt commands that require master authentication.

### 3.4.7 Salt Bootstrap

The Salt Bootstrap script allows for a user to install the Salt Minion or Master on a variety of system distributions and versions. This shell script known as `bootstrap-salt.sh` runs through a series of checks to determine the operating system type and version. It then installs the Salt binaries using the appropriate methods. The Salt Bootstrap script installs the minimum number of packages required to run Salt. This means that in the event you run the bootstrap to install via package, Git will not be installed. Installing the minimum number of packages helps ensure the script stays as lightweight as possible, assuming the user will install any other required packages after the Salt binaries are present on the system. The script source is available on GitHub: <https://github.com/saltstack/salt-bootstrap>

#### Supported Operating Systems

- Amazon Linux 2012.09
- Arch
- CentOS 5/6
- Debian 6.x/7.x/8(git installations only)
- Fedora 17/18
- FreeBSD 9.1/9.2/10
- Gentoo
- Linaro
- Linux Mint 13/14
- OpenSUSE 12.x
- Oracle Linux 5/5
- Red Hat 5/6
- Red Hat Enterprise 5/6
- Scientific Linux 5/6
- SmartOS
- SuSE 11 SP1/11 SP2
- Ubuntu 10.x/11.x/12.x/13.04/13.10
- Elementary OS 0.2

---

**Note:** In the event you do not see your distribution or version available please review the develop branch on Github as it main contain updates that are not present in the stable release: <https://github.com/saltstack/salt-bootstrap/tree/develop>

---

## Example Usage

If you're looking for the *one-liner* to install salt, please scroll to the bottom and use the instructions for *Installing via an Insecure One-Liner*

**Note:** In every two-step example, you would be well-served to examine the downloaded file and examine it to ensure that it does what you expect.

Using `curl` to install latest git:

```
curl -L https://bootstrap.saltstack.com -o install_salt.sh
sudo sh install_salt.sh git develop
```

Using `wget` to install your distribution's stable packages:

```
wget -O install_salt.sh https://bootstrap.saltstack.com
sudo sh install_salt.sh
```

Install a specific version from git using `wget`:

```
wget -O install_salt.sh https://bootstrap.saltstack.com
sudo sh install_salt.sh -P git v0.16.4
```

If you already have python installed, python 2.6, then it's as easy as:

```
python -m urllib "https://bootstrap.saltstack.com" > install_salt.sh
sudo sh install_salt.sh git develop
```

All python versions should support the following one liner:

```
python -c 'import urllib; print urllib.urlopen("https://bootstrap.saltstack.com").read()' > install_s
sudo sh install_salt.sh git develop
```

On a FreeBSD base system you usually don't have either of the above binaries available. You **do** have `fetch` available though:

```
fetch -o install_salt.sh https://bootstrap.saltstack.com
sudo sh install_salt.sh
```

If all you want is to install a `salt-master` using latest git:

```
curl -o install_salt.sh -L https://bootstrap.saltstack.com
sudo sh install_salt.sh -M -N git develop
```

If you want to install a specific release version (based on the git tags):

```
curl -o install_salt.sh -L https://bootstrap.saltstack.com
sudo sh install_salt.sh git v0.16.4
```

To install a specific branch from a git fork:

```
curl -o install_salt.sh -L https://bootstrap.saltstack.com
sudo sh install_salt.sh -g https://github.com/myuser/salt.git git mybranch
```

## Installing via an Insecure One-Liner

The following examples illustrate how to install Salt via a one-liner.

**Note:** Warning! These methods do not involve a verification step and assume that the delivered file is trustworthy.

---

## Examples

Installing the latest develop branch of Salt:

```
curl -L https://bootstrap.saltstack.com | sudo sh -s -- git develop
```

Any of the example above which use two-lines can be made to run in a single-line configuration with minor modifications.

## Example Usage

The Salt Bootstrap script has a wide variety of options that can be passed as well as several ways of obtaining the bootstrap script itself.

For example, using `curl` to install your distribution's stable packages:

```
curl -L https://bootstrap.saltstack.com | sudo sh
```

Using `wget` to install your distribution's stable packages:

```
wget -O - https://bootstrap.saltstack.com | sudo sh
```

Installing the latest version available from git with `curl`:

```
curl -L https://bootstrap.saltstack.com | sudo sh -s -- git develop
```

Install a specific version from git using `wget`:

```
wget -O - https://bootstrap.saltstack.com | sh -s -- -P git v0.16.4
```

If you already have python installed, python 2.6, then it's as easy as:

```
python -m urllib "https://bootstrap.saltstack.com" | sudo sh -s -- git develop
```

All python versions should support the following one liner:

```
python -c 'import urllib; print urllib.urlopen("https://bootstrap.saltstack.com").read()' | \
sudo sh -s -- git develop
```

On a FreeBSD base system you usually don't have either of the above binaries available. You **do** have `fetch` available though:

```
fetch -o - https://bootstrap.saltstack.com | sudo sh
```

If all you want is to install a `salt-master` using latest git:

```
curl -L https://bootstrap.saltstack.com | sudo sh -s -- -M -N git develop
```

If you want to install a specific release version (based on the git tags):

```
curl -L https://bootstrap.saltstack.com | sudo sh -s -- git v0.16.4
```

Downloading the develop branch (from here standard command line options may be passed):

```
wget https://bootstrap.saltstack.com/develop
```

## Command Line Options

Here's a summary of the command line options:

```
$ sh bootstrap-salt.sh -h

Usage : bootstrap-salt.sh [options] <install-type> <install-type-args>

Installation types:
- stable (default)
- daily (ubuntu specific)
- git

Examples:
$ bootstrap-salt.sh
$ bootstrap-salt.sh stable
$ bootstrap-salt.sh daily
$ bootstrap-salt.sh git
$ bootstrap-salt.sh git develop
$ bootstrap-salt.sh git v0.17.0
$ bootstrap-salt.sh git 8c3fadf15ec183e5ce8c63739850d543617e4357

Options:
-h Display this message
-v Display script version
-n No colours.
-D Show debug output.
-c Temporary configuration directory
-g Salt repository URL. (default: git://github.com/saltstack/salt.git)
-k Temporary directory holding the minion keys which will pre-seed
  the master.
-M Also install salt-master
-S Also install salt-syndic
-N Do not install salt-minion
-X Do not start daemons after installation
-C Only run the configuration function. This option automatically
  bypasses any installation.
-P Allow pip based installations. On some distributions the required salt
  packages or its dependencies are not available as a package for that
  distribution. Using this flag allows the script to use pip as a last
  resort method. NOTE: This only works for functions which actually
  implement pip based installations.
-F Allow copied files to overwrite existing(config, init.d, etc)
-U If set, fully upgrade the system prior to bootstrapping salt
-K If set, keep the temporary files in the temporary directories specified
  with -c and -k.
-I If set, allow insecure connections while downloading any files. For
  example, pass '--no-check-certificate' to 'wget' or '--insecure' to 'curl'
-A Pass the salt-master DNS name or IP. This will be stored under
  ${BS_SALT_ETC_DIR}/minion.d/99-master-address.conf
-i Pass the salt-minion id. This will be stored under
  ${BS_SALT_ETC_DIR}/minion_id
-L Install the Apache Libcloud package if possible(required for salt-cloud)
-p Extra-package to install while installing salt dependencies. One package
  per -p flag. You're responsible for providing the proper package name.
```

### 3.4.8 Git Fileserver Backend Walkthrough

---

**Note:** This walkthrough assumes basic knowledge of Salt. To get up to speed, check out the [Salt Walkthrough](#).

---

The gitfs backend allows Salt to serve files from git repositories. It can be enabled by adding `git` to the `fileserver_backend` list, and configuring one or more repositories in `gitfs_remotes`.

Branches and tags become Salt fileserver environments.

#### Installing Dependencies

Beginning with version 2014.7.0, both `pygit2` and `Dulwich` are supported as alternatives to `GitPython`. The desired provider can be configured using the `gitfs_provider` parameter in the master config file.

If `gitfs_provider` is not configured, then Salt will prefer `pygit2` if a suitable version is available, followed by `GitPython` and `Dulwich`.

---

**Note:** It is recommended to always run the most recent version of any the below dependencies. Certain features of gitfs may not be available without the most recent version of the chosen library.

---

#### `pygit2`

The minimum supported version of `pygit2` is 0.20.3. Availability for this version of `pygit2` is still limited, though the SaltStack team is working to get compatible versions available for as many platforms as possible.

For the Fedora/EPEL versions which have a new enough version packaged, the following command would be used to install `pygit2`:

```
# yum install python-pygit2
```

Provided a valid version is packaged for Debian/Ubuntu (which is not currently the case), the package name would be the same, and the following command would be used to install it:

```
# apt-get install python-pygit2
```

If `pygit2` is not packaged for the platform on which the Master is running, the `pygit2` website has installation instructions [here](#). Keep in mind however that following these instructions will install `libgit2` and `pygit2` without system packages. Additionally, keep in mind that *SSH authentication in pygit2* requires `libssh2` (not `libssh`) development libraries to be present before `libgit2` is built.

#### GitPython

`GitPython` 0.3.0 or newer is required to use `GitPython` for gitfs. For RHEL-based Linux distros, a compatible version is available in EPEL, and can be easily installed on the master using yum:

```
# yum install GitPython
```

Ubuntu 14.04 LTS and Debian Wheezy (7.x) also have a compatible version packaged:

```
# apt-get install python-git
```

If your master is running an older version (such as Ubuntu 12.04 LTS or Debian Squeeze), then you will need to install `GitPython` using either `pip` or `easy_install` (it is recommended to use `pip`). Version 0.3.2.RC1 is now marked as the

stable release in PyPI, so it should be a simple matter of running `pip install GitPython` (or `easy_install GitPython`) as root.

**Warning:** Keep in mind that if GitPython has been previously installed on the master using pip (even if it was subsequently uninstalled), then it may still exist in the build cache (typically `/tmp/pip-build-root/GitPython`) if the cache is not cleared after installation. The package in the build cache will override any requirement specifiers, so if you try upgrading to version 0.3.2.RC1 by running `pip install 'GitPython==0.3.2.RC1'` then it will ignore this and simply install the version from the cache directory. Therefore, it may be necessary to delete the GitPython directory from the build cache in order to ensure that the specified version is installed.

## Dulwich

Dulwich 0.9.4 or newer is required to use Dulwich as backend for gitfs.

Dulwich is available in EPEL, and can be easily installed on the master using yum:

```
# yum install python-dulwich
```

For APT-based distros such as Ubuntu and Debian:

```
# apt-get install python-dulwich
```

**Important:** If switching to Dulwich from GitPython/pygit2, or switching from GitPython/pygit2 to Dulwich, it is necessary to clear the gitfs cache to avoid unpredictable behavior. This is probably a good idea whenever switching to a new *gitfs\_provider*, but it is less important when switching between GitPython and pygit2.

Beginning in version 2015.5.0, the gitfs cache can be easily cleared using the `filesERVER.clear_cache` runner.

```
salt-run fileserver.clear_cache backend=git
```

If the Master is running an earlier version, then the cache can be cleared by removing the `gitfs` and `file_lists/gitfs` directories (both paths relative to the master cache directory, usually `/var/cache/salt/master`).

```
rm -rf /var/cache/salt/master{,/file_lists}/gitfs
```

## Simple Configuration

To use the gitfs backend, only two configuration changes are required on the master:

1. Include `git` in the `fileserver_backend` list in the master config file:

```
fileserver_backend:
  - git
```

2. Specify one or more `git://`, `https://`, `file://`, or `ssh://` URLs in `gitfs_remotes` to configure which repositories to cache and search for requested files:

```
gitfs_remotes:
  - https://github.com/saltstack-formulas/salt-formula.git
```

SSH remotes can also be configured using scp-like syntax:

```
gitfs_remotes:
- git@github.com:user/repo.git
- ssh://user@domain.tld/path/to/repo.git
```

Information on how to authenticate to SSH remotes can be found [here](#).

---

**Note:** Dulwich does not recognize `ssh://` URLs, `git+ssh://` must be used instead. Salt version 2015.5.0 and later will automatically add the `git+` to the beginning of these URLs before fetching, but earlier Salt versions will fail to fetch unless the URL is specified using `git+ssh://`.

---

3. Restart the master to load the new configuration.

---

**Note:** In a master/minion setup, files from a gitfs remote are cached once by the master, so minions do not need direct access to the git repository.

---

## Multiple Remotes

The `gitfs_remotes` option accepts an ordered list of git remotes to cache and search, in listed order, for requested files.

A simple scenario illustrates this cascading lookup behavior:

If the `gitfs_remotes` option specifies three remotes:

```
gitfs_remotes:
- git://github.com/example/first.git
- https://github.com/example/second.git
- file:///root/third
```

And each repository contains some files:

```
first.git:
  top.sls
  edit/vim.sls
  edit/vimrc
  nginx/init.sls

second.git:
  edit/dev_vimrc
  haproxy/init.sls

third:
  haproxy/haproxy.conf
  edit/dev_vimrc
```

Salt will attempt to lookup the requested file from each gitfs remote repository in the order in which they are defined in the configuration. The `git://github.com/example/first.git` remote will be searched first. If the requested file is found, then it is served and no further searching is executed. For example:

- A request for the file `salt://haproxy/init.sls` will be served from the `https://github.com/example/second.git` git repo.
- A request for the file `salt://haproxy/haproxy.conf` will be served from the `file:///root/third` repo.

---

**Note:** This example is purposefully contrived to illustrate the behavior of the gitfs backend. This example should not be read as a recommended way to lay out files and git repos.

---

The `file://` prefix denotes a git repository in a local directory. However, it will still use the given `file://` URL as a remote, rather than copying the git repo to the salt cache. This means that any refs you want accessible must exist as *local* refs in the specified repo.

**Warning:** Salt versions prior to 2014.1.0 are not tolerant of changing the order of remotes or modifying the URI of existing remotes. In those versions, when modifying remotes it is a good idea to remove the gitfs cache directory (`/var/cache/salt/master/gitfs`) before restarting the salt-master service.

### Per-remote Configuration Parameters

New in version 2014.7.0.

The following master config parameters are global (that is, they apply to all configured gitfs remotes):

- `gitfs_base`
- `gitfs_root`
- `gitfs_mountpoint` (new in 2014.7.0)
- `gitfs_user` (**pygit2 only**, new in 2014.7.0)
- `gitfs_password` (**pygit2 only**, new in 2014.7.0)
- `gitfs_insecure_auth` (**pygit2 only**, new in 2014.7.0)
- `gitfs_pubkey` (**pygit2 only**, new in 2014.7.0)
- `gitfs_privkey` (**pygit2 only**, new in 2014.7.0)
- `gitfs_passphrase` (**pygit2 only**, new in 2014.7.0)

These parameters can now be overridden on a per-remote basis. This allows for a tremendous amount of customization. Here's some example usage:

```
gitfs_provider: pygit2
gitfs_base: develop

gitfs_remotes:
- https://foo.com/foo.git
- https://foo.com/bar.git:
  - root: salt
  - mountpoint: salt://foo/bar/baz
  - base: salt-base
- http://foo.com/baz.git:
  - root: salt/states
  - user: joe
  - password: mysupersecretpassword
  - insecure_auth: True
```

**Important:** There are two important distinctions which should be noted for per-remote configuration:

1. The URL of a remote which has per-remote configuration must be suffixed with a colon.
2. Per-remote configuration parameters are named like the global versions, with the `gitfs_` removed from the beginning.

In the example configuration above, the following is true:

1. The first and third gitfs remotes will use the `develop` branch/tag as the `base` environment, while the second one will use the `salt-base` branch/tag as the base environment.
2. The first remote will serve all files in the repository. The second remote will only serve files from the `salt` directory (and its subdirectories), while the third remote will only serve files from the `salt/states` directory (and its subdirectories).
3. The files from the second remote will be located under `salt://foo/bar/baz`, while the files from the first and third remotes will be located under the root of the Salt fileserver namespace (`salt://`).
4. The third remote overrides the default behavior of *not authenticating to insecure (non-HTTPS) remotes*.

### Serving from a Subdirectory

The `gitfs_root` parameter allows files to be served from a subdirectory within the repository. This allows for only part of a repository to be exposed to the Salt fileserver.

Assume the below layout:

```
.gitignore
README.txt
foo/
foo/bar/
foo/bar/one.txt
foo/bar/two.txt
foo/bar/three.txt
foo/baz/
foo/baz/top.sls
foo/baz/edit/vim.sls
foo/baz/edit/vimrc
foo/baz/nginx/init.sls
```

The below configuration would serve only the files under `foo/baz`, ignoring the other files in the repository:

```
gitfs_remotes:
  - git://mydomain.com/stuff.git

gitfs_root: foo/baz
```

The root can also be configured on a *per-remote basis*.

### Mountpoints

New in version 2014.7.0.

The `gitfs_mountpoint` parameter will prepend the specified path to the files served from gitfs. This allows an existing repository to be used, rather than needing to reorganize a repository or design it around the layout of the Salt fileserver.

Before the addition of this feature, if a file being served up via gitfs was deeply nested within the root directory (for example, `salt://webapps/foo/files/foo.conf`, it would be necessary to ensure that the file was properly located in the remote repository, and that all of the the parent directories were present (for example, the directories `webapps/foo/files/` would need to exist at the root of the repository).

The below example would allow for a file `foo.conf` at the root of the repository to be served up from the Salt fileserver path `salt://webapps/foo/files/foo.conf`.

```
gitfs_remotes:
- https://mydomain.com/stuff.git

gitfs_mountpoint: salt://webapps/foo/files
```

Mountpoints can also be configured on a *per-remote basis*.

### Using gitfs Alongside Other Backends

Sometimes it may make sense to use multiple backends; for instance, if `sls` files are stored in git but larger files are stored directly on the master.

The cascading lookup logic used for multiple remotes is also used with multiple backends. If the `fileserver_backend` option contains multiple backends:

```
fileserver_backend:
- roots
- git
```

Then the `roots` backend (the default backend of files in `/srv/salt`) will be searched first for the requested file; then, if it is not found on the master, each configured git remote will be searched.

### Branches, Environments, and Top Files

When using the gitfs backend, branches, and tags will be mapped to environments using the branch/tag name as an identifier.

There is one exception to this rule: the `master` branch is implicitly mapped to the `base` environment.

So, for a typical `base`, `qa`, `dev` setup, the following branches could be used:

```
master
qa
dev
```

`top.sls` files from different branches will be merged into one at runtime. Since this can lead to overly complex configurations, the recommended setup is to have the `top.sls` file only in the master branch and use environment-specific branches for state definitions.

To map a branch other than `master` as the `base` environment, use the `gitfs_base` parameter.

```
gitfs_base: salt-base
```

The base can also be configured on a *per-remote basis*.

### Environment Whitelist/Blacklist

New in version 2014.7.0.

The `gitfs_env_whitelist` and `gitfs_env_blacklist` parameters allow for greater control over which branches/tags are exposed as fileserver environments. Exact matches, globs, and regular expressions are supported, and are evaluated in that order. If using a regular expression, `^` and `$` must be omitted, and the expression must match the entire branch/tag.

```
gitfs_env_whitelist:  
- base  
- v1.*  
- 'mybranch\d+'
```

---

**Note:** `v1.*`, in this example, will match as both a glob and a regular expression (though it will have been matched as a glob, since globs are evaluated before regular expressions).

---

The behavior of the blacklist/whitelist will differ depending on which combination of the two options is used:

- If only `gitfs_env_whitelist` is used, then **only** branches/tags which match the whitelist will be available as environments
- If only `gitfs_env_blacklist` is used, then the branches/tags which match the blacklist will **not** be available as environments
- If both are used, then the branches/tags which match the whitelist, but do **not** match the blacklist, will be available as environments.

## Authentication

### pygit2

New in version 2014.7.0.

Both HTTPS and SSH authentication are supported as of version 0.20.3, which is the earliest version of `pygit2` supported by Salt for gitfs.

---

**Note:** The examples below make use of per-remote configuration parameters, a feature new to Salt 2014.7.0. More information on these can be found [here](#).

---

**HTTPS** For HTTPS repositories which require authentication, the username and password can be provided like so:

```
gitfs_remotes:  
- https://domain.tld/myrepo.git:  
  - user: git  
  - password: mypassword
```

If the repository is served over HTTP instead of HTTPS, then Salt will by default refuse to authenticate to it. This behavior can be overridden by adding an `insecure_auth` parameter:

```
gitfs_remotes:  
- http://domain.tld/insecure_repo.git:  
  - user: git  
  - password: mypassword  
  - insecure_auth: True
```

**SSH** SSH repositories can be configured using the `ssh://` protocol designation, or using scp-like syntax. So, the following two configurations are equivalent:

- `ssh://git@github.com/user/repo.git`
- `git@github.com:user/repo.git`

Both `gitfs_pubkey` and `gitfs_privkey` (or their *per-remote counterparts*) must be configured in order to authenticate to SSH-based repos. If the private key is protected with a passphrase, it can be configured using `gitfs_passphrase` (or simply `passphrase` if being configured *per-remote*). For example:

```
gitfs_remotes:
- git@github.com:user/repo.git:
  - pubkey: /root/.ssh/id_rsa.pub
  - privkey: /root/.ssh/id_rsa
  - passphrase: myawesomepassphrase
```

Finally, the SSH host key must be *added to the known\_hosts file*.

### GitPython

With `GitPython`, only passphrase-less SSH public key authentication is supported. The auth parameters (`pubkey`, `privkey`, etc.) shown in the `pygit2` authentication examples above do not work with `GitPython`.

```
gitfs_remotes:
- ssh://git@github.com/example/salt-states.git
```

Since `GitPython` wraps the git CLI, the private key must be located in `~/.ssh/id_rsa` for the user under which the Master is running, and should have permissions of `0600`. Also, in the absence of a user in the repo URL, `GitPython` will (just as SSH does) attempt to login as the current user (in other words, the user under which the Master is running, usually `root`).

If a key needs to be used, then `~/.ssh/config` can be configured to use the desired key. Information on how to do this can be found by viewing the manpage for `ssh_config`. Here's an example entry which can be added to the `~/.ssh/config` to use an alternate key for `gitfs`:

```
Host github.com
  IdentityFile /root/.ssh/id_rsa_gitfs
```

The `Host` parameter should be a hostname (or hostname glob) that matches the domain name of the git repository.

It is also necessary to *add the SSH host key to the known\_hosts file*. The exception to this would be if strict host key checking is disabled, which can be done by adding `StrictHostKeyChecking no` to the entry in `~/.ssh/config`

```
Host github.com
  IdentityFile /root/.ssh/id_rsa_gitfs
  StrictHostKeyChecking no
```

However, this is generally regarded as insecure, and is not recommended.

### Adding the SSH Host Key to the known\_hosts File

To use SSH authentication, it is necessary to have the remote repository's SSH host key in the `~/.ssh/known_hosts` file. If the master is also a minion, this can be done using the `ssh.set_known_host` function:

```
# salt mymaster ssh.set_known_host user=root hostname=github.com
mymaster:
-----
new:
-----
enc:
```

```

ssh-rsa
fingerprint:
  16:27:ac:a5:76:28:2d:36:63:1b:56:4d:eb:df:a6:48
hostname:
  |1|OiefWWqOD4kw03BhoIGa0loR5AA=|BIXVtmcTbPER+68HvXmceodDcfI=
key:
  AAAAB3NzaC1yc2EAAAABIwAAAQEAq2A7hRGmdnm9tUDb09IDSwBK6TbQa+PXYPcPy6rbTrTtw7PHkccKrpp0yVhp
old:
  None
status:
  updated

```

If not, then the easiest way to add the key is to su to the user (usually root) under which the salt-master runs and attempt to login to the server via SSH:

```

$ su
Password:
# ssh github.com
The authenticity of host 'github.com (192.30.252.128)' can't be established.
RSA key fingerprint is 16:27:ac:a5:76:28:2d:36:63:1b:56:4d:eb:df:a6:48.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'github.com,192.30.252.128' (RSA) to the list of known hosts.
Permission denied (publickey).

```

It doesn't matter if the login was successful, as answering yes will write the fingerprint to the known\_hosts file.

**Verifying the Fingerprint** To verify that the correct fingerprint was added, it is a good idea to look it up. One way to do this is to use nmap:

```

$ nmap github.com --script ssh-hostkey

Starting Nmap 5.51 ( http://nmap.org ) at 2014-08-18 17:47 CDT
Nmap scan report for github.com (192.30.252.129)
Host is up (0.17s latency).
Not shown: 996 filtered ports
PORT      STATE SERVICE
22/tcp    open  ssh
| ssh-hostkey: 1024 ad:1c:08:a4:40:e3:6f:9c:f5:66:26:5d:4b:33:5d:8c (DSA)
|_2048 16:27:ac:a5:76:28:2d:36:63:1b:56:4d:eb:df:a6:48 (RSA)
80/tcp    open  http
443/tcp   open  https
9418/tcp   open  git

Nmap done: 1 IP address (1 host up) scanned in 28.78 seconds

```

Another way is to check one's own known\_hosts file, using this one-liner:

```

$ ssh-keygen -l -f /dev/stdin <<<`ssh-keyscan -t rsa github.com 2>/dev/null` | awk '{print $2}'
16:27:ac:a5:76:28:2d:36:63:1b:56:4d:eb:df:a6:48

```

### Refreshing gitfs Upon Push

By default, Salt updates the remote fileserver backends every 60 seconds. However, if it is desirable to refresh quicker than that, the *Reactor System* can be used to signal the master to update the fileserver on each push, provided that the git server is also a Salt minion. There are three steps to this process:

1. On the master, create a file `/srv/reactor/update_fileserver.sls`, with the following contents:

```
update_fileserver:
  runner.filesserver.update
```

2. Add the following reactor configuration to the master config file:

```
reactor:
  - 'salt/filesserver/gitfs/update':
    - /srv/reactor/update_fileserver.sls
```

3. On the git server, add a `post-receive` hook with the following contents:

```
#!/usr/bin/env sh

salt-call event.fire_master update salt/filesserver/gitfs/update
```

The `update` argument right after `event.fire_master` in this example can really be anything, as it represents the data being passed in the event, and the passed data is ignored by this reactor.

Similarly, the tag name `salt/filesserver/gitfs/update` can be replaced by anything, so long as the usage is consistent.

### Using Git as an External Pillar Source

Git repositories can also be used to provide [Pillar](#) data, using the [External Pillar](#) system. Note that this is different from `gitfs`, and is not yet at feature parity with it.

To define a git external pillar, add a section like the following to the salt master config file:

```
ext_pillar:
  - git: <branch> <repo> [root=<gitroot>]
```

Changed in version 2014.7.0: The optional `root` parameter was added

The `<branch>` param is the branch containing the pillar SLS tree. The `<repo>` param is the URI for the repository. To add the `master` branch of the specified repo as an external pillar source:

```
ext_pillar:
  - git: master https://domain.com/pillar.git
```

Use the `root` parameter to use pillars from a subdirectory of a git repository:

```
ext_pillar:
  - git: master https://domain.com/pillar.git root=subdirectory
```

More information on the git external pillar can be found in the [salt.pillar.git\\_pillar docs](#).

### Why aren't my custom modules/states/etc. syncing to my Minions?

In versions 0.16.3 and older, when using the [git fileserver backend](#), certain versions of GitPython may generate errors when fetching, which Salt fails to catch. While not fatal to the fetch process, these interrupt the fileserver update that takes place before custom types are synced, and thus interrupt the sync itself. Try disabling the git fileserver backend in the master config, restarting the master, and attempting the sync again.

This issue is worked around in Salt 0.16.4 and newer.

### 3.4.9 The MacOS X (Maverick) Developer Step By Step Guide To Salt Installation

This document provides a step-by-step guide to installing a Salt cluster consisting of one master, and one minion running on a local VM hosted on Mac OS X.

---

**Note:** This guide is aimed at developers who wish to run Salt in a virtual machine. The official (Linux) walkthrough can be found [here](#).

---

#### The 5 Cent Salt Intro

Since you're here you've probably already heard about Salt, so you already know Salt lets you configure and run commands on hordes of servers easily. Here's a brief overview of a Salt cluster:

- Salt works by having a ``master" server sending commands to one or multiple ``minion" servers <sup>1</sup>. The master server is the ``command center". It is going to be the place where you store your configuration files, aka: ``which server is the db, which is the web server, and what libraries and software they should have installed". The minions receive orders from the master. Minions are the servers actually performing work for your business.
- Salt has two types of configuration files:
  1. the ``salt communication channels" or ``meta" or ``config" configuration files (not official names): one for the master (usually is /etc/salt/master , **on the master server**), and one for minions (default is /etc/salt/minion or /etc/salt/minion.conf, **on the minion servers**). Those files are used to determine things like the Salt Master IP, port, Salt folder locations, etc.. If these are configured incorrectly, your minions will probably be unable to receive orders from the master, or the master will not know which software a given minion should install.
  2. the ``business" or ``service" configuration files (once again, not an official name): these are configuration files, ending with ".sls" extension, that describe which software should run on which server, along with particular configuration properties for the software that is being installed. These files should be created in the /srv/salt folder by default, but their location can be changed using ... /etc/salt/master configuration file!

---

**Note:** This tutorial contains a third important configuration file, not to be confused with the previous two: the virtual machine provisioning configuration file. This in itself is not specifically tied to Salt, but it also contains some Salt configuration. More on that in step 3. Also note that all configuration files are YAML files. So indentation matters.

---

#### Before Digging In, The Architecture Of The Salt Cluster

##### Salt Master

The ``Salt master" server is going to be the Mac OS machine, directly. Commands will be run from a terminal app, so Salt will need to be installed on the Mac. This is going to be more convenient for toying around with configuration files.

##### Salt Minion

We'll only have one ``Salt minion" server. It is going to be running on a Virtual Machine running on the Mac, using VirtualBox. It will run an Ubuntu distribution.

---

<sup>1</sup> Salt also works with ``masterless" configuration where a minion is autonomous (in which case salt can be seen as a local configuration tool), or in ``multiple master" configuration. See the documentation for more on that.

### 3.4.10 Step 1 - Configuring The Salt Master On Your Mac

[official documentation](#)

Because Salt has a lot of dependencies that are not built in Mac OS X, we will use Homebrew to install Salt. Homebrew is a package manager for Mac, it's great, use it (for this tutorial at least!). Some people spend a lot of time installing libs by hand to better understand dependencies, and then realize how useful a package manager is once they're configuring a brand new machine and have to do it all over again. It also lets you *uninstall* things easily.

---

**Note:** Brew is a Ruby program (Ruby is installed by default with your Mac). Brew downloads, compiles, and links software. The linking phase is when compiled software is deployed on your machine. It may conflict with manually installed software, especially in the `/usr/local` directory. It's ok, remove the manually installed version then refresh the link by typing `brew link 'packageName'`. Brew has a `brew doctor` command that can help you troubleshoot. It's a great command, use it often. Brew requires `xcode` command line tools. When you run brew the first time it asks you to install them if they're not already on your system. Brew installs software in `/usr/local/bin` (system bins are in `/usr/bin`). In order to use those bins you need your `$PATH` to search there first. Brew tells you if your `$PATH` needs to be fixed.

---

**Tip:** Use the keyboard shortcut `cmd + shift + period` in the ```open` Mac OS X dialog box to display hidden files and folders, such as `.profile`.

---

#### Install Homebrew

Install Homebrew here <http://brew.sh/> Or just type

```
ruby -e "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/homebrew/go/install)"
```

Now type the following commands in your terminal (you may want to type `brew doctor` after each to make sure everything's fine):

```
brew install python
brew install swig
brew install zmq
```

---

**Note:** `zmq` is ZeroMQ. It's a fantastic library used for server to server network communication and is at the core of Salt efficiency.

---

#### Install Salt

You should now have everything ready to launch this command:

```
pip install salt
```

---

**Note:** There should be no need for `sudo pip install salt`. Brew installed Python for your user, so you should have all the access. In case you would like to check, type `which python` to ensure that it's `/usr/local/bin/python`, and `which pip` which should be `/usr/local/bin/pip`.

---

Now type `python` in a terminal then, `import salt`. There should be no errors. Now exit the Python terminal using `exit()`.

---

## Create The Master Configuration

If the default `/etc/salt/master` configuration file was not created, copy-paste it from here: <http://docs.saltstack.com/ref/configuration/examples.html#configuration-examples-master>

---

**Note:** `/etc/salt/master` is a file, not a folder.

---

Salt Master configuration changes. The Salt master needs a few customization to be able to run on Mac OS X:

```
sudo launchctl limit maxfiles 4096 8192
```

In the `/etc/salt/master` file, change `max_open_files` to 8192 (or just add the line: `max_open_files: 8192` (no quote) if it doesn't already exist).

You should now be able to launch the Salt master:

```
sudo salt-master --log-level=all
```

There should be no errors when running the above command.

---

**Note:** This command is supposed to be a daemon, but for toying around, we'll keep it running on a terminal to monitor the activity.

---

Now that the master is set, let's configure a minion on a VM.

### 3.4.11 Step 2 - Configuring The Minion VM

The Salt minion is going to run on a Virtual Machine. There are a lot of software options that let you run virtual machines on a mac, But for this tutorial we're going to use VirtualBox. In addition to virtualBox, we will use Vagrant, which allows you to create the base VM configuration.

Vagrant lets you build ready to use VM images, starting from an OS image and customizing it using ``provisioners". In our case, we'll use it to:

- Download the base Ubuntu image
- Install salt on that Ubuntu image (Salt is going to be the ``provisioner" for the VM).
- Launch the VM
- SSH into the VM to debug
- Stop the VM once you're done.

#### Install VirtualBox

Go get it here: <https://www.virtualBox.org/wiki/Downloads> (click on VirtualBox for OS X hosts => x86/amd64)

#### Install Vagrant

Go get it here: <http://downloads.vagrantup.com/> and choose the latest version (1.3.5 at time of writing), then the .dmg file. Double-click to install it. Make sure the `vagrant` command is found when run in the terminal. Type `vagrant`. It should display a list of commands.

### Create The Minion VM Folder

Create a folder in which you will store your minion's VM. In this tutorial, it's going to be a minion folder in the \$home directory.

```
cd $home
mkdir minion
```

### Initialize Vagrant

From the minion folder, type

```
vagrant init
```

This command creates a default Vagrantfile configuration file. This configuration file will be used to pass configuration parameters to the Salt provisioner in Step 3.

### Import Precise64 Ubuntu Box

```
vagrant box add precise64 http://files.vagrantup.com/precise64.box
```

**Note:** This box is added at the global Vagrant level. You only need to do it once as each VM will use this same file.

### Modify the Vagrantfile

Modify `./minion/Vagrantfile` to use the precise64 box. Change the `config.vm.box` line to:

```
config.vm.box = "precise64"
```

Uncomment the line creating a host-only IP. This is the ip of your minion (you can change it to something else if that IP is already in use):

```
config.vm.network :private_network, ip: "192.168.33.10"
```

At this point you should have a VM that can run, although there won't be much in it. Let's check that.

### Checking The VM

From the \$home/minion folder type:

```
vagrant up
```

A log showing the VM booting should be present. Once it's done you'll be back to the terminal:

```
ping 192.168.33.10
```

The VM should respond to your ping request.

Now log into the VM in ssh using Vagrant again:

```
vagrant ssh
```

You should see the shell prompt change to something similar to `vagrant@precise64:~$` meaning you're inside the VM. From there, enter the following:

```
ping 10.0.2.2
```

**Note:** That ip is the ip of your VM host (the Mac OS X OS). The number is a VirtualBox default and is displayed in the log after the Vagrant ssh command. We'll use that IP to tell the minion where the Salt master is. Once you're done, end the ssh session by typing `exit`.

---

It's now time to connect the VM to the salt master

### 3.4.12 Step 3 - Connecting Master and Minion

#### Creating The Minion Configuration File

Create the `/etc/salt/minion` file. In that file, put the following lines, giving the ID for this minion, and the IP of the master:

```
master: 10.0.2.2
id: 'minion1'
file_client: remote
```

Minions authenticate with the master using keys. Keys are generated automatically if you don't provide one and can accept them later on. However, this requires accepting the minion key every time the minion is destroyed or created (which could be quite often). A better way is to create those keys in advance, feed them to the minion, and authorize them once.

#### Preseed minion keys

From the minion folder on your Mac run:

```
sudo salt-key --gen-keys=minion1
```

This should create two files: `minion1.pem`, and `minion1.pub`. Since those files have been created using `sudo`, but will be used by `vagrant`, you need to change ownership:

```
sudo chown youruser:yourgroup minion1.pem
sudo chown youruser:yourgroup minion1.pub
```

Then copy the `.pub` file into the list of accepted minions:

```
sudo cp minion1.pub /etc/salt/pki/master/minions/minion1
```

#### Modify Vagrantfile to Use Salt Provisioner

Let's now modify the Vagrantfile used to provision the Salt VM. Add the following section in the Vagrantfile (note: it should be at the same indentation level as the other properties):

```
# salt-vagrant config
config.vm.provision :salt do |salt|
  salt.run_highstate = true
  salt.minion_config = "/etc/salt/minion"
  salt.minion_key = "./minion1.pem"
  salt.minion_pub = "./minion1.pub"
end
```

Now destroy the vm and recreate it from the /minion folder:

```
vagrant destroy
vagrant up
```

If everything is fine you should see the following message:

```
"Bootstrapping Salt... (this may take a while)
Salt successfully configured and installed!"
```

### Checking Master-Minion Communication

To make sure the master and minion are talking to each other, enter the following:

```
sudo salt '*' test.ping
```

You should see your minion answering the ping. It's now time to do some configuration.

### 3.4.13 Step 4 - Configure Services to Install On the Minion

In this step we'll use the Salt master to instruct our minion to install Nginx.

#### Checking the system's original state

First, make sure that an HTTP server is not installed on our minion. When opening a browser directed at <http://192.168.33.10/> You should get an error saying the site cannot be reached.

#### Initialize the top.sls file

System configuration is done in `/srv/salt/top.sls` (and subfiles/folders), and then applied by running the `state.apply` function to have the Salt master order its minions to update their instructions and run the associated commands.

First Create an empty file on your Salt master (Mac OS X machine):

```
touch /srv/salt/top.sls
```

When the file is empty, or if no configuration is found for our minion an error is reported:

```
sudo salt 'minion1' state.apply
```

This should return an error stating: **No Top file or external nodes data matches found.**

#### Create The Nginx Configuration

Now is finally the time to enter the real meat of our server's configuration. For this tutorial our minion will be treated as a web server that needs to have Nginx installed.

Insert the following lines into `/srv/salt/top.sls` (which should current be empty).

```
base:
  'minion1':
    - bin.nginx
```

Now create `/srv/salt/bin/nginx.sls` containing the following:

```
nginx:
  pkg.installed:
    - name: nginx
  service.running:
    - enable: True
    - reload: True
```

### Check Minion State

Finally, run the `state.apply` function again:

```
sudo salt 'minion1' state.apply
```

You should see a log showing that the Nginx package has been installed and the service configured. To prove it, open your browser and navigate to <http://192.168.33.10/>, you should see the standard Nginx welcome page.

Congratulations!

### Where To Go From Here

A full description of configuration management within Salt (sls files among other things) is available here: <http://docs.saltstack.com/index.html#configuration-management>

## 3.4.14 Writing Salt Tests

---

**Note:** THIS TUTORIAL IS A WORK IN PROGRESS

---

Salt comes with a powerful integration and unit test suite. The test suite allows for the fully automated run of integration and/or unit tests from a single interface. The integration tests are surprisingly easy to write and can be written to be either destructive or non-destructive.

### Getting Set Up For Tests

To walk through adding an integration test, start by getting the latest development code and the test system from GitHub:

---

**Note:** The develop branch often has failing tests and should always be considered a staging area. For a checkout that tests should be running perfectly on, please check out a specific release tag (such as v2014.1.4).

---

```
git clone git@github.com:saltstack/salt.git
pip install git+https://github.com/saltstack/salt-testing.git#egg=SaltTesting
```

Now that a fresh checkout is available run the test suite

### Destructive vs Non-destructive

Since Salt is used to change the settings and behavior of systems, often, the best approach to run tests is to make actual changes to an underlying system. This is where the concept of destructive integration tests comes into play.

Tests can be written to alter the system they are running on. This capability is what fills in the gap needed to properly test aspects of system management like package installation.

To write a destructive test import and use the `destructiveTest` decorator for the test method:

```
import integration
from salttesting.helpers import destructiveTest

class PkgTest(integration.ModuleCase):
    @destructiveTest
    def test_pkg_install(self):
        ret = self.run_function('pkg.install', name='finch')
        self.assertSaltTrueReturn(ret)
        ret = self.run_function('pkg.purge', name='finch')
        self.assertSaltTrueReturn(ret)
```

### Automated Test Runs

SaltStack maintains a Jenkins server which can be viewed at <http://jenkins.saltstack.com>. The tests executed from this Jenkins server create fresh virtual machines for each test run, then execute the destructive tests on the new clean virtual machine. This allows for the execution of tests across supported platforms.

### 3.4.15 HTTP Modules

This tutorial demonstrates using the various HTTP modules available in Salt. These modules wrap the Python `urllib2` and `requests` libraries, extending them in a manner that is more consistent with Salt workflows.

#### The `salt.utils.http` Library

This library forms the core of the HTTP modules. Since it is designed to be used from the minion as an execution module, in addition to the master as a runner, it was abstracted into this multi-use library. This library can also be imported by 3rd-party programs wishing to take advantage of its extended functionality.

Core functionality of the execution, state, and runner modules is derived from this library, so common usages between them are described here. Documentation specific to each module is described below.

This library can be imported with:

```
import salt.utils.http
```

#### Configuring Libraries

This library can make use of either `urllib2`, which ships with Python, or `requests`, which can be installed separately. By default, `urllib2` will be used. In order to switch to `requests`, set the following variable:

```
requests_lib: True
```

This can be set in the master or minion configuration file, or passed as an option directly to any `http.query()` functions.

### `salt.utils.http.query()`

This function forms a basic query, but with some add-ons not present in the `urllib2` and `requests` libraries. Not all functionality currently available in these libraries has been added, but can be in future iterations.

A basic query can be performed by calling this function with no more than a single URL:

```
salt.utils.http.query('http://example.com')
```

By default the query will be performed with a GET method. The method can be overridden with the `method` argument:

```
salt.utils.http.query('http://example.com/delete/url', 'DELETE')
```

When using the POST method (and others, such as PUT), extra data is usually sent as well. This data can be sent directly, in whatever format is required by the remote server (XML, JSON, plain text, etc).

```
salt.utils.http.query(
    'http://example.com/delete/url',
    method='POST',
    data=json.loads(mydict)
)
```

Bear in mind that this data must be sent pre-formatted; this function will not format it for you. However, a templated file stored on the local system may be passed through, along with variables to populate it with. To pass through only the file (untemplated):

```
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.xml'
)
```

To pass through a file that contains jinja + yaml templating (the default):

```
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.jinja',
    data_render=True,
    template_data={'key1': 'value1', 'key2': 'value2'}
)
```

To pass through a file that contains mako templating:

```
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.mako',
    data_render=True,
    data_renderer='mako',
    template_data={'key1': 'value1', 'key2': 'value2'}
)
```

Because this function uses Salt's own rendering system, any Salt renderer can be used. Because Salt's renderer requires `__opts__` to be set, an `opts` dictionary should be passed in. If it is not, then the default `__opts__` values for the node type (master or minion) will be used. Because this library is intended primarily for use by minions, the default node type is `minion`. However, this can be changed to `master` if necessary.

```

salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.jinja',
    data_render=True,
    template_data={'key1': 'value1', 'key2': 'value2'},
    opts=__opts__
)

salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.jinja',
    data_render=True,
    template_data={'key1': 'value1', 'key2': 'value2'},
    node='master'
)

```

Headers may also be passed through, either as a `header_list`, a `header_dict`, or as a `header_file`. As with the `data_file`, the `header_file` may also be templated. Take note that because HTTP headers are normally syntactically-correct YAML, they will automatically be imported as an a Python dict.

```

salt.utils.http.query(
    'http://example.com/delete/url',
    method='POST',
    header_file='/srv/salt/headers.jinja',
    header_render=True,
    header_renderer='jinja',
    template_data={'key1': 'value1', 'key2': 'value2'}
)

```

Because much of the data that would be templated between headers and data may be the same, the `template_data` is the same for both. Correcting possible variable name collisions is up to the user.

The `query()` function supports basic HTTP authentication. A username and password may be passed in as `username` and `password`, respectively.

```

salt.utils.http.query(
    'http://example.com',
    username='larry',
    password='5700g3543v4r',
)

```

Cookies are also supported, using Python's built-in `cookielib`. However, they are turned off by default. To turn cookies on, set `cookies` to `True`.

```

salt.utils.http.query(
    'http://example.com',
    cookies=True
)

```

By default cookies are stored in Salt's cache directory, normally `/var/cache/salt`, as a file called `cookies.txt`. However, this location may be changed with the `cookie_jar` argument:

```

salt.utils.http.query(
    'http://example.com',
    cookies=True,
    cookie_jar='/path/to/cookie_jar.txt'
)

```

By default, the format of the cookie jar is LWP (aka, lib-www-perl). This default was chosen because it is a human-readable text file. If desired, the format of the cookie jar can be set to Mozilla:

```
salt.utils.http.query(
    'http://example.com',
    cookies=True,
    cookie_jar='/path/to/cookie_jar.txt',
    cookie_format='mozilla'
)
```

Because Salt commands are normally one-off commands that are piped together, this library cannot normally behave as a normal browser, with session cookies that persist across multiple HTTP requests. However, the session can be persisted in a separate cookie jar. The default filename for this file, inside Salt's cache directory, is `cookies.session.p`. This can also be changed.

```
salt.utils.http.query(
    'http://example.com',
    persist_session=True,
    session_cookie_jar='/path/to/jar.p'
)
```

The format of this file is `msgpack`, which is consistent with much of the rest of Salt's internal structure. Historically, the extension for this file is `.p`. There are no current plans to make this configurable.

## Return Data

---

**Note:** Return data encoding

If `decode` is set to `True`, `query()` will attempt to decode the return data. `decode_type` defaults to `auto`. Set it to a specific encoding, `xml`, for example, to override autodetection.

---

Because Salt's `http` library was designed to be used with REST interfaces, `query()` will attempt to decode the data received from the remote server when `decode` is set to `True`. First it will check the `Content-type` header to try and find references to XML. If it does not find any, it will look for references to JSON. If it does not find any, it will fall back to plain text, which will not be decoded.

JSON data is translated into a dict using Python's built-in `json` library. XML is translated using `salt.utils.xml_util`, which will use Python's built-in XML libraries to attempt to convert the XML into a dict. In order to force either JSON or XML decoding, the `decode_type` may be set:

```
salt.utils.http.query(
    'http://example.com',
    decode_type='xml'
)
```

Once translated, the return dict from `query()` will include a dict called `dict`.

If the data is not to be translated using one of these methods, decoding may be turned off.

```
salt.utils.http.query(
    'http://example.com',
    decode=False
)
```

If decoding is turned on, and references to JSON or XML cannot be found, then this module will default to plain text, and return the undecoded data as `text` (even if `text` is set to `False`; see below).

The `query()` function can return the HTTP status code, headers, and/or text as required. However, each must individually be turned on.

```
salt.utils.http.query(
    'http://example.com',
    status=True,
    headers=True,
    text=True
)
```

The return from these will be found in the return dict as `status`, `headers` and `text`, respectively.

### Writing Return Data to Files

It is possible to write either the return data or headers to files, as soon as the response is received from the server, but specifying file locations via the `text_out` or `headers_out` arguments. `text` and `headers` do not need to be returned to the user in order to do this.

```
salt.utils.http.query(
    'http://example.com',
    text=False,
    headers=False,
    text_out='/path/to/url_download.txt',
    headers_out='/path/to/headers_download.txt',
)
```

### SSL Verification

By default, this function will verify SSL certificates. However, for testing or debugging purposes, SSL verification can be turned off.

```
salt.utils.http.query(
    'https://example.com',
    verify_ssl=False,
)
```

### CA Bundles

The `requests` library has its own method of detecting which CA (certificate authority) bundle file to use. Usually this is implemented by the packager for the specific operating system distribution that you are using. However, `urllib2` requires a little more work under the hood. By default, Salt will try to auto-detect the location of this file. However, if it is not in an expected location, or a different path needs to be specified, it may be done so using the `ca_bundle` variable.

```
salt.utils.http.query(
    'https://example.com',
    ca_bundle='/path/to/ca_bundle.pem',
)
```

**Updating CA Bundles** The `update_ca_bundle()` function can be used to update the bundle file at a specified location. If the target location is not specified, then it will attempt to auto-detect the location of the bundle file. If the URL to download the bundle from does not exist, a bundle will be downloaded from the cURL website.

CAUTION: The `target` and the `source` should always be specified! Failure to specify the `target` may result in the file being written to the wrong location on the local system. Failure to specify the `source` may cause the upstream URL to receive excess unnecessary traffic, and may cause a file to be download which is hazardous or does not meet the needs of the user.

```
salt.utils.http.update_ca_bundle(  
    target='/path/to/ca-bundle.crt',  
    source='https://example.com/path/to/ca-bundle.crt',  
    opts=__opts__,  
)
```

The `opts` parameter should also always be specified. If it is, then the `target` and the `source` may be specified in the relevant configuration file (master or minion) as `ca_bundle` and `ca_bundle_url`, respectively.

```
ca_bundle: /path/to/ca-bundle.crt  
ca_bundle_url: https://example.com/path/to/ca-bundle.crt
```

If Salt is unable to auto-detect the location of the CA bundle, it will raise an error.

The `update_ca_bundle()` function can also be passed a string or a list of strings which represent files on the local system, which should be appended (in the specified order) to the end of the CA bundle file. This is useful in environments where private certs need to be made available, and are not otherwise reasonable to add to the bundle file.

```
salt.utils.http.update_ca_bundle(  
    opts=__opts__,  
    merge_files=[  
        '/etc/ssl/private_cert_1.pem',  
        '/etc/ssl/private_cert_2.pem',  
        '/etc/ssl/private_cert_3.pem',  
    ]  
)
```

### Test Mode

This function may be run in test mode. This mode will perform all work up until the actual HTTP request. By default, instead of performing the request, an empty dict will be returned. Using this function with TRACE logging turned on will reveal the contents of the headers and POST data to be sent.

Rather than returning an empty dict, an alternate `test_url` may be passed in. If this is detected, then test mode will replace the `url` with the `test_url`, set `test` to `True` in the return data, and perform the rest of the requested operations as usual. This allows a custom, non-destructive URL to be used for testing when necessary.

### Execution Module

The `http` execution module is a very thin wrapper around the `salt.utils.http` library. The `opts` can be passed through as well, but if they are not specified, the minion defaults will be used as necessary.

Because passing complete data structures from the command line can be tricky at best and dangerous (in terms of execution injection attacks) at worse, the `data_file`, and `header_file` are likely to see more use here.

All methods for the library are available in the execution module, as kwargs.

```
salt myminion http.query http://example.com/restapi method=POST \  
    username='larry' password='5700g3543v4r' headers=True text=True \  
    status=True decode_type=xml data_render=True \  
    \
```

```
header_file=/tmp/headers.txt data_file=/tmp/data.txt \
header_render=True cookies=True persist_session=True
```

### Runner Module

Like the execution module, the `http` runner module is a very thin wrapper around the `salt.utils.http` library. The only significant difference is that because runners execute on the master instead of a minion, a target is not required, and default opts will be derived from the master config, rather than the minion config.

All methods for the library are available in the runner module, as kwargs.

```
salt-run http.query http://example.com/restapi method=POST \
  username='larry' password='5700g3543v4r' headers=True text=True \
  status=True decode_type=xml data_render=True \
  header_file=/tmp/headers.txt data_file=/tmp/data.txt \
  header_render=True cookies=True persist_session=True
```

### State Module

The state module is a wrapper around the runner module, which applies stateful logic to a query. All kwargs as listed above are specified as usual in state files, but two more kwargs are available to apply stateful logic. A required parameter is `match`, which specifies a pattern to look for in the return text. By default, this will perform a string comparison of looking for the value of `match` in the return text. In Python terms this looks like:

```
if match in html_text:
    return True
```

If more complex pattern matching is required, a regular expression can be used by specifying a `match_type`. By default this is set to `string`, but it can be manually set to `pcre` instead. Please note that despite the name, this will use Python's `re.search()` rather than `re.match()`.

Therefore, the following states are valid:

```
http://example.com/restapi:
  http.query:
    - match: 'SUCCESS'
    - username: 'larry'
    - password: '5700g3543v4r'
    - data_render: True
    - header_file: /tmp/headers.txt
    - data_file: /tmp/data.txt
    - header_render: True
    - cookies: True
    - persist_session: True

http://example.com/restapi:
  http.query:
    - match_type: pcre
    - match: '(?i)succe[ss|ed]'
    - username: 'larry'
    - password: '5700g3543v4r'
    - data_render: True
    - header_file: /tmp/headers.txt
    - data_file: /tmp/data.txt
    - header_render: True
```

```
- cookies: True
- persist_session: True
```

In addition to, or instead of a match pattern, the status code for a URL can be checked. This is done using the `status` argument:

```
http://example.com/:
  http.query:
    - status: '200'
```

If both are specified, both will be checked, but if only one is `True` and the other is `False`, then `False` will be returned. In this case, the comments in the return data will contain information for troubleshooting.

Because this is a monitoring state, it will return extra data to code that expects it. This data will always include `text` and `status`. Optionally, `headers` and `dict` may also be requested by setting the `headers` and `decode` arguments to `True`, respectively.

### 3.4.16 LXC Management with Salt

---

**Note:** This walkthrough assumes basic knowledge of Salt. To get up to speed, check out the [Salt Walkthrough](#).

---

#### Dependencies

Manipulation of LXC containers in Salt requires the minion to have an LXC version of at least 1.0 (an alpha or beta release of LXC 1.0 is acceptable). The following distributions are known to have new enough versions of LXC packaged:

- RHEL/CentOS 6 and later (via [EPEL](#))
- Fedora (All non-EOL releases)
- Debian 8.0 (Jessie)
- Ubuntu 14.04 LTS and later (LXC templates are packaged separately as `lxc-templates`, it is recommended to also install this package)
- openSUSE 13.2 and later

#### Profiles

Profiles allow for a sort of shorthand for commonly-used configurations to be defined in the minion config file, *grains*, *pillar*, or the master config file. The profile is retrieved by Salt using the `config.get` function, which looks in those locations, in that order. This allows for profiles to be defined centrally in the master config file, with several options for overriding them (if necessary) on groups of minions or individual minions.

There are two types of profiles:

- One for defining the parameters used in container creation/clone.
- One for defining the container's network interface(s) settings.

#### Container Profiles

LXC container profiles are defined underneath the `lxc.container_profile` config option:

```
lxc.container_profile:
  centos:
    template: centos
    backing: lvm
    vgname: vg1
    lvname: lxclv
    size: 10G
  centos_big:
    template: centos
    backing: lvm
    vgname: vg1
    lvname: lxclv
    size: 20G
```

Profiles are retrieved using the `config.get` function, with the `recurse` merge strategy. This means that a profile can be defined at a lower level (for example, the master config file) and then parts of it can be overridden at a higher level (for example, in pillar data). Consider the following container profile data:

#### In the Master config file:

```
lxc.container_profile:
  centos:
    template: centos
    backing: lvm
    vgname: vg1
    lvname: lxclv
    size: 10G
```

#### In the Pillar data

```
lxc.container_profile:
  centos:
    size: 20G
```

Any minion with the above Pillar data would have the `size` parameter in the `centos` profile overridden to 20G, while those minions without the above Pillar data would have the 10G `size` value. This is another way of achieving the same result as the `centos_big` profile above, without having to define another whole profile that differs in just one value.

**Note:** In the 2014.7.x release cycle and earlier, container profiles are defined under `lxc.profile`. This parameter will still work in version 2015.5.0, but is deprecated and will be removed in a future release. Please note however that the profile merging feature described above will only work with profiles defined under `lxc.container_profile`, and only in versions 2015.5.0 and later.

Additionally, in version 2015.5.0 container profiles have been expanded to support passing template-specific CLI options to `lxc.create`. Below is a table describing the parameters which can be configured in container profiles:

Parameter	2015.5.0 and Newer	2014.7.x and Earlier
<i>template</i> <sup>1</sup>	Yes	Yes
<i>options</i> <sup>1</sup>	Yes	No
<i>image</i> <sup>1</sup>	Yes	Yes
<i>backing</i>	Yes	Yes
<i>snapshot</i> <sup>2</sup>	Yes	Yes
<i>lvname</i> <sup>1</sup>	Yes	Yes
<i>fstype</i> <sup>1</sup>	Yes	Yes
<i>size</i>	Yes	Yes

1. Parameter is only supported for container creation, and will be ignored if the profile is used when cloning a

container.

2. Parameter is only supported for container cloning, and will be ignored if the profile is used when not cloning a container.

### Network Profiles

LXC network profiles are defined defined underneath the `lxc.network_profile` config option. By default, the module uses a DHCP based configuration and try to guess a bridge to get connectivity.

**Warning:** on pre 2015.5.2, you need to specify explicitly the network bridge

```
lxc.network_profile:
  centos:
    eth0:
      link: br0
      type: veth
      flags: up
  ubuntu:
    eth0:
      link: lxcbr0
      type: veth
      flags: up
```

As with container profiles, network profiles are retrieved using the `config.get` function, with the `recurse` merge strategy. Consider the following network profile data:

#### In the Master config file:

```
lxc.network_profile:
  centos:
    eth0:
      link: br0
      type: veth
      flags: up
```

#### In the Pillar data

```
lxc.network_profile:
  centos:
    eth0:
      link: lxcbr0
```

Any minion with the above Pillar data would use the `lxcbr0` interface as the bridge interface for any container configured using the `centos` network profile, while those minions without the above Pillar data would use the `br0` interface for the same.

---

**Note:** In the 2014.7.x release cycle and earlier, network profiles are defined under `lxc.nic`. This parameter will still work in version 2015.5.0, but is deprecated and will be removed in a future release. Please note however that the profile merging feature described above will only work with profiles defined under `lxc.network_profile`, and only in versions 2015.5.0 and later.

---

The following are parameters which can be configured in network profiles. These will directly correspond to a parameter in an LXC configuration file (see `man 5 lxc.container.conf`).

- `type` - Corresponds to `lxc.network.type`

- **link** - Corresponds to `lxc.network.link`
- **flags** - Corresponds to `lxc.network.flags`

Interface-specific options (MAC address, IPv4/IPv6, etc.) must be passed on a container-by-container basis, for instance using the `nic_opts` argument to `lxc.create`:

```
salt myminion lxc.create container1 profile=centos network_profile=centos nic_opts='{eth0: {ipv4: 10
```

**Warning:** The `ipv4`, `ipv6`, `gateway`, and `link` (bridge) settings in network profiles / `nic_opts` will only work if the container doesn't redefine the network configuration (for example in `/etc/sysconfig/network-scripts/ifcfg-<interface_name>` on RHEL/CentOS, or `/etc/network/interfaces` on Debian/Ubuntu/etc.). Use these with caution. The container images installed using the `download` template, for instance, typically are configured for `eth0` to use DHCP, which will conflict with static IP addresses set at the container level.

### Old lxc support (<1.0.7)

With saltstack 2015.5.2 and above, normally the setting is autoselected, but before, you'll need to teach your network profile to set `lxc.network.ipv4.gateway` to `auto` when using a classic ipv4 configuration.

Thus you'll need

```
lxc.network_profile.foo:
  eth0:
    link: lxcbr0
    ipv4.gateway: auto
```

### Tricky network setups Examples

This example covers how to make a container with both an internal ip and a public routable ip, wired on two veth pairs.

The another interface which receives directly a public routable ip can't be on the first interface that we reserve for private inter LXC networking.

```
lxc.network_profile.foo:
  eth0: {gateway: null, bridge: lxcbr0}
  eth1:
    # replace that by your main interface
    'link': 'br0'
    'mac': '00:16:5b:01:24:e1'
    'gateway': '2.20.9.14'
    'ipv4': '2.20.9.1'
```

## Creating a Container on the CLI

### From a Template

LXC is commonly distributed with several template scripts in `/usr/share/lxc/templates`. Some distros may package these separately in an `lxc-templates` package, so make sure to check if this is the case.

There are LXC template scripts for several different operating systems, but some of them are designed to use tools specific to a given distribution. For instance, the `ubuntu` template uses `deb_bootstrap`, the `centos` template uses `yum`, etc., making these templates impractical when a container from a different OS is desired.

The `lxc.create` function is used to create containers using a template script. To create a CentOS container named `container1` on a CentOS minion named `mycentosminion`, using the `centos` LXC template, one can simply run the following command:

```
salt mycentosminion lxc.create container1 template=centos
```

For these instances, there is a `download` template which retrieves minimal container images for several different operating systems. To use this template, it is necessary to provide an `options` parameter when creating the container, with three values:

1. **dist** - the Linux distribution (i.e. `ubuntu` or `centos`)
2. **release** - the release name/version (i.e. `trusty` or `6`)
3. **arch** - CPU architecture (i.e. `amd64` or `i386`)

The `lxc.images` function (new in version 2015.5.0) can be used to list the available images. Alternatively, the releases can be viewed on <http://images.linuxcontainers.org/images/>. The images are organized in such a way that the `dist`, `release`, and `arch` can be determined using the following URL format: `http://images.linuxcontainers.org/images/dist/release/arch`. For example, `http://images.linuxcontainers.org/images/centos/6/amd64` would correspond to a `dist` of `centos`, a `release` of `6`, and an `arch` of `amd64`.

Therefore, to use the `download` template to create a new 64-bit CentOS 6 container, the following command can be used:

```
salt myminion lxc.create container1 template=download options='{dist: centos, release: 6, arch: amd64}
```

---

**Note:** These command-line options can be placed into a *container profile*, like so:

```
lxc.container_profile.cent6:
  template: download
  options:
    dist: centos
    release: 6
    arch: amd64
```

The `options` parameter is not supported in profiles for the 2014.7.x release cycle and earlier, so it would still need to be provided on the command-line.

---

### Cloning an Existing Container

To clone a container, use the `lxc.clone` function:

```
salt myminion lxc.clone container2 orig=container1
```

### Using a Container Image

While cloning is a good way to create new containers from a common base container, the source container that is being cloned needs to already exist on the minion. This makes deploying a common container across minions difficult. For this reason, Salt's `lxc.create` is capable of installing a container from a tar archive of another container's rootfs. To create an image of a container named `cent6`, run the following command as root:

```
tar czf cent6.tar.gz -C /var/lib/lxc/cent6 rootfs
```

**Note:** Before doing this, it is recommended that the container is stopped.

The resulting tarball can then be placed alongside the files in the salt fileserver and referenced using a `salt://` URL. To create a container using an image, use the `image` parameter with `lxc.create`:

```
salt myminion lxc.create new-cent6 image=salt://path/to/cent6.tar.gz
```

**Note:** Making images of containers with LVM backing

For containers with LVM backing, the `rootfs` is not mounted, so it is necessary to mount it first before creating the tar archive. When a container is created using LVM backing, an empty `rootfs` dir is handily created within `/var/lib/lxc/container_name`, so this can be used as the mountpoint. The location of the logical volume for the container will be `/dev/vgname/lvname`, where `vgname` is the name of the volume group, and `lvname` is the name of the logical volume. Therefore, assuming a volume group of `vg1`, a logical volume of `lxc-cent6`, and a container name of `cent6`, the following commands can be used to create a tar archive of the `rootfs`:

```
mount /dev/vg1/lxc-cent6 /var/lib/lxc/cent6/rootfs
tar czf cent6.tar.gz -C /var/lib/lxc/cent6 rootfs
umount /var/lib/lxc/cent6/rootfs
```

**Warning:** One caveat of using this method of container creation is that `/etc/hosts` is left unmodified. This could cause confusion for some distros if salt-minion is later installed on the container, as the functions that determine the hostname take `/etc/hosts` into account.

Additionally, when creating an `rootfs` image, be sure to remove `/etc/salt/minion_id` and make sure that `id` is not defined in `/etc/salt/minion`, as this will cause similar issues.

### Initializing a New Container as a Salt Minion

The above examples illustrate a few ways to create containers on the CLI, but often it is desirable to also have the new container run as a Minion. To do this, the `lxc.init` function can be used. This function will do the following:

1. Create a new container
2. Optionally set password and/or DNS
3. Bootstrap the minion (using either `salt-bootstrap` or a custom command)

By default, the new container will be pointed at the same Salt Master as the host machine on which the container was created. It will then request to authenticate with the Master like any other bootstrapped Minion, at which point it can be accepted.

```
salt myminion lxc.init test1 profile=centos
salt-key -a test1
```

For even greater convenience, the `LXC runner` contains a runner function of the same name (`lxc.init`), which creates a keypair, seeds the new minion with it, and pre-accepts the key, allowing for the new Minion to be created and authorized in a single step:

```
salt-run lxc.init test1 host=myminion profile=centos
```

## Running Commands Within a Container

For containers which are not running their own Minion, commands can be run within the container in a manner similar to using `cmd.run <salt.modules.cmdmod.run>`. The means of doing this have been changed significantly in version 2015.5.0 (though the deprecated behavior will still be supported for a few releases). Both the old and new usage are documented below.

### 2015.5.0 and Newer

New functions have been added to mimic the behavior of the functions in the `cmd` module. Below is a table with the `cmd` functions and their `lxc` module equivalents:

Description	<code>cmd</code> module	<code>lxc</code> module
Run a command and get all output	<code>cmd.run</code>	<code>lxc.run</code>
Run a command and get just stdout	<code>cmd.run_stdout</code>	<code>lxc.run_stdout</code>
Run a command and get just stderr	<code>cmd.run_stderr</code>	<code>lxc.run_stderr</code>
Run a command and get just the retcode	<code>cmd.retcode</code>	<code>lxc.retcode</code>
Run a command and get all information	<code>cmd.run_all</code>	<code>lxc.run_all</code>

### 2014.7.x and Earlier

Earlier Salt releases use a single function (`lxc.run_cmd`) to run commands within containers. Whether stdout, stderr, etc. are returned depends on how the function is invoked.

To run a command and return the stdout:

```
salt myminion lxc.run_cmd web1 'tail /var/log/messages'
```

To run a command and return the stderr:

```
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=False stderr=True
```

To run a command and return the retcode:

```
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=False stderr=False
```

To run a command and return all information:

```
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=True stderr=True
```

## Container Management Using salt-cloud

Salt cloud uses under the hood the salt runner and module to manage containers, Please look at [this chapter](#)

## Container Management Using States

Several states are being renamed or otherwise modified in version 2015.5.0. The information in this tutorial refers to the new states. For 2014.7.x and earlier, please refer to the [documentation for the LXC states](#).

### Ensuring a Container Is Present

To ensure the existence of a named container, use the `lxc.present` state. Here are some examples:

```
# Using a template
web1:
  lxc.present:
    - template: download
    - options:
      dist: centos
      release: 6
      arch: amd64

# Cloning
web2:
  lxc.present:
    - clone_from: web-base

# Using a rootfs image
web3:
  lxc.present:
    - image: salt://path/to/cent6.tar.gz

# Using profiles
web4:
  lxc.present:
    - profile: centos_web
    - network_profile: centos
```

**Warning:** The `lxc.present` state will not modify an existing container (in other words, it will not re-create the container). If an `lxc.present` state is run on an existing container, there will be no change and the state will return a True result.

The `lxc.present` state also includes an optional `running` parameter which can be used to ensure that a container is running/stopped. Note that there are standalone `lxc.running` and `lxc.stopped` states which can be used for this purpose.

### Ensuring a Container Does Not Exist

To ensure that a named container is not present, use the `lxc.absent` state. For example:

```
web1:
  lxc.absent
```

### Ensuring a Container is Running/Stopped/Frozen

Containers can be in one of three states:

- **running** - Container is running and active
- **frozen** - Container is running, but all process are blocked and the container is essentially non-active until the container is ``unfrozen``
- **stopped** - Container is not running

Salt has three states (*lxc.running*, *lxc.frozen*, and *lxc.stopped*) which can be used to ensure a container is in one of these states:

```
web1:
  lxc.running

# Restart the container if it was already running
web2:
  lxc.running:
    - restart: True

web3:
  lxc.stopped

# Explicitly kill all tasks in container instead of gracefully stopping
web4:
  lxc.stopped:
    - kill: True

web5:
  lxc.frozen

# If container is stopped, do not start it (in which case the state will fail)
web6:
  lxc.frozen:
    - start: False
```

## 3.5 Salt Virt

### 3.5.1 Salt as a Cloud Controller

In Salt 0.14.0, an advanced cloud control system were introduced, allow private cloud vms to be managed directly with Salt. This system is generally referred to as **Salt Virt**.

The Salt Virt system already exists and is installed within Salt itself, this means that beside setting up Salt, no additional salt code needs to be deployed.

The main goal of Salt Virt is to facilitate a very fast and simple cloud. The cloud that can scale and fully featured. Salt Virt comes with the ability to set up and manage complex virtual machine networking, powerful image, and disk management, as well as virtual machine migration with and without shared storage.

This means that Salt Virt can be used to create a cloud from a blade center and a SAN, but can also create a cloud out of a swarm of Linux Desktops without a single shared storage system. Salt Virt can make clouds from truly commodity hardware, but can also stand up the power of specialized hardware as well.

#### Setting up Hypervisors

The first step to set up the hypervisors involves getting the correct software installed and setting up the hypervisor network interfaces.

#### Installing Hypervisor Software

Salt Virt is made to be hypervisor agnostic but currently the only fully implemented hypervisor is KVM via libvirt.

The required software for a hypervisor is libvirt and kvm. For advanced features install libguestfs or qemu-nbd.

**Note:** Libguestfs and qemu-nbd allow for virtual machine images to be mounted before startup and get pre-seeded with configurations and a salt minion

This sls will set up the needed software for a hypervisor, and run the routines to set up the libvirt pki keys.

**Note:** Package names and setup used is Red Hat specific, different package names will be required for different platforms

```
libvirt:
  pkg.installed: []
  file.managed:
    - name: /etc/sysconfig/libvirtd
    - contents: 'LIBVIRT_ARGS="--listen"'
    - require:
      - pkg: libvirt
  libvirt.keys:
    - require:
      - pkg: libvirt
  service.running:
    - name: libvirtd
    - require:
      - pkg: libvirt
      - network: br0
      - libvirt: libvirt
    - watch:
      - file: libvirt

libvirt-python:
  pkg.installed: []

libguestfs:
  pkg.installed:
    - pkgs:
      - libguestfs
      - libguestfs-tools
```

### Hypervisor Network Setup

The hypervisors will need to be running a network bridge to serve up network devices for virtual machines, this formula will set up a standard bridge on a hypervisor connecting the bridge to eth0:

```
eth0:
  network.managed:
    - enabled: True
    - type: eth
    - bridge: br0

br0:
  network.managed:
    - enabled: True
    - type: bridge
    - proto: dhcp
    - require:
      - network: eth0
```

### Virtual Machine Network Setup

Salt Virt comes with a system to model the network interfaces used by the deployed virtual machines; by default a single interface is created for the deployed virtual machine and is bridged to `br0`. To get going with the default networking setup, ensure that the bridge interface named `br0` exists on the hypervisor and is bridged to an active network device.

---

**Note:** To use more advanced networking in Salt Virt, read the *Salt Virt Networking* document:

[Salt Virt Networking](#)

---

### Libvirt State

One of the challenges of deploying a libvirt based cloud is the distribution of libvirt certificates. These certificates allow for virtual machine migration. Salt comes with a system used to auto deploy these certificates. Salt manages the signing authority key and generates keys for libvirt clients on the master, signs them with the certificate authority and uses pillar to distribute them. This is managed via the `libvirt` state. Simply execute this formula on the minion to ensure that the certificate is in place and up to date:

---

**Note:** The above formula includes the calls needed to set up libvirt keys.

---

```
libvirt_keys:
  libvirt.keys
```

### Getting Virtual Machine Images Ready

Salt Virt, requires that virtual machine images be provided as these are not generated on the fly. Generating these virtual machine images differs greatly based on the underlying platform.

Virtual machine images can be manually created using KVM and running through the installer, but this process is not recommended since it is very manual and prone to errors.

Virtual Machine generation applications are available for many platforms:

**vm-builder:** <https://wiki.debian.org/VMBuilder>

**See also:**

[vmbuilder-formula](#)

Once virtual machine images are available, the easiest way to make them available to Salt Virt is to place them in the Salt file server. Just copy an image into `/srv/salt` and it can now be used by Salt Virt.

For purposes of this demo, the file name `centos.img` will be used.

### Existing Virtual Machine Images

Many existing Linux distributions distribute virtual machine images which can be used with Salt Virt. Please be advised that NONE OF THESE IMAGES ARE SUPPORTED BY SALTSTACK.

**CentOS** These images have been prepared for OpenNebula but should work without issue with Salt Virt, only the raw qcow image file is needed: <http://wiki.centos.org/Cloud/OpenNebula>

---

**Fedora Linux** Images for Fedora Linux can be found here: <http://fedoraproject.org/en/get-fedora#clouds>

**Ubuntu Linux** Images for Ubuntu Linux can be found here: <http://cloud-images.ubuntu.com/>

### Using Salt Virt

With hypervisors set up and virtual machine images ready, Salt can start issuing cloud commands.

Start by running a Salt Virt hypervisor info command:

```
salt-run virt.hyper_info
```

This will query what the running hypervisor stats are and display information for all configured hypervisors. This command will also validate that the hypervisors are properly configured.

Now that hypervisors are available a virtual machine can be provisioned. The `virt.init` routine will create a new virtual machine:

```
salt-run virt.init centos1 2 512 salt://centos.img
```

This command assumes that the CentOS virtual machine image is sitting in the root of the Salt fileserver. Salt Virt will now select a hypervisor to deploy the new virtual machine on and copy the virtual machine image down to the hypervisor.

Once the VM image has been copied down the new virtual machine will be seeded. Seeding the VMs involves setting pre-authenticated Salt keys on the new VM and if needed, will install the Salt Minion on the new VM before it is started.

---

**Note:** The biggest bottleneck in starting VMs is when the Salt Minion needs to be installed. Making sure that the source VM images already have Salt installed will GREATLY speed up virtual machine deployment.

---

Now that the new VM has been prepared, it can be seen via the `virt.query` command:

```
salt-run virt.query
```

This command will return data about all of the hypervisors and respective virtual machines.

Now that the new VM is booted it should have contacted the Salt Master, a `test.ping` will reveal if the new VM is running.

### Migrating Virtual Machines

Salt Virt comes with full support for virtual machine migration, and using the `libvirt` state in the above formula makes migration possible.

A few things need to be available to support migration. Many operating systems turn on firewalls when originally set up, the firewall needs to be opened up to allow for `libvirt` and `kvm` to cross communicate and execution migration routines. On Red Hat based hypervisors in particular port 16514 needs to be opened on hypervisors:

```
iptables -A INPUT -m state --state NEW -m tcp -p tcp --dport 16514 -j ACCEPT
```

---

**Note:** More in-depth information regarding distribution specific firewall settings can read in:

[Opening the Firewall up for Salt](#)

---

Salt also needs an additional flag to be turned on as well. The `virt.tunnel` option needs to be turned on. This flag tells Salt to run migrations securely via the libvirt TLS tunnel and to use port 16514. Without `virt.tunnel` libvirt tries to bind to random ports when running migrations. To turn on `virt.tunnel` simple apply it to the master config file:

```
virt.tunnel: True
```

Once the master config has been updated, restart the master and send out a call to the minions to refresh the pillar to pick up on the change:

```
salt \* saltutil.refresh_modules
```

Now, migration routines can be run! To migrate a VM, simply run the Salt Virt migrate routine:

```
salt-run virt.migrate centos <new hypervisor>
```

### VNC Consoles

Salt Virt also sets up VNC consoles by default, allowing for remote visual consoles to be opened up. The information from a `virt.query` routine will display the vnc console port for the specific vms:

```
centos
CPU: 2
Memory: 524288
State: running
Graphics: vnc - hyper6:5900
Disk - vda:
  Size: 2.0G
  File: /srv/salt-images/ubuntu2/system.qcow2
  File Format: qcow2
Nic - ac:de:48:98:08:77:
  Source: br0
  Type: bridge
```

The line *Graphics: vnc - hyper6:5900* holds the key. First the port named, in this case 5900, will need to be available in the hypervisor's firewall. Once the port is open, then the console can be easily opened via `vncviewer`:

```
vncviewer hyper6:5900
```

By default there is no VNC security set up on these ports, which suggests that keeping them firewalled and mandating that SSH tunnels be used to access these VNC interfaces. Keep in mind that activity on a VNC interface that is accessed can be viewed by any other user that accesses that same VNC interface, and any other user logging in can also operate with the logged in user on the virtual machine.

### Conclusion

Now with Salt Virt running, new hypervisors can be seamlessly added just by running the above states on new bare metal machines, and these machines will be instantly available to Salt Virt.

## 3.6 Halite

### 3.6.1 Installing and Configuring Halite

In this tutorial, we'll walk through installing and setting up Halite. The current version of Halite is considered pre-alpha and is supported only in Salt v2014.1.0 or greater. Additional information is available on GitHub: <https://github.com/saltstack/halite>

Before beginning this tutorial, ensure that the salt-master is installed. To install the salt-master, please review the installation documentation: <http://docs.saltstack.com/topics/installation/index.html>

---

**Note:** Halite only works with Salt versions greater than 2014.1.0.

---

#### Installing Halite Via Package

On CentOS, RHEL, or Fedora:

```
$ yum install python-halite
```

---

**Note:** By default python-halite only installs CherryPy. If you would like to use a different webserver please review the instructions below to install pip and your server of choice. The package does not modify the master configuration with `/etc/salt/master`.

---

#### Installing Halite Using pip

To begin the installation of Halite from PyPI, you'll need to install pip. The Salt package, as well as the bootstrap, do not install pip by default.

On CentOS, RHEL, or Fedora:

```
$ yum install python-pip
```

On Debian:

```
$ apt-get install python-pip
```

Once you have pip installed, use it to install halite:

```
$ pip install -U halite
```

Depending on the webserver you want to run halite through, you'll need to install that piece as well. On RHEL based distros, use one of the following:

```
$ pip install cherrypy
```

```
$ pip install paste
```

```
$ yum install python-devel
$ yum install gcc
$ pip install gevent
$ pip install pyopenssl
```

On Debian based distributions:

```
$ pip install CherryPy
```

```
$ pip install paste
```

```
$ apt-get install gcc
$ apt-get install python-dev
$ apt-get install libevent-dev
$ pip install gevent
$ pip install pyopenssl
```

### Configuring Halite Permissions

Configuring Halite access permissions is easy. By default, you only need to ensure that the `@runner` group is configured. In the `/etc/salt/master` file, uncomment and modify the following lines:

```
external_auth:
  pam:
    testuser:
      - .*
      - '@runner'
```

---

**Note:** You cannot use the root user for pam login; it will fail to authenticate.

---

Halite uses the runner `manage.present` to get the status of minions, so runner permissions are required. For example:

```
external_auth:
  pam:
    mytestuser:
      - .*
      - '@runner'
      - '@wheel'
```

Currently Halite allows, but does not require, any wheel modules.

### Configuring Halite Settings

Once you've configured the permissions for Halite, you'll need to set up the Halite settings in the `/etc/salt/master` file. Halite supports CherryPy, Paste, and Gevent out of the box.

To configure cherryypy, add the following to the bottom of your `/etc/salt/master` file:

```
halite:
  level: 'debug'
  server: 'cherryypy'
  host: '0.0.0.0'
  port: '8080'
  cors: False
  tls: True
  certpath: '/etc/pki/tls/certs/localhost.crt'
  keypath: '/etc/pki/tls/certs/localhost.key'
  pempath: '/etc/pki/tls/certs/localhost.pem'
```

If you wish to use paste:

```
halite:
  level: 'debug'
  server: 'paste'
  host: '0.0.0.0'
  port: '8080'
  cors: False
  tls: True
  certpath: '/etc/pki/tls/certs/localhost.crt'
  keypath: '/etc/pki/tls/certs/localhost.key'
  pempath: '/etc/pki/tls/certs/localhost.pem'
```

To use gevent:

```
halite:
  level: 'debug'
  server: 'gevent'
  host: '0.0.0.0'
  port: '8080'
  cors: False
  tls: True
  certpath: '/etc/pki/tls/certs/localhost.crt'
  keypath: '/etc/pki/tls/certs/localhost.key'
  pempath: '/etc/pki/tls/certs/localhost.pem'
```

The ``cherrypy`` and ``gevent`` servers require the certpath and keypath files to run tls/ssl. The .crt file holds the public cert and the .key file holds the private key. Whereas the ``paste`` server requires a single .pem file that contains both the cert and key. This can be created simply by concatenating the .crt and .key files.

If you want to use a self-signed cert, you can create one using the Salt.tls module:

---

**Note:** The following command needs to be run on your salt master.

---

```
salt-call tls.create_self_signed_cert tls
```

Note that certs generated by the above command can be found under the /etc/pki/tls/certs/ directory. When using self-signed certs, browsers will need approval before accepting the cert. If the web application page has been cached with a non-HTTPS version of the app, then the browser cache will have to be cleared before it will recognize and prompt to accept the self-signed certificate.

### Starting Halite

Once you've configured the halite section of your /etc/salt/master, you can restart the salt-master service, and your halite instance will be available. Depending on your configuration, the instance will be available either at <https://localhost:8080/app>, <https://domain:8080/app>, or <https://123.456.789.012:8080/app>.

---

**Note:** halite requires an HTML 5 compliant browser.

---

All logs relating to halite are logged to the default /var/log/salt/master file.

## 3.7 LXC

## 3.8 Using Salt at scale

### 3.8.1 Using Salt at scale

The focus of this tutorial will be building a Salt infrastructure for handling large numbers of minions. This will include tuning, topology, and best practices.

For how to install the Salt Master please go here: [Installing saltstack](#)

---

**Note:** This tutorial is intended for large installations, although these same settings won't hurt, it may not be worth the complexity to smaller installations.

When used with minions, the term `many` refers to at least a thousand and `a few` always means 500.

For simplicity reasons, this tutorial will default to the standard ports used by Salt.

---

### The Master

The most common problems on the Salt Master are:

1. too many minions authing at once
2. too many minions re-authing at once
3. too many minions re-connecting at once
4. too many minions returning at once
5. too few resources (CPU/HDD)

The first three are all ``thundering herd" problems. To mitigate these issues we must configure the minions to back-off appropriately when the Master is under heavy load.

The fourth is caused by masters with little hardware resources in combination with a possible bug in ZeroMQ. At least that's what it looks like till today ([Issue 118651](#), [Issue 5948](#), [Mail thread](#))

To fully understand each problem, it is important to understand, how Salt works.

Very briefly, the Salt Master offers two services to the minions.

- a job publisher on port 4505
- an open port 4506 to receive the minions returns

All minions are always connected to the publisher on port 4505 and only connect to the open return port 4506 if necessary. On an idle Master, there will only be connections on port 4505.

### Too many minions authing

When the Minion service is first started up, it will connect to its Master's publisher on port 4505. If too many minions are started at once, this can cause a ``thundering herd". This can be avoided by not starting too many minions at once.

The connection itself usually isn't the culprit, the more likely cause of master-side issues is the authentication that the Minion must do with the Master. If the Master is too heavily loaded to handle the auth request it will time it out.

The Minion will then wait `acceptance_wait_time` to retry. If `acceptance_wait_time_max` is set then the Minion will increase its wait time by the `acceptance_wait_time` each subsequent retry until reaching `acceptance_wait_time_max`.

### Too many minions re-authing

This is most likely to happen in the testing phase of a Salt deployment, when all Minion keys have already been accepted, but the framework is being tested and parameters are frequently changed in the Salt Master's configuration file(s).

The Salt Master generates a new AES key to encrypt its publications at certain events such as a Master restart or the removal of a Minion key. If you are encountering this problem of too many minions re-authing against the Master, you will need to recalibrate your setup to reduce the rate of events like a Master restart or Minion key removal (`salt-key -d`).

When the Master generates a new AES key, the minions aren't notified of this but will discover it on the next pub job they receive. When the Minion receives such a job it will then re-auth with the Master. Since Salt does minion-side filtering this means that all the minions will re-auth on the next command published on the master-- causing another ``thundering herd". This can be avoided by setting the

```
random_reauth_delay: 60
```

in the minions configuration file to a higher value and stagger the amount of re-auth attempts. Increasing this value will of course increase the time it takes until all minions are reachable via Salt commands.

### Too many minions re-connecting

By default the zmq socket will re-connect every 100ms which for some larger installations may be too quick. This will control how quickly the TCP session is re-established, but has no bearing on the auth load.

To tune the minions sockets reconnect attempts, there are a few values in the sample configuration file (default values)

```
recon_default: 1000
recon_max: 5000
recon_randomize: True
```

- `recon_default`: the default value the socket should use, i.e. 1000. This value is in milliseconds. (1000ms = 1 second)
- `recon_max`: the max value that the socket should use as a delay before trying to reconnect This value is in milliseconds. (5000ms = 5 seconds)
- `recon_randomize`: enables randomization between `recon_default` and `recon_max`

To tune this values to an existing environment, a few decision have to be made.

1. How long can one wait, before the minions should be online and reachable via Salt?
2. How many reconnects can the Master handle without a syn flood?

These questions can not be answered generally. Their answers depend on the hardware and the administrators requirements.

Here is an example scenario with the goal, to have all minions reconnect within a 60 second time-frame on a Salt Master service restart.

```
recon_default: 1000
recon_max: 59000
recon_randomize: True
```

Each Minion will have a randomized reconnect value between ``recon_default'` and ``recon_default + recon_max'`, which in this example means between 1000ms and 60000ms (or between 1 and 60 seconds). The generated random-value will be doubled after each attempt to reconnect (ZeroMQ default behavior).

Lets say the generated random value is 11 seconds (or 11000ms).

```
reconnect 1: wait 11 seconds
reconnect 2: wait 22 seconds
reconnect 3: wait 33 seconds
reconnect 4: wait 44 seconds
reconnect 5: wait 55 seconds
reconnect 6: wait time is bigger than 60 seconds (recon_default + recon_max)
reconnect 7: wait 11 seconds
reconnect 8: wait 22 seconds
reconnect 9: wait 33 seconds
reconnect x: etc.
```

With a thousand minions this will mean

```
1000/60 = ~16
```

round about 16 connection attempts a second. These values should be altered to values that match your environment. Keep in mind though, that it may grow over time and that more minions might raise the problem again.

### Too many minions returning at once

This can also happen during the testing phase, if all minions are addressed at once with

```
$ salt * test.ping
```

it may cause thousands of minions trying to return their data to the Salt Master open port 4506. Also causing a flood of syn-flood if the Master can't handle that many returns at once.

This can be easily avoided with Salt's batch mode:

```
$ salt * test.ping -b 50
```

This will only address 50 minions at once while looping through all addressed minions.

### Too few resources

The masters resources always have to match the environment. There is no way to give good advise without knowing the environment the Master is supposed to run in. But here are some general tuning tips for different situations:

#### The Master is CPU bound

Salt uses RSA-Key-Pairs on the masters and minions end. Both generate 4096 bit key-pairs on first start. While the key-size for the Master is currently not configurable, the minions keysize can be configured with different key-sizes. For example with a 2048 bit key:

```
keysize: 2048
```

With thousands of decryptions, the amount of time that can be saved on the masters end should not be neglected. See here for reference: [Pull Request 9235](#) how much influence the key-size can have.

Downsizing the Salt Master's key is not that important, because the minions do not encrypt as many messages as the Master does.

### The Master is disk IO bound

By default, the Master saves every Minion's return for every job in its job-cache. The cache can then be used later, to lookup results for previous jobs. The default directory for this is:

```
cachedir: /var/cache/salt
```

and then in the `/proc` directory.

Each job return for every Minion is saved in a single file. Over time this directory can grow quite large, depending on the number of published jobs. The amount of files and directories will scale with the number of jobs published and the retention time defined by

```
keep_jobs: 24
```

```
250 jobs/day * 2000 minions returns = 500.000 files a day
```

If no job history is needed, the job cache can be disabled:

```
job_cache: False
```

If the job cache is necessary there are (currently) 2 options:

- `ext_job_cache`: this will have the minions store their return data directly into a returner (not sent through the Master)
- `master_job_cache` (New in 2014.7.0): this will make the Master store the job data using a returner (instead of the local job cache on disk).

---

## Targeting Minions

---

Targeting minions is specifying which minions should run a command or execute a state by matching against host-names, or system information, or defined groups, or even combinations thereof.

For example the command `salt web1 apache.signal restart` to restart the Apache httpd server specifies the machine `web1` as the target and the command will only be run on that one minion.

Similarly when using States, the following *top file* specifies that only the `web1` minion should execute the contents of `webserver.sls`:

```
base:
  'web1':
    - webserver
```

There are many ways to target individual minions or groups of minions in Salt:

### 4.1 Matching the minion id

Each minion needs a unique identifier. By default when a minion starts for the first time it chooses its FQDN (fully qualified domain name) as that identifier. The minion id can be overridden via the minion's *id* configuration setting.

**Tip:** minion id and minion keys

The *minion id* is used to generate the minion's public/private keys and if it ever changes the master must then accept the new key as though the minion was a new host.

#### 4.1.1 Globbing

The default matching that Salt utilizes is *shell-style globbing* around the *minion id*. This also works for states in the *top file*.

**Note:** You must wrap `salt` calls that use globbing in single-quotes to prevent the shell from expanding the globs before Salt is invoked.

Match all minions:

```
salt '*' test.ping
```

Match all minions in the example.net domain or any of the example domains:

```
salt '*.example.net' test.ping
salt '*.example.*' test.ping
```

Match all the webN minions in the example.net domain (web1.example.net, web2.example.net ... webN.example.net):

```
salt 'web?.example.net' test.ping
```

Match the web1 through web5 minions:

```
salt 'web[1-5]' test.ping
```

Match the web1 and web3 minions:

```
salt 'web[1,3]' test.ping
```

Match the web-x, web-y, and web-z minions:

```
salt 'web-[x-z]' test.ping
```

---

**Note:** For additional targeting methods please review the [compound matchers](#) documentation.

---

## 4.1.2 Regular Expressions

Minions can be matched using Perl-compatible [regular expressions](#) (which is globbing on steroids and a ton of caffeine).

Match both web1-prod and web1-devel minions:

```
salt -E 'web1-(prod|devel)' test.ping
```

When using regular expressions in a State's *top file*, you must specify the matcher as the first option. The following example executes the contents of `webserver.sls` on the above-mentioned minions.

```
base:
  'web1-(prod|devel)':
    - match: pcre
    - webserver
```

## 4.1.3 Lists

At the most basic level, you can specify a flat list of minion IDs:

```
salt -L 'web1,web2,web3' test.ping
```

## 4.2 Grains

Salt comes with an interface to derive information about the underlying system. This is called the grains interface, because it presents salt with grains of information. Grains are collected for the operating system, domain name, IP address, kernel, OS type, memory, and many other system properties.

The grains interface is made available to Salt modules and components so that the right salt minion commands are automatically available on the right systems.

Grain data is relatively static, though if system information changes (for example, if network settings are changed), or if a new value is assigned to a custom grain, grain data is refreshed.

**Note:** Grains resolve to lowercase letters. For example, F00, and foo target the same grain.

**Important:** See *Is Targeting using Grain Data Secure?* for important security information.

Match all CentOS minions:

```
salt -G 'os:CentOS' test.ping
```

Match all minions with 64-bit CPUs, and return number of CPU cores for each matching minion:

```
salt -G 'cpuarch:x86_64' grains.item num_cpus
```

Additionally, globs can be used in grain matches, and grains that are nested in a [dictionary](#) can be matched by adding a colon for each level that is traversed. For example, the following will match hosts that have a grain called `ec2_tags`, which itself is a [dict](#) with a key named `environment`, which has a value that contains the word `production`:

```
salt -G 'ec2_tags:environment:*production*'
```

## 4.2.1 Listing Grains

Available grains can be listed by using the `grains.ls` module:

```
salt '*' grains.ls
```

Grains data can be listed by using the `grains.items` module:

```
salt '*' grains.items
```

## 4.2.2 Grains in the Minion Config

Grains can also be statically assigned within the minion configuration file. Just add the option `grains` and pass options to it:

```
grains:
  roles:
    - webserver
    - memcache
  deployment: datacenter4
  cabinet: 13
  cab_u: 14-15
```

Then status data specific to your servers can be retrieved via Salt, or used inside of the State system for matching. It also makes targeting, in the case of the example above, simply based on specific data about your deployment.

## 4.2.3 Grains in `/etc/salt/grains`

If you do not want to place your custom static grains in the minion config file, you can also put them in `/etc/salt/grains` on the minion. They are configured in the same way as in the above example, only without a top-level `grains:` key:

```
roles:
  - webserver
  - memcache
deployment: datacenter4
cabinet: 13
cab_u: 14-15
```

#### 4.2.4 Matching Grains in the Top File

With correctly configured grains on the Minion, the *top file* used in Pillar or during Highstate can be made very efficient. For example, consider the following configuration:

```
'node_type:web':
  - match: grain
  - webserver

'node_type:postgres':
  - match: grain
  - database

'node_type:redis':
  - match: grain
  - redis

'node_type:lb':
  - match: grain
  - lb
```

For this example to work, you would need to have defined the grain `node_type` for the minions you wish to match. This simple example is nice, but too much of the code is similar. To go one step further, Jinja templating can be used to simplify the *top file*.

```
{% set node_type = salt['grains.get']('node_type', '') %}

{% if node_type %}
  'node_type:{{ self }}':
    - match: grain
    - {{ self }}
{% endif %}
```

Using Jinja templating, only one match entry needs to be defined.

---

**Note:** The example above uses the `grains.get` function to account for minions which do not have the `node_type` grain set.

---

#### 4.2.5 Writing Grains

The grains interface is derived by executing all of the ``public`` functions found in the modules located in the grains package or the custom grains directory. The functions in the modules of the grains must return a Python `dict`, where the keys in the `dict` are the names of the grains and the values are the values.

Custom grains should be placed in a `_grains` directory located under the `file_roots` specified by the master config file. The default path would be `/srv/salt/_grains`. Custom grains will be distributed to the minions when `state.apply` is run, or by executing the `saltutil.sync_grains` or `saltutil.sync_all` functions.

Grains are easy to write, and only need to return a dictionary. A common approach would be code something similar to the following:

```
#!/usr/bin/env python
def yourfunction():
    # initialize a grains dictionary
    grains = {}
    # Some code for logic that sets grains like
    grains['yourcustomgrain']=True
    grains['anothergrain']='somevalue'
    return grains
```

Before adding a grain to Salt, consider what the grain is and remember that grains need to be static data. If the data is something that is likely to change, consider using [Pillar](#) instead.

**Warning:** Custom grains will not be available in the top file until after the first *highstate*. To make custom grains available on a minion's first *highstate*, it is recommended to use *this example* to ensure that the custom grains are synced when the minion starts.

## 4.2.6 Precedence

Core grains can be overridden by custom grains. As there are several ways of defining custom grains, there is an order of precedence which should be kept in mind when defining them. The order of evaluation is as follows:

1. Core grains.
2. Custom grains in `/etc/salt/grains`.
3. Custom grains in `/etc/salt/minion`.
4. Custom grain modules in `_grains` directory, synced to minions.

Each successive evaluation overrides the previous ones, so any grains defined by custom grains modules synced to minions that have the same name as a core grain will override that core grain. Similarly, grains from `/etc/salt/minion` override both core grains and custom grain modules, and grains in `_grains` will override *any* grains of the same name.

## 4.2.7 Examples of Grains

The core module in the grains package is where the main grains are loaded by the Salt minion and provides the principal example of how to write grains:

<https://github.com/saltstack/salt/blob/develop/salt/grains/core.py>

## 4.2.8 Syncing Grains

Syncing grains can be done a number of ways, they are automatically synced when `state.apply` is called, or (as noted above) the grains can be manually synced and reloaded by calling the `saltutil.sync_grains` or `saltutil.sync_all` functions.

## 4.3 Targeting with Pillar

Pillar data can be used when targeting minions. This allows for ultimate control and flexibility when targeting minions.

```
salt -I 'somekey:specialvalue' test.ping
```

Like with *Grains*, it is possible to use globbing as well as match nested values in Pillar, by adding colons for each level that is being traversed. The below example would match minions with a pillar named `foo`, which is a dict containing a key `bar`, with a value beginning with `baz`:

```
salt -I 'foo:bar:baz*' test.ping
```

## 4.4 Subnet/IP Address Matching

Minions can easily be matched based on IP address, or by subnet (using *CIDR* notation).

```
salt -S 192.168.40.20 test.ping
salt -S 10.0.0.0/24 test.ping
```

---

**Note:** Only IPv4 matching is supported at this time.

---

## 4.5 Compound matchers

Compound matchers allow very granular minion targeting using any of Salt's matchers. The default matcher is a *glob* match, just as with CLI and *top file* matching. To match using anything other than a glob, prefix the match string with the appropriate letter from the table below, followed by an @ sign.

Letter	Match Type	Example
G	Grains glob	G@os:Ubuntu
E	PCRE Minion ID	E@web\d+\.(dev qa prod)\.loc
P	Grains PCRE	P@os:(RedHat Fedora CentOS)
L	List of minions	L@minion1.example.com,minion3.domain.com or bl*.domain.com
I	Pillar glob	I@pdata:foobar
S	Subnet/IP address	S@192.168.1.0/24 or S@192.168.1.100
R	Range cluster	R@%foo.bar

Matchers can be joined using boolean `and`, `or`, and `not` operators.

For example, the following string matches all Debian minions with a hostname that begins with `webserv`, as well as any minions that have a hostname which matches the *regular expression* `web-dc1-srv.*`:

```
salt -C 'webserv* and G@os:Debian or E@web-dc1-srv.*' test.ping
```

That same example expressed in a *top file* looks like the following:

```
base:
  'webserv* and G@os:Debian or E@web-dc1-srv.*':
    - match: compound
    - webserver
```

Note that a leading `not` is not supported in compound matches. Instead, something like the following must be done:

```
salt -C '* and not G@kernel:Darwin' test.ping
```

Excluding a minion based on its ID is also possible:

```
salt -C '* and not web-dc1-srv' test.ping
```

### 4.5.1 Precedence Matching

Matches can be grouped together with parentheses to explicitly declare precedence amongst groups.

```
salt -C '( ms-1 or G@id:ms-3 ) and G@id:ms-3' test.ping
```

**Note:** Be certain to note that spaces are required between the parentheses and targets. Failing to obey this rule may result in incorrect targeting!

## 4.6 Node groups

Nodegroups are declared using a compound target specification. The compound target documentation can be found [here](#).

The `nodegroups` master config file parameter is used to define nodegroups. Here's an example nodegroup configuration within `/etc/salt/master`:

```
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
  group3: 'G@os:Debian and N@group1'
```

**Note:** The `L` within `group1` is matching a list of minions, while the `G` in `group2` is matching specific grains. See the [compound matchers](#) documentation for more details.

**Note:** Nodegroups can reference other nodegroups as seen in `group3`. Ensure that you do not have circular references. Circular references will be detected and cause partial expansion with a logged error message.

To match a nodegroup on the CLI, use the `-N` command-line option:

```
salt -N group1 test.ping
```

To match a nodegroup in your *top file*, make sure to put `- match: nodegroup` on the line directly following the nodegroup name.

```
base:
  group1:
    - match: nodegroup
    - webserver
```

**Note:** When adding or modifying nodegroups to a master configuration file, the master must be restarted for those changes to be fully recognized.

A limited amount of functionality, such as targeting with `-N` from the command-line may be available without a restart.

## 4.7 Batch Size

The `-b` (or `--batch-size`) option allows commands to be executed on only a specified number of minions at a time. Both percentages and finite numbers are supported.

```
salt '*' -b 10 test.ping
salt -G 'os:RedHat' --batch-size 25% apache.signal restart
```

This will only run `test.ping` on 10 of the targeted minions at a time and then restart `apache` on 25% of the minions matching `os:RedHat` at a time and work through them all until the task is complete. This makes jobs like rolling web server restarts behind a load balancer or doing maintenance on BSD firewalls using `carp` much easier with salt.

The batch system maintains a window of running minions, so, if there are a total of 150 minions targeted and the batch size is 10, then the command is sent to 10 minions, when one minion returns then the command is sent to one additional minion, so that the job is constantly running on 10 minions.

## 4.8 SECO Range

SECO range is a cluster-based metadata store developed and maintained by Yahoo!

The Range project is hosted here:

<https://github.com/ytoolshed/range>

Learn more about range here:

<https://github.com/ytoolshed/range/wiki/>

### 4.8.1 Prerequisites

To utilize range support in Salt, a range server is required. Setting up a range server is outside the scope of this document. Apache modules are included in the range distribution.

With a working range server, cluster files must be defined. These files are written in YAML and define hosts contained inside a cluster. Full documentation on writing YAML range files is here:

<https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec>

Additionally, the Python `seco` range libraries must be installed on the salt master. One can verify that they have been installed correctly via the following command:

```
python -c 'import seco.range'
```

If no errors are returned, range is installed successfully on the salt master.

### 4.8.2 Preparing Salt

Range support must be enabled on the salt master by setting the hostname and port of the range server inside the master configuration file:

```
range_server: my.range.server.com:80
```

Following this, the master must be restarted for the change to have an effect.

### 4.8.3 Targeting with Range

Once a cluster has been defined, it can be targeted with a salt command by using the `-R` or `--range` flags.

For example, given the following range YAML file being served from a range server:

```
$ cat /etc/range/test.yaml
CLUSTER: host1..100.test.com
APPS:
  - frontend
  - backend
  - mysql
```

One might target host1 through host100 in the test.com domain with Salt as follows:

```
salt --range %test:CLUSTER test.ping
```

The following salt command would target three hosts: `frontend`, `backend`, and `mysql`:

```
salt --range %test:APPS test.ping
```

---

## Storing Static Data in the Pillar

---

Pillar is an interface for Salt designed to offer global values that can be distributed to all minions. Pillar data is managed in a similar way as the Salt State Tree.

Pillar was added to Salt in version 0.9.8

---

**Note:** Storing sensitive data

Unlike state tree, pillar data is only available for the targeted minion specified by the matcher type. This makes it useful for storing sensitive data specific to a particular minion.

---

### 5.1 Declaring the Master Pillar

The Salt Master server maintains a `pillar_roots` setup that matches the structure of the `file_roots` used in the Salt file server. Like the Salt file server the `pillar_roots` option in the master config is based on environments mapping to directories. The pillar data is then mapped to minions based on matchers in a top file which is laid out in the same way as the state top file. Salt pillars can use the same matcher types as the standard top file.

The configuration for the `pillar_roots` in the master config file is identical in behavior and function as `file_roots`:

```
pillar_roots:
  base:
    - /srv/pillar
```

This example configuration declares that the base environment will be located in the `/srv/pillar` directory. It must not be in a subdirectory of the state tree.

The top file used matches the name of the top file used for States, and has the same structure:

```
/srv/pillar/top.sls
```

```
base:
  '*':
    - packages
```

In the above top file, it is declared that in the `base` environment, the glob matching all minions will have the pillar data found in the `packages` pillar available to it. Assuming the `pillar_roots` value of `/srv/pillar` taken from above, the `packages` pillar would be located at `/srv/pillar/packages.sls`.

Another example shows how to use other standard top matching types to deliver specific salt pillar data to minions with different properties.

Here is an example using the `grains` matcher to target pillars to minions by their `os` grain:

```
dev:
  'os:Debian':
    - match: grain
    - servers
```

`/srv/pillar/packages.sls`

```
{% if grains['os'] == 'RedHat' %}
apache: httpd
git: git
{% elif grains['os'] == 'Debian' %}
apache: apache2
git: git-core
{% endif %}

company: Foo Industries
```

---

**Important:** See *Is Targeting using Grain Data Secure?* for important security information.

---

The above pillar sets two key/value pairs. If a minion is running RedHat, then the `apache` key is set to `httpd` and the `git` key is set to the value of `git`. If the minion is running Debian, those values are changed to `apache2` and `git-core` respectively. All minions that have this pillar targeting to them via a top file will have the key of `company` with a value of `Foo Industries`.

Consequently this data can be used from within modules, renderers, State SLS files, and more via the shared pillar `dict`:

```
apache:
  pkg.installed:
    - name: {{ pillar['apache'] }}
```

```
git:
  pkg.installed:
    - name: {{ pillar['git'] }}
```

Finally, the above states can utilize the values provided to them via Pillar. All pillar values targeted to a minion are available via the `'pillar'` dictionary. As seen in the above example, Jinja substitution can then be utilized to access the keys and values in the Pillar dictionary.

Note that you cannot just list key/value-information in `top.sls`. Instead, target a minion to a pillar file and then list the keys and values in the pillar. Here is an example top file that illustrates this point:

```
base:
  '*':
    - common_pillar
```

And the actual pillar file at ``/srv/pillar/common_pillar.sls``:

```
foo: bar
boo: baz
```

## 5.2 Pillar namespace flattened

The separate pillar files all share the same namespace. Given a `top.sls` of:

```
base:
  '*':
    - packages
    - services
```

a `packages.sls` file of:

```
bind: bind9
```

and a `services.sls` file of:

```
bind: named
```

Then a request for the `bind` pillar will only return `named`; the `bind9` value is not available. It is better to structure your pillar files with more hierarchy. For example your `package.sls` file could look like:

```
packages:
  bind: bind9
```

### 5.3 Pillar Namespace Merges

With some care, the pillar namespace can merge content from multiple pillar files under a single key, so long as conflicts are avoided as described above.

For example, if the above example were modified as follows, the values are merged below a single key:

```
base:
  '*':
    - packages
    - services
```

And a `packages.sls` file like:

```
bind:
  package-name: bind9
  version: 9.9.5
```

And a `services.sls` file like:

```
bind:
  port: 53
  listen-on: any
```

The resulting pillar will be as follows:

```
$ salt-call pillar.get bind
local:
-----
  listen-on:
    any
  package-name:
    bind9
  port:
    53
  version:
    9.9.5
```

**Note:** Remember: conflicting keys will be overwritten in a non-deterministic manner!

## 5.4 Including Other Pillars

New in version 0.16.0.

Pillar SLS files may include other pillar files, similar to State files. Two syntaxes are available for this purpose. The simple form simply includes the additional pillar as if it were part of the same file:

```
include:
  - users
```

The full include form allows two additional options -- passing default values to the templating engine for the included pillar file as well as an optional key under which to nest the results of the included pillar:

```
include:
  - users:
      defaults:
        sudo: ['bob', 'paul']
      key: users
```

With this form, the included file (users.sls) will be nested within the `users` key of the compiled pillar. Additionally, the `sudo` value will be available as a template variable to users.sls.

## 5.5 Viewing Minion Pillar

Once the pillar is set up the data can be viewed on the minion via the `pillar` module, the pillar module comes with functions, `pillar.items` and `pillar.raw`. `pillar.items` will return a freshly reloaded pillar and `pillar.raw` will return the current pillar without a refresh:

```
salt '*' pillar.items
```

---

**Note:** Prior to version 0.16.2, this function is named `pillar.data`. This function name is still supported for backwards compatibility.

---

## 5.6 Pillar `get` Function

New in version 0.14.0.

The `pillar.get` function works much in the same way as the `get` method in a python dict, but with an enhancement: nested dict components can be extracted using a `:` delimiter.

If a structure like this is in pillar:

```
foo:
  bar:
    baz: qux
```

Extracting it from the raw pillar in an sls formula or file template is done this way:

```
{{ pillar['foo']['bar']['baz'] }}
```

Now, with the new `pillar.get` function the data can be safely gathered and a default can be set, allowing the template to fall back if the value is not available:

```
{{ salt['pillar.get']('foo:bar:baz', 'qux') }}
```

This makes handling nested structures much easier.

**Note:** `pillar.get()` vs `salt['pillar.get']()`

It should be noted that within templating, the `pillar` variable is just a dictionary. This means that calling `pillar.get()` inside of a template will just use the default dictionary `.get()` function which does not include the extra `:` delimiter functionality. It must be called using the above syntax (`salt['pillar.get']('foo:bar:baz', 'qux')`) to get the salt function, instead of the default dictionary behavior.

## 5.7 Refreshing Pillar Data

When pillar data is changed on the master the minions need to refresh the data locally. This is done with the `saltutil.refresh_pillar` function.

```
salt '*' saltutil.refresh_pillar
```

This function triggers the minion to asynchronously refresh the pillar and will always return `None`.

## 5.8 Set Pillar Data at the Command Line

Pillar data can be set at the command line like the following example:

```
salt '*' state.apply pillar='{"cheese": "spam"}'
```

This will add a Pillar key of `cheese` with its value set to `spam`.

## 5.9 Master Config In Pillar

For convenience the data stored in the master configuration file can be made available in all minion's pillars. This makes global configuration of services and systems very easy but may not be desired if sensitive data is stored in the master configuration. This option is disabled by default.

To enable the master config from being added to the pillar set `pillar_opts` to `True`:

```
pillar_opts: True
```

## 5.10 Master Provided Pillar Error

By default if there is an error rendering a pillar, the detailed error is hidden and replaced with:

```
Rendering SLS 'my.sls' failed. Please see master log for details.
```

The error is protected because it's possible to contain templating data which would give that minion information it shouldn't know, like a password!

To have the master provide the detailed error that could potentially carry protected data set `pillar_safe_render_error` to `False`:

```
pillar_safe_render_error: True
```

---

## Reactor System

---

Salt version 0.11.0 introduced the reactor system. The premise behind the reactor system is that with Salt's events and the ability to execute commands, a logic engine could be put in place to allow events to trigger actions, or more accurately, reactions.

This system binds sls files to event tags on the master. These sls files then define reactions. This means that the reactor system has two parts. First, the reactor option needs to be set in the master configuration file. The reactor option allows for event tags to be associated with sls reaction files. Second, these reaction files use highdata (like the state system) to define reactions to be executed.

### 6.1 Event System

A basic understanding of the event system is required to understand reactors. The event system is a local ZeroMQ PUB interface which fires salt events. This event bus is an open system used for sending information notifying Salt and other systems about operations.

The event system fires events with a very specific criteria. Every event has a **tag**. Event tags allow for fast top level filtering of events. In addition to the tag, each event has a data structure. This data structure is a dict, which contains information about the event.

### 6.2 Mapping Events to Reactor SLS Files

Reactor SLS files and event tags are associated in the master config file. By default this is `/etc/salt/master`, or `/etc/salt/master.d/reactor.conf`.

New in version 2014.7.0: Added Reactor support for `salt://` file paths.

In the master config section ``reactor:'` is a list of event tags to be matched and each event tag has a list of reactor SLS files to be run.

```
reactor:                                     # Master config section "reactor"
- 'salt/minion/*/start':                     # Match tag "salt/minion/*/start"
  - /srv/reactor/start.sls                   # Things to do when a minion starts
  - /srv/reactor/monitor.sls                 # Other things to do
- 'salt/cloud/*/destroyed':                  # Globs can be used to matching tags
  - /srv/reactor/destroy/*.sls              # Globs can be used to match file names
```

```
- 'myco/custom/event/tag':      # React to custom event tags
- salt://reactor/mycustom.sls  # Put reactor files under file_roots
```

Reactor sls files are similar to state and pillar sls files. They are by default yaml + Jinja templates and are passed familiar context variables.

They differ because of the addition of the `tag` and `data` variables.

- The `tag` variable is just the tag in the fired event.
- The `data` variable is the event's data dict.

Here is a simple reactor sls:

```
{% if data['id'] == 'mysql' %}
highstate_run:
  local.state.apply:
    - tgt: mysql
{% endif %}
```

This simple reactor file uses Jinja to further refine the reaction to be made. If the `id` in the event data is `mysql` (in other words, if the name of the minion is `mysql`) then the following reaction is defined. The same data structure and compiler used for the state system is used for the reactor system. The only difference is that the data is matched up to the salt command API and the runner system. In this example, a command is published to the `mysql` minion with a function of `state.apply`. Similarly, a runner can be called:

```
{% if data['data']['overstate'] == 'refresh' %}
overstate_run:
  runner.state.orchestrate
{% endif %}
```

This example will execute the `state.orchestrate` runner.

## 6.3 Fire an event

To fire an event from a minion call `event.send`

```
salt-call event.send 'foo' '{overstate: refresh}'
```

After this is called, any reactor sls files matching event tag `foo` will execute with `{{ data['data']['overstate'] }}` equal to `'refresh'`.

See `salt.modules.event` for more information.

## 6.4 Knowing what event is being fired

The best way to see exactly what events are fired and what data is available in each event is to use the `state.event runner`.

See also:

*Common Salt Events*

Example usage:

```
salt-run state.event pretty=True
```

Example output:

```

salt/job/20150213001905721678/new      {
  "_stamp": "2015-02-13T00:19:05.724583",
  "arg": [],
  "fun": "test.ping",
  "jid": "20150213001905721678",
  "minions": [
    "jerry"
  ],
  "tgt": "*",
  "tgt_type": "glob",
  "user": "root"
}
salt/job/20150213001910749506/ret/jerry {
  "_stamp": "2015-02-13T00:19:11.136730",
  "cmd": "_return",
  "fun": "saltutil.find_job",
  "fun_args": [
    "20150213001905721678"
  ],
  "id": "jerry",
  "jid": "20150213001910749506",
  "retcode": 0,
  "return": {},
  "success": true
}

```

## 6.5 Debugging the Reactor

The best window into the Reactor is to run the master in the foreground with debug logging enabled. The output will include when the master sees the event, what the master does in response to that event, and it will also include the rendered SLS file (or any errors generated while rendering the SLS file).

1. Stop the master.
2. Start the master manually:

```
salt-master -l debug
```

3. Look for log entries in the form:

```

[DEBUG ] Gathering reactors for tag foo/bar
[DEBUG ] Compiling reactions for tag foo/bar
[DEBUG ] Rendered data from file: /path/to/the/reactor_file.sls:
<... Rendered output appears here. ...>

```

The rendered output is the result of the Jinja parsing and is a good way to view the result of referencing Jinja variables. If the result is empty then Jinja produced an empty result and the Reactor will ignore it.

## 6.6 Understanding the Structure of Reactor Formulas

I.e., when to use `arg` and `kwarg` and when to specify the function arguments directly.

While the reactor system uses the same basic data structure as the state system, the functions that will be called using that data structure are different functions than are called via Salt's state system. The Reactor can call Runner

modules using the *runner* prefix, Wheel modules using the *wheel* prefix, and can also cause minions to run Execution modules using the *local* prefix.

Changed in version 2014.7.0: The `cmd` prefix was renamed to `local` for consistency with other parts of Salt. A backward-compatible alias was added for `cmd`.

The Reactor runs on the master and calls functions that exist on the master. In the case of Runner and Wheel functions the Reactor can just call those functions directly since they exist on the master and are run on the master.

In the case of functions that exist on minions and are run on minions, the Reactor still needs to call a function on the master in order to send the necessary data to the minion so the minion can execute that function.

The Reactor calls functions exposed in [Salt's Python API documentation](#). and thus the structure of Reactor files very transparently reflects the function signatures of those functions.

### 6.6.1 Calling Execution modules on Minions

The Reactor sends commands down to minions in the exact same way Salt's CLI interface does. It calls a function locally on the master that sends the name of the function as well as a list of any arguments and a dictionary of any keyword arguments that the minion should use to execute that function.

Specifically, the Reactor calls the async version of *this function*. You can see that function has ``arg`` and ``kwarg`` parameters which are both values that are sent down to the minion.

Executing remote commands maps to the `LocalClient` interface which is used by the `salt` command. This interface more specifically maps to the `cmd_async` method inside of the `LocalClient` class. This means that the arguments passed are being passed to the `cmd_async` method, not the remote method. A field starts with `local` to use the `LocalClient` subsystem. The result is, to execute a remote command, a reactor formula would look like this:

```
clean_tmp:
  local.cmd.run:
    - tgt: '*'
    - arg:
      - rm -rf /tmp/*
```

The `arg` option takes a list of arguments as they would be presented on the command line, so the above declaration is the same as running this salt command:

```
salt '*' cmd.run 'rm -rf /tmp/*'
```

Use the `expr_form` argument to specify a matcher:

```
clean_tmp:
  local.cmd.run:
    - tgt: 'os:Ubuntu'
    - expr_form: grain
    - arg:
      - rm -rf /tmp/*

clean_tmp:
  local.cmd.run:
    - tgt: 'G@roles:hbase_master'
    - expr_form: compound
    - arg:
      - rm -rf /tmp/*
```

Any other parameters in the `LocalClient().cmd()` method can be specified as well.

## 6.6.2 Calling Runner modules and Wheel modules

Calling Runner modules and Wheel modules from the Reactor uses a more direct syntax since the function is being executed locally instead of sending a command to a remote system to be executed there. There are no ``arg`` or ``kwargs`` parameters (unless the Runner function or Wheel function accepts a parameter with either of those names.)

For example:

```
clear_the_grains_cache_for_all_minions:
  runner.cache.clear_grains
```

If *the runner takes arguments* then they can be specified as well:

```
spin_up_more_web_machines:
  runner.cloud.profile:
    - prof: centos_6
    - instances:
      - web11      # These VM names would be generated via Jinja in a
      - web12      # real-world example.
```

## 6.6.3 Passing event data to Minions or Orchestrate as Pillar

An interesting trick to pass data from the Reactor script to `state.apply` is to pass it as inline Pillar data since both functions take a keyword argument named `pillar`.

The following example uses Salt's Reactor to listen for the event that is fired when the key for a new minion is accepted on the master using `salt-key`.

`/etc/salt/master.d/reactor.conf:`

```
reactor:
  - 'salt/key':
    - /srv/salt/haproxy/react_new_minion.sls
```

The Reactor then fires a `:state.apply` command targeted to the HAProxy servers and passes the ID of the new minion from the event to the state file via inline Pillar.

`/srv/salt/haproxy/react_new_minion.sls:`

```
{% if data['act'] == 'accept' and data['id'].startswith('web') %}
add_new_minion_to_pool:
  local.state.apply:
    - tgt: 'haproxy*'
    - arg:
      - haproxy.refresh_pool
    - kwargs:
      pillar:
        new_minion: {{ data['id'] }}
{% endif %}
```

The above command is equivalent to the following command at the CLI:

```
salt 'haproxy*' state.apply haproxy.refresh_pool 'pillar={new_minion: minionid}'
```

This works with Orchestrate files as well:

```
call_some_orchestrate_file:
  runner.state.orchestrate:
    - mods: some_orchestrate_file
```

```
- pillar:
  stuff: things
```

Which is equivalent to the following command at the CLI:

```
salt-run state.orchestrate some_orchestrate_file pillar='{stuff: things}'
```

Finally, that data is available in the state file using the normal Pillar lookup syntax. The following example is grabbing web server names and IP addresses from *Salt Mine*. If this state is invoked from the Reactor then the custom Pillar value from above will be available and the new minion will be added to the pool but with the `disabled` flag so that HAProxy won't yet direct traffic to it.

`/srv/salt/haproxy/refresh_pool.sls:`

```
{% set new_minion = salt['pillar.get']('new_minion') %}

listen web *:80
  balance source
  {% for server,ip in salt['mine.get']('web*', 'network.interfaces', ['eth0']).items() %}
  {% if server == new_minion %}
  server {{ server }} {{ ip }}:80 disabled
  {% else %}
  server {{ server }} {{ ip }}:80 check
  {% endif %}
{% endfor %}
```

## 6.7 A Complete Example

In this example, we're going to assume that we have a group of servers that will come online at random and need to have keys automatically accepted. We'll also add that we don't want all servers being automatically accepted. For this example, we'll assume that all hosts that have an id that starts with `ink` will be automatically accepted and have `state.apply` executed. On top of this, we're going to add that a host coming up that was replaced (meaning a new key) will also be accepted.

Our master configuration will be rather simple. All minions that attempt to authenticate will match the tag of `salt/auth`. When it comes to the minion key being accepted, we get a more refined tag that includes the minion id, which we can use for matching.

`/etc/salt/master.d/reactor.conf:`

```
reactor:
- 'salt/auth':
- /srv/reactor/auth-pending.sls
- 'salt/minion/ink*/start':
- /srv/reactor/auth-complete.sls
```

In this sls file, we say that if the key was rejected we will delete the key on the master and then also tell the master to ssh in to the minion and tell it to restart the minion, since a minion process will die if the key is rejected.

We also say that if the key is pending and the id starts with `ink` we will accept the key. A minion that is waiting on a pending key will retry authentication every ten seconds by default.

`/srv/reactor/auth-pending.sls:`

```
{# Ink server failed to authenticate -- remove accepted key #}
{% if not data['result'] and data['id'].startswith('ink') %}
minion_remove:
```

```

wheel.key.delete:
  - match: {{ data['id'] }}
minion_rejoin:
  local.cmd.run:
    - tgt: salt-master.domain.tld
    - arg:
      - ssh -o UserKnownHostsFile=/dev/null -o StrictHostKeyChecking=no "{{ data['id'] }}" 'sleep 10'
{% endif %}

{# Ink server is sending new key -- accept this key #}
{% if 'act' in data and data['act'] == 'pend' and data['id'].startswith('ink') %}
minion_add:
  wheel.key.accept:
    - match: {{ data['id'] }}
{% endif %}

```

No if statements are needed here because we already limited this action to just Ink servers in the master configuration.

`/srv/reactor/auth-complete.sls:`

```

{# When an Ink server connects, run state.apply. #}
highstate_run:
  local.state.apply:
    - tgt: {{ data['id'] }}
    - ret: smtp

```

The above will also return the *highstate* result data using the *smtp\_return* returner (use virtualname like when using from the command line with *--return*). The returner needs to be configured on the minion for this to work. See *salt.returners.smtp\_return* documentation for that.

## 6.8 Syncing Custom Types on Minion Start

Salt will sync all custom types (by running a *saltutil.sync\_all*) on every *highstate*. However, there is a chicken-and-egg issue where, on the initial *highstate*, a minion will not yet have these custom types synced when the top file is first compiled. This can be worked around with a simple reactor which watches for *minion\_start* events, which each minion fires when it first starts up and connects to the master.

On the master, create `/srv/reactor/sync_grains.sls` with the following contents:

```

sync_grains:
  local.saltutil.sync_grains:
    - tgt: {{ data['id'] }}

```

And in the master config file, add the following reactor configuration:

```

reactor:
  - 'minion_start':
    - /srv/reactor/sync_grains.sls

```

This will cause the master to instruct each minion to sync its custom grains when it starts, making these grains available when the initial *highstate* is executed.

Other types can be synced by replacing `local.saltutil.sync_grains` with `local.saltutil.sync_modules`, `local.saltutil.sync_all`, or whatever else suits the intended use case.

---

## The Salt Mine

---

The Salt Mine is used to collect arbitrary data from Minions and store it on the Master. This data is then made available to all Minions via the `salt.modules.mine` module.

Mine data is gathered on the Minion and sent back to the Master where only the most recent data is maintained (if long term data is required use returners or the external job cache).

### 7.1 Mine vs Grains

Mine data is designed to be much more up-to-date than grain data. Grains are refreshed on a very limited basis and are largely static data. Mines are designed to replace slow peer publishing calls when Minions need data from other Minions. Rather than having a Minion reach out to all the other Minions for a piece of data, the Salt Mine, running on the Master, can collect it from all the Minions every mine-interval, resulting in almost fresh data at any given time, with much less overhead.

### 7.2 Mine Functions

To enable the Salt Mine the `mine_functions` option needs to be applied to a Minion. This option can be applied via the Minion's configuration file, or the Minion's Pillar. The `mine_functions` option dictates what functions are being executed and allows for arguments to be passed in. If no arguments are passed, an empty list must be added:

```
mine_functions:
  test.ping: []
  network.ip_addrs:
    interface: eth0
    cidr: '10.0.0.0/8'
```

#### 7.2.1 Mine Functions Aliases

Function aliases can be used to provide usage intentions or to allow multiple calls of the same function with different arguments.

New in version 2014.7.0.

```
mine_functions:
  network.ip_addrs: [eth0]
  networkplus.internal_ip_addrs: []
```

```
internal_ip_addrs:
  mine_function: network.ip_addrs
  cidr: 192.168.0.0/16
loopback_ip_addrs:
  mine_function: network.ip_addrs
  lo: True
```

## 7.3 Mine Interval

The Salt Mine functions are executed when the Minion starts and at a given interval by the scheduler. The default interval is every 60 minutes and can be adjusted for the Minion via the `mine_interval` option:

```
mine_interval: 60
```

## 7.4 Mine in Salt-SSH

As of the 2015.5.0 release of salt, salt-ssh supports `mine.get`.

Because the Minions cannot provide their own `mine_functions` configuration, we retrieve the args for specified mine functions in one of three places, searched in the following order:

1. Roster data
2. Pillar
3. Master config

The `mine_functions` are formatted exactly the same as in normal salt, just stored in a different location. Here is an example of a flat roster containing `mine_functions`:

```
test:
  host: 104.237.131.248
  user: root
  mine_functions:
    cmd.run: ['echo "hello!"]
    network.ip_addrs:
      interface: eth0
```

---

**Note:** Because of the differences in the architecture of salt-ssh, `mine.get` calls are somewhat inefficient. Salt must make a new salt-ssh call to each of the Minions in question to retrieve the requested data, much like a publish call. However, unlike publish, it must run the requested function as a wrapper function, so we can retrieve the function args from the pillar of the Minion in question. This results in a non-trivial delay in retrieving the requested data.

---

## 7.5 Example

One way to use data from Salt Mine is in a State. The values can be retrieved via Jinja and used in the SLS file. The following example is a partial HAProxy configuration file and pulls IP addresses from all Minions with the `web` grain to add them to the pool of load balanced servers.

```
/srv/pillar/top.sls:
```

```
base:
  '@roles:web':
    - web
```

```
/srv/pillar/web.sls:
```

```
mine_functions:
  network.ip_addrs: [eth0]
```

```
/etc/salt/minion.d/mine.conf:
```

```
mine_interval: 5
```

```
/srv/salt/haproxy.sls:
```

```
haproxy_config:
  file.managed:
    - name: /etc/haproxy/config
    - source: salt://haproxy_config
    - template: jinja
```

```
/srv/salt/haproxy_config:
```

```
<...file contents snipped...>
```

```
{% for server, addrs in salt['mine.get']('roles:web', 'network.ip_addrs', expr_form='pillar').items()
server {{ server }} {{ addrs[0] }}:80 check
{% endfor %}
```

```
<...file contents snipped...>
```

---

## External Authentication System

---

Salt's External Authentication System (eAuth) allows for Salt to pass through command authorization to any external authentication system, such as PAM or LDAP.

### 8.1 Access Control System

The external authentication system allows for specific users to be granted access to execute specific functions on specific minions. Access is configured in the master configuration file and uses the *access control system*:

```
external_auth:
  pam:
    thatch:
      - 'web*':
      - test.*
      - network.*
    steve:
      - .*
```

The above configuration allows the user `thatch` to execute functions in the `test` and `network` modules on the minions that match the `web*` target. User `steve` is given unrestricted access to minion commands.

Salt respects the current PAM configuration in place, and uses the `'login'` service to authenticate.

---

**Note:** The PAM module does not allow authenticating as `root`.

---

To allow access to *wheel modules* or *runner modules* the following `@` syntax must be used:

```
external_auth:
  pam:
    thatch:
      - '@wheel' # to allow access to all wheel modules
      - '@runner' # to allow access to all runner modules
      - '@jobs' # to allow access to the jobs runner and/or wheel module
```

---

**Note:** The runner/wheel markup is different, since there are no minions to scope the acl to.

---

**Note:** Globs will not match wheel or runners! They must be explicitly allowed with `@wheel` or `@runner`.

---

The external authentication system can then be used from the command-line by any user on the same system as the master with the `-a` option:

```
$ salt -a pam web\* test.ping
```

The system will ask the user for the credentials required by the authentication system and then publish the command. To apply permissions to a group of users in an external authentication system, append a % to the ID:

```
external_auth:
  pam:
    admins%:
      - '*':
        - 'pkg.*'
```

**Warning:** All users that have external authentication privileges are allowed to run `saltutil.findjob`. Be aware that this could inadvertently expose some data such as minion IDs.

## 8.2 Tokens

With external authentication alone, the authentication credentials will be required with every call to Salt. This can be alleviated with Salt tokens.

Tokens are short term authorizations and can be easily created by just adding a `-T` option when authenticating:

```
$ salt -T -a pam web\* test.ping
```

Now a token will be created that has a expiration of 12 hours (by default). This token is stored in a file named `.salt_token` in the active user's home directory.

Once the token is created, it is sent with all subsequent communications. User authentication does not need to be entered again until the token expires.

Token expiration time can be set in the Salt master config file.

### 8.2.1 LDAP and Active Directory

Salt supports both user and group authentication for LDAP (and Active Directory accessed via its LDAP interface)

## 8.3 OpenLDAP and similar systems

LDAP configuration happens in the Salt master configuration file.

Server configuration values and their defaults:

```
# Server to auth against
auth.ldap.server: localhost

# Port to connect via
auth.ldap.port: 389

# Use TLS when connecting
auth.ldap.tls: False

# LDAP scope level, almost always 2
auth.ldap.scope: 2
```

```

# Server specified in URI format
auth.ldap.uri: '' # Overrides .ldap.server, .ldap.port, .ldap.tls above

# Verify server's TLS certificate
auth.ldap.no_verify: False

# Bind to LDAP anonymously to determine group membership
# Active Directory does not allow anonymous binds without special configuration
auth.ldap.anonymous: False

# FOR TESTING ONLY, this is a VERY insecure setting.
# If this is True, the LDAP bind password will be ignored and
# access will be determined by group membership alone with
# the group memberships being retrieved via anonymous bind
auth.ldap.auth_by_group_membership_only: False

# Require authenticating user to be part of this Organizational Unit
# This can be blank if your LDAP schema does not use this kind of OU
auth.ldap.groupou: 'Groups'

# Object Class for groups. An LDAP search will be done to find all groups of this
# class to which the authenticating user belongs.
auth.ldap.groupclass: 'posixGroup'

# Unique ID attribute name for the user
auth.ldap.accountattributename: 'memberUid'

# These are only for Active Directory
auth.ldap.activedirectory: False
auth.ldap.persontype: 'person'

```

There are two phases to LDAP authentication. First, Salt authenticates to search for a user's Distinguished Name and group membership. The user it authenticates as in this phase is often a special LDAP system user with read-only access to the LDAP directory. After Salt searches the directory to determine the actual user's DN and groups, it re-authenticates as the user running the Salt commands.

If you are already aware of the structure of your DNs and permissions in your LDAP store are set such that users can look up their own group memberships, then the first and second users can be the same. To tell Salt this is the case, omit the `auth.ldap.bindpw` parameter. You can template the `binddn` like this:

```

auth.ldap.basedn: dc=saltstack,dc=com
auth.ldap.binddn: uid={{ username }},cn=users,cn=accounts,dc=saltstack,dc=com

```

Salt will use the password entered on the salt command line in place of the `bindpw`.

To use two separate users, specify the LDAP lookup user in the `binddn` directive, and include a `bindpw` like so

```

auth.ldap.binddn: uid=ldaplookup,cn=sysaccounts,cn=etc,dc=saltstack,dc=com
auth.ldap.bindpw: mypassword

```

As mentioned before, Salt uses a filter to find the DN associated with a user. Salt substitutes the `{{ username }}` value for the `username` when querying LDAP

```

auth.ldap.filter: uid={{ username }}

```

For OpenLDAP, to determine group membership, one can specify an OU that contains group data. This is prepended to the `basedn` to create a search path. Then the results are filtered against `auth.ldap.groupclass`, default `posixGroup`, and the account's `name` attribute, `memberUid` by default.

```
auth.ldap.groupou: Groups
```

## 8.4 Active Directory

Active Directory handles group membership differently, and does not utilize the `groupou` configuration variable. AD needs the following options in the master config:

```
auth.ldap.activedirectory: True
auth.ldap.filter: sAMAccountName={{username}}
auth.ldap.accountattributename: sAMAccountName
auth.ldap.groupclass: group
auth.ldap.persontype: person
```

To determine group membership in AD, the username and password that is entered when LDAP is requested as the eAuth mechanism on the command line is used to bind to AD's LDAP interface. If this fails, then it doesn't matter what groups the user belongs to, he or she is denied access. Next, the distinguishedName of the user is looked up with the following LDAP search:

```
(<value of auth.ldap.accountattributename>={{username}})
(objectClass=<value of auth.ldap.persontype>)
)
```

This should return a distinguishedName that we can use to filter for group membership. Then the following LDAP query is executed:

```
(&(member=<distinguishedName from search above>)
(objectClass=<value of auth.ldap.groupclass>)
)
```

```
external_auth:
  ldap:
    test_ldap_user:
      - '*':
        - test.ping
```

To configure an LDAP group, append a % to the ID:

```
external_auth:
  ldap:
    test_ldap_group%:
      - '*':
        - test.echo
```

---

## Access Control System

---

New in version 0.10.4.

Salt maintains a standard system used to open granular control to non administrative users to execute Salt commands. The access control system has been applied to all systems used to configure access to non administrative control interfaces in Salt. These interfaces include, the `peer` system, the `external_auth` system and the `client_acl` system.

The access control system mandated a standard configuration syntax used in all of the three aforementioned systems. While this adds functionality to the configuration in 0.10.4, it does not negate the old configuration.

Now specific functions can be opened up to specific minions from specific users in the case of external auth and client ACLs, and for specific minions in the case of the peer system.

The access controls are manifested using matchers in these configurations:

```
client_acl:
  fred:
    - web\*:
      - pkg.list_pkgs
      - test.*
      - apache.*
```

In the above example, fred is able to send commands only to minions which match the specified glob target. This can be expanded to include other functions for other minions based on standard targets.

```
external_auth:
  pam:
    dave:
      - test.ping
      - mongo\*:
        - network.*
      - log\*:
        - network.*
      - pkg.*
      - 'G@os:RedHat':
        - kmod.*
    steve:
      - .*
```

The above allows for all minions to be hit by test.ping by dave, and adds a few functions that dave can execute on other minions. It also allows steve unrestricted access to salt commands.

---

## Job Management

---

New in version 0.9.7.

Since Salt executes jobs running on many systems, Salt needs to be able to manage jobs running on many systems.

### 10.1 The Minion *proc* System

Salt Minions maintain a *proc* directory in the Salt `cachedir`. The *proc* directory maintains files named after the executed job ID. These files contain the information about the current running jobs on the minion and allow for jobs to be looked up. This is located in the *proc* directory under the `cachedir`, with a default configuration it is under `/var/cache/salt/proc`.

### 10.2 Functions in the `saltutil` Module

Salt 0.9.7 introduced a few new functions to the `saltutil` module for managing jobs. These functions are:

1. `running` Returns the data of all running jobs that are found in the *proc* directory.
2. `find_job` Returns specific data about a certain job based on job id.
3. `signal_job` Allows for a given jid to be sent a signal.
4. `term_job` Sends a termination signal (SIGTERM, 15) to the process controlling the specified job.
5. `kill_job` Sends a kill signal (SIGKILL, 9) to the process controlling the specified job.

These functions make up the core of the back end used to manage jobs at the minion level.

### 10.3 The jobs Runner

A convenience runner front end and reporting system has been added as well. The jobs runner contains functions to make viewing data easier and cleaner.

The jobs runner contains a number of functions...

### 10.3.1 active

The active function runs `saltutil.running` on all minions and formats the return data about all running jobs in a much more usable and compact format. The active function will also compare jobs that have returned and jobs that are still running, making it easier to see what systems have completed a job and what systems are still being waited on.

```
# salt-run jobs.active
```

### 10.3.2 lookup\_jid

When jobs are executed the return data is sent back to the master and cached. By default it is cached for 24 hours, but this can be configured via the `keep_jobs` option in the master configuration. Using the `lookup_jid` runner will display the same return data that the initial job invocation with the `salt` command would display.

```
# salt-run jobs.lookup_jid <job id number>
```

### 10.3.3 list\_jobs

Before finding a historic job, it may be required to find the job id. `list_jobs` will parse the cached execution data and display all of the job data for jobs that have already, or partially returned.

```
# salt-run jobs.list_jobs
```

## 10.4 Scheduling Jobs

In Salt versions greater than 0.12.0, the scheduling system allows incremental executions on minions or the master. The schedule system exposes the execution of any execution function on minions or any runner on the master.

Scheduling is enabled via the `schedule` option on either the master or minion config files, or via a minion's pillar data. Schedules that are implemented via pillar data, only need to refresh the minion's pillar data, for example by using `saltutil.refresh_pillar`. Schedules implemented in the master or minion config have to restart the application in order for the schedule to be implemented.

---

**Note:** The scheduler executes different functions on the master and minions. When running on the master the functions reference runner functions, when running on the minion the functions specify execution functions.

---

A scheduled run has no output on the minion unless the config is set to info level or higher. Refer to [minion logging settings](#).

Specify `maxrunning` to ensure that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or otherwise double execute. The default for `maxrunning` is 1.

States are executed on the minion, as all states are. You can pass positional arguments and provide a yml dict of named arguments.

The below example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour):

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
```

```
args:
  - httpd
kwargs:
  test: True
```

This next example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) splaying the time between 0 and 15 seconds:

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay: 15
```

Finally, the next example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) splaying the time between 10 and 15 seconds:

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay:
      start: 10
      end: 15
```

New in version 2014.7.0.

Frequency of jobs can also be specified using date strings supported by the python dateutil library. This requires python-dateutil to be installed on the minion.

For example, this will schedule the command `state.apply httpd test=True` at 5:00pm localtime on the minion.

```
schedule:
  job1:
    function: state.apply
    args:
      - httpd
    kwargs:
      test: True
    when: 5:00pm
```

To schedule the command `state.apply httpd test=True` at 5pm on Monday, Wednesday, and Friday, and 3pm on Tuesday and Thursday, use the following:

```
schedule:
  job1:
    function: state.apply
    args:
      - httpd
    kwargs:
      test: True
```

```
when:
  - Monday 5:00pm
  - Tuesday 3:00pm
  - Wednesday 5:00pm
  - Thursday 3:00pm
  - Friday 5:00pm
```

Time ranges are also supported. For example, the below configuration will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) between the hours of 8am and 5pm. The range parameter must be a dictionary with the date strings using the `dateutil` format.

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    range:
      start: 8:00am
      end: 5:00pm
```

---

**Note:** Using time ranges requires `python-dateutil` to be installed on the minion.

---

New in version 2014.7.0.

The scheduler also supports ensuring that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or pile up in case of infrastructure outage.

The default for `maxrunning` is 1.

```
schedule:
  long_running_job:
    function: big_file_transfer
    jid_include: True
```

## 10.5 States

```
schedule:
  log-loadavg:
    function: cmd.run
    seconds: 3660
    args:
      - 'logger -t salt < /proc/loadavg'
    kwargs:
      stateful: False
      shell: \bin\sh
```

## 10.6 Highstates

To set up a *highstate* to run on a minion every 60 minutes set this in the minion config or pillar:

```

schedule:
  highstate:
    function: state.apply
    minutes: 60

```

Time intervals can be specified as seconds, minutes, hours, or days.

## 10.7 Runners

Runner executions can also be specified on the master within the master configuration file:

```

schedule:
  run_my_orch:
    function: state.orchestrate
    hours: 6
    splay: 600
    args:
      - orchestration.my_orch

```

The above configuration is analogous to running `salt-run state.orch orchestration.my_orch` every 6 hours.

## 10.8 Scheduler With Returner

The scheduler is also useful for tasks like gathering monitoring data about a minion, this schedule option will gather status data and send it to a MySQL returner database:

```

schedule:
  uptime:
    function: status.uptime
    seconds: 60
    returner: mysql
  meminfo:
    function: status.meminfo
    minutes: 5
    returner: mysql

```

Since specifying the returner repeatedly can be tiresome, the `schedule_returner` option is available to specify one or a list of global returners to be used by the minions when scheduling.

In Salt versions greater than 0.12.0, the scheduling system allows incremental executions on minions or the master. The schedule system exposes the execution of any execution function on minions or any runner on the master.

Scheduling is enabled via the `schedule` option on either the master or minion config files, or via a minion's pillar data. Schedules that are implemented via pillar data, only need to refresh the minion's pillar data, for example by using `saltutil.refresh_pillar`. Schedules implemented in the master or minion config have to restart the application in order for the schedule to be implemented.

---

**Note:** The scheduler executes different functions on the master and minions. When running on the master the functions reference runner functions, when running on the minion the functions specify execution functions.

---

A scheduled run has no output on the minion unless the config is set to info level or higher. Refer to [minion logging settings](#).

Specify `maxrunning` to ensure that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or otherwise double execute. The default for `maxrunning` is 1.

States are executed on the minion, as all states are. You can pass positional arguments and provide a yaml dict of named arguments.

The below example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour):

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
```

This next example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) splaying the time between 0 and 15 seconds:

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay: 15
```

Finally, the next example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) splaying the time between 10 and 15 seconds:

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay:
      start: 10
      end: 15
```

New in version 2014.7.0.

Frequency of jobs can also be specified using date strings supported by the `python dateutil` library. This requires `python-dateutil` to be installed on the minion.

For example, this will schedule the command `state.apply httpd test=True` at 5:00pm localtime on the minion.

```
schedule:
  job1:
    function: state.apply
    args:
      - httpd
```

```
kwargs:
  test: True
  when: 5:00pm
```

To schedule the command `state.apply httpd test=True` at 5pm on Monday, Wednesday, and Friday, and 3pm on Tuesday and Thursday, use the following:

```
schedule:
  job1:
    function: state.apply
    args:
      - httpd
    kwargs:
      test: True
    when:
      - Monday 5:00pm
      - Tuesday 3:00pm
      - Wednesday 5:00pm
      - Thursday 3:00pm
      - Friday 5:00pm
```

Time ranges are also supported. For example, the below configuration will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) between the hours of 8am and 5pm. The range parameter must be a dictionary with the date strings using the `dateutil` format.

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    range:
      start: 8:00am
      end: 5:00pm
```

**Note:** Using time ranges requires `python-dateutil` to be installed on the minion.

New in version 2014.7.0.

The scheduler also supports ensuring that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or pile up in case of infrastructure outage.

The default for `maxrunning` is 1.

```
schedule:
  long_running_job:
    function: big_file_transfer
    jid_include: True
```

### 10.8.1 States

```
schedule:
  log-loadavg:
    function: cmd.run
```

```
seconds: 3660
args:
  - 'logger -t salt < /proc/loadavg'
kwargs:
  stateful: False
  shell: \bin\sh
```

## 10.8.2 Highstates

To set up a *highstate* to run on a minion every 60 minutes set this in the minion config or pillar:

```
schedule:
  highstate:
    function: state.apply
    minutes: 60
```

Time intervals can be specified as seconds, minutes, hours, or days.

## 10.8.3 Runners

Runner executions can also be specified on the master within the master configuration file:

```
schedule:
  run_my_orch:
    function: state.orchestrate
    hours: 6
    splay: 600
    args:
      - orchestration.my_orch
```

The above configuration is analogous to running `salt-run state.orch orchestration.my_orch` every 6 hours.

## 10.8.4 Scheduler With Returner

The scheduler is also useful for tasks like gathering monitoring data about a minion, this schedule option will gather status data and send it to a MySQL returner database:

```
schedule:
  uptime:
    function: status.uptime
    seconds: 60
    returner: mysql
  meminfo:
    function: status.meminfo
    minutes: 5
    returner: mysql
```

Since specifying the returner repeatedly can be tiresome, the `schedule_returner` option is available to specify one or a list of global returners to be used by the minions when scheduling.

---

## Managing the Job Cache

---

The Salt Master maintains a job cache of all job executions which can be queried via the jobs runner. This job cache is called the Default Job Cache.

### 11.1 Default Job Cache

A number of options are available when configuring the job cache. The default caching system uses local storage on the Salt Master and can be found in the job cache directory (on Linux systems this is typically `/var/cache/salt/master/jobs`). The default caching system is suitable for most deployments as it does not typically require any further configuration or management.

The default job cache is a temporary cache and jobs will be stored for 24 hours. If the default cache needs to store jobs for a different period the time can be easily adjusted by changing the `keep_jobs` parameter in the Salt Master configuration file. The value passed in is measured via hours:

```
keep_jobs: 24
```

### 11.2 Additional Job Cache Options

Many deployments may wish to use an external database to maintain a long term register of executed jobs. Salt comes with two main mechanisms to do this, the master job cache and the external job cache.

See *Storing Job Results in an External System*.

---

## Storing Job Results in an External System

---

After a job executes, job results are returned to the Salt Master by each Salt Minion. These results are stored in the *Default Job Cache*.

In addition to the Default Job Cache, Salt provides two additional mechanisms to send job results to other systems (databases, local syslog, and others):

- External Job Cache
- Master Job Cache

The major difference between these two mechanisms is from where results are returned (from the Salt Master or Salt Minion).

### 12.1 External Job Cache - Minion-Side Returner

When an External Job Cache is configured, data is returned to the Default Job Cache on the Salt Master like usual, and then results are also sent to an External Job Cache using a Salt returner module running on the Salt Minion.

- Advantages: Data is stored without placing additional load on the Salt Master.
- Disadvantages: Each Salt Minion connects to the external job cache, which can result in a large number of connections. Also requires additional configuration to get returner module settings on all Salt Minions.

## 12.2 Master Job Cache - Master-Side Returner

New in version 2014.7.0.

Instead of configuring an External Job Cache on each Salt Minion, you can configure the Master Job Cache to send job results from the Salt Master instead. In this configuration, Salt Minions send data to the Default Job Cache as usual, and then the Salt Master sends the data to the external system using a Salt returner module running on the Salt Master.

- Advantages: A single connection is required to the external system. This is preferred for databases and similar systems.
- Disadvantages: Places additional load on your Salt Master.

## 12.3 Configure an External or Master Job Cache

### 12.3.1 Step 1: Understand Salt Returners

Before you configure a job cache, it is essential to understand Salt returner modules ("returners"). Returners are pluggable Salt Modules that take the data returned by jobs, and then perform any necessary steps to send the data to an external system. For example, a returner might establish a connection, authenticate, and then format and transfer data.

The Salt Returner system provides the core functionality used by the External and Master Job Cache systems, and the same returners are used by both systems.

Salt currently provides many different returners that let you connect to a wide variety of systems. A complete list is available at [all Salt returners](#). Each returner is configured differently, so make sure you read and follow the instructions linked from that page.

For example, the MySQL returner requires:

- A database created using provided schema (structure is available at [MySQL returner](#))
- A user created with with privileges to the database
- Optional SSL configuration

A simpler returner, such as Slack or HipChat, requires:

- An API key/version
- The target channel/room
- The username that should be used to send the message

### 12.3.2 Step 2: Configure the Returner

After you understand the configuration and have the external system ready, add the returner configuration settings to the Salt Minion configuration file for the External Job Cache, or to the Salt Master configuration file for the Master Job Cache.

For example, MySQL requires:

```
mysql.host: 'salt'  
mysql.user: 'salt'  
mysql.pass: 'salt'  
mysql.db: 'salt'  
mysql.port: 3306
```

Slack requires:

```
slack.channel: 'channel'  
slack.api_key: 'key'  
slack.from_name: 'name'
```

After you have configured the returner and added settings to the configuration file, you can enable the External or Master Job Cache.

### 12.3.3 Step 3: Enable the External or Master Job Cache

Configuration is a single line that specifies an already-configured returner to use to send all job data to an external system.

#### External Job Cache

To enable a returner as the External Job Cache (Minion-side), add the following line to the Salt Master configuration file:

```
ext_job_cache: <returner>
```

For example:

```
ext_job_cache: mysql
```

---

**Note:** When configuring an External Job Cache (Minion-side), the returner settings are added to the Minion configuration file, but the External Job Cache setting is configured in the Master configuration file.

---

#### Master Job Cache

To enable a returner as a Master Job Cache (Master-side), add the following line to the Salt Master configuration file:

```
master_job_cache: <returner>
```

For example:

```
master_job_cache: mysql
```

Verify that the returner configuration settings are in the Master configuration file, and be sure to restart the salt-master service after you make configuration changes. (`service salt-master restart`).

---

## Storing Data in Other Databases

---

The SDB interface is designed to store and retrieve data that, unlike pillars and grains, is not necessarily minion-specific. The initial design goal was to allow passwords to be stored in a secure database, such as one managed by the keyring package, rather than as plain-text files. However, as a generic database interface, it could conceptually be used for a number of other purposes.

SDB was added to Salt in version 2014.7.0. SDB is currently experimental, and should probably not be used in production.

### 13.1 SDB Configuration

In order to use the SDB interface, a configuration profile must be set up in either the master or minion configuration file. The configuration stanza includes the name/ID that the profile will be referred to as, a `driver` setting, and any other arguments that are necessary for the SDB module that will be used. For instance, a profile called `mykeyring`, which uses the `system` service in the `keyring` module would look like:

```
mykeyring:
  driver: keyring
  service: system
```

It is recommended to keep the name of the profile simple, as it is used in the SDB URI as well.

### 13.2 SDB URIs

SDB is designed to make small database queries (hence the name, SDB) using a compact URL. This allows users to reference a database value quickly inside a number of Salt configuration areas, without a lot of overhead. The basic format of an SDB URI is:

```
sdb://<profile>/<args>
```

The profile refers to the configuration profile defined in either the master or the minion configuration file. The args are specific to the module referred to in the profile, but will typically only need to refer to the key of a key/value pair inside the database. This is because the profile itself should define as many other parameters as possible.

For example, a profile might be set up to reference credentials for a specific OpenStack account. The profile might look like:

```
kevinopenstack:
  driver: keyring
  service: salt.cloud.openstack.kevin
```

And the URI used to reference the password might look like:

```
sdb://kevinopenstack/password
```

## 13.3 Writing SDB Modules

There is currently one function that **MUST** exist in any SDB module (`get()`) and one that **MAY** exist (`set_()`). If using a (`set_()`) function, a `__func_alias__` dictionary **MUST** be declared in the module as well:

```
__func_alias__ = {  
    'set_': 'set',  
}
```

This is because `set` is a Python built-in, and therefore functions should not be created which are called `set()`. The `__func_alias__` functionality is provided via Salt's loader interfaces, and allows legally-named functions to be referred to using names that would otherwise be unwise to use.

The `get()` function is required, as it will be called via functions in other areas of the code which make use of the `sdb://` URI. For example, the `config.get` function in the `config` execution module uses this function.

The `set_()` function may be provided, but is not required, as some sources may be read-only, or may be otherwise unwise to access via a URI (for instance, because of SQL injection attacks).

A simple example of an SDB module is `salt/sdb/keyring_db.py`, as it provides basic examples of most, if not all, of the types of functionality that are available not only for SDB modules, but for Salt modules in general.

---

## Salt Event System

---

The Salt Event System is used to fire off events enabling third party applications or external processes to react to behavior within Salt.

The event system is comprised of a two primary components:

- The event sockets which publishes events.
- The event library which can listen to events and send events into the salt system.

### 14.1 Event types

#### 14.1.1 Salt Master Events

These events are fired on the Salt Master event bus. This list is **not** comprehensive.

##### Authentication events

###### **salt/auth**

Fired when a minion performs an authentication check with the master.

###### Variables

- **id** -- The minion ID.
- **act** -- The current status of the minion key: `accept`, `pend`, `reject`.
- **pub** -- The minion public key.

---

**Note:** Minions fire auth events on fairly regular basis for a number of reasons. Writing reactors to respond to events through the auth cycle can lead to infinite reactor event loops (minion tries to auth, reactor responds by doing something that generates another auth event, minion sends auth event, etc.). Consider reacting to `salt/key` or `salt/minion/<MID>/start` or firing a custom event tag instead.

---

##### Start events

###### **salt/minion/<MID>/start**

Fired every time a minion connects to the Salt master.

Variables **id** -- The minion ID.

## Key events

### **salt/key**

Fired when accepting and rejecting minions keys on the Salt master.

#### Variables

- **id** -- The minion ID.
- **act** -- The new status of the minion key: `accept`, `pend`, `reject`.

**Warning:** If a master is in `auto_accept` mode, `salt/key` events will not be fired when the keys are accepted. In addition, pre-seeding keys (like happens through *Salt-Cloud*) will not cause firing of these events.

## Job events

### **salt/job/<JID>/new**

Fired as a new job is sent out to minions.

#### Variables

- **jid** -- The job ID.
- **tgt** -- The target of the job: `*`, a minion ID, `G@os_family:RedHat`, etc.
- **tgt\_type** -- The type of targeting used: `glob`, `grain`, `compound`, etc.
- **fun** -- The function to run on minions: `test.ping`, `network.interfaces`, etc.
- **arg** -- A list of arguments to pass to the function that will be called.
- **minions** -- A list of minion IDs that Salt expects will return data for this job.
- **user** -- The name of the user that ran the command as defined in Salt's Client ACL or external auth.

### **salt/job/<JID>/ret/<MID>**

Fired each time a minion returns data for a job.

#### Variables

- **id** -- The minion ID.
- **jid** -- The job ID.
- **retcode** -- The return code for the job.
- **fun** -- The function the minion ran. E.g., `test.ping`.
- **return** -- The data returned from the execution module.

### **salt/job/<JID>/prog/<MID>/<RUN NUM>**

Fired each time a each function in a state run completes execution. Must be enabled using the `state_events` option.

#### Variables

- **data** -- The data returned from the state module function.
- **id** -- The minion ID.
- **jid** -- The job ID.

## Presence events

### **salt/presence/present**

Events fired on a regular interval about currently connected, newly connected, or recently disconnected minions. Requires the *presence\_events* setting to be enabled.

Variables **present** -- A list of minions that are currently connected to the Salt master.

### **salt/presence/change**

Fired when the Presence system detects new minions connect or disconnect.

Variables

- **new** -- A list of minions that have connected since the last presence event.
- **lost** -- A list of minions that have disconnected since the last presence event.

## Cloud Events

Unlike other Master events, *salt-cloud* events are not fired on behalf of a Salt Minion. Instead, *salt-cloud* events are fired on behalf of a VM. This is because the minion-to-be may not yet exist to fire events to or also may have been destroyed.

This behavior is reflected by the *name* variable in the event data for *salt-cloud* events as compared to the *id* variable for Salt Minion-triggered events.

### **salt/cloud/<VM NAME>/creating**

Fired when *salt-cloud* starts the VM creation process.

Variables

- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **provider** -- the cloud provider of the VM being created.
- **profile** -- the cloud profile for the VM being created.

### **salt/cloud/<VM NAME>/deploying**

Fired when the VM is available and *salt-cloud* begins deploying Salt to the new VM.

Variables

- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **kwargs** -- options available as the deploy script is invoked: *conf\_file*, *deploy\_command*, *display\_ssh\_output*, *host*, *keep\_tmp*, *key\_filename*, *make\_minion*, *minion\_conf*, *name*, *parallel*, *preseed\_minion\_keys*, *script*, *script\_args*, *script\_env*, *sock\_dir*, *start\_action*, *sudo*, *tmp\_dir*, *tty*, *username*

### **salt/cloud/<VM NAME>/requesting**

Fired when *salt-cloud* sends the request to create a new VM.

Variables

- **event** -- description of the event.
- **location** -- the location of the VM being requested.

- **kwargs** -- options available as the VM is being requested: Action, ImageId, InstanceType, KeyName, MaxCount, MinCount, SecurityGroup.1

#### **salt/cloud/<VM NAME>/querying**

Fired when salt-cloud queries data for a new instance.

##### Variables

- **event** -- description of the event.
- **instance\_id** -- the ID of the new VM.

#### **salt/cloud/<VM NAME>/tagging**

Fired when salt-cloud tags a new instance.

##### Variables

- **event** -- description of the event.
- **tags** -- tags being set on the new instance.

#### **salt/cloud/<VM NAME>/waiting\_for\_ssh**

Fired while the salt-cloud deploy process is waiting for ssh to become available on the new instance.

##### Variables

- **event** -- description of the event.
- **ip\_address** -- IP address of the new instance.

#### **salt/cloud/<VM NAME>/deploy\_script**

Fired once the deploy script is finished.

Variables **event** -- description of the event.

#### **salt/cloud/<VM NAME>/created**

Fired once the new instance has been fully created.

##### Variables

- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **instance\_id** -- the ID of the new instance.
- **provider** -- the cloud provider of the VM being created.
- **profile** -- the cloud profile for the VM being created.

#### **salt/cloud/<VM NAME>/destroying**

Fired when salt-cloud requests the destruction of an instance.

##### Variables

- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **instance\_id** -- the ID of the new instance.

#### **salt/cloud/<VM NAME>/destroyed**

Fired when an instance has been destroyed.

##### Variables

- **name** -- the name of the VM being created.
- **event** -- description of the event.

- **instance\_id** -- the ID of the new instance.

## 14.2 Listening for Events

Salt's Event Bus is used heavily within Salt and it is also written to integrate heavily with existing tooling and scripts. There is a variety of ways to consume it.

### 14.2.1 From the CLI

The quickest way to watch the event bus is by calling the `state.event runner`:

```
salt-run state.event pretty=True
```

That runner is designed to interact with the event bus from external tools and shell scripts. See the documentation for more examples.

### 14.2.2 Remotely via the REST API

Salt's event bus can be consumed `salt.netapi.rest_cherry.py.app.Events` as an HTTP stream from external tools or services.

```
curl -sSsk https://salt-api.example.com:8000/events?token=05A3
```

### 14.2.3 From Python

Python scripts can access the event bus only as the same system user that Salt is running as.

The event system is accessed via the event library and can only be accessed by the same system user that Salt is running as. To listen to events a `SaltEvent` object needs to be created and then the `get_event` function needs to be run. The `SaltEvent` object needs to know the location that the Salt Unix sockets are kept. In the configuration this is the `sock_dir` option. The `sock_dir` option defaults to `"/var/run/salt/master"` on most systems.

The following code will check for a single event:

```
import salt.config
import salt.utils.event

opts = salt.config.client_config('/etc/salt/master')

event = salt.utils.event.get_event(
    'master',
    sock_dir=opts['sock_dir'],
    transport=opts['transport'],
    opts=opts)

data = event.get_event()
```

Events will also use a `tag`. Tags allow for events to be filtered by prefix. By default all events will be returned. If only authentication events are desired, then pass the tag `"/salt/auth"`.

The `get_event` method has a default poll time assigned of 5 seconds. To change this time set the `wait` option.

The following example will only listen for auth events and will wait for 10 seconds instead of the default 5.

```
data = event.get_event(wait=10, tag='salt/auth')
```

To retrieve the tag as well as the event data, pass `full=True`:

```
evdata = event.get_event(wait=10, tag='salt/job', full=True)

tag, data = evdata['tag'], evdata['data']
```

Instead of looking for a single event, the `iter_events` method can be used to make a generator which will continually yield salt events.

The `iter_events` method also accepts a tag but not a wait time:

```
for data in event.iter_events(tag='salt/auth'):
    print(data)
```

And finally event tags can be globbed, such as they can be in the Reactor, using the `fnmatch` library.

```
import fnmatch

import salt.config
import salt.utils.event

opts = salt.config.client_config('/etc/salt/master')

sevent = salt.utils.event.get_event(
    'master',
    sock_dir=opts['sock_dir'],
    transport=opts['transport'],
    opts=opts)

while True:
    ret = sevent.get_event(full=True)
    if ret is None:
        continue

    if fnmatch.fnmatch(ret['tag'], 'salt/job/*/ret/*'):
        do_something_with_job_return(ret['data'])
```

## 14.3 Firing Events

It is possible to fire events on either the minion's local bus or to fire events intended for the master.

To fire a local event from the minion on the command line call the `event.fire` execution function:

```
salt-call event.fire '{"data": "message to be sent in the event"}' 'tag'
```

To fire an event to be sent up to the master from the minion call the `event.send` execution function. Remember YAML can be used at the CLI in function arguments:

```
salt-call event.send 'myco/mytag/success' '{success: True, message: "It works!"}'
```

If a process is listening on the minion, it may be useful for a user on the master to fire an event to it:

```
# Job on minion
import salt.utils.event
```

```
event = salt.utils.event.MinionEvent(**__opts__)
```

```
for evdata in event.iter_events(tag='customtag/'):
    return evdata # do your processing here...
```

```
salt minionname event.fire '{"data": "message for the minion"}' 'customtag/african/unladen'
```

## 14.4 Firing Events from Python

### 14.4.1 From Salt execution modules

Events can be very useful when writing execution modules, in order to inform various processes on the master when a certain task has taken place. This is easily done using the normal cross-calling syntax:

```
# /srv/salt/_modules/my_custom_module.py

def do_something():
    """
    Do something and fire an event to the master when finished

    CLI Example::

        salt '*' my_custom_module:do_something
    """
    # do something!
    __salt__['event.send']('myco/my_custom_module/finished', {
        'finished': True,
        'message': "The something is finished!",
    })
```

### 14.4.2 From Custom Python Scripts

Firing events from custom Python code is quite simple and mirrors how it is done at the CLI:

```
import salt.client

caller = salt.client.Caller()

caller.sminion.functions['event.send'](
    'myco/myevent/success',
    {
        'success': True,
        'message': "It works!",
    }
)
```

---

## Beacons

---

The beacon system allows the minion to hook into a variety of system processes and continually monitor these processes. When monitored activity occurs in a system process, an event is sent on the Salt event bus that can be used to trigger a *reactor*.

Salt beacons can currently monitor and send Salt events for many system activities, including:

- file system changes
- system load
- service status
- shell activity, such as user login
- network and disk usage

See *beacon modules* for a current list.

---

**Note:** Salt beacons are an event generation mechanism. Beacons leverage the Salt *reactor* system to make changes when beacon events occur.

---

### 15.1 Configuring Beacons

Salt beacons do not require any changes to the system process that is being monitored, everything is configured using Salt.

Beacons are typically enabled by placing a `beacons: top` level block in the minion configuration file:

```
beacons:
  inotify:
    /etc/httpd/conf.d: {}
    /opt: {}
```

The beacon system, like many others in Salt, can also be configured via the minion pillar, grains, or local config file.

#### 15.1.1 Beacon Monitoring Interval

Beacons monitor on a 1-second interval by default. To set a different interval, provide an `interval` argument to a beacon. The following beacons run on 5- and 10-second intervals:

```
beacons:
  inotify:
    /etc/httpd/conf.d: {}
    /opt: {}
    interval: 5
  load:
    - 1m:
      - 0.0
      - 2.0
    - 5m:
      - 0.0
      - 1.5
    - 15m:
      - 0.1
      - 1.0
    - interval: 10
```

## 15.2 Beacon Example

This example demonstrates configuring the *inotify* beacon to monitor a file for changes, and then create a backup each time a change is detected.

---

**Note:** The *inotify* beacon requires *Pyinotify* on the minion, install it using `salt myminion pkg.install python-inotify`.

---

First, on the Salt minion, add the following beacon configuration to `/etc/salt/minion`:

```
beacons:
  inotify:
    home/user/importantfile:
      mask:
        - modify
```

Replace `user` in the previous example with the name of your user account, and then save the configuration file and restart the minion service.

Next, create a file in your home directory named `importantfile` and add some simple content. The beacon is now set up to monitor this file for modifications.

### 15.2.1 View Events on the Master

On your Salt master, start the event runner using the following command:

```
salt-run state.event pretty=true
```

This runner displays events as they are received on the Salt event bus. To test the beacon you set up in the previous section, make and save a modification to the `importantfile` you created. You'll see an event similar to the following on the event bus:

```
salt/beacon/minion1/inotify/home/user/importantfile {
  "_stamp": "2015-09-09T15:59:37.972753",
  "data": {
    "change": "IN_IGNORED",
    "id": "minion1",
```

```

    "path": "/home/user/importantfile"
  },
  "tag": "salt/beacon/minion1/inotify/home/user/importantfile"
}

```

This indicates that the event is being captured and sent correctly. Now you can create a reactor to take action when this event occurs.

### 15.2.2 Create a Reactor

On your Salt master, create a file named `srv/reactor/backup.sls`. If the reactor directory doesn't exist, create it. Add the following to `backup.sls`:

```

backup file:
  cmd.file.copy:
    - tgt: {{ data['data']['id'] }}
    - arg:
      - {{ data['data']['path'] }}
      - {{ data['data']['path'] }}.bak

```

Next, add the code to trigger the reactor to `etc/salt/master`:

```

reactor:
  - salt/beacon/*/inotify/*/importantfile:
    - /srv/reactor/backup.sls

```

This reactor creates a backup each time a file named `importantfile` is modified on a minion that has the `inotify` beacon configured as previously shown.

**Note:** You can have only one top level `reactor` section, so if one already exists, add this code to the existing section. See [Understanding the Structure of Reactor Formulas](#) to learn more about reactor SLS syntax.

### 15.2.3 Start the Salt Master in Debug Mode

To help with troubleshooting, start the Salt master in debug mode:

```

service salt-master stop
salt-master -l debug

```

When debug logging is enabled, event and reactor data are displayed so you can discover syntax and other issues.

### 15.2.4 Trigger the Reactor

On your minion, make and save another change to `importantfile`. On the Salt master, you'll see debug messages that indicate the event was received and the `file.copy` job was sent. When you list the directory on the minion, you'll now see `importantfile.bak`.

All beacons are configured using a similar process of enabling the beacon, writing a reactor SLS, and mapping a beacon event to the reactor SLS.

## 15.3 Writing Beacon Plugins

Beacon plugins use the standard Salt loader system, meaning that many of the constructs from other plugin systems holds true, such as the `__virtual__` function.

The important function in the Beacon Plugin is the `beacon` function. When the beacon is configured to run, this function will be executed repeatedly by the minion. The `beacon` function therefore cannot block and should be as lightweight as possible. The `beacon` also must return a list of dicts, each dict in the list will be translated into an event on the master.

Please see the *inotify* beacon as an example.

---

## Running Custom Master Processes

---

In addition to the processes that the Salt Master automatically spawns, it is possible to configure it to start additional custom processes.

This is useful if a dedicated process is needed that should run throughout the life of the Salt Master. For periodic independent tasks, a `scheduled` runner may be more appropriate.

Processes started in this way will be restarted if they die and will be killed when the Salt Master is shut down.

### 16.1 Example Configuration

Processes are declared in the master config file with the `ext_processes` option. Processes will be started in the order they are declared.

```
ext_processes:
  - mymodule.TestProcess
  - mymodule.AnotherProcess
```

### 16.2 Example Process Class

```
# Import python libs
import time
import logging
from multiprocessing import Process

# Import Salt libs
from salt.utils.event import SaltEvent

log = logging.getLogger(__name__)

class TestProcess(Process):
    def __init__(self, opts):
        Process.__init__(self)
        self.opts = opts

    def run(self):
        self.event = SaltEvent('master', self.opts['sock_dir'])
        i = 0
```

```
while True:
    self.event.fire_event({'iteration': i}, 'ext_processes/test{0}')
    time.sleep(60)
```

---

## High Availability Features in Salt

---

Salt supports several features for high availability and fault tolerance. Brief documentation for these features is listed alongside their configuration parameters in [Configuration file examples](#).

### 17.1 Multimaster

Salt minions can connect to multiple masters at one time by configuring the `master` configuration parameter as a YAML list of all the available masters. By default, all masters are ``hot'', meaning that any master can direct commands to the Salt infrastructure.

In a multimaster configuration, each master must have the same cryptographic keys, and minion keys must be accepted on all masters separately. The contents of `file_roots` and `pillar_roots` need to be kept in sync with processes external to Salt as well.

A tutorial on setting up multimaster with ``hot'' masters is here:

[Multimaster Tutorial](#)

### 17.2 Multimaster with Failover

Changing the `master_type` parameter from `str` to `failover` will cause minions to connect to the first responding master in the list of masters. Every `master_alive_interval` seconds the minions will check to make sure the current master is still responding. If the master does not respond, the minion will attempt to connect to the next master in the list. If the minion runs out of masters, the list will be recycled in case dead masters have been restored. Note that `master_alive_interval` must be present in the minion configuration, or else the recurring job to check master status will not get scheduled.

Failover can be combined with PKI-style encrypted keys, but PKI is NOT REQUIRED to use failover.

Multimaster with PKI and Failover is discussed in [this tutorial](#)

`master_type: failover` can be combined with `master_shuffle: True` to spread minion connections across all masters (one master per minion, not each minion connecting to all masters). Adding Salt Syndics into the mix makes it possible to create a load-balanced Salt infrastructure. If a master fails, minions will notice and select another master from the available list.

## 17.3 Syndic

Salt's Syndic feature is a way to create differing infrastructure topologies. It is not strictly an HA feature, but can be treated as such.

With the syndic, a Salt infrastructure can be partitioned in such a way that certain masters control certain segments of the infrastructure, and "Master of Masters" nodes can control multiple segments underneath them.

Syndics are covered in depth in [Salt Syndic](#).

## 17.4 Syndic with Multimaster

New in version 2015.5.0.

Syndic with Multimaster lets you connect a syndic to multiple masters to provide an additional layer of redundancy in a syndic configuration.

Syndics are covered in depth in [Salt Syndic](#).

---

## Salt Syndic

---

The most basic or typical Salt topology consists of a single Master node controlling a group of Minion nodes. An intermediate node type, called Syndic, when used offers greater structural flexibility and scalability in the construction of Salt topologies than topologies constructed only out of Master and Minion node types.

A Syndic node can be thought of as a special passthrough Minion node. A Syndic node consists of a `salt-syndic` daemon and a `salt-master` daemon running on the same system. The `salt-master` daemon running on the Syndic node controls a group of lower level Minion nodes and the `salt-syndic` daemon connects higher level Master node, sometimes called a Master of Masters.

The `salt-syndic` daemon relays publications and events between the Master node and the local `salt-master` daemon. This gives the Master node control over the Minion nodes attached to the `salt-master` daemon running on the Syndic node.

### 18.1 Configuring the Syndic

To setup a Salt Syndic you need to tell the Syndic node and its Master node about each other. If your Master node is located at `10.10.0.1`, then your configurations would be:

On the Syndic node:

```
# /etc/salt/master
syndic_master: 10.10.0.1 # may be either an IP address or a hostname
```

```
# /etc/salt/minion
# id is shared by the salt-syndic daemon and a possible salt-minion daemon
# on the Syndic node
id: my_syndic
```

On the Master node:

```
# /etc/salt/master
order_masters: True
```

The `syndic_master` option tells the Syndic node where to find the Master node in the same way that the `master` option tells a Minion node where to find a Master node.

The `id` option is used by the `salt-syndic` daemon to identify with the Master node and if unset will default to the hostname or IP address of the Syndic just as with a Minion.

The `order_masters` option configures the Master node to send extra information with its publications that is needed by Syndic nodes connected directly to it.

**Note:** Each Syndic must provide its own `file_roots` directory. Files will not be automatically transferred from the Master node.

---

## 18.2 Configuring the Syndic with Multimaster

New in version 2015.5.0.

Syndic with Multimaster lets you connect a syndic to multiple masters to provide an additional layer of redundancy in a syndic configuration.

Higher level masters should first be configured in a multimaster configuration. See [Multimaster Tutorial](#).

On the syndic, the `syndic_master` option is populated with a list of the higher level masters.

Since each syndic is connected to each master, jobs sent from any master are forwarded to minions that are connected to each syndic. If the `master_id` value is set in the master config on the higher level masters, job results are returned to the master that originated the request in a best effort fashion. Events/jobs without a `master_id` are returned to any available master.

## 18.3 Running the Syndic

The `salt-syndic` daemon is a separate process that needs to be started in addition to the `salt-master` daemon running on the Syndic node. Starting the `salt-syndic` daemon is the same as starting the other Salt daemons.

The Master node in many ways sees the Syndic as an ordinary Minion node. In particular, the Master will need to accept the Syndic's Minion key as it would for any other Minion.

On the Syndic node:

```
# salt-syndic
or
# service salt-syndic start
```

On the Master node:

```
# salt-key -a my_syndic
```

The Master node will now be able to control the Minion nodes connected to the Syndic. Only the Syndic key will be listed in the Master node's key registry but this also means that key activity between the Syndic's Minions and the Syndic does not encumber the Master node. In this way, the Syndic's key on the Master node can be thought of as a placeholder for the keys of all the Minion and Syndic nodes beneath it, giving the Master node a clear, high level structural view on the Salt cluster.

On the Master node:

```
# salt-key -L
Accepted Keys:
my_syndic
Denied Keys:
Unaccepted Keys:
Rejected Keys:

# salt '*' test.ping
minion_1:
  True
```

```
minion_2:
  True
minion_4:
  True
minion_3:
  True
```

## 18.4 Topology

A Master node (a node which is itself not a Syndic to another higher level Master node) must run a `salt-master` daemon and optionally a `salt-minion` daemon.

A Syndic node must run `salt-syndic` and `salt-master` daemons and optionally a `salt-minion` daemon.

A Minion node must run a `salt-minion` daemon.

When a `salt-master` daemon issues a command, it will be received by the Syndic and Minion nodes directly connected to it. A Minion node will process the command in the way it ordinarily would. On a Syndic node, the `salt-syndic` daemon will relay the command to the `salt-master` daemon running on the Syndic node, which then propagates the command to to the Minions and Syndics connected to it.

When events and job return data are generated by `salt-minion` daemons, they are aggregated by the `salt-master` daemon they are connected to, which `salt-master` daemon then relays the data back through its `salt-syndic` daemon until the data reaches the Master or Syndic node that issued the command.

## 18.5 Syndic wait

---

**Note:** To reduce the amount of time the CLI waits for Minions to respond, install a Minion on the Syndic or tune the value of the `syndic_wait` configuration.

---

While it is possible to run a Syndic without a Minion installed on the same system, it is recommended, for a faster CLI response time, to do so. Without a Minion installed on the Syndic node, the timeout value of `syndic_wait` increases significantly - about three-fold. With a Minion installed on the Syndic, the CLI timeout resides at the value defined in `syndic_wait`.

---

**Note:** If you have a very large infrastructure or many layers of Syndics, you may find that the CLI doesn't wait long enough for the Syndics to return their events. If you think this is the case, you can set the `syndic_wait` value in the Master configs on the Master or Syndic nodes from which commands are executed. The default value is 5, and should work for the majority of deployments.

---

In order for a Master or Syndic node to return information from Minions that are below their Syndics, the CLI requires a short wait time in order to allow the Syndics to gather responses from their Minions. This value is defined in the `syndic_wait` config option and has a default of five seconds.

## 18.6 Syndic config options

These are the options that can be used to configure a Syndic node. Note that other than `id`, Syndic config options are placed in the Master config on the Syndic node.

- `id`: Syndic id (shared by the `salt-syndic` daemon with a potential `salt-minion` daemon on the same system)

- *syndic\_master*: Master node IP address or hostname
- *syndic\_master\_port*: Master node ret\_port
- *syndic\_log\_file*: path to the logfile (absolute or not)
- *syndic\_pidfile*: path to the pidfile (absolute or not)
- *syndic\_wait*: time in seconds to wait on returns from this syndic

---

## Salt Proxy Minion Documentation

---

Proxy minions are a developing Salt feature that enables controlling devices that, for whatever reason, cannot run a standard salt-minion. Examples include network gear that has an API but runs a proprietary OS, devices with limited CPU or memory, or devices that could run a minion, but for security reasons, will not.

*Proxy minions are not an "out of the box" feature.* Because there are an infinite number of controllable devices, you will most likely have to write the interface yourself. Fortunately, this is only as difficult as the actual interface to the proxied device. Devices that have an existing Python module (PyUSB for example) would be relatively simple to interface. Code to control a device that has an HTML REST-based interface should be easy. Code to control your typical housecat would be excellent source material for a PhD thesis.

Salt proxy-minions provide the 'plumbing' that allows device enumeration and discovery, control, status, remote execution, and state management.

### 19.1 Getting Started

The following diagram may be helpful in understanding the structure of a Salt installation that includes proxy-minions:

The key thing to remember is the left-most section of the diagram. Salt's nature is to have a minion connect to a master, then the master may control the minion. However, for proxy minions, the target device cannot run a minion, and thus must rely on a separate minion to fire up the proxy-minion and make the initial and persistent connection.

After the proxy minion is started and initiates its connection to the `dumb` device, it connects back to the salt-master and ceases to be affiliated in any way with the minion that started it.

To create support for a proxied device one needs to create four things:

1. The *proxy\_connection\_module* (located in salt/proxy).
2. The *grains support code* (located in salt/grains).
3. *Salt modules* specific to the controlled device.
4. *Salt states* specific to the controlled device.

### 19.1.1 Configuration parameters on the master

Proxy minions require no configuration parameters in `/etc/salt/master`.

Salt's Pillar system is ideally suited for configuring proxy-minions. Proxies can either be designated via a pillar file in `pillar_roots`, or through an external pillar. External pillars afford the opportunity for interfacing with a configuration management system, database, or other knowledgeable system that that may already contain all the details of proxy targets. To use static files in `pillar_roots`, pattern your files after the following examples, which are based on the diagram above:

`/srv/pillar/top.sls`

```
base:
  minioncontroller1:
    - networkswitches
  minioncontroller2:
    - reallydumbdevices
  minioncontroller3:
    - msggateway
```

`/srv/pillar/networkswitches.sls`

```
proxy:
  dumbdevice1:
    proxytype: networkswitch
    host: 172.23.23.5
    username: root
    passwd: letmein
  dumbdevice2:
    proxytype: networkswitch
    host: 172.23.23.6
    username: root
    passwd: letmein
  dumbdevice3:
    proxytype: networkswitch
    host: 172.23.23.7
    username: root
    passwd: letmein
```

`/srv/pillar/reallydumbdevices.sls`

```
proxy:
  dumbdevice4:
    proxytype: i2c_lightshow
    i2c_address: 1
  dumbdevice5:
    proxytype: i2c_lightshow
    i2c_address: 2
  dumbdevice6:
    proxytype: 433mhz_wireless
```

`/srv/pillar/msggateway.sls`

```
proxy:
  minioncontroller3:
    dumbdevice7:
      proxytype: sms_serial
      deventry: /dev/tty04
```

Note the contents of each minioncontroller key may differ widely based on the type of device that the proxy-minion is managing.

In the above example

- dumbdevices 1, 2, and 3 are network switches that have a management interface available at a particular IP address.
- dumbdevices 4 and 5 are very low-level devices controlled over an i2c bus. In this case the devices are physically connected to machine `minioncontroller2`, and are addressable on the i2c bus at their respective i2c addresses.
- dumbdevice6 is a 433 MHz wireless transmitter, also physically connected to minioncontroller2
- dumbdevice7 is an SMS gateway connected to machine minioncontroller3 via a serial port.

Because of the way pillar works, each of the salt-minions that fork off the proxy minions will only see the keys specific to the proxies it will be handling. In other words, from the above example, only minioncontroller1 will see the connection information for dumbdevices 1, 2, and 3. Minioncontroller2 will see configuration data for dumbdevices 4, 5, and 6, and minioncontroller3 will be privy to dumbdevice7.

Also, in general, proxy-minions are lightweight, so the machines that run them could conceivably control a large number of devices. The example above is just to illustrate that it is possible for the proxy services to be spread across many machines if necessary, or intentionally run on machines that need to control devices because of some physical interface (e.g. i2c and serial above). Another reason to divide proxy services might be security. In more secure environments only certain machines may have a network path to certain devices.

Now our salt-minions know if they are supposed to spawn a proxy-minion process to control a particular device. That proxy-minion process will initiate a connection back to the master to enable control.

### 19.1.2 Proxymodules

A proxy module encapsulates all the code necessary to interface with a device. Proxymodules are located inside the salt.proxy module. At a minimum a proxymodule object must implement the following functions:

`__virtual__()`: This function performs the same duty that it does for other types of Salt modules. Logic goes here to determine if the module can be loaded, checking for the presence of Python modules on which the proxy depends. Returning `False` will prevent the module from loading.

`init(opts)`: Perform any initialization that the device needs. This is a good place to bring up a persistent connection to a device, or authenticate to create a persistent authorization token.

`id(opts)`: Returns a unique, unchanging id for the controlled device. This is the ``name" of the device, and is used by the salt-master for targeting and key authentication.

`shutdown()`: Code to cleanly shut down or close a connection to a controlled device goes here. This function must exist, but can contain only the keyword `pass` if there is no shutdown logic required.

`ping()`: While not required, it is highly recommended that this function also be defined in the proxymodule. The code for `ping` should contact the controlled device and make sure it is really available.

Here is an example proxymodule used to interface to a *very* simple REST server. Code for the server is in the [salt-contrib GitHub repository](#)

This proxymodule enables ``service" enumeration, starting, stopping, restarting, and status; ``package" installation, and a ping.

```
# -*- coding: utf-8 -*-
'''
This is a simple proxy-minion designed to connect to and communicate with
the bottle-based web service contained in
https://github.com/saltstack/salt-contrib/proxyminion\_rest\_example
'''
```

```

'''
from __future__ import absolute_import

# Import python libs
import logging
import salt.utils.http

HAS_REST_EXAMPLE = True

# This must be present or the Salt loader won't load this module
__proxyenabled__ = ['rest_sample']

# Variables are scoped to this module so we can have persistent data
# across calls to fns in here.
GRAINS_CACHE = {}
DETAILS = {}

# Want logging!
log = logging.getLogger(__file__)

# This does nothing, it's here just as an example and to provide a log
# entry when the module is loaded.
def __virtual__():
    '''
    Only return if all the modules are available
    '''
    log.debug('rest_sample proxy __virtual__() called...')
    return True

# Every proxy module needs an 'init', though you can
# just put a 'pass' here if it doesn't need to do anything.
def init(opts):
    log.debug('rest_sample proxy init() called...')

    # Save the REST URL
    DETAILS['url'] = opts['proxy']['url']

    # Make sure the REST URL ends with a '/'
    if not DETAILS['url'].endswith('/'):
        DETAILS['url'] += '/'

def id(opts):
    '''
    Return a unique ID for this proxy minion. This ID MUST NOT CHANGE.
    If it changes while the proxy is running the salt-master will get
    really confused and may stop talking to this minion
    '''
    r = salt.utils.http.query(opts['proxy']['url']+id', decode_type='json', decode=True)
    return r['dict']['id'].encode('ascii', 'ignore')

def grains():
    '''
    Get the grains from the proxied device
    '''

```

```
    if not GRAINS_CACHE:
        r = salt.utils.http.query(DETAILS['url']+'info', decode_type='json', decode=True)
        GRAINS_CACHE = r['dict']
    return GRAINS_CACHE

def grains_refresh():
    """
    Refresh the grains from the proxied device
    """
    GRAINS_CACHE = {}
    return grains()

def service_start(name):
    """
    Start a "service" on the REST server
    """
    r = salt.utils.http.query(DETAILS['url']+'service/start/'+name, decode_type='json', decode=True)
    return r['dict']

def service_stop(name):
    """
    Stop a "service" on the REST server
    """
    r = salt.utils.http.query(DETAILS['url']+'service/stop/'+name, decode_type='json', decode=True)
    return r['dict']

def service_restart(name):
    """
    Restart a "service" on the REST server
    """
    r = salt.utils.http.query(DETAILS['url']+'service/restart/'+name, decode_type='json', decode=True)
    return r['dict']

def service_list():
    """
    List "services" on the REST server
    """
    r = salt.utils.http.query(DETAILS['url']+'service/list', decode_type='json', decode=True)
    return r['dict']

def service_status(name):
    """
    Check if a service is running on the REST server
    """
    r = salt.utils.http.query(DETAILS['url']+'service/status/'+name, decode_type='json', decode=True)
    return r['dict']

def package_list():
    """
    List "packages" installed on the REST server
    """
```

```

r = salt.utils.http.query(DETAILS['url']+'package/list', decode_type='json', decode=True)
return r['dict']

def package_install(name, **kwargs):
    """
    Install a "package" on the REST server
    """
    cmd = DETAILS['url']+'package/install/'+name
    if 'version' in kwargs:
        cmd += '/' + kwargs['version']
    else:
        cmd += '/1.0'
    r = salt.utils.http.query(cmd, decode_type='json', decode=True)

def package_remove(name):
    """
    Remove a "package" on the REST server
    """
    r = salt.utils.http.query(DETAILS['url']+'package/remove/'+name, decode_type='json', decode=True)
    return r['dict']

def package_status(name):
    """
    Check the installation status of a package on the REST server
    """
    r = salt.utils.http.query(DETAILS['url']+'package/status/'+name, decode_type='json', decode=True)
    return r['dict']

def ping():
    """
    Is the REST server up?
    """
    r = salt.utils.http.query(DETAILS['url']+'ping', decode_type='json', decode=True)
    try:
        return r['dict'].get('ret', False)
    except Exception:
        return False

def shutdown(opts):
    """
    For this proxy shutdown is a no-op
    """
    log.debug('rest_sample proxy shutdown() called...')
    pass

```

Grains are data about minions. Most proxied devices will have a paltry amount of data as compared to a typical Linux server. By default, a proxy minion will have no grains set at all. Salt core code requires values for `kernel`, `os`, and `os_family`. To add them (and others) to your proxy minion for a particular device, create a file in `salt/grains` named `[proxytype].py` and place inside it the different functions that need to be run to collect the data you are interested in. Here's an example:

## 19.2 The `__proxyenabled__` directive

Salt execution modules, by and large, cannot "automatically" work with proxied devices. Execution modules like `pkg` or `sqlite3` have no meaning on a network switch or a housecat. For an execution module to be available to a proxy-minion, the `__proxyenabled__` variable must be defined in the module as an array containing the names of all the proxytypes that this module can support. The array can contain the special value `*` to indicate that the module supports all proxies.

If no `__proxyenabled__` variable is defined, then by default, the execution module is unavailable to any proxy.

Here is an excerpt from a module that was modified to support proxy-minions:

```
__proxyenabled__ = ['*']

[...]

def ping():

    if 'proxymodule' in __opts__:
        if 'ping' in __opts__['proxyobject'].__attr__():
            return __opts__['proxyobject'].ping()
        else:
            return False
    else:
        return True
```

And then in `salt.proxy.rest_sample.py` we find

```
def ping():
    """
    Is the REST server up?
    """
    r = salt.utils.http.query(DETAILS['url']+'ping', decode_type='json', decode=True)
    try:
        return r['dict'].get('ret', False)
    except Exception:
        return False
```

---

## The RAET Transport

---

---

**Note:** The RAET transport is in very early development, it is functional but no promises are yet made as to its reliability or security. As for reliability and security, the encryption used has been audited and our tests show that raet is reliable. With this said we are still conducting more security audits and pushing the reliability. This document outlines the encryption used in RAET

---

New in version 2014.7.0.

The Reliable Asynchronous Event Transport, or RAET, is an alternative transport medium developed specifically with Salt in mind. It has been developed to allow queuing to happen up on the application layer and comes with socket layer encryption. It also abstracts a great deal of control over the socket layer and makes it easy to bubble up errors and exceptions.

RAET also offers very powerful message routing capabilities, allowing for messages to be routed between processes on a single machine all the way up to processes on multiple machines. Messages can also be restricted, allowing processes to be sent messages of specific types from specific sources allowing for trust to be established.

### 20.1 Using RAET in Salt

Using RAET in Salt is easy, the main difference is that the core dependencies change, instead of needing pycrypto, M2Crypto, ZeroMQ, and PYZMQ, the packages libsodium, libnacl, ioflo, and raet are required. Encryption is handled very cleanly by libnacl, while the queueing and flow control is handled by ioflo. Distribution packages are forthcoming, but libsodium can be easily installed from source, or many distributions do ship packages for it. The libnacl and ioflo packages can be easily installed from pypi, distribution packages are in the works.

Once the new deps are installed the 2014.7 release or higher of Salt needs to be installed.

Once installed, modify the configuration files for the minion and master to set the transport to raet:

/etc/salt/master:

```
transport: raet
```

/etc/salt/minion:

```
transport: raet
```

Now start salt as it would normally be started, the minion will connect to the master and share long term keys, which can then in turn be managed via salt-key. Remote execution and salt states will function in the same way as with Salt over ZeroMQ.

## 20.2 Limitations

The 2014.7 release of RAET is not complete! The Syndic and Multi Master have not been completed yet and these are slated for completion in the 2015.5.0 release.

Also, Salt-Raet allows for more control over the client but these hooks have not been implemented yet, therefore the client still uses the same system as the ZeroMQ client. This means that the extra reliability that RAET exposes has not yet been implemented in the CLI client.

## 20.3 Why?

### 20.3.1 Customer and User Request

Why make an alternative transport for Salt? There are many reasons, but the primary motivation came from customer requests, many large companies came with requests to run Salt over an alternative transport, the reasoning was varied, from performance and scaling improvements to licensing concerns. These customers have partnered with SaltStack to make RAET a reality.

### 20.3.2 More Capabilities

RAET has been designed to allow salt to have greater communication capabilities. It has been designed to allow for development into features which out ZeroMQ topologies can't match.

Many of the proposed features are still under development and will be announced as they enter proof of concept phases, but these features include *salt-fuse* - a filesystem over salt, *salt-vt* - a parallel api driven shell over the salt transport and many others.

## 20.4 RAET Reliability

RAET is reliable, hence the name (Reliable Asynchronous Event Transport).

The concern posed by some over RAET reliability is based on the fact that RAET uses UDP instead of TCP and UDP does not have built in reliability.

RAET itself implements the needed reliability layers that are not natively present in UDP, this allows RAET to dynamically optimize packet delivery in a way that keeps it both reliable and asynchronous.

## 20.5 RAET and ZeroMQ

When using RAET, ZeroMQ is not required. RAET is a complete networking replacement. It is noteworthy that RAET is not a ZeroMQ replacement in a general sense, the ZeroMQ constructs are not reproduced in RAET, but they are instead implemented in such a way that is specific to Salt's needs.

RAET is primarily an async communication layer over truly async connections, defaulting to UDP. ZeroMQ is over TCP and abstracts async constructs within the socket layer.

Salt is not dropping ZeroMQ support and has no immediate plans to do so.

## 20.6 Encryption

RAET uses Dan Bernstein's NACL encryption libraries and CurveCP handshake. The libnacl python binding binds to both libsodium and tweetnacl to execute the underlying cryptography. This allows us to completely rely on an externally developed cryptography system.

For more information on libsodium and CurveCP please see: <http://doc.libsodium.org/> <http://curvecp.org/>

## 20.7 Programming Intro

Raet Programming Introduction

---

## Windows Software Repository

---

The Salt Windows Software Repository provides a package manager and software repository similar to what is provided by yum and apt on Linux.

It permits the installation of software using the installers on remote windows machines. In many senses, the operation is similar to that of the other package managers salt is aware of:

- the `pkg.installed` and similar states work on Windows.
- the `pkg.install` and similar module functions work on Windows.
- each windows machine needs to have `pkg.refresh_db` executed against it to pick up the latest version of the package database.

High level differences to yum and apt are:

- The repository metadata (sls files) is hosted through either salt or git.
- Packages can be downloaded from within the salt repository, a git repository or from http(s) or ftp urls.
- No dependencies are managed. Dependencies between packages needs to be managed manually.

### 21.1 Operation

The install state/module function of the windows package manager works roughly as follows:

1. Execute `pkg.list_pkgs` and store the result
2. Check if any action needs to be taken. (i.e. compare required package and version against `pkg.list_pkgs` results)
3. If so, run the installer command.
4. Execute `pkg.list_pkgs` and compare to the result stored from before installation.
5. Success/Failure/Changes will be reported based on the differences between the original and final `pkg.list_pkgs` results.

If there are any problems in using the package manager it is likely to be due to the data in your sls files not matching the difference between the pre and post `pkg.list_pkgs` results.

## 21.2 Usage

By default, the Windows software repository is found at `/srv/salt/win/repo`. This can be changed in the master config file (default location is `/etc/salt/master`) by modifying the `win_repo` variable. Each piece of software should have its own directory which contains the installers and a package definition file. This package definition file is a YAML file named `init.sls`.

The package definition file should look similar to this example for Firefox: `/srv/salt/win/repo/firefox/init.sls`

```
Firefox:
  '17.0.1':
    installer: 'salt://win/repo/firefox/English/Firefox Setup 17.0.1.exe'
    full_name: Mozilla Firefox 17.0.1 (x86 en-US)
    locale: en_US
    reboot: False
    install_flags: '-ms'
    uninstaller: '%ProgramFiles(x86)%/Mozilla Firefox/uninstall/helper.exe'
    uninstall_flags: '/S'
  '16.0.2':
    installer: 'salt://win/repo/firefox/English/Firefox Setup 16.0.2.exe'
    full_name: Mozilla Firefox 16.0.2 (x86 en-US)
    locale: en_US
    reboot: False
    install_flags: '-ms'
    uninstaller: '%ProgramFiles(x86)%/Mozilla Firefox/uninstall/helper.exe'
    uninstall_flags: '/S'
  '15.0.1':
    installer: 'salt://win/repo/firefox/English/Firefox Setup 15.0.1.exe'
    full_name: Mozilla Firefox 15.0.1 (x86 en-US)
    locale: en_US
    reboot: False
    install_flags: '-ms'
    uninstaller: '%ProgramFiles(x86)%/Mozilla Firefox/uninstall/helper.exe'
    uninstall_flags: '/S'
```

More examples can be found here: <https://github.com/saltstack/salt-winrepo>

The version number and `full_name` need to match the output from `pkg.list_pkgs` so that the status can be verified when running `state.apply`.

**Note:** It is still possible to successfully install packages using `pkg.install` even if they don't match which can make this hard to troubleshoot.

```
salt 'test-2008' pkg.list_pkgs
test-2008
-----
7-Zip 9.20 (x64 edition):
  9.20.00.0
Microsoft .NET Framework 4 Client Profile:
  4.0.30319,4.0.30319
Microsoft .NET Framework 4 Extended:
  4.0.30319,4.0.30319
Microsoft Visual C++ 2008 Redistributable - x64 9.0.21022:
  9.0.21022
Mozilla Firefox 17.0.1 (x86 en-US):
  17.0.1
```

```

Mozilla Maintenance Service:
  17.0.1
NSClient++ (x64):
  0.3.8.76
Notepad++:
  6.4.2

  Microsoft .NET Framework 4 Extended:
    4.0.30319,4.0.30319
  Microsoft Visual C++ 2008 Redistributable - x64 9.0.21022:
    9.0.21022
  Mozilla Maintenance Service:
    17.0.1
  Notepad++:
    6.4.2
  Salt Minion 0.16.0:
    0.16.0
  firefox:
    17.0.1
  nsclient:
    0.3.9.328

```

Add `msiexec`: True if using an MSI installer requiring the use of `msiexec /i` to install and `msiexec /x` to uninstall.

The `install_flags` and `uninstall_flags` are flags passed to the software installer to cause it to perform a silent install. These can often be found by adding `/?` or `/h` when running the installer from the command line. A great resource for finding these silent install flags can be found on the WPKG project's [wiki](#):

```

7zip:
  9.20.00.0:
    installer: salt://win/repo/7zip/7z920-x64.msi
    full_name: 7-Zip 9.20 (x64 edition)
    reboot: False
    install_flags: '/qn /norestart'
    msiexec: True
    uninstaller: '{23170F69-40C1-2702-0920-000001000000}'
    uninstall_flags: '/qn /norestart'

```

Alternatively the `uninstaller` can also simply repeat the URL of the msi file.

```

7zip:
  9.20.00.0:
    installer: salt://win/repo/7zip/7z920-x64.msi
    full_name: 7-Zip 9.20 (x64 edition)
    reboot: False
    install_flags: '/qn /norestart'
    msiexec: True

```

```
uninstaller: salt://win/repo/7zip/7z920-x64.msi
uninstall_flags: '/qn /norestart'
```

## 21.3 Generate Repo Cache File

Once the sls file has been created, generate the repository cache file with the winrepo runner:

```
salt-run winrepo.genrepo
```

Then update the repository cache file on your minions, exactly how it's done for the Linux package managers:

```
salt '*' pkg.refresh_db
```

## 21.4 Install Windows Software

Now you can query the available version of Firefox using the Salt pkg module.

```
salt '*' pkg.available_version Firefox
{'Firefox': {'15.0.1': 'Mozilla Firefox 15.0.1 (x86 en-US)',
             '16.0.2': 'Mozilla Firefox 16.0.2 (x86 en-US)',
             '17.0.1': 'Mozilla Firefox 17.0.1 (x86 en-US)'}}
```

As you can see, there are three versions of Firefox available for installation. You can refer a software package by its name or its full\_name surround by single quotes.

```
salt '*' pkg.install 'Firefox'
```

The above line will install the latest version of Firefox.

```
salt '*' pkg.install 'Firefox' version=16.0.2
```

The above line will install version 16.0.2 of Firefox.

If a different version of the package is already installed it will be replaced with the version in winrepo (only if the package itself supports live updating).

You can also specify the full name:

```
salt '*' pkg.install 'Mozilla Firefox 17.0.1 (x86 en-US)'
```

## 21.5 Uninstall Windows Software

Uninstall software using the pkg module:

```
salt '*' pkg.remove 'Firefox'
salt '*' pkg.purge 'Firefox'
```

pkg.purge just executes pkg.remove on Windows. At some point in the future pkg.purge may direct the installer to remove all configs and settings for software packages that support that option.

## 21.6 Standalone Minion Salt Windows Repo Module

In order to facilitate managing a Salt Windows software repo with Salt on a Standalone Minion on Windows, a new module named `winrepo` has been added to Salt. `winrepo` matches what is available in the salt runner and allows you to manage the Windows software repo contents. Example: `salt '*' winrepo.genrepo`

## 21.7 Git Hosted Repo

Windows software package definitions can also be hosted in one or more git repositories. The default repo is one hosted on Github.com by SaltStack,Inc., which includes package definitions for open source software. This repo points to the HTTP or ftp locations of the installer files. Anyone is welcome to send a pull request to this repo to add new package definitions. Browse the repo here: <https://github.com/saltstack/salt-winrepo>.

Configure which git repos the master can search for package definitions by modifying or extending the `win_gitrepos` configuration option list in the master config.

Checkout each git repo in `win_gitrepos`, compile your package repository cache and then refresh each minion's package cache:

```
salt-run winrepo.update_git_repos
salt-run winrepo.genrepo
salt '*' pkg.refresh_db
```

## 21.8 Troubleshooting

### 21.8.1 Incorrect name/version

If the package seems to install properly, but salt reports a failure then it is likely you have a version or `full_name` mismatch.

Check the exact `full_name` and version used by the package. Use `pkg.list_pkgs` to check that the names and version exactly match what is installed.

### 21.8.2 Changes to sls files not being picked up

Ensure you have (re)generated the repository cache file and then updated the repository cache on the relevant minions:

```
salt-run winrepo.genrepo
salt 'MINION' pkg.refresh_db
```

### 21.8.3 Packages management under Windows 2003

On windows server 2003, you need to install optional windows component "`wmi windows installer provider" to have full list of installed packages. If you don't have this, salt-minion can't report some installed software.

---

## Windows-specific Behaviour

---

Salt is capable of managing Windows systems, however due to various differences between the operating systems, there are some things you need to keep in mind.

This document will contain any quirks that apply across Salt or generally across multiple module functions. Any Windows-specific behavior for particular module functions will be documented in the module function documentation. Therefore this document should be read in conjunction with the module function documentation.

### 22.1 Group parameter for files

Salt was originally written for managing Unix-based systems, and therefore the file module functions were designed around that security model. Rather than trying to shoehorn that model on to Windows, Salt ignores these parameters and makes non-applicable module functions unavailable instead.

One of the commonly ignored parameters is the `group` parameter for managing files. Under Windows, while files do have a `'primary group'` property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Because of this, any file module functions that typically require a group, do not under Windows. Attempts to directly use file module functions that operate on the group (e.g. `file.chgrp`) will return a pseudo-value and cause a log message to appear. No group parameters will be acted on.

If you do want to access and change the `'primary group'` property and understand the implications, use the `file.get_pgid` or `file.get_pgroup` functions or the `pgroup` parameter on the `file.chown` module function.

### 22.2 Dealing with case-insensitive but case-preserving names

Windows is case-insensitive, but however preserves the case of names and it is this preserved form that is returned from system functions. This causes some issues with Salt because it assumes case-sensitive names. These issues generally occur in the state functions and can cause bizarre looking errors.

To avoid such issues, always pretend Windows is case-sensitive and use the right case for names, e.g. specify `user=Administrator` instead of `user=administrator`.

Follow [issue 11801](#) for any changes to this behavior.

## 22.3 Dealing with various username forms

Salt does not understand the various forms that Windows usernames can come in, e.g. `username`, `mydomain\username`, `username@mydomain.tld` can all refer to the same user. In fact, Salt generally only considers the raw username value, i.e. the username without the domain or host information.

Using these alternative forms will likely confuse Salt and cause odd errors to happen. Use only the raw username value in the correct case to avoid problems.

Follow [issue 11801](#) for any changes to this behavior.

## 22.4 Specifying the None group

Each Windows system has built-in `_None_` group. This is the default 'primary group' for files for users not on a domain environment.

Unfortunately, the word `_None_` has special meaning in Python - it is a special value indicating 'nothing', similar to `null` or `nil` in other languages.

To specify the None group, it must be specified in quotes, e.g. `./salt '*' file.chgrp C:\path\to\file "'None'"`.

## 22.5 Symbolic link loops

Under Windows, if any symbolic link loops are detected or if there are too many levels of symlinks (defaults to 64), an error is always raised.

For some functions, this behavior is different to the behavior on Unix platforms. In general, avoid symlink loops on either platform.

## 22.6 Modifying security properties (ACLs) on files

There is no support in Salt for modifying ACLs, and therefore no support for changing file permissions, besides modifying the owner/user.

## 23.1 Getting Started

Salt Cloud is built-in to Salt and is configured on and executed from your Salt Master.

### 23.1.1 Define a Profile

The first step is to add the credentials for your cloud provider. Credentials and provider settings are stored in provider configuration files. Provider configurations contain the details needed to connect, and any global options that you want set on your cloud minions (such as the location of your Salt Master).

On your Salt Master, browse to `/etc/salt/cloud.providers.d/` and create a file called `<provider>.provider.conf`, replacing `<provider>` with `ec2`, `softlayer`, and so on. The name helps you identify the contents, and is not important as long as the file ends in `.conf`.

Next, browse to the *Provider specifics* and add any required settings for your provider to this file. Here is an example for Amazon EC2:

```
my-ec2:
  provider: ec2
  # Set the EC2 access credentials (see below)
  #
  id: 'HJGRYCILJLKJYG'
  key: 'kdjgfgsm;woormgl/aseregksjdhasdfgn'
  # Make sure this key is owned by root with permissions 0400.
  #
  private_key: /etc/salt/my_test_key.pem
  keyname: my_test_key
  securitygroup: default
  # Optional: Set up the location of the Salt Master
  #
  minion:
    master: saltmaster.example.com
```

The required configuration varies between providers so make sure you read the provider specifics.

### 23.1.2 List Cloud Provider Options

You can now query the cloud provider you configured for available locations, images, and sizes. This information is used when you set up VM profiles.

```
salt-cloud --list-locations <provider_name> # my-ec2 in the previous example
salt-cloud --list-images <provider_name>
salt-cloud --list-sizes <provider_name>
```

Replace <provider\_name> with the name of the provider configuration you defined.

### 23.1.3 Create VM Profiles

On your Salt Master, browse to `/etc/salt/cloud.profiles.d/` and create a file called `<provider>.profiles.conf`, replacing `<provider>` with `ec2`, `softlayer`, and so on. The file must end in `.conf`.

You can now add any custom profiles you'd like to define to this file. Here are a few examples:

```
micro_ec2:
  provider: my-ec2
  image: ami-d514f291
  size: t1.micro

medium_ec2:
  provider: my-ec2
  image: ami-d514f291
  size: m3.medium

large_ec2:
  provider: my-ec2
  image: ami-d514f291
  size: m3.large
```

Notice that the `provider` in our profile matches the provider name that we defined? That is how Salt Cloud knows how to connect to create a VM with these attributes.

### 23.1.4 Create VMs

VMs are created by calling `salt-cloud` with the following options:

```
salt-cloud -p <profile> <name1> <name2> ...
```

For example:

```
salt-cloud -p micro_ec2 minion1 minion2
```

### 23.1.5 Destroy VMs

Add a `-d` and the minion name you provided to destroy:

```
salt-cloud -d minion1 minion2
```

### 23.1.6 Query VMs

You can view details about the VMs you've created using `--query`:

```
salt-cloud --query
```

## 23.2 Using Salt Cloud

### 23.2.1 salt-cloud

Provision virtual machines in the cloud with Salt

#### Synopsis

```
salt-cloud -m /etc/salt/cloud.map
salt-cloud -m /etc/salt/cloud.map NAME
salt-cloud -m /etc/salt/cloud.map NAME1 NAME2
salt-cloud -p PROFILE NAME
salt-cloud -p PROFILE NAME1 NAME2 NAME3 NAME4 NAME5 NAME6
```

#### Description

Salt Cloud is the system used to provision virtual machines on various public clouds via a cleanly controlled profile and mapping system.

#### Options

##### **--version**

Print the version of Salt that is running.

##### **--versions-report**

Show program's dependencies and version number, and then exit

##### **-h, --help**

Show the help message and exit

##### **-c CONFIG\_DIR, --config-dir=CONFIG\_dir**

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

#### Execution Options

##### **-L LOCATION, --location=LOCATION**

Specify which region to connect to.

##### **-a ACTION, --action=ACTION**

Perform an action that may be specific to this cloud provider. This argument requires one or more instance names to be specified.

- f** <FUNC-NAME> <PROVIDER>, **--function**=<FUNC-NAME> <PROVIDER>  
Perform an function that may be specific to this cloud provider, that does not apply to an instance. This argument requires a provider to be specified (i.e.: nova).
- p** PROFILE, **--profile**=PROFILE  
Select a single profile to build the named cloud VMs from. The profile must be defined in the specified profiles file.
- m** MAP, **--map**=MAP  
Specify a map file to use. If used without any other options, this option will ensure that all of the mapped VMs are created. If the named VM already exists then it will be skipped.
- H**, **--hard**  
When specifying a map file, the default behavior is to ensure that all of the VMs specified in the map file are created. If the **--hard** option is set, then any VMs that exist on configured cloud providers that are not specified in the map file will be destroyed. Be advised that this can be a destructive operation and should be used with care.
- d**, **--destroy**  
Pass in the name(s) of VMs to destroy, salt-cloud will search the configured cloud providers for the specified names and destroy the VMs. Be advised that this is a destructive operation and should be used with care. Can be used in conjunction with the **-m** option to specify a map of VMs to be deleted.
- P**, **--parallel**  
Normally when building many cloud VMs they are executed serially. The **-P** option will run each cloud vm build in a separate process allowing for large groups of VMs to be build at once.  
  
Be advised that some cloud provider's systems don't seem to be well suited for this influx of vm creation. When creating large groups of VMs watch the cloud provider carefully.
- u**, **--update-bootstrap**  
Update salt-bootstrap to the latest develop version on GitHub.
- y**, **--assume-yes**  
Default yes in answer to all confirmation questions.
- k**, **--keep-tmp**  
Do not remove files from /tmp/ after deploy.sh finishes.
- show-deploy-args**  
Include the options used to deploy the minion in the data returned.
- script-args**=SCRIPT\_ARGS  
Script arguments to be fed to the bootstrap script when deploying the VM.

#### Query Options

- Q**, **--query**  
Execute a query and return some information about the nodes running on configured cloud providers
- F**, **--full-query**  
Execute a query and print out all available information about all cloud VMs. Can be used in conjunction with **-m** to display only information about the specified map.
- S**, **--select-query**  
Execute a query and print out selected information about all cloud VMs. Can be used in conjunction with **-m** to display only information about the specified map.
- list-providers**  
Display a list of configured providers.

**--list-profiles**

New in version 2014.7.0.

Display a list of configured profiles. Pass in a cloud provider to view the provider's associated profiles, such as `digital_ocean`, or pass in `all` to list all the configured profiles.

**Cloud Providers Listings****--list-locations=LIST\_LOCATIONS**

Display a list of locations available in configured cloud providers. Pass the cloud provider that available locations are desired on, aka `linode`, or pass `all` to list locations for all configured cloud providers

**--list-images=LIST\_IMAGES**

Display a list of images available in configured cloud providers. Pass the cloud provider that available images are desired on, aka `linode`, or pass `all` to list images for all configured cloud providers

**--list-sizes=LIST\_SIZES**

Display a list of sizes available in configured cloud providers. Pass the cloud provider that available sizes are desired on, aka `AWS`, or pass `all` to list sizes for all configured cloud providers

**Cloud Credentials****--set-password=<USERNAME> <PROVIDER>**

Configure password for a cloud provider and save it to the keyring. PROVIDER can be specified with or without a driver, for example: `--set-password bob rackspace` or more specific `--set-password bob rackspace:openstack` DEPRECATED!

**Output Options****--out**

Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:

`grains`, `highstate`, `json`, `key`, `overstatestage`, `pprint`, `raw`, `txt`, `yaml`

Some outputters are formatted only for data returned from specific functions; for instance, the `grains` outputter will not work for non-grains data.

If an outputter is used that does not support the data passed into it, then Salt will fall back on the `pprint` outputter and display the return data using the Python `pprint` standard library module.

---

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use `--static` as well.

---

**--out-indent OUTPUT\_INDENT, --output-indent OUTPUT\_INDENT**

Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.

**--out-file=OUTPUT\_FILE, --output-file=OUTPUT\_FILE**

Write the output to the specified file.

**--no-color**

Disable all colored output

### **--force-color**

Force colored output

---

**Note:** When using colored output the color codes are as follows:

green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

---

### Examples

To create 4 VMs named web1, web2, db1, and db2 from specified profiles:

```
salt-cloud -p fedora_rackspace web1 web2 db1 db2
```

To read in a map file and create all VMs specified therein:

```
salt-cloud -m /path/to/cloud.map
```

To read in a map file and create all VMs specified therein in parallel:

```
salt-cloud -m /path/to/cloud.map -P
```

To delete any VMs specified in the map file:

```
salt-cloud -m /path/to/cloud.map -d
```

To delete any VMs NOT specified in the map file:

```
salt-cloud -m /path/to/cloud.map -H
```

To display the status of all VMs specified in the map file:

```
salt-cloud -m /path/to/cloud.map -Q
```

### See also

*salt-cloud(7)* *salt(7)* *salt-master(1)* *salt-minion(1)*

## 23.2.2 Salt Cloud basic usage

Salt Cloud needs, at least, one configured *Provider* and *Profile* to be functional.

### Creating a VM

To create a VM with salt cloud, use command:

```
salt-cloud -p <profile> name_of_vm
```

Assuming there is a profile configured as following:

```
fedora_rackspace:
  provider: rackspace
  image: Fedora 17
  size: 256 server
  script: bootstrap-salt
```

Then, the command to create new VM named `fedora_http_01` is:

```
salt-cloud -p fedora_rackspace fedora_http_01
```

### Destroying a VM

To destroy a created-by-salt-cloud VM, use command:

```
salt-cloud -d name_of_vm
```

For example, to delete the VM created on above example, use:

```
salt-cloud -d fedora_http_01
```

### 23.2.3 VM Profiles

Salt cloud designates virtual machines inside the profile configuration file. The profile configuration file defaults to `/etc/salt/cloud.profiles` and is a yaml configuration. The syntax for declaring profiles is simple:

```
fedora_rackspace:
  provider: rackspace
  image: Fedora 17
  size: 256 server
  script: bootstrap-salt
```

It should be noted that the `script` option defaults to `bootstrap-salt`, and does not normally need to be specified. Further examples in this document will not show the `script` option.

A few key pieces of information need to be declared and can change based on the public cloud provider. A number of additional parameters can also be inserted:

```
centos_rackspace:
  provider: rackspace
  image: CentOS 6.2
  size: 1024 server
  minion:
    master: salt.example.com
    append_domain: webs.example.com
  grains:
    role: webserver
```

The image must be selected from available images. Similarly, sizes must be selected from the list of sizes. To get a list of available images and sizes use the following command:

```
salt-cloud --list-images openstack
salt-cloud --list-sizes openstack
```

Some parameters can be specified in the main Salt cloud configuration file and then are applied to all cloud profiles. For instance if only a single cloud provider is being used then the `provider` option can be declared in the Salt cloud configuration file.

### Multiple Configuration Files

In addition to `/etc/salt/cloud.profiles`, profiles can also be specified in any file matching `cloud.profiles.d/*conf` which is a sub-directory relative to the profiles configuration file (with the above

configuration file as an example, `/etc/salt/cloud.profiles.d/*.conf`). This allows for more extensible configuration, and plays nicely with various configuration management tools as well as version control systems.

### Larger Example

```
rhel_ec2:
  provider: ec2
  image: ami-e565ba8c
  size: t1.micro
  minion:
    cheese: edam

ubuntu_ec2:
  provider: ec2
  image: ami-7e2da54e
  size: t1.micro
  minion:
    cheese: edam

ubuntu_rackspace:
  provider: rackspace
  image: Ubuntu 12.04 LTS
  size: 256 server
  minion:
    cheese: edam

fedora_rackspace:
  provider: rackspace
  image: Fedora 17
  size: 256 server
  minion:
    cheese: edam

cent_linode:
  provider: linode
  image: CentOS 6.2 64bit
  size: Linode 512

cent_gogrid:
  provider: gogrid
  image: 12834
  size: 512MB

cent_joyent:
  provider: joyent
  image: centos-6
  size: Small 1GB
```

### 23.2.4 Cloud Map File

A number of options exist when creating virtual machines. They can be managed directly from profiles and the command line execution, or a more complex map file can be created. The map file allows for a number of virtual machines to be created and associated with specific profiles.

Map files have a simple format, specify a profile and then a list of virtual machines to make from said profile:

```

fedora_small:
- web1
- web2
- web3
fedora_high:
- redis1
- redis2
- redis3
cent_high:
- riak1
- riak2
- riak3

```

This map file can then be called to roll out all of these virtual machines. Map files are called from the salt-cloud command with the -m option:

```
$ salt-cloud -m /path/to/mapfile
```

Remember, that as with direct profile provisioning the -P option can be passed to create the virtual machines in parallel:

```
$ salt-cloud -m /path/to/mapfile -P
```

**Note:** Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the -P argument should not be used on maps referencing GoGrid instances.

A map file can also be enforced to represent the total state of a cloud deployment by using the --hard option. When using the hard option any vms that exist but are not specified in the map file will be destroyed:

```
$ salt-cloud -m /path/to/mapfile -P -H
```

Be careful with this argument, it is very dangerous! In fact, it is so dangerous that in order to use it, you must explicitly enable it in the main configuration file.

```
enable_hard_maps: True
```

A map file can include grains and minion configuration options:

```

fedora_small:
- web1:
  minion:
    log_level: debug
  grains:
    cheese: tasty
    omelet: du fromage
- web2:
  minion:
    log_level: warn
  grains:
    cheese: more tasty
    omelet: with peppers

```

A map file may also be used with the various query options:

```

$ salt-cloud -m /path/to/mapfile -Q
{'ec2': {'web1': {'id': 'i-e6aqfegb',
                  'image': None,
                  'private_ips': []},

```

```

        'public_ips': [],
        'size': None,
        'state': 0}},
    'web2': {'Absent'}}

```

...or with the delete option:

```

$ salt-cloud -m /path/to/mapfile -d
The following virtual machines are set to be destroyed:
  web1
  web2

Proceed? [N/y]

```

**Warning:** Specifying Nodes with Maps on the Command Line Specifying the name of a node or nodes with the maps options on the command line is *not* supported. This is especially important to remember when using `--destroy` with maps; `salt-cloud` will ignore any arguments passed in which are not directly relevant to the map file. *When using `--destroy` with a map, every node in the map file will be deleted!* Maps don't provide any useful information for destroying individual nodes, and should not be used to destroy a subset of a map.

## Setting up New Salt Masters

Bootstrapping a new master in the map is as simple as:

```

fedora_small:
- web1:
    make_master: True
- web2
- web3

```

Notice that **ALL** bootstrapped minions from the map will answer to the newly created salt-master.

To make any of the bootstrapped minions answer to the bootstrapping salt-master as opposed to the newly created salt-master, as an example:

```

fedora_small:
- web1:
    make_master: True
    minion:
        master: <the local master ip address>
        local_master: True
- web2
- web3

```

The above says the minion running on the newly created salt-master responds to the local master, ie, the master used to bootstrap these VMs.

Another example:

```

fedora_small:
- web1:
    make_master: True
- web2
- web3:
    minion:
        master: <the local master ip address>
        local_master: True

```

The above example makes the web3 minion answer to the local master, not the newly created master.

### 23.2.5 Cloud Actions

Once a VM has been created, there are a number of actions that can be performed on it. The ``reboot" action can be used across all providers, but all other actions are specific to the cloud provider. In order to perform an action, you may specify it from the command line, including the name(s) of the VM to perform the action on:

```
$ salt-cloud -a reboot vm_name
$ salt-cloud -a reboot vm1 vm2 vm2
```

Or you may specify a map which includes all VMs to perform the action on:

```
$ salt-cloud -a reboot -m /path/to/mapfile
```

The following is a list of actions currently supported by salt-cloud:

```
all providers:
  - reboot
ec2:
  - start
  - stop
joyent:
  - stop
```

Another useful reference for viewing more salt-cloud actions is the [:ref:Salt Cloud Feature Matrix <salt-cloud-feature-matrix>](#)

### 23.2.6 Cloud Functions

Cloud functions work much the same way as cloud actions, except that they don't perform an operation on a specific instance, and so do not need a machine name to be specified. However, since they perform an operation on a specific cloud provider, that provider must be specified.

```
$ salt-cloud -f show_image ec2 image=ami-fd20ad94
```

There are three universal salt-cloud functions that are extremely useful for gathering information about instances on a provider basis:

- `list_nodes`: Returns some general information about the instances for the given provider.
- `list_nodes_full`: Returns all information about the instances for the given provider.
- `list_nodes_select`: Returns select information about the instances for the given provider.

```
$ salt-cloud -f list_nodes linode
$ salt-cloud -f list_nodes_full linode
$ salt-cloud -f list_nodes_select linode
```

Another useful reference for viewing salt-cloud functions is the [:ref:Salt Cloud Feature Matrix <salt-cloud-feature-matrix>](#)

## 23.3 Core Configuration

### 23.3.1 Install Salt Cloud

Salt Cloud is now part of Salt proper. It was merged in as of [Salt version 2014.1.0](#).

On Ubuntu, install Salt Cloud by using following command:

```
sudo add-apt-repository ppa:saltstack/salt
sudo apt-get install salt-cloud
```

If using Salt Cloud on OS X, `curl-ca-bundle` must be installed. Presently, this package is not available via `brew`, but it is available using MacPorts:

```
sudo port install curl-ca-bundle
```

Salt Cloud depends on `apache-libcloud`. Libcloud can be installed via `pip` with `pip install apache-libcloud`.

#### Installing Salt Cloud for development

Installing Salt for development enables Salt Cloud development as well, just make sure `apache-libcloud` is installed as per above paragraph.

See these instructions: [Installing Salt for development](#).

### 23.3.2 Core Configuration

A number of core configuration options and some options that are global to the VM profiles can be set in the cloud configuration file. By default this file is located at `/etc/salt/cloud`.

#### Thread Pool Size

When salt cloud is operating in parallel mode via the `-P` argument, you can control the thread pool size by specifying the `pool_size` parameter with a positive integer value.

By default, the thread pool size will be set to the number of VMs that salt cloud is operating on.

```
pool_size: 10
```

#### Minion Configuration

The default minion configuration is set up in this file. Minions created by salt-cloud derive their configuration from this file. Almost all parameters found in [Configuring the Salt Minion](#) can be used here.

```
minion:
  master: saltmaster.example.com
```

In particular, this is the location to specify the location of the salt master and its listening port, if the port is not set to the default.

## Cloud Configuration Syntax

The data specific to interacting with public clouds is set up here.

Cloud provider configuration syntax can live in several places. The first is in `/etc/salt/cloud`:

```
# /etc/salt/cloud
providers:
  my-aws-migrated-config:
    id: HJGRYCILJLKJYG
    key: 'kdjgfsqm;woormgl/asorigjksjdhasdfgn'
    keyname: test
    securitygroup: quick-start
    private_key: /root/test.pem
    provider: aws
```

Cloud provider configuration data can also be housed in `/etc/salt/cloud.providers` or any file matching `/etc/salt/cloud.providers.d/*.conf`. All files in any of these locations will be parsed for cloud provider data.

Using the example configuration above:

```
# /etc/salt/cloud.providers
# or could be /etc/salt/cloud.providers.d/*.conf
my-aws-config:
  id: HJGRYCILJLKJYG
  key: 'kdjgfsqm;woormgl/asorigjksjdhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  provider: aws
```

**Note:** Salt Cloud provider configurations within `/etc/cloud.provider.d/` should not specify the `providers` starting key.

It is also possible to have multiple cloud configuration blocks within the same alias block. For example:

```
production-config:
  - id: HJGRYCILJLKJYG
    key: 'kdjgfsqm;woormgl/asorigjksjdhasdfgn'
    keyname: test
    securitygroup: quick-start
    private_key: /root/test.pem
    provider: aws

  - user: example_user
    apikey: 123984bjjas87034
    provider: rackspace
```

However, using this configuration method requires a change with profile configuration blocks. The provider alias needs to have the provider key value appended as in the following example:

```
rhel_aws_dev:
  provider: production-config:aws
  image: ami-e565ba8c
  size: t1.micro

rhel_aws_prod:
  provider: production-config:aws
```

```
image: ami-e565ba8c
size: High-CPU Extra Large Instance

database_prod:
  provider: production-config:rackspace
  image: Ubuntu 12.04 LTS
  size: 256 server
```

Notice that because of the multiple entries, one has to be explicit about the provider alias and name, from the above example, `production-config: aws`.

This data interactions with the `salt-cloud` binary regarding its `--list-location`, `--list-images`, and `--list-sizes` which needs a cloud provider as an argument. The argument used should be the configured cloud provider alias. If the provider alias has multiple entries, `<provider-alias>: <provider-name>` should be used.

To allow for a more extensible configuration, `--providers-config`, which defaults to `/etc/salt/cloud.providers`, was added to the cli parser. It allows for the providers' configuration to be added on a per-file basis.

### Pillar Configuration

It is possible to configure cloud providers using pillars. This is only used when inside the cloud module. You can setup a variable called `cCloud` that contains your profile and provider to pass that information to the cloud servers instead of having to copy the full configuration to every minion. In your pillar file, you would use something like this:

```
cloud:
  ssh_key_name: saltstack
  ssh_key_file: /root/.ssh/id_rsa
  update_cachedir: True
  diff_cache_events: True
  change_password: True

providers:
  my-nova:
    identity_url: https://identity.api.rackspacecloud.com/v2.0/
    compute_region: IAD
    user: myuser
    api_key: apikey
    tenant: 123456
    provider: nova

  my-openstack:
    identity_url: https://identity.api.rackspacecloud.com/v2.0/tokens
    user: user2
    apikey: apikey2
    tenant: 654321
    compute_region: DFW
    provider: openstack
    compute_name: cloudServersOpenStack

profiles:
  ubuntu-nova:
    provider: my-nova
    size: performance1-8
    image: bb02b1a3-bc77-4d17-ab5b-421d89850fca
```

```

script_args: git develop

ubuntu-openstack:
  provider: my-openstack
  size: performance1-8
  image: bb02b1a3-bc77-4d17-ab5b-421d89850fca
  script_args: git develop

```

## Cloud Configurations

### Rackspace

Rackspace cloud requires two configuration options; a `user` and an `apikey`:

```

my-rackspace-config:
  user: example_user
  apikey: 123984bjjas87034
  provider: rackspace-config

```

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be `provider: my-rackspace-config`.

### Amazon AWS

A number of configuration options are required for Amazon AWS including `id`, `key`, `keyname`, `securitygroup`, and `private_key`:

```

my-aws-quick-start:
  id: HJGRYCILJLKJYG
  key: 'kdjgfsqm;woormgl/asorigjksjdhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  provider: aws

my-aws-default:
  id: HJGRYCILJLKJYG
  key: 'kdjgfsqm;woormgl/asorigjksjdhasdfgn'
  keyname: test
  securitygroup: default
  private_key: /root/test.pem
  provider: aws

```

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be either `provider: my-aws-quick-start` or `provider: my-aws-default`.

### Linode

Linode requires a single API key, but the default root password also needs to be set:

```
my-linode-config:
  apikey: asldkgfakl;sdfjsjaslfjaklsdjf;askldjfaaklsjdfhasldsadfgdkf
  password: F00barbaz
  ssh_pubkey: ssh-ed25519 AAAAC3NzaC1lZDI1NTE5AAAAIKHE0LLbeXgaqRQT9NBAopVz366SdYc0KKX33vAnq+2R user@
  ssh_key_file: ~/.ssh/id_ed25519
  provider: linode
```

The password needs to be 8 characters and contain lowercase, uppercase, and numbers.

---

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be `provider: my-linode-config`

---

### Joyent Cloud

The Joyent cloud requires three configuration parameters: The username and password that are used to log into the Joyent system, as well as the location of the private SSH key associated with the Joyent account. The SSH key is needed to send the provisioning commands up to the freshly created virtual machine.

```
my-joyent-config:
  user: fred
  password: saltybacon
  private_key: /root/joyent.pem
  provider: joyent
```

---

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be `provider: my-joyent-config`

---

### GoGrid

To use Salt Cloud with GoGrid, log into the GoGrid web interface and create an API key. Do this by clicking on "My Account" and then going to the API Keys tab.

The `apikey` and the `sharedsecret` configuration parameters need to be set in the configuration file to enable interfacing with GoGrid:

```
my-gogrid-config:
  apikey: asdff7896asdh789
  sharedsecret: saltybacon
  provider: gogrid
```

---

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be `provider: my-gogrid-config`

---

### OpenStack

OpenStack configuration differs between providers, and at the moment several options need to be specified. This module has been officially tested against the HP and the Rackspace implementations, and some examples are provided for both.

```
# For HP
my-openstack-hp-config:
  identity_url:
    'https://region-a.geo-1.identity.hpcloudsvc.com:35357/v2.0/'
  compute_name: Compute
  compute_region: 'az-1.region-a.geo-1'
  tenant: myuser-tenant1
  user: myuser
  ssh_key_name: mykey
  ssh_key_file: '/etc/salt/hpcloud/mykey.pem'
  password: mypass
  provider: openstack

# For Rackspace
my-openstack-rackspace-config:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/tokens'
  compute_name: cloudServersOpenStack
  protocol: ipv4
  compute_region: DFW
  protocol: ipv4
  user: myuser
  tenant: 5555555
  password: mypass
  provider: openstack
```

If you have an API key for your provider, it may be specified instead of a password:

```
my-openstack-hp-config:
  apikey: 901d3f579h23c8v73q9

my-openstack-rackspace-config:
  apikey: 901d3f579h23c8v73q9
```

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be either `provider: my-openstack-hp-config` or `provider: my-openstack-rackspace-config`.

You will certainly need to configure the `user`, `tenant`, and either `password` or `apikey`.

If your OpenStack instances only have private IP addresses and a CIDR range of private addresses are not reachable from the salt-master, you may set your preference to have Salt ignore it:

```
my-openstack-config:
  ignore_cidr: 192.168.0.0/16
```

For in-house OpenStack Essex installation, libcloud needs the `service_type` :

```
my-openstack-config:
  identity_url: 'http://control.openstack.example.org:5000/v2.0/'
  compute_name : Compute Service
  service_type : compute
```

## DigitalOcean

Using Salt for DigitalOcean requires a `client_key` and an `api_key`. These can be found in the DigitalOcean web interface, in the "My Settings" section, under the API Access tab.

```
my-digitalocean-config:
  provider: digital_ocean
  personal_access_token: xxx
  location: New York 1
```

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be `provider: my-digital-ocean-config`.

---

### Parallels

Using Salt with Parallels requires a `user`, `password` and `URL`. These can be obtained from your cloud provider.

```
my-parallels-config:
  user: myuser
  password: xyzyy
  url: https://api.cloud.xmission.com:4465/paci/v1.0/
  provider: parallels
```

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be `provider: my-parallels-config`.

---

### Proxmox

Using Salt with Proxmox requires a `user`, `password`, and `URL`. These can be obtained from your cloud provider. Both PAM and PVE users can be used.

```
my-proxmox-config:
  provider: proxmox
  user: saltcloud@pve
  password: xyzyy
  url: your.proxmox.host
```

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be `provider: my-proxmox-config`.

---

### LXC

The `lxc` driver uses `saltify` to install salt and attach the `lxc` container as a new `lxc` minion. As soon as we can, we manage baremetal operation over SSH. You can also destroy those containers via this driver.

```
devhost10-lxc:
  target: devhost10
  provider: lxc
```

And in the map file:

```
devhost10-lxc:
  provider: devhost10-lxc
  from_container: ubuntu
  backing: lvm
  sudo: True
```

```

size: 3g
ip: 10.0.3.9
minion:
  master: 10.5.0.1
  master_port: 4506
lxc_conf:
  - lxc.utsname: superlxc

```

**Note:** In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: devhost10-lxc`.

## Saltify

The Saltify driver is a new, experimental driver designed to install Salt on a remote machine, virtual or bare metal, using SSH. This driver is useful for provisioning machines which are already installed, but not Salted. For more information about using this driver and for configuration examples, please see the [Getting Started with Saltify](#) documentation.

## Extending Profiles and Cloud Providers Configuration

As of 0.8.7, the option to extend both the profiles and cloud providers configuration and avoid duplication was added. The `extends` feature works on the current profiles configuration, but, regarding the cloud providers configuration, **only** works in the new syntax and respective configuration files, i.e. `/etc/salt/salt/cloud.providers` or `/etc/salt/cloud.providers.d/*.conf`.

**Note:** Extending cloud profiles and providers is not recursive. For example, a profile that is extended by a second profile is possible, but the second profile cannot be extended by a third profile.

Also, if a profile (or provider) is extending another profile and each contains a list of values, the lists from the extending profile will override the list from the original profile. The lists are not merged together.

## Extending Profiles

Some example usage on how to use `extends` with profiles. Consider `/etc/salt/salt/cloud.profiles` containing:

```

development-instances:
  provider: my-ec2-config
  size: t1.micro
  ssh_username: ec2_user
  securitygroup:
    - default
  deploy: False

Amazon-Linux-AMI-2012.09-64bit:
  image: ami-54cf5c3d
  extends: development-instances

Fedora-17:
  image: ami-08d97e61
  extends: development-instances

```

```
CentOS-5:
  provider: my-aws-config
  image: ami-09b61d60
  extends: development-instances
```

The above configuration, once parsed would generate the following profiles data:

```
[{'deploy': False,
  'image': 'ami-08d97e61',
  'profile': 'Fedora-17',
  'provider': 'my-ec2-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'},
 {'deploy': False,
  'image': 'ami-09b61d60',
  'profile': 'CentOS-5',
  'provider': 'my-aws-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'},
 {'deploy': False,
  'image': 'ami-54cf5c3d',
  'profile': 'Amazon-Linux-AMI-2012.09-64bit',
  'provider': 'my-ec2-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'},
 {'deploy': False,
  'profile': 'development-instances',
  'provider': 'my-ec2-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'}]
```

Pretty cool right?

### Extending Providers

Some example usage on how to use extends within the cloud providers configuration. Consider `/etc/salt/salt/cloud.providers` containing:

```
my-develop-envs:
- id: HJGRYCILJLKJYG
  key: 'kdjgfsqm;woormgl/aseregksjdhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  location: ap-southeast-1
  availability_zone: ap-southeast-1b
  provider: aws

- user: myuser@mycorp.com
  password: mypass
  ssh_key_name: mykey
  ssh_key_file: '/etc/salt/ibm/mykey.pem'
  location: Raleigh
```

```

provider: ibmsce

my-productions-envs:
- extends: my-develop-envs:ibmsce
  user: my-production-user@mycorp.com
  location: us-east-1
  availability_zone: us-east-1

```

The above configuration, once parsed would generate the following providers data:

```

'providers': {
  'my-develop-envs': [
    {'availability_zone': 'ap-southeast-1b',
     'id': 'HJGRYCILJLKJYG',
     'key': 'kdjgfgsm;woormgl/aseregjksjdhasdfgn',
     'keyname': 'test',
     'location': 'ap-southeast-1',
     'private_key': '/root/test.pem',
     'provider': 'aws',
     'securitygroup': 'quick-start'
    },
    {'location': 'Raleigh',
     'password': 'mypass',
     'provider': 'ibmsce',
     'ssh_key_file': '/etc/salt/ibm/mykey.pem',
     'ssh_key_name': 'mykey',
     'user': 'myuser@mycorp.com'
    }
  ],
  'my-productions-envs': [
    {'availability_zone': 'us-east-1',
     'location': 'us-east-1',
     'password': 'mypass',
     'provider': 'ibmsce',
     'ssh_key_file': '/etc/salt/ibm/mykey.pem',
     'ssh_key_name': 'mykey',
     'user': 'my-production-user@mycorp.com'
    }
  ]
}

```

## 23.4 Windows Configuration

### 23.4.1 Spinning up Windows Minions

It is possible to use Salt Cloud to spin up Windows instances, and then install Salt on them. This functionality is available on all cloud providers that are supported by Salt Cloud. However, it may not necessarily be available on all Windows images.

#### Requirements

Salt Cloud makes use of *impacket* and *wine* to set up the Windows Salt Minion installer.

*impacket* is usually available as either the *impacket* or the *python-impacket* package, depending on the distribution. More information on *impacket* can be found at the project home:

- [impacket project home](#)

*winexe* is less commonly available in distribution-specific repositories. However, it is currently being built for various distributions in 3rd party channels:

- [RPMs at pbone.net](#)
- [OpenSuse Build Service](#)

Additionally, a copy of the Salt Minion Windows installer must be present on the system on which Salt Cloud is running. This installer may be downloaded from [saltstack.com](#):

- [SaltStack Download Area](#)

## Firewall Settings

Because Salt Cloud makes use of *smbclient* and *winexe*, port 445 must be open on the target image. This port is not generally open by default on a standard Windows distribution, and care must be taken to use an image in which this port is open, or the Windows firewall is disabled.

If supported by the cloud provider, a PowerShell script may be used to open up this port automatically, using the cloud provider's *userdata*. The following script would open up port 445, and apply the changes:

```
<powershell>
New-NetFirewallRule -Name "SMB445" -DisplayName "SMB445" -Protocol TCP -LocalPort 445
Set-Item (dir wsman:\localhost\Listener\*\Port -Recurse).pspath 445 -Force
Restart-Service winrm
</powershell>
```

For EC2, this script may be saved as a file, and specified in the provider or profile configuration as *userdata\_file*. For instance:

```
userdata_file: /etc/salt/windows-firewall.ps1
```

## Configuration

Configuration is set as usual, with some extra configuration settings. The location of the Windows installer on the machine that Salt Cloud is running on must be specified. This may be done in any of the regular configuration files (main, providers, profiles, maps). For example:

Setting the installer in `/etc/salt/cloud.providers`:

```
my-softlayer:
  provider: softlayer
  user: MYUSER1138
  apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062ddbaca5f7e465bfdc9'
  minion:
    master: saltmaster.example.com
  win_installer: /root/Salt-Minion-2014.7.0-AMD64-Setup.exe
  win_username: Administrator
  win_password: letmein
```

The default Windows user is *Administrator*, and the default Windows password is blank.

## Auto-Generated Passwords on EC2

On EC2, when the `win_password` is set to `auto`, Salt Cloud will query EC2 for an auto-generated password. This password is expected to take at least 4 minutes to generate, adding additional time to the deploy process.

When the EC2 API is queried for the auto-generated password, it will be returned in a message encrypted with the specified `keyname`. This requires that the appropriate `private_key` file is also specified. Such a profile configuration might look like:

```
windows-server-2012:
  provider: my-ec2-config
  image: ami-c49c0dac
  size: m1.small
  securitygroup: windows
  keyname: mykey
  private_key: /root/mykey.pem
  userdata_file: /etc/salt/windows-firewall.ps1
  win_installer: /root/Salt-Minion-2014.7.0-AMD64-Setup.exe
  win_username: Administrator
  win_password: auto
```

## 23.5 Cloud Provider Specifics

### 23.5.1 Getting Started With Aliyun ECS

The Aliyun ECS (Elastic Computer Service) is one of the most popular public cloud providers in China. This cloud provider can be used to manage aliyun instance using salt-cloud.

<http://www.aliyun.com/>

#### Dependencies

This driver requires the Python `requests` library to be installed.

#### Configuration

Using Salt for Aliyun ECS requires aliyun access key id and key secret. These can be found in the aliyun web interface, in the "User Center" section, under "My Service" tab.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-aliyun-config:
  # aliyun Access Key ID
  id: wDGEwGrededg3435gDgxd
  # aliyun Access Key Secret
  key: GDd45t43RDBTrkkg43934t34qT43t4dgegerGEgg
  location: cn-qingdao
  provider: aliyun
```

## Profiles

### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```
aliyun_centos:
  provider: my-aliyun-config
  size: ecs.t1.small
  location: cn-qingdao
  securitygroup: G1989096784427999
  image: centos6u3_64_20G_aliaegis_20130816.vhd
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-aliyun-config
my-aliyun-config:
  -----
  aliyun:
    -----
    ecs.c1.large:
      -----
      CpuCoreCount:
        8
      InstanceTypeId:
        ecs.c1.large
      MemorySize:
        16.0
  ...SNIP...
```

Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```
# salt-cloud --list-images my-aliyun-config
my-aliyun-config:
  -----
  aliyun:
    -----
    centos5u8_64_20G_aliaegis_20131231.vhd:
      -----
      Architecture:
        x86_64
      Description:

      ImageId:
        centos5u8_64_20G_aliaegis_20131231.vhd
      ImageName:
        CentOS 5.8 64
      ImageOwnerAlias:
        system
      ImageVersion:
        1.0
      OSName:
        CentOS 5.8 64
      Platform:
        CENTOS5
      Size:
```

```

    20
  Visibility:
    public
...SNIP...

```

Locations can be obtained using the `--list-locations` option for the `salt-cloud` command:

```

my-aliyun-config:
-----
  aliyun:
-----
    cn-beijing:
-----
      LocalName:
        ☒☒
      RegionId:
        cn-beijing
    cn-hangzhou:
-----
      LocalName:
        ☒☒
      RegionId:
        cn-hangzhou
    cn-hongkong:
-----
      LocalName:
        ☒☒
      RegionId:
        cn-hongkong
    cn-qingdao:
-----
      LocalName:
        ☒☒
      RegionId:
        cn-qingdao

```

Security Group can be obtained using the `-f list_securitygroup` option for the `salt-cloud` command:

```

# salt-cloud --location=cn-qingdao -f list_securitygroup my-aliyun-config
my-aliyun-config:
-----
  aliyun:
-----
    G1989096784427999:
-----
      Description:

## 23.5.2 Getting Started With Azure

New in version 2014.1.0.

Azure is a cloud service by Microsoft providing virtual machines, SQL services, media services, and more. This document describes how to use Salt Cloud to create a virtual machine on Azure, with Salt installed.

More information about Azure is located at <http://www.windowsazure.com/>.

### Dependencies

- The [Azure Python SDK](#).
- A Microsoft Azure account
- OpenSSL (to generate the certificates)
- Salt

### Configuration

Set up the provider config at `/etc/salt/cloud.providers.d/azure.conf`:

```
# Note: This example is for /etc/salt/cloud.providers.d/azure.conf

my-azure-config:
  provider: azure
  subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
  certificate_path: /etc/salt/azure.pem

# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Optional
management_host: management.core.windows.net
```

The certificate used must be generated by the user. OpenSSL can be used to create the management certificates. Two certificates are needed: a .cer file, which is uploaded to Azure, and a .pem file, which is stored locally.

To create the .pem file, execute the following command:

```
openssl req -x509 -nodes -days 365 -newkey rsa:1024 -keyout /etc/salt/azure.pem -out /etc/salt/azure
```

To create the .cer file, execute the following command:

```
openssl x509 -inform pem -in /etc/salt/azure.pem -outform der -out /etc/salt/azure.cer
```

After creating these files, the .cer file will need to be uploaded to Azure via the "Upload a Management Certificate" action of the "Management Certificates" tab within the "Settings" section of the management portal.

Optionally, a `management_host` may be configured, if necessary for the region.

### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles`:

```
azure-ubuntu:
  provider: my-azure-config
  image: 'b39f27a8b8c64d52b05eac6a62ebad85__Ubuntu-12_04_3-LTS-amd64-server-20131003-en-us-30GB'
  size: Small
```

```
location: 'East US'  
ssh_username: azureuser  
ssh_password: verybadpass  
slot: production  
media_link: 'http://portalvhdbcddefghijklmn.blob.core.windows.net/vhds'
```

These options are described in more detail below. Once configured, the profile can be realized with a salt command:

```
salt-cloud -p azure-ubuntu newinstance
```

This will create an salt minion instance named `newinstance` in Azure. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
salt newinstance test.ping
```

## Profile Options

The following options are currently available for Azure.

### provider

The name of the provider as configured in `/etc/salt/cloud.providers.d/azure.conf`.

### image

The name of the image to use to create a VM. Available images can be viewed using the following command:

```
salt-cloud --list-images my-azure-config
```

### size

The name of the size to use to create a VM. Available sizes can be viewed using the following command:

```
salt-cloud --list-sizes my-azure-config
```

### location

The name of the location to create a VM in. Available locations can be viewed using the following command:

```
salt-cloud --list-locations my-azure-config
```

### ssh\_username

The user to use to log into the newly-created VM to install Salt.

#### ssh\_password

The password to use to log into the newly-created VM to install Salt.

#### slot

The environment to which the hosted service is deployed. Valid values are *staging* or *production*. When set to *production*, the resulting URL of the new VM will be `<vm_name>.cloudapp.net`. When set to *staging*, the resulting URL will contain a generated hash instead.

#### media\_link

This is the URL of the container that will store the disk that this VM uses. Currently, this container must already exist. If a VM has previously been created in the associated account, a container should already exist. In the web interface, go into the Storage area and click one of the available storage selections. Click the Containers link, and then copy the URL from the container that will be used. It generally looks like:

```
http://portalvhdbcddefghijklmn.blob.core.windows.net/vhds
```

#### Show Instance

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
salt-cloud -a show_instance myinstance
```

### 23.5.3 Getting Started With DigitalOcean

DigitalOcean is a public cloud provider that specializes in Linux instances.

#### Configuration

Starting in Salt 2015.5.0, a new DigitalOcean driver was added to Salt Cloud to support DigitalOcean's new API, APIv2. The original driver, referred to `digital_ocean` will be supported throughout the 2015.5.x releases of Salt, but will then be removed in Salt Beryllium in favor of the APIv2 driver, `digital_ocean_v2`. The following documentation is relevant to the new driver, `digital_ocean_v2`. To see documentation related to the original `digital_ocean` driver, please see the [DigitalOcean Salt Cloud Driver](#)

---

**Note:** When Salt Beryllium is released, the original `digital_ocean` driver will no longer be supported and the `digital_ocean_v2` driver will become the `digital_ocean` driver.

---

Using Salt for DigitalOcean requires a `personal_access_token`, an `ssh_key_file`, and at least one SSH key name in `ssh_key_names`. More can be added by separating each key with a comma. The `personal_access_token` can be found in the DigitalOcean web interface in the "Apps & API" section. The SSH key name can be found under the "SSH Keys" section.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
```

```
my-digitalocean-config:
  provider: digital_ocean
  personal_access_token: xxx
  ssh_key_file: /path/to/ssh/key/file
  ssh_key_names: my-key-name,my-key-name-2
  location: New York 1
```

## Profiles

### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```
digitalocean-ubuntu:
  provider: my-digitalocean-config
  image: Ubuntu 14.04 x32
  size: 512MB
  location: New York 1
  private_networking: True
  backups_enabled: True
  ipv6: True
```

Locations can be obtained using the `--list-locations` option for the `salt-cloud` command:

```
# salt-cloud --list-locations my-digitalocean-config
my-digitalocean-config:
  -----
  digital_ocean:
    -----
    Amsterdam 1:
      -----
      available:
        False
      features:
        [u'backups']
      name:
        Amsterdam 1
      sizes:
        []
      slug:
        ams1
  ...SNIP...
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-digitalocean-config
my-digitalocean-config:
  -----
  digital_ocean:
    -----
    512MB:
      -----
      cost_per_hour:
```

```
0.00744
cost_per_month:
  5.0
cpu:
  1
disk:
  20
id:
  66
memory:
  512
name:
  512MB
slug:
  None
...SNIP...
```

Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```
# salt-cloud --list-images my-digitalocean-config
my-digitalocean-config:
-----
digital_ocean:
-----
  Arch Linux 2013.05 x64:
  -----
  distribution:
    Arch Linux
  id:
    350424
  name:
    Arch Linux 2013.05 x64
  public:
    True
  slug:
    None
...SNIP...
```

---

**Note:** DigitalOcean's concept of Applications is nothing more than a pre-configured instance (same as a normal Droplet). You will find examples such `Docker 0.7 Ubuntu 13.04 x64` and `Wordpress on Ubuntu 12.10` when using the `--list-images` option. These names can be used just like the rest of the standard instances when specifying an image in the cloud profile configuration.

---

---

**Note:** If your domain's DNS is managed with DigitalOcean, you can automatically create A-records for newly created droplets. Use `create_dns_record: True` in your config to enable this. Add `delete_dns_record: True` to also delete records when a droplet is destroyed.

---

---

**Note:** Additional documentation is available from [DigitalOcean](#).

---

### 23.5.4 Getting Started With AWS EC2

Amazon EC2 is a very widely used public cloud platform and one of the core platforms Salt Cloud has been built to support.

Previously, the suggested provider for AWS EC2 was the `aws` provider. This has been deprecated in favor of the `ec2` provider. Configuration using the old `aws` provider will still function, but that driver is no longer in active development.

## Dependencies

This driver requires the Python `requests` library to be installed.

## Configuration

The following example illustrates some of the options that can be set. These parameters are discussed in more detail below.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-ec2-southeast-public-ips:
  # Set up the location of the salt master
  #
  minion:
    master: saltmaster.example.com

  # Set up grains information, which will be common for all nodes
  # using this provider
  grains:
    node_type: broker
    release: 1.0.1

  # Specify whether to use public or private IP for deploy script.
  #
  # Valid options are:
  #   private_ips - The salt-cloud command is run inside the EC2
  #   public_ips - The salt-cloud command is run outside of EC2
  #
  ssh_interface: public_ips

  # Optionally configure the Windows credential validation number of
  # retries and delay between retries. This defaults to 10 retries
  # with a one second delay between retries
  win_deploy_auth_retries: 10
  win_deploy_auth_retry_delay: 1

  # Set the EC2 access credentials (see below)
  #
  id: HJGRYCILJLKJYG
  key: 'kdjgfsqm;woormgl/asorigjksjdhasdfgn'

  # Make sure this key is owned by root with permissions 0400.
  #
  private_key: /etc/salt/my_test_key.pem
  keyname: my_test_key
  securitygroup: default

  # Optionally configure default region
  # Use salt-cloud --list-locations <provider> to obtain valid regions
  #
```

```
location: ap-southeast-1
availability_zone: ap-southeast-1b

# Configure which user to use to run the deploy script. This setting is
# dependent upon the AMI that is used to deploy. It is usually safer to
# configure this individually in a profile, than globally. Typical users
# are:
#
# Amazon Linux -> ec2-user
# RHEL          -> ec2-user
# CentOS       -> ec2-user
# Ubuntu       -> ubuntu
#
ssh_username: ec2-user

# Optionally add an IAM profile
iam_profile: 'arn:aws:iam::123456789012:instance-profile/ExampleInstanceProfile'

provider: ec2

my-ec2-southeast-private-ips:
# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Specify whether to use public or private IP for deploy script.
#
# Valid options are:
#   private_ips - The salt-master is also hosted with EC2
#   public_ips  - The salt-master is hosted outside of EC2
#
ssh_interface: private_ips

# Optionally configure the Windows credential validation number of
# retries and delay between retries. This defaults to 10 retries
# with a one second delay between retries
win_deploy_auth_retries: 10
win_deploy_auth_retry_delay: 1

# Set the EC2 access credentials (see below)
#
id: HJGRYCILJLKJYG
key: 'kdjgfsqm;woormgl/aseregjksjdhasdfgn'

# Make sure this key is owned by root with permissions 0400.
#
private_key: /etc/salt/my_test_key.pem
keyname: my_test_key
securitygroup: default

# Optionally configure default region
#
location: ap-southeast-1
availability_zone: ap-southeast-1b

# Configure which user to use to run the deploy script. This setting is
```

```

# dependent upon the AMI that is used to deploy. It is usually safer to
# configure this individually in a profile, than globally. Typical users
# are:
#
# Amazon Linux -> ec2-user
# RHEL          -> ec2-user
# CentOS       -> ec2-user
# Ubuntu       -> ubuntu
#
ssh_username: ec2-user

# Optionally add an IAM profile
iam_profile: 'my other profile name'

provider: ec2

```

## Access Credentials

The `id` and `key` settings may be found in the Security Credentials area of the AWS Account page:

<https://portal.aws.amazon.com/gp/aws/securityCredentials>

Both are located in the Access Credentials area of the page, under the Access Keys tab. The `id` setting is labeled Access Key ID, and the `key` setting is labeled Secret Access Key.

## Windows Deploy Timeouts

For Windows instances, it may take longer than normal for the instance to be ready. In these circumstances, the provider configuration can be configured with a `win_deploy_auth_retries` and/or a `win_deploy_auth_retry_delay` setting, which default to 10 retries and a one second delay between retries. These retries and timeouts relate to validating the Administrator password once AWS provides the credentials via the AWS API.

## Key Pairs

In order to create an instance with Salt installed and configured, a key pair will need to be created. This can be done in the EC2 Management Console, in the Key Pairs area. These key pairs are unique to a specific region. Keys in the `us-east-1` region can be configured at:

<https://console.aws.amazon.com/ec2/home?region=us-east-1#s=KeyPairs>

Keys in the `us-west-1` region can be configured at

<https://console.aws.amazon.com/ec2/home?region=us-west-1#s=KeyPairs>

...and so on. When creating a key pair, the browser will prompt to download a pem file. This file must be placed in a directory accessible by Salt Cloud, with permissions set to either 0400 or 0600.

## Security Groups

An instance on EC2 needs to belong to a security group. Like key pairs, these are unique to a specific region. These are also configured in the EC2 Management Console. Security groups for the `us-east-1` region can be configured at:

<https://console.aws.amazon.com/ec2/home?region=us-east-1#s=SecurityGroups>

...and so on.

A security group defines firewall rules which an instance will adhere to. If the salt-master is configured outside of EC2, the security group must open the SSH port (usually port 22) in order for Salt Cloud to install Salt.

## IAM Profile

Amazon EC2 instances support the concept of an [instance profile](#), which is a logical container for the IAM role. At the time that you launch an EC2 instance, you can associate the instance with an instance profile, which in turn corresponds to the IAM role. Any software that runs on the EC2 instance is able to access AWS using the permissions associated with the IAM role.

Scaffolding the profile is a 2-step configuration process:

1. Configure an IAM Role from the [IAM Management Console](#).
2. Attach this role to a new profile. It can be done with the [AWS CLI](#):

```
> aws iam create-instance-profile --instance-profile-name PROFILE_NAME
> aws iam add-role-to-instance-profile --instance-profile-name PROFILE_NAME --role-name ROLE
```

Once the profile is created, you can use the `PROFILE_NAME` to configure your cloud profiles.

## Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles`:

```
base_ec2_private:
  provider: my-ec2-southeast-private-ips
  image: ami-e565ba8c
  size: t2.micro
  ssh_username: ec2-user

base_ec2_public:
  provider: my-ec2-southeast-public-ips
  image: ami-e565ba8c
  size: t2.micro
  ssh_username: ec2-user

base_ec2_db:
  provider: my-ec2-southeast-public-ips
  image: ami-e565ba8c
  size: m1.xlarge
  ssh_username: ec2-user
  volumes:
    - { size: 10, device: /dev/sdf }
    - { size: 10, device: /dev/sdg, type: io1, iops: 1000 }
    - { size: 10, device: /dev/sdh, type: io1, iops: 1000 }
  # optionally add tags to profile:
  tag: {'Environment': 'production', 'Role': 'database'}
  # force grains to sync after install
  sync_after_install: grains

base_ec2_vpc:
  provider: my-ec2-southeast-public-ips
  image: ami-a73264ce
  size: m1.xlarge
  ssh_username: ec2-user
  script: /etc/salt/cloud.deploy.d/user_data.sh
```

```

network_interfaces:
  - DeviceIndex: 0
    PrivateIpAddresses:
      - Primary: True
      #auto assign public ip (not EIP)
    AssociatePublicIpAddress: True
    SubnetId: subnet-813d4bbf
    SecurityGroupId:
      - sg-750af413
del_root_vol_on_destroy: True
del_all_vol_on_destroy: True
volumes:
  - { size: 10, device: /dev/sdf }
  - { size: 10, device: /dev/sdg, type: io1, iops: 1000 }
  - { size: 10, device: /dev/sdh, type: io1, iops: 1000 }
tag: {'Environment': 'production', 'Role': 'database'}
sync_after_install: grains

```

The profile can now be realized with a salt command:

```

# salt-cloud -p base_ec2 ami.example.com
# salt-cloud -p base_ec2_public ami.example.com
# salt-cloud -p base_ec2_private ami.example.com

```

This will create an instance named `ami.example.com` in EC2. The minion that is installed on this instance will have an `id` of `ami.example.com`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```

# salt 'ami.example.com' test.ping

```

## Required Settings

The following settings are always required for EC2:

```

# Set the EC2 login data
my-ec2-config:
  id: HJGRYCILJLKJYG
  key: 'kdjgfgsm;woormgl/asorigjksjdhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  provider: ec2

```

## Optional Settings

EC2 allows a userdata file to be passed to the instance to be created. This functionality was added to Salt in the 2015.5.0 release.

```

my-ec2-config:
  # Pass userdata to the instance to be created
  userdata_file: /etc/salt/my-userdata-file

```

EC2 allows a location to be set for servers to be deployed in. Availability zones exist inside regions, and may be added to increase specificity.

```
my-ec2-config:
  # Optionally configure default region
  location: ap-southeast-1
  availability_zone: ap-southeast-1b
```

EC2 instances can have a public or private IP, or both. When an instance is deployed, Salt Cloud needs to log into it via SSH to run the deploy script. By default, the public IP will be used for this. If the salt-cloud command is run from another EC2 instance, the private IP should be used.

```
my-ec2-config:
  # Specify whether to use public or private IP for deploy script
  # private_ips or public_ips
  ssh_interface: public_ips
```

Many EC2 instances do not allow remote access to the root user by default. Instead, another user must be used to run the deploy script using sudo. Some common usernames include ec2-user (for Amazon Linux), ubuntu (for Ubuntu instances), admin (official Debian) and bitnami (for images provided by Bitnami).

```
my-ec2-config:
  # Configure which user to use to run the deploy script
  ssh_username: ec2-user
```

Multiple usernames can be provided, in which case Salt Cloud will attempt to guess the correct username. This is mostly useful in the main configuration file:

```
my-ec2-config:
  ssh_username:
    - ec2-user
    - ubuntu
    - admin
    - bitnami
```

Multiple security groups can also be specified in the same fashion:

```
my-ec2-config:
  securitygroup:
    - default
    - extra
```

Your instances may optionally make use of EC2 Spot Instances. The following example will request that spot instances be used and your maximum bid will be \$0.10. Keep in mind that different spot prices may be needed based on the current value of the various EC2 instance sizes. You can check current and past spot instance pricing via the EC2 API or AWS Console.

```
my-ec2-config:
  spot_config:
    spot_price: 0.10
```

By default, the spot instance type is set to `one-time`, meaning it will be launched and, if it's ever terminated for whatever reason, it will not be recreated. If you would like your spot instances to be relaunched after a termination (by your or AWS), set the type to `persistent`.

NOTE: Spot instances are a great way to save a bit of money, but you do run the risk of losing your spot instances if the current price for the instance size goes above your maximum bid.

The following parameters may be set in the cloud configuration file to control various aspects of the spot instance launching:

- `wait_for_spot_timeout`: seconds to wait before giving up on spot instance launch (default=600)

- `wait_for_spot_interval`: seconds to wait in between polling requests to determine if a spot instance is available (default=30)
- `wait_for_spot_interval_multiplier`: a multiplier to add to the interval in between requests, which is useful if AWS is throttling your requests (default=1)
- `wait_for_spot_max_failures`: maximum number of failures before giving up on launching your spot instance (default=10)

If you find that you're being throttled by AWS while polling for spot instances, you can set the following in your core cloud configuration file that will double the polling interval after each request to AWS.

```
wait_for_spot_interval: 1
wait_for_spot_interval_multiplier: 2
```

See the [AWS Spot Instances](#) documentation for more information.

Block device mappings enable you to specify additional EBS volumes or instance store volumes when the instance is launched. This setting is also available on each cloud profile. Note that the number of instance stores varies by instance type. If more mappings are provided than are supported by the instance type, mappings will be created in the order provided and additional mappings will be ignored. Consult the [AWS documentation](#) for a listing of the available instance stores, and device names.

```
my-ec2-config:
  block_device_mappings:
    - DeviceName: /dev/sdb
      VirtualName: ephemeral0
    - DeviceName: /dev/sdc
      VirtualName: ephemeral1
```

You can also use block device mappings to change the size of the root device at the provisioning time. For example, assuming the root device is `/dev/sda`, you can set its size to 100G by using the following configuration.

```
my-ec2-config:
  block_device_mappings:
    - DeviceName: /dev/sda
      Ebs.VolumeSize: 100
      Ebs.VolumeType: gp2
      Ebs.SnapshotId: dummy0
```

Existing EBS volumes may also be attached (not created) to your instances or you can create new EBS volumes based on EBS snapshots. To simply attach an existing volume use the `volume_id` parameter.

```
device: /dev/xvdj
volume_id: vol-12345abcd
```

Or, to create a volume from an EBS snapshot, use the `snapshot` parameter.

```
device: /dev/xvdj
snapshot: snap-abcd12345
```

Note that `volume_id` will take precedence over the `snapshot` parameter.

Tags can be set once an instance has been launched.

```
my-ec2-config:
  tag:
    tag0: value
    tag1: value
```

## Modify EC2 Tags

One of the features of EC2 is the ability to tag resources. In fact, under the hood, the names given to EC2 instances by salt-cloud are actually just stored as a tag called Name. Salt Cloud has the ability to manage these tags:

```
salt-cloud -a get_tags mymachine
salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'
salt-cloud -a del_tags mymachine tag1,tag2,tag3
```

It is possible to manage tags on any resource in EC2 with a Resource ID, not just instances:

```
salt-cloud -f get_tags my_ec2 resource_id=af5467ba
salt-cloud -f set_tags my_ec2 resource_id=af5467ba tag1=somestuff
salt-cloud -f del_tags my_ec2 resource_id=af5467ba tag1,tag2,tag3
```

## Rename EC2 Instances

As mentioned above, EC2 instances are named via a tag. However, renaming an instance by renaming its tag will cause the salt keys to mismatch. A rename function exists which renames both the instance, and the salt keys.

```
salt-cloud -a rename mymachine newname=yourmachine
```

## EC2 Termination Protection

EC2 allows the user to enable and disable termination protection on a specific instance. An instance with this protection enabled cannot be destroyed.

```
salt-cloud -a enable_term_protect mymachine
salt-cloud -a disable_term_protect mymachine
```

## Rename on Destroy

When instances on EC2 are destroyed, there will be a lag between the time that the action is sent, and the time that Amazon cleans up the instance. During this time, the instance still retains a Name tag, which will cause a collision if the creation of an instance with the same name is attempted before the cleanup occurs. In order to avoid such collisions, Salt Cloud can be configured to rename instances when they are destroyed. The new name will look something like:

```
myinstance-DEL20f5b8ad4eb64ed88f2c428df80a1a0c
```

In order to enable this, add `rename_on_destroy` line to the main configuration file:

```
my-ec2-config:
  rename_on_destroy: True
```

## Listing Images

Normally, images can be queried on a cloud provider by passing the `--list-images` argument to Salt Cloud. This still holds true for EC2:

```
salt-cloud --list-images my-ec2-config
```

However, the full list of images on EC2 is extremely large, and querying all of the available images may cause Salt Cloud to behave as if frozen. Therefore, the default behavior of this option may be modified, by adding an `owner` argument to the provider configuration:

```
owner: aws-marketplace
```

The possible values for this setting are `amazon`, `aws-marketplace`, `self`, `<AWS account ID>` or `all`. The default setting is `amazon`. Take note that `all` and `aws-marketplace` may cause Salt Cloud to appear as if it is freezing, as it tries to handle the large amount of data.

It is also possible to perform this query using different settings without modifying the configuration files. To do this, call the `avail_images` function directly:

```
salt-cloud -f avail_images my-ec2-config owner=aws-marketplace
```

## EC2 Images

The following are lists of available AMI images, generally sorted by OS. These lists are on 3rd-party websites, are not managed by Salt Stack in any way. They are provided here as a reference for those who are interested, and contain no warranty (express or implied) from anyone affiliated with Salt Stack. Most of them have never been used, much less tested, by the Salt Stack team.

- [Arch Linux](#)
- [FreeBSD](#)
- [Fedora](#)
- [CentOS](#)
- [Ubuntu](#)
- [Debian](#)
- [OmniOS](#)
- [All Images on Amazon](#)

## show\_image

This is a function that describes an AMI on EC2. This will give insight as to the defaults that will be applied to an instance using a particular AMI.

```
$ salt-cloud -f show_image ec2 image=ami-fd20ad94
```

## show\_instance

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
$ salt-cloud -a show_instance myinstance
```

### ebs\_optimized

This argument enables switching of the EbsOptimized setting which default to `false`. Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal Amazon EBS I/O performance. This optimization isn't available with all instance types. Additional usage charges apply when using an EBS-optimized instance.

This setting can be added to the profile or map file for an instance.

If set to True, this setting will enable an instance to be EbsOptimized

```
ebs_optimized: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```
my-ec2-config:  
  ebs_optimized: True
```

### del\_root\_vol\_on\_destroy

This argument overrides the default DeleteOnTermination setting in the AMI for the EBS root volumes for an instance. Many AMIs contain `false` as a default, resulting in orphaned volumes in the EC2 account, which may unknowingly be charged to the account. This setting can be added to the profile or map file for an instance.

If set, this setting will apply to the root EBS volume

```
del_root_vol_on_destroy: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```
my-ec2-config:  
  del_root_vol_on_destroy: True
```

### del\_all\_vols\_on\_destroy

This argument overrides the default DeleteOnTermination setting in the AMI for the not-root EBS volumes for an instance. Many AMIs contain `false` as a default, resulting in orphaned volumes in the EC2 account, which may unknowingly be charged to the account. This setting can be added to the profile or map file for an instance.

If set, this setting will apply to any (non-root) volumes that were created by salt-cloud using the `volumes` setting.

The volumes will not be deleted under the following conditions \* If a volume is detached before terminating the instance \* If a volume is created without this setting and attached to the instance

```
del_all_vols_on_destroy: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```
my-ec2-config:  
  del_all_vols_on_destroy: True
```

The setting for this may be changed on all volumes of an existing instance using one of the following commands:

```
salt-cloud -a delvol_on_destroy myinstance  
salt-cloud -a keepvol_on_destroy myinstance  
salt-cloud -a show_delvol_on_destroy myinstance
```

The setting for this may be changed on a volume on an existing instance using one of the following commands:

```
salt-cloud -a delvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a delvol_on_destroy myinstance volume_id=vol-1a2b3c4d
salt-cloud -a keepvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a keepvol_on_destroy myinstance volume_id=vol-1a2b3c4d
salt-cloud -a show_delvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a show_delvol_on_destroy myinstance volume_id=vol-1a2b3c4d
```

### EC2 Termination Protection

EC2 allows the user to enable and disable termination protection on a specific instance. An instance with this protection enabled cannot be destroyed. The EC2 driver adds a `show_term_protect` action to the regular EC2 functionality.

```
salt-cloud -a show_term_protect mymachine
salt-cloud -a enable_term_protect mymachine
salt-cloud -a disable_term_protect mymachine
```

### Alternate Endpoint

Normally, EC2 endpoints are build using the region and the `service_url`. The resulting endpoint would follow this pattern:

```
ec2.<region>.<service_url>
```

This results in an endpoint that looks like:

```
ec2.us-east-1.amazonaws.com
```

There are other projects that support an EC2 compatibility layer, which this scheme does not account for. This can be overridden by specifying the endpoint directly in the main cloud configuration file:

```
my-ec2-config:
  endpoint: myendpoint.example.com:1138/services/Cloud
```

### Volume Management

The EC2 driver has several functions and actions for management of EBS volumes.

#### Creating Volumes

A volume may be created, independent of an instance. A zone must be specified. A size or a snapshot may be specified (in GiB). If neither is given, a default size of 10 GiB will be used. If a snapshot is given, the size of the snapshot will be used.

```
salt-cloud -f create_volume ec2 zone=us-east-1b
salt-cloud -f create_volume ec2 zone=us-east-1b size=10
salt-cloud -f create_volume ec2 zone=us-east-1b snapshot=snap12345678
salt-cloud -f create_volume ec2 size=10 type=standard
salt-cloud -f create_volume ec2 size=10 type=io1 iops=1000
```

### Attaching Volumes

Unattached volumes may be attached to an instance. The following values are required; name or instance\_id, volume\_id, and device.

```
salt-cloud -a attach_volume myinstance volume_id=vol-12345 device=/dev/sdb1
```

### Show a Volume

The details about an existing volume may be retrieved.

```
salt-cloud -a show_volume myinstance volume_id=vol-12345  
salt-cloud -f show_volume ec2 volume_id=vol-12345
```

### Detaching Volumes

An existing volume may be detached from an instance.

```
salt-cloud -a detach_volume myinstance volume_id=vol-12345
```

### Deleting Volumes

A volume that is not attached to an instance may be deleted.

```
salt-cloud -f delete_volume ec2 volume_id=vol-12345
```

### Managing Key Pairs

The EC2 driver has the ability to manage key pairs.

#### Creating a Key Pair

A key pair is required in order to create an instance. When creating a key pair with this function, the return data will contain a copy of the private key. This private key is not stored by Amazon, will not be obtainable past this point, and should be stored immediately.

```
salt-cloud -f create_keypair ec2 keyname=mykeypair
```

#### Show a Key Pair

This function will show the details related to a key pair, not including the private key itself (which is not stored by Amazon).

```
salt-cloud -f show_keypair ec2 keyname=mykeypair
```

## Delete a Key Pair

This function removes the key pair from Amazon.

```
salt-cloud -f delete_keypair ec2 keyname=mykeypair
```

## Launching instances into a VPC

### Simple launching into a VPC

In the amazon web interface, identify the id of the subnet into which your image should be created. Then, edit your cloud.profiles file like so:-

```
profile-id:
  provider: provider-name
  subnetid: subnet-XXXXXXXX
  image: ami-XXXXXXXX
  size: m1.medium
  ssh_username: ubuntu
  securitygroupid:
    - sg-XXXXXXXX
```

### Specifying interface properties

New in version 2014.7.0.

Launching into a VPC allows you to specify more complex configurations for the network interfaces of your virtual machines, for example:-

```
profile-id:
  provider: provider-name
  image: ami-XXXXXXXX
  size: m1.medium
  ssh_username: ubuntu

  # Do not include either 'subnetid' or 'securitygroupid' here if you are
  # going to manually specify interface configuration
  #
  network_interfaces:
    - DeviceIndex: 0
      SubnetId: subnet-XXXXXXXX
      SecurityGroupId:
        - sg-XXXXXXXX

      # Uncomment this to associate an existing Elastic IP Address with
      # this network interface:
      #
      # associate_eip: eni-XXXXXXXX

      # You can allocate more than one IP address to an interface. Use the
      # 'ip addr list' command to see them.
      #
      # SecondaryPrivateIpAddressCount: 2

      # Uncomment this to allocate a new Elastic IP Address to this
```

```
# interface (will be associated with the primary private ip address
# of the interface
#
# allocate_new_eip: True

# Uncomment this instead to allocate a new Elastic IP Address to
# both the primary private ip address and each of the secondary ones
#
allocate_new_eips: True
```

Note that it is an error to assign a `subnetid` or `securitygroupid` to a profile where the interfaces are manually configured like this. These are both really properties of each network interface, not of the machine itself.

### 23.5.5 Getting Started With GoGrid

GoGrid is a public cloud provider supporting Linux and Windows.

#### Dependencies

- Libcloud >= 0.13.2

#### Configuration

To use Salt Cloud with GoGrid log into the GoGrid web interface and create an API key. Do this by clicking on "My Account" and then going to the API Keys tab.

The `apikey` and the `sharedsecret` configuration parameters need to be set in the configuration file to enable interfacing with GoGrid:

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-gogrid-config:
  provider: gogrid
  apikey: asdff7896asdh789
  sharedsecret: saltybacon
```

---

**Note:** A Note about using Map files with GoGrid:

Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the `-P` argument should not be used on maps referencing GoGrid instances.

---

#### Profiles

##### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```
gogrid_512:
  provider: my-gogrid-config
```

```
size: 512MB
image: CentOS 6.2 (64-bit) w/ None
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-gogrid-config
my-gogrid-config:
-----
  gogrid:
-----
    512MB:
-----
      bandwidth:
        None
      disk:
        30
      driver:
      get_uuid:
      id:
        512MB
      name:
        512MB
      price:
        0.095
      ram:
        512
      uuid:
        bde1e4d7c3a643536e42a35142c7caac34b060e9
...SNIP...
```

Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```
# salt-cloud --list-images my-gogrid-config
my-gogrid-config:
-----
  gogrid:
-----
    CentOS 6.4 (64-bit) w/ None:
-----
      driver:
      extra:
-----
      get_uuid:
      id:
        18094
      name:
        CentOS 6.4 (64-bit) w/ None
      uuid:
        bfd4055389919e01aa6261828a96cf54c8dcc2c4
...SNIP...
```

### 23.5.6 Getting Started With Google Compute Engine

Google Compute Engine (GCE) is Google-infrastructure as a service that lets you run your large-scale computing workloads on virtual machines. This document covers how to use Salt Cloud to provision and manage your virtual machines hosted within Google's infrastructure.

You can find out more about GCE and other Google Cloud Platform services at <https://cloud.google.com>.

## Dependencies

- Libcloud `>= 0.14.0-beta3`
- PyCrypto `>= 2.1`.
- A Google Cloud Platform account with Compute Engine enabled
- A registered Service Account for authorization
- Oh, and obviously you'll need `salt`

## Google Compute Engine Setup

### 1. Sign up for Google Cloud Platform

Go to <https://cloud.google.com> and use your Google account to sign up for Google Cloud Platform and complete the guided instructions.

### 2. Create a Project

Next, go to the console at <https://cloud.google.com/console> and create a new Project. Make sure to select your new Project if you are not automatically directed to the Project.

Projects are a way of grouping together related users, services, and billing. You may opt to create multiple Projects and the remaining instructions will need to be completed for each Project if you wish to use GCE and Salt Cloud to manage your virtual machines.

### 3. Enable the Google Compute Engine service

In your Project, either just click *Compute Engine* to the left, or go to the *APIs & auth* section and *APIs* link and enable the Google Compute Engine service.

### 4. Create a Service Account

To set up authorization, navigate to *APIs & auth* section and then the *Credentials* link and click the *CREATE NEW CLIENT ID* button. Select *Service Account* and click the *Create Client ID* button. This will automatically download a `.json` file which can be ignored.

Look for a new *Service Account* section in the page and record the generated email address for the matching key/fingerprint. The email address will be used in the `service_account_email_address` of the `/etc/salt/cloud` file.

### 5. Key Format

*If you are using ``libcloud >= 0.17.0`` it is recommended that you use the ``JSON format`` file you downloaded above and skip to the ``Configuration`` section below, using the JSON file `**_in` in place of `NEW.pem` in the documentation.*

If you are using an older version of libcloud or are unsure of the version you have, please follow the instructions below to generate and format a new P12 key.\*

In the new *Service Account* section, click *Generate new P12 key*, which will automatically download a `.p12` private key file. The `.p12` private key needs to be converted to a format compatible with libcloud. This new Google-generated private key was encrypted using `notasecret` as a passphrase. Use the following command and record the location of the converted private key and record the location for use in the `service_account_private_key` of the `/etc/salt/cloud` file:

```
openssl pkcs12 -in ORIG.p12 -passin pass:notasecret \
-nodes -nocerts | openssl rsa -out NEW.pem
```

## Provider Configuration

Set up the provider cloud config at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/*.conf`:

```
gce-config:
  # Set up the Project name and Service Account authorization
  project: "your-project-id"
  service_account_email_address: "123-a5gt@developer.gserviceaccount.com"
  service_account_private_key: "/path/to/your/NEW.pem"

  # Set up the location of the salt master
  minion:
    master: saltmaster.example.com

  # Set up grains information, which will be common for all nodes
  # using this provider
  grains:
    node_type: broker
    release: 1.0.1

  provider: gce
```

**Note:** The value provided for `project` must not contain underscores or spaces and is labeled as ``Project ID" on the Google Developers Console.

## Profile Configuration

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/*.conf`:

```
my-gce-profile:
  image: centos-6
  size: n1-standard-1
  location: europe-west1-b
  network: default
  tags: '["one", "two", "three"]'
  metadata: '{"one": "1", "2": "two"}'
  use_persistent_disk: True
  delete_boot_pd: False
  deploy: True
  make_master: False
  provider: gce-config
```

The profile can be realized now with a salt command:

```
salt-cloud -p my-gce-profile gce-instance
```

This will create an salt minion instance named `gce-instance` in GCE. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with a salt-minion installed, connectivity to it can be verified with Salt:

```
salt gce-instance test.ping
```

## GCE Specific Settings

Consult the sample profile below for more information about GCE specific settings. Some of them are mandatory and are properly labeled below but typically also include a hard-coded default.

### Initial Profile

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/gce.conf`:

```
my-gce-profile:
  image: centos-6
  size: n1-standard-1
  location: europe-west1-b
  network: default
  tags: '["one", "two", "three"]'
  metadata: '{"one": "1", "2": "two"}'
  use_persistent_disk: True
  delete_boot_pd: False
  ssh_interface: public_ips
  external_ip: "ephemeral"
```

### image

Image is used to define what Operating System image should be used to for the instance. Examples are Debian 7 (wheezy) and CentOS 6. Required.

### size

A `size`, in GCE terms, refers to the instance's `machine type`. See the on-line documentation for a complete list of GCE machine types. Required.

### location

A `location`, in GCE terms, refers to the instance's `zone`. GCE has the notion of both Regions (e.g. us-central1, europe-west1, etc) and Zones (e.g. us-central1-a, us-central1-b, etc). Required.

### network

Use this setting to define the network resource for the instance. All GCE projects contain a network named `default` but it's possible to use this setting to create instances belonging to a different network resource.

### tags

GCE supports instance/network tags and this setting allows you to set custom tags. It should be a list of strings and must be parse-able by the python `ast.literal_eval()` function to convert it to a python list.

### metadata

GCE supports instance metadata and this setting allows you to set custom metadata. It should be a hash of key/value strings and parse-able by the python `ast.literal_eval()` function to convert it to a python dictionary.

### use\_persistent\_disk

Use this setting to ensure that when new instances are created, they will use a persistent disk to preserve data between instance terminations and re-creations.

### delete\_boot\_pd

In the event that you wish the boot persistent disk to be permanently deleted when you destroy an instance, set `delete_boot_pd` to `True`.

### ssh\_interface

New in version 2015.5.0.

Specify whether to use public or private IP for deploy script.

Valid options are:

- `private_ips`: The salt-master is also hosted with GCE
- `public_ips`: The salt-master is hosted outside of GCE

### external\_ip

Per instance setting: Used a named fixed IP address to this host.

Valid options are:

- `ephemeral`: The host will use a GCE ephemeral IP
- `None`: No external IP will be configured on this host.

Optionally, pass the name of a GCE address to use a fixed IP address. If the address does not already exist, it will be created.

### ex\_disk\_type

GCE supports two different disk types, `pd-standard` and `pd-ssd`. The default disk type setting is `pd-standard`. To specify using an SSD disk, set `pd-ssd` as the value.

New in version 2014.7.0.

## SSH Remote Access

GCE instances do not allow remote access to the root user by default. Instead, another user must be used to run the deploy script using `sudo`. Append something like this to `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/*.conf`:

```
my-gce-profile:
  ...

  # SSH to GCE instances as gceuser
  ssh_username: gceuser

  # Use the local private SSH key file located here
  ssh_keyfile: /etc/cloud/google_compute_engine
```

If you have not already used this SSH key to login to instances in this GCE project you will also need to add the public key to your projects metadata at <https://cloud.google.com/console>. You could also add it via the metadata setting too:

```
my-gce-profile:
  ...

  metadata: '{"one": "1", "2": "two",
             "sshKeys": "gceuser:ssh-rsa <Your SSH Public Key> gceuser@host"}'
```

### Single instance details

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
salt-cloud -a show_instance myinstance
```

### Destroy, persistent disks, and metadata

As noted in the provider configuration, it's possible to force the boot persistent disk to be deleted when you destroy the instance. The way that this has been implemented is to use the instance metadata to record the cloud profile used when creating the instance. When `destroy` is called, if the instance contains a `salt-cloud-profile` key, its value is used to reference the matching profile to determine if `delete_boot_pd` is set to `True`.

Be aware that any GCE instances created with salt cloud will contain this custom `salt-cloud-profile` metadata entry.

### List various resources

It's also possible to list several GCE resources similar to what can be done with other providers. The following commands can be used to list GCE zones (locations), machine types (sizes), and images.

```
salt-cloud --list-locations gce
salt-cloud --list-sizes gce
salt-cloud --list-images gce
```

### Persistent Disk

The Compute Engine provider provides functions via salt-cloud to manage your Persistent Disks. You can create and destroy disks as well as attach and detach them from running instances.

## Create

When creating a disk, you can create an empty disk and specify its size (in GB), or specify either an `image` or `snapshot`.

```
salt-cloud -f create_disk gce disk_name=pd location=us-central1-b size=200
```

## Delete

Deleting a disk only requires the name of the disk to delete

```
salt-cloud -f delete_disk gce disk_name=old-backup
```

## Attach

Attaching a disk to an existing instance is really an `action` and requires both an instance name and disk name. It's possible to use this action to create bootable persistent disks if necessary. Compute Engine also supports attaching a persistent disk in READ\_ONLY mode to multiple instances at the same time (but then cannot be attached in READ\_WRITE to any instance).

```
salt-cloud -a attach_disk myinstance disk_name=pd mode=READ_WRITE boot=yes
```

## Detach

Detaching a disk is also an action against an instance and only requires the name of the disk. Note that this does *not* safely sync and unmount the disk from the instance. To ensure no data loss, you must first make sure the disk is unmounted from the instance.

```
salt-cloud -a detach_disk myinstance disk_name=pd
```

## Show disk

It's also possible to look up the details for an existing disk with either a function or an action.

```
salt-cloud -a show_disk myinstance disk_name=pd  
salt-cloud -f show_disk gce disk_name=pd
```

## Create snapshot

You can take a snapshot of an existing disk's content. The snapshot can then in turn be used to create other persistent disks. Note that to prevent data corruption, it is strongly suggested that you unmount the disk prior to taking a snapshot. You must name the snapshot and provide the name of the disk.

```
salt-cloud -f create_snapshot gce name=backup-20140226 disk_name=pd
```

### Delete snapshot

You can delete a snapshot when it's no longer needed by specifying the name of the snapshot.

```
salt-cloud -f delete_snapshot gce name=backup-20140226
```

### Show snapshot

Use this function to look up information about the snapshot.

```
salt-cloud -f show_snapshot gce name=backup-20140226
```

## Networking

Compute Engine supports multiple private networks per project. Instances within a private network can easily communicate with each other by an internal DNS service that resolves instance names. Instances within a private network can also communicate with either directly without needing special routing or firewall rules even if they span different regions/zones.

Networks also support custom firewall rules. By default, traffic between instances on the same private network is open to all ports and protocols. Inbound SSH traffic (port 22) is also allowed but all other inbound traffic is blocked.

### Create network

New networks require a name and CIDR range. New instances can be created and added to this network by setting the network name during create. It is not possible to add/remove existing instances to a network.

```
salt-cloud -f create_network gce name=mynet cidr=10.10.10.0/24
```

### Destroy network

Destroy a network by specifying the name. Make sure that there are no instances associated with the network prior to deleting it or you'll have a bad day.

```
salt-cloud -f delete_network gce name=mynet
```

### Show network

Specify the network name to view information about the network.

```
salt-cloud -f show_network gce name=mynet
```

### Create address

Create a new named static IP address in a region.

```
salt-cloud -f create_address gce name=my-fixed-ip region=us-central1
```

### Delete address

Delete an existing named fixed IP address.

```
salt-cloud -f delete_address gce name=my-fixed-ip region=us-central1
```

### Show address

View details on a named address.

```
salt-cloud -f show_address gce name=my-fixed-ip region=us-central1
```

### Create firewall

You'll need to create custom firewall rules if you want to allow other traffic than what is described above. For instance, if you run a web service on your instances, you'll need to explicitly allow HTTP and/or SSL traffic. The firewall rule must have a name and it will use the `default` network unless otherwise specified with a `network` attribute. Firewalls also support instance tags for source/destination

```
salt-cloud -f create_fwrule gce name=web allow=tcp:80,tcp:443,icmp
```

### Delete firewall

Deleting a firewall rule will prevent any previously allowed traffic for the named firewall rule.

```
salt-cloud -f delete_fwrule gce name=web
```

### Show firewall

Use this function to review an existing firewall rule's information.

```
salt-cloud -f show_fwrule gce name=web
```

## Load Balancer

Compute Engine possess a load-balancer feature for splitting traffic across multiple instances. Please reference the [documentation](#) for a more complete discription.

The load-balancer functionality is slightly different than that described in Google's documentation. The concept of *TargetPool* and *ForwardingRule* are consolidated in salt-cloud/libcloud. HTTP Health Checks are optional.

### HTTP Health Check

HTTP Health Checks can be used as a means to toggle load-balancing across instance members, or to detect if an HTTP site is functioning. A common use-case is to set up a health check URL and if you want to toggle traffic on/off to an instance, you can temporarily have it return a non-200 response. A non-200 response to the load-balancer's health check will keep the LB from sending any new traffic to the ``down" instance. Once the instance's health check URL beings returning 200-responses, the LB will again start to send traffic to it. Review Compute Engine's

documentation for allowable parameters. You can use the following salt-cloud functions to manage your HTTP health checks.

```
salt-cloud -f create_hc gce name=myhc path=/ port=80
salt-cloud -f delete_hc gce name=myhc
salt-cloud -f show_hc gce name=myhc
```

### Load-balancer

When creating a new load-balancer, it requires a name, region, port range, and list of members. There are other optional parameters for protocol, and list of health checks. Deleting or showing details about the LB only requires the name.

```
salt-cloud -f create_lb gce name=lb region=... ports=80 members=w1,w2,w3
salt-cloud -f delete_lb gce name=lb
salt-cloud -f show_lb gce name=lb
```

You can also create a load balancer using a named fixed IP address by specifying the name of the address. If the address does not exist yet it will be created.

```
salt-cloud -f create_lb gce name=my-lb region=us-central1 ports=234 members=s1,s2,s3 address=my-lb-ip
```

### Attach and Detach LB

It is possible to attach or detach an instance from an existing load-balancer. Both the instance and load-balancer must exist before using these functions.

```
salt-cloud -f attach_lb gce name=lb member=w4
salt-cloud -f detach_lb gce name=lb member=oops
```

## 23.5.7 Getting Started With HP Cloud

HP Cloud is a major public cloud platform and uses the libcloud *openstack* driver. The current version of OpenStack that HP Cloud uses is Havana. When an instance is booted, it must have a floating IP added to it in order to connect to it and further below you will see an example that adds context to this statement.

### Set up a cloud provider configuration file

To use the *openstack* driver for HP Cloud, set up the cloud provider configuration file as in the example shown below:  
`/etc/salt/cloud.providers.d/hpcloud.conf`:

```
hpcloud-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure HP Cloud using the OpenStack plugin
  #
  identity_url: https://region-b.geo-1.identity.hpcloudsvc.com:35357/v2.0/tokens
  compute_name: Compute
  protocol: ipv4
```

```
# Set the compute region:
#
compute_region: region-b.geo-1

# Configure HP Cloud authentication credentials
#
user: myname
tenant: myname-project1
password: xxxxxxxxx

# keys to allow connection to the instance launched
#
ssh_key_name: yourkey
ssh_key_file: /path/to/key/yourkey.priv

provider: openstack
```

The subsequent example that follows is using the openstack driver.

### Compute Region

Originally, HP Cloud, in its OpenStack Essex version (1.0), had 3 availability zones in one region, US West (region-a.geo-1), which each behaved each as a region.

This has since changed, and the current OpenStack Havana version of HP Cloud (1.1) now has simplified this and now has two regions to choose from:

```
region-a.geo-1 -> US West
region-b.geo-1 -> US East
```

### Authentication

The `user` is the same user as is used to log into the HP Cloud management UI. The `tenant` can be found in the upper left under ``Project/Region/Scope``. It is often named the same as `user` albeit with a `-project1` appended. The `password` is of course what you created your account with. The management UI also has other information such as being able to select US East or US West.

### Set up a cloud profile config file

The profile shown below is a know working profile for an Ubuntu instance. The profile configuration file is stored in the following location:

```
/etc/salt/cloud.profiles.d/hp_ae1_ubuntu.conf:
```

```
hp_ae1_ubuntu:
  provider: hp_ae1
  image: 9302692b-b787-4b52-a3a6-daebb79cb498
  ignore_cidr: 10.0.0.1/24
  networks:
    - floating: Ext-Net
  size: standard.small
  ssh_key_file: /root/keys/test.key
  ssh_key_name: test
  ssh_username: ubuntu
```

Some important things about the example above:

- The `image` parameter can use either the image name or image ID which you can obtain by running in the example below (this case US East):

```
# salt-cloud --list-images hp_ae1
```

- The parameter `ignore_cidr` specifies a range of addresses to ignore when trying to connect to the instance. In this case, it's the range of IP addresses used for an private IP of the instance.
- The parameter `networks` is very important to include. In previous versions of Salt Cloud, this is what made it possible for salt-cloud to be able to attach a floating IP to the instance in order to connect to the instance and set up the minion. The current version of salt-cloud doesn't require it, though having it is of no harm either. Newer versions of salt-cloud will use this, and without it, will attempt to find a list of floating IP addresses to use regardless.
- The `ssh_key_file` and `ssh_key_name` are the keys that will make it possible to connect to the instance to set up the minion
- The `ssh_username` parameter, in this case, being that the image used will be ubuntu, will make it possible to not only log in but install the minion

### Launch an instance

To instantiate a machine based on this profile (example):

```
# salt-cloud -p hp_ae1_ubuntu ubuntu_instance_1
```

After several minutes, this will create an instance named `ubuntu_instance_1` running in HP Cloud in the US East region and will set up the minion and then return information about the instance once completed.

### Manage the instance

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt ubuntu_instance_1 ping
```

### SSH to the instance

Additionally, the instance can be accessed via SSH using the floating IP assigned to it

```
# ssh ubuntu@<floating ip>
```

### Using a private IP

Alternatively, in the cloud profile, using the private IP to log into the instance to set up the minion is another option, particularly if salt-cloud is running within the cloud on an instance that is on the same network with all the other instances (minions)

The example below is a modified version of the previous example. Note the use of `ssh_interface`:

```
hp_ae1_ubuntu:
  provider: hp_ae1
  image: 9302692b-b787-4b52-a3a6-daebb79cb498
  size: standard.small
```

```
ssh_key_file: /root/keys/test.key
ssh_key_name: test
ssh_username: ubuntu
ssh_interface: private_ips
```

With this setup, salt-cloud will use the private IP address to ssh into the instance and set up the salt-minion

### 23.5.8 Getting Started With Joyent

Joyent is a public cloud provider supporting SmartOS, Linux, FreeBSD, and Windows.

#### Dependencies

This driver requires the Python requests library to be installed.

#### Configuration

The Joyent cloud requires three configuration parameters. The user name and password that are used to log into the Joyent system, and the location of the private ssh key associated with the Joyent account. The ssh key is needed to send the provisioning commands up to the freshly created virtual machine.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-joyent-config:
  provider: joyent
  user: fred
  password: saltybacon
  private_key: /root/mykey.pem
  keyname: mykey
```

#### Profiles

##### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```
joyent_512
  provider: my-joyent-config
  size: Extra Small 512 MB
  image: Arch Linux 2013.06
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-joyent-config
my-joyent-config:
  -----
  joyent:
    -----
      Extra Small 512 MB:
        -----
          default:
```

```
        false
    disk:
        15360
    id:
        Extra Small 512 MB
    memory:
        512
    name:
        Extra Small 512 MB
    swap:
        1024
    vcpus:
        1
...SNIP...
```

Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```
# salt-cloud --list-images my-joyent-config
my-joyent-config:
-----
  joyent:
-----
    base:
-----
      description:
        A 32-bit SmartOS image with just essential packages
        installed. Ideal for users who are comfortable with setting
        up their own environment and tools.
      disabled:
        False
      files:
-----
        - compression:
            bzip2
        - sha1:
            40cdc6457c237cf6306103c74b5f45f5bf2d9bbe
        - size:
            82492182
      name:
        base
      os:
        smartos
      owner:
        352971aa-31ba-496c-9ade-a379feaecd52
      public:
        True
...SNIP...
```

## SmartDataCenter

This driver can also be used with the Joyent SmartDataCenter project. More details can be found at:

Using SDC requires that an `api_host_suffix` is set. The default value for this is `.api.joyentcloud.com`. All characters, including the leading `.`, should be included:

```
api_host_suffix: .api.myhostname.com
```

## Miscellaneous Configuration

The following configuration items can be set in either `provider` or `profile` configuration files.

### `use_ssl`

When set to `True` (the default), attach `https://` to any URL that does not already have `http://` or `https://` included at the beginning. The best practice is to leave the protocol out of the URL, and use this setting to manage it.

### `verify_ssl`

When set to `True` (the default), the underlying web library will verify the SSL certificate. This should only be set to `False` for debugging.

## 23.5.9 Getting Started With LXC

The LXC module is designed to install Salt in an LXC container on a controlled and possibly remote minion.

In other words, Salt will connect to a minion, then from that minion:

- Provision and configure a container for networking access
- Use those modules to deploy salt and re-attach to master.
  - `lxc runner`
  - `lxc module`
  - `seed`

### Limitations

- You can only act on one minion and one provider at a time.
- Listing images must be targeted to a particular LXC provider (nothing will be outputted with `all`)

**Warning:** On pre 2015.5.2, you need to specify explicitly the network bridge

### Operation

Salt's LXC support does use `lxc.init` via the `lxc.cloud_init_interface` and seeds the minion via `seed.mkconfig`.

You can provide to those lxc VMs a profile and a network profile like if you were directly using the minion module.

Order of operation:

- Create the LXC container on the desired minion (clone or template)
- Change LXC config options (if any need to be changed)
- Start container
- Change base passwords if any

- Change base DNS configuration if necessary
- Wait for LXC container to be up and ready for ssh
- Test SSH connection and bailout in error
- Upload deploy script and seeds, then re-attach the minion.

### Provider configuration

Here is a simple provider configuration:

```
# Note: This example goes in /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
devhost10-lxc:
  target: devhost10
  provider: lxc
```

### Profile configuration

Please read *LXC Management with Salt* before anything else. And specially *Profiles*.

Here are the options to configure your containers:

**target** Host minion id to install the lxc Container into

**lxc\_profile** Name of the profile or inline options for the LXC vm creation/cloning, please see *Container Profiles*.

**network\_profile** Name of the profile or inline options for the LXC vm network settings, please see *Network Profiles*.

**nic\_opts** Totally optionnal. Per interface new-style configuration options mappings which will override any profile default option:

```
eth0: {'mac': '00:16:3e:01:29:40',
       'gateway': None, (default)
       'link': 'br0', (default)
       'gateway': None, (default)
       'netmask': '', (default)
       'ip': '22.1.4.25'}}
```

**password** password for root and sysadmin users

**dnsservers** List of DNS servers to use. This is optional.

**minion** minion configuration (see *Minion Configuration in Salt Cloud*)

**bootstrap\_shell** shell for bootstrapping script (default: /bin/sh)

**script** defaults to salt-bootstrap

**script\_args** arguments which are given to the bootstrap script. the {0} placeholder will be replaced by the path which contains the minion config and key files, eg:

```
script_args="-c {0}"
```

Using profiles:

```
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  lxc_profile: foo
  network_profile: bar
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Using inline profiles (eg to override the network bridge):

```
devhost11-lxc:
  provider: devhost10-lxc
  lxc_profile:
    clone_from: foo
  network_profile:
    etho:
      link: lxcbr0
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Template instead of a clone:

```
devhost11-lxc:
  provider: devhost10-lxc
  lxc_profile:
    template: ubuntu
  network_profile:
    etho:
      link: lxcbr0
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Static ip:

```
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  nic_opts:
    eth0:
      ipv4: 10.0.3.9
  minion:
    master: 10.5.0.1
    master_port: 4506
```

DHCP:

```
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  minion:
    master: 10.5.0.1
    master_port: 4506
```

## Driver Support

- Container creation
- Image listing (LXC templates)
- Running container information (IP addresses, etc.)

### 23.5.10 Getting Started With Linode

Linode is a public cloud provider with a focus on Linux instances.

#### Dependencies

- `linode-python >= 1.1.1`

OR

- `Libcloud >= 0.13.2`

This driver supports accessing Linode via `linode-python` or Apache Libcloud. `linode-python` is recommended, it is more full-featured than Libcloud. In particular using `linode-python` enables stopping, starting, and cloning machines.

Driver selection is automatic. If `linode-python` is present it will be used. If it is absent, `salt-cloud` will fall back to Libcloud. If neither are present `salt-cloud` will abort.

NOTE: `linode-python` 1.1.1 or later is recommended. Earlier versions of `linode-python` should work but leak sensitive information into the debug logs.

`linode-python` can be downloaded from <https://github.com/tjfontaine/linode-python> or installed via `pip`.

#### Configuration

Linode requires a single API key, but the default root password for new instances also needs to be set:

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-linode-config:
  apikey: asldkgfakl;sdfjsjaslfljaklsdjf;askldjfaaklsjdfhasldsadfgdhkf
  password: F00barbaz
  ssh_pubkey: ssh-ed25519 AAAAC3NzaC1lZDI1NTE5AAAAIKHEOLLbeXgaqRQT9NBAopVz366SdYc0KKX33vAnq+2R user@
  ssh_key_file: ~/.ssh/id_ed25519
  provider: linode
```

The password needs to be 8 characters and contain lowercase, uppercase, and numbers.

## Profiles

### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```
linode_1024:
  provider: my-linode-config
  size: Linode 1024
  image: Arch Linux 2013.06
  location: london
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-linode-config
my-linode-config:
  -----
  linode:
    -----
    Linode 1024:
      -----
      bandwidth:
        2000
      disk:
        49152
      driver:
      get_uuid:
      id:
        1
      name:
        Linode 1024
      price:
        20.0
      ram:
        1024
      uuid:
        03e18728ce4629e2ac07c9cbb48afffb8cb499c4
  ...SNIP...
```

Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```
# salt-cloud --list-images my-linode-config
my-linode-config:
  -----
  linode:
    -----
    Arch Linux 2013.06:
      -----
      driver:
      extra:
        -----
        64bit:
          1
        pvops:
          1
      get_uuid:
      id:
        112
      name:
        Arch Linux 2013.06
      uuid:
        8457f92eaffc92b7666b6734a96ad7abe1a8a6dd
  ...SNIP...
```

Locations can be obtained using the `--list-locations` option for the `salt-cloud` command:

```
# salt-cloud --list-locations my-linode-config
my-linode-config:
-----
  linode:
-----
    Atlanta, GA, USA:
-----
      abbreviation:
        atlanta
      id:
        4
    Dallas, TX, USA:
-----
      abbreviation:
        dallas
      id:
        2
...SNIP...
```

## Cloning

When salt-cloud accesses Linode via linode-python it can clone machines.

It is safest to clone a stopped machine. To stop a machine run

```
salt-cloud -a stop machine_to_clone
```

To create a new machine based on another machine, add an entry to your linode cloud profile that looks like this:

```
li-clone:
  provider: linode
  clonefrom: machine_to_clone
  script_args: -C
```

Then run salt-cloud as normal, specifying `-p li-clone`. The profile name can be anything--it doesn't have to be `li-clone`.

`Clonefrom`: is the name of an existing machine in Linode from which to clone. `Script_args`: `-C` is necessary to avoid re-deploying Salt via salt-bootstrap. `-C` will just re-deploy keys so the new minion will not have a duplicate key or `minion_id` on the master.

## 23.5.11 Getting Started With OpenStack

OpenStack is one the most popular cloud projects. It's an open source project to build public and/or private clouds. You can use Salt Cloud to launch OpenStack instances.

### Dependencies

- Libcloud >= 0.13.2

### Configuration

- Using the new format, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/openstack.conf`:

```

my-openstack-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure the OpenStack driver
  #
  identity_url: http://identity.youopenstack.com/v2.0/tokens
  compute_name: nova
  protocol: ipv4

  compute_region: RegionOne

  # Configure Openstack authentication credentials
  #
  user: myname
  password: 123456
  # tenant is the project name
  tenant: myproject

  provider: openstack

  # skip SSL certificate validation (default false)
  insecure: false

```

### Using nova client to get information from OpenStack

One of the best ways to get information about OpenStack is using the novaclient python package (available in pypi as python-novaclient). The client configuration is a set of environment variables that you can get from the Dashboard. Log in and then go to Project -> Access & security -> API Access and download the ``OpenStack RC file``. Then:

```

source /path/to/your/rcfile
nova credentials
nova endpoints

```

In the nova endpoints output you can see the information about compute\_region and compute\_name.

### Compute Region

It depends on the OpenStack cluster that you are using. Please, have a look at the previous sections.

### Authentication

The user and password is the same user as is used to log into the OpenStack Dashboard.

### Profiles

Here is an example of a profile:

```

openstack_512:
  provider: my-openstack-config
  size: m1.tiny
  image: cirros-0.3.1-x86_64-uec

```

```
ssh_key_file: /tmp/test.pem
ssh_key_name: test
ssh_interface: private_ips
```

The following list explains some of the important properties.

**size** can be one of the options listed in the output of `nova flavor-list`.

**image** can be one of the options listed in the output of `nova image-list`.

**ssh\_key\_file** The SSH private key that the salt-cloud uses to SSH into the VM after its first booted in order to execute a command or script. This private key's *public key* must be the openstack public key inserted into the `authorized_key`'s file of the VM's root user account.

**ssh\_key\_name** The name of the openstack SSH public key that is inserted into the `authorized_keys` file of the VM's root user account. Prior to using this public key, you must use openstack commands or the horizon web UI to load that key into the tenant's account. Note that this openstack tenant must be the one you defined in the cloud provider.

**ssh\_interface** This option allows you to create a VM without a public IP. If this option is omitted and the VM does not have a public IP, then the salt-cloud waits for a certain period of time and then destroys the VM.

For more information concerning cloud profiles, see [here](#).

#### **change\_password**

If no `ssh_key_file` is provided, and the server already exists, `change_password` will use the api to change the root password of the server so that it can be bootstrapped.

```
change_password: True
```

#### **userdata\_file**

Use `userdata_file` to specify the userdata file to upload for use with cloud-init if available.

```
userdata_file: /etc/salt/cloud-init/packages.yml
```

### **23.5.12 Getting Started With Parallels**

Parallels Cloud Server is a product by Parallels that delivers a cloud hosting solution. The PARALLELS module for Salt Cloud enables you to manage instances hosted by a provider using PCS. Further information can be found at:

<http://www.parallels.com/products/pcs/>

- Using the old format, set up the cloud configuration at `/etc/salt/cloud`:

```
# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Set the PARALLELS access credentials (see below)
#
PARALLELS.user: myuser
PARALLELS.password: badpass
```

```
# Set the access URL for your PARALLELS provider
#
PARALLELS.url: https://api.cloud.xmission.com:4465/paci/v1.0/
```

- Using the new format, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/parallels.conf`:

```
my-parallels-config:
# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Set the PARALLELS access credentials (see below)
#
user: myuser
password: badpass

# Set the access URL for your PARALLELS provider
#
url: https://api.cloud.xmission.com:4465/paci/v1.0/
provider: parallels
```

### Access Credentials

The `user`, `password`, and `url` will be provided to you by your cloud provider. These are all required in order for the PARALLELS driver to work.

### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/parallels.conf`:

- Using the old cloud configuration format:

```
parallels-ubuntu:
  provider: parallels
  image: ubuntu-12.04-x86_64
```

- Using the new cloud configuration format and the cloud configuration example from above:

```
parallels-ubuntu:
  provider: my-parallels-config
  image: ubuntu-12.04-x86_64
```

The profile can be realized now with a salt command:

```
# salt-cloud -p parallels-ubuntu myubuntu
```

This will create an instance named `myubuntu` on the cloud provider. The minion that is installed on this instance will have an `id` of `myubuntu`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt myubuntu test.ping
```

## Required Settings

The following settings are always required for PARALLELS:

- Using the old cloud configuration format:

```
PARALLELS.user: myuser
PARALLELS.password: badpass
PARALLELS.url: https://api.cloud.xmission.com:4465/paci/v1.0/
```

- Using the new cloud configuration format:

```
my-parallels-config:
  user: myuser
  password: badpass
  url: https://api.cloud.xmission.com:4465/paci/v1.0/
  provider: parallels
```

## Optional Settings

Unlike other cloud providers in Salt Cloud, Parallels does not utilize a `size` setting. This is because Parallels allows the end-user to specify a more detailed configuration for their instances, than is allowed by many other cloud providers. The following options are available to be used in a profile, with their default settings listed.

```
# Description of the instance. Defaults to the instance name.
desc: <instance_name>

# How many CPU cores, and how fast they are (in MHz)
cpu_number: 1
cpu_power: 1000

# How many megabytes of RAM
ram: 256

# Bandwidth available, in kbps
bandwidth: 100

# How many public IPs will be assigned to this instance
ip_num: 1

# Size of the instance disk (in GiB)
disk_size: 10

# Username and password
ssh_username: root
password: <value from PARALLELS.password>

# The name of the image, from ``salt-cloud --list-images parallels``
image: ubuntu-12.04-x86_64
```

### 23.5.13 Getting Started With Proxmox

Proxmox Virtual Environment is a complete server virtualization management solution, based on LXC and full virtualization with KVM. Further information can be found at:

<http://www.proxmox.org/>

## Dependencies

- IPy >= 0.81
- requests >= 2.2.1

Please note: This module allows you to create both OpenVZ and KVM but installing Salt on it will only be done when the VM is an OpenVZ container rather than a KVM virtual machine.

- Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/proxmox.conf`:

```
my-proxmox-config:
# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Set the PROXMOX access credentials (see below)
#
user: myuser@pve
password: badpass

# Set the access URL for your PROXMOX provider
#
url: your.proxmox.host
provider: proxmox
```

## Access Credentials

The `user`, `password`, and `url` will be provided to you by your cloud provider. These are all required in order for the PROXMOX driver to work.

## Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/proxmox.conf`:

- Configure a profile to be used:

```
proxmox-ubuntu:
  provider: proxmox
  image: local:vztmpl/ubuntu-12.04-standard_12.04-1_amd64.tar.gz
  technology: openvz
  host: myvmhost
  ip_address: 192.168.100.155
  password: topsecret
```

The profile can be realized now with a salt command:

```
# salt-cloud -p proxmox-ubuntu myubuntu
```

This will create an instance named `myubuntu` on the cloud provider. The minion that is installed on this instance will have a hostname of `myubuntu`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt myubuntu test.ping
```

## Required Settings

The following settings are always required for PROXMOX:

- Using the new cloud configuration format:

```
my-proxmox-config:  
  provider: proxmox  
  user: saltcloud@pve  
  password: xyzyzy  
  url: your.proxmox.host
```

## Optional Settings

Unlike other cloud providers in Salt Cloud, Proxmox does not utilize a `size` setting. This is because Proxmox allows the end-user to specify a more detailed configuration for their instances, than is allowed by many other cloud providers. The following options are available to be used in a profile, with their default settings listed.

```
# Description of the instance.  
desc: <instance_name>  
  
# How many CPU cores, and how fast they are (in MHz)  
cpus: 1  
cpuunits: 1000  
  
# How many megabytes of RAM  
memory: 256  
  
# How much swap space in MB  
swap: 256  
  
# Whether to auto boot the vm after the host reboots  
onboot: 1  
  
# Size of the instance disk (in GiB)  
disk: 10  
  
# Host to create this vm on  
host: myvmhost  
  
# Nameservers. Defaults to host  
nameserver: 8.8.8.8 8.8.4.4  
  
# Username and password  
ssh_username: root  
password: <value from PROXMOX.password>  
  
# The name of the image, from ``salt-cloud --list-images proxmox``  
image: local:vztmpl/ubuntu-12.04-standard_12.04-1_amd64.tar.gz
```

### 23.5.14 Getting Started With Rackspace

Rackspace is a major public cloud platform which may be configured using either the *rackspace* or the *openstack* driver, depending on your needs.

Please note that the *rackspace* driver is only intended for 1st gen instances, aka, ``the old cloud" at Rackspace. It is required for 1st gen instances, but will *not* work with OpenStack-based instances. Unless you explicitly have a reason to use it, it is highly recommended that you use the *openstack* driver instead.

#### Dependencies

- Libcloud >= 0.13.2

#### Configuration

To use the *openstack* driver (recommended), set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/rackspace.conf`:

```
my-rackspace-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure Rackspace using the OpenStack plugin
  #
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/tokens'
  compute_name: cloudServersOpenStack
  protocol: ipv4

  # Set the compute region:
  #
  compute_region: DFW

  # Configure Rackspace authentication credentials
  #
  user: myname
  tenant: 123456
  apikey: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

  provider: openstack
```

To use the *rackspace* driver, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/rackspace.conf`:

```
my-rackspace-config:
  provider: rackspace
  # The Rackspace login user
  user: fred
  # The Rackspace user's apikey
  apikey: 901d3f579h23c8v73q9
```

The settings that follow are for using Rackspace with the *openstack* driver, and will not work with the *rackspace* driver.

## Compute Region

Rackspace currently has six compute regions which may be used:

```
DFW -> Dallas/Forth Worth
ORD -> Chicago
SYD -> Sydney
LON -> London
IAD -> Northern Virginia
HKG -> Hong Kong
```

Note: Currently the LON region is only available with a UK account, and UK accounts cannot access other regions

## Authentication

The `user` is the same user as is used to log into the Rackspace Control Panel. The `tenant` and `apikey` can be found in the API Keys area of the Control Panel. The `apikey` will be labeled as API Key (and may need to be generated), and `tenant` will be labeled as Cloud Account Number.

An initial profile can be configured in `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/rackspace.conf`:

```
openstack_512:
  provider: my-rackspace-config
  size: 512 MB Standard
  image: Ubuntu 12.04 LTS (Precise Pangolin)
```

To instantiate a machine based on this profile:

```
# salt-cloud -p openstack_512 myinstance
```

This will create a virtual machine at Rackspace with the name `myinstance`. This operation may take several minutes to complete, depending on the current load at the Rackspace data center.

Once the instance has been created with `salt-minion` installed, connectivity to it can be verified with Salt:

```
# salt myinstance test.ping
```

## RackConnect Environments

Rackspace offers a hybrid hosting configuration option called RackConnect that allows you to use a physical firewall appliance with your cloud servers. When this service is in use the `public_ip` assigned by nova will be replaced by a NAT ip on the firewall. For `salt-cloud` to work properly it must use the newly assigned `access ip` instead of the Nova assigned public ip. You can enable that capability by adding this to your profiles:

```
openstack_512:
  provider: my-openstack-config
  size: 512 MB Standard
  image: Ubuntu 12.04 LTS (Precise Pangolin)
  rackconnect: True
```

## Managed Cloud Environments

Rackspace offers a managed service level of hosting. As part of the managed service level you have the ability to choose from base of lamp installations on cloud server images. The post build process for both the base and the lamp

installations used Chef to install things such as the cloud monitoring agent and the cloud backup agent. It also takes care of installing the lamp stack if selected. In order to prevent the post installation process from stomping over the bootstrapping you can add the below to your profiles.

```
openstack_512:
  provider: my-rackspace-config
  size: 512 MB Standard
  image: Ubuntu 12.04 LTS (Precise Pangolin)
  managedcloud: True
```

### First and Next Generation Images

Rackspace provides two sets of virtual machine images, *first*, and *next* generation. As of 0.8.9 salt-cloud will default to using the *next* generation images. To force the use of first generation images, on the profile configuration please add:

```
FreeBSD-9.0-512:
  provider: my-rackspace-config
  size: 512 MB Standard
  image: FreeBSD 9.0
  force_first_gen: True
```

### Private Subnets

By default salt-cloud will not add Rackspace private networks to new servers. To enable a private network to a server instantiated by salt cloud, add the following section to the provider file (typically `/etc/salt/cloud.providers.d/rackspace.conf`)

```
networks:
- fixed:
  # This is the private network
  - private-network-id
  # This is Rackspace's "PublicNet"
  - 00000000-0000-0000-0000-000000000000
  # This is Rackspace's "ServiceNet"
  - 11111111-1111-1111-1111-111111111111
```

To get the Rackspace private network ID, go to Networking, Networks and hover over the private network name.

The order of the networks in the above code block does not map to the order of the ethernet devices on newly created servers. Public IP will always be first ( `eth0` ) followed by `servicenet` ( `eth1` ) and then private networks.

Enabling the private network per above gives the option of using the private subnet for all master-minion communication, including the bootstrap install of salt-minion. To enable the minion to use the private subnet, update the master: line in the minion: section of the providers file. To configure the master to only listen on the private subnet IP, update the interface: line in the `/etc/salt/master` file to be the private subnet IP of the salt master.

## 23.5.15 Getting Started With Saltify

The Saltify driver is a new, experimental driver for installing Salt on existing machines (virtual or bare metal).

### Dependencies

The Saltify driver has no external dependencies.

## Configuration

Because the Saltify driver does not use an actual cloud provider host, it has a simple provider configuration. The only thing that is required to be set is the driver name, and any other potentially useful information, like the location of the salt-master:

```
# Note: This example is for /etc/salt/cloud.providers file or any file in
# the /etc/salt/cloud.providers.d/ directory.

my-saltify-config:
  minion:
    master: 111.222.333.444
    provider: saltify
```

## Profiles

Saltify requires a profile to be configured for each machine that needs Salt installed. The initial profile can be set up at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory. Each profile requires both an `ssh_host` and an `ssh_username` key parameter as well as either a `key_filename` or a password.

Profile configuration example:

```
# /etc/salt/cloud.profiles.d/saltify.conf

salt-this-machine:
  ssh_host: 12.34.56.78
  ssh_username: root
  key_filename: '/etc/salt/mysshkey.pem'
  provider: my-saltify-config
```

The machine can now be "Salted" with the following command:

```
salt-cloud -p salt-this-machine my-machine
```

This will install salt on the machine specified by the cloud profile, `salt-this-machine`, and will give the machine the minion id of `my-machine`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once a salt-minion has been successfully installed on the instance, connectivity to it can be verified with Salt:

```
salt my-machine test.ping
```

## Using Map Files

The settings explained in the section above may also be set in a map file. An example of how to use the Saltify driver with a map file follows:

```
# /etc/salt/saltify-map

make_salty:
  - my-instance-0:
    ssh_host: 12.34.56.78
    ssh_username: root
    password: very-bad-password
  - my-instance-1:
```

```
ssh_host: 44.33.22.11
ssh_username: root
password: another-bad-pass
```

Note: When using a cloud map with the Saltify driver, the name of the profile to use, in this case `make_salty`, must be defined in a profile config. For example:

```
# /etc/salt/cloud.profiles.d/saltify.conf

make_salty:
  provider: my-saltify-config
```

The machines listed in the map file can now be "Salted" by applying the following salt map command:

```
salt-cloud -m /etc/salt/saltify-map
```

This command will install salt on the machines specified in the map and will give each machine their minion id of `my-instance-0` and `my-instance-1`, respectively. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Connectivity to the new "Salted" instances can now be verified with Salt:

```
salt 'my-instance-*' test.ping
```

### 23.5.16 Getting Started With SoftLayer

SoftLayer is a public cloud provider, and baremetal hardware hosting provider.

#### Dependencies

The SoftLayer driver for Salt Cloud requires the `softlayer` package, which is available at PyPI:

<https://pypi.python.org/pypi/SoftLayer>

This package can be installed using `pip` or `easy_install`:

```
# pip install softlayer
# easy_install softlayer
```

#### Configuration

Set up the cloud config at `/etc/salt/cloud.providers`:

```
# Note: These examples are for /etc/salt/cloud.providers

my-softlayer:
  # Set up the location of the salt master
  minion:
    master: saltmaster.example.com

  # Set the SoftLayer access credentials (see below)
  user: MYUSER1138
  apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062ddbaca5f7e465bfdc9'

  provider: softlayer
```

```
my-softlayer-hw:
  # Set up the location of the salt master
  minion:
    master: saltmaster.example.com

  # Set the SoftLayer access credentials (see below)
  user: MYUSER1138
  apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062ddbaca5f7e465bfdc9'

  provider: softlayer_hw
```

## Access Credentials

The `user` setting is the same user as is used to log into the SoftLayer Administration area. The `apikey` setting is found inside the Admin area after logging in:

- Hover over the Account menu item.
- Click the Users link.
- Find the API Key column and click View.

## Profiles

### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles`:

```
base_softlayer_ubuntu:
  provider: my-softlayer
  image: UBUNTU_LATEST
  cpu_number: 1
  ram: 1024
  disk_size: 100
  local_disk: True
  hourly_billing: True
  domain: example.com
  location: sjc01
  # Optional
  max_net_speed: 1000
  private_vlan: 396
  private_network: True
  private_ssh: True
  # May be used instead of image
  global_identifier: 320d8be5-46c0-dead-cafe-13e3c51
```

Most of the above items are required; optional items are specified below.

**image** Images to build an instance can be found using the `--list-images` option:

```
# salt-cloud --list-images my-softlayer
```

The setting used will be labeled as `template`.

**cpu\_number** This is the number of CPU cores that will be used for this instance. This number may be dependent upon the image that is used. For instance:

```
Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (1 - 4 Core):
-----
name:
  Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (1 - 4 Core)
template:
  REDHAT_6_64
Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (5 - 100 Core):
-----
name:
  Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (5 - 100 Core)
template:
  REDHAT_6_64
```

Note that the template (meaning, the *image* option) for both of these is the same, but the names suggests how many CPU cores are supported.

**ram** This is the amount of memory, in megabytes, that will be allocated to this instance.

**disk\_size** The amount of disk space that will be allocated to this image, in megabytes.

**local\_disk** When true the disks for the computing instance will be provisioned on the host which it runs, otherwise SAN disks will be provisioned.

**hourly\_billing** When true the computing instance will be billed on hourly usage, otherwise it will be billed on a monthly basis.

**domain** The domain name that will be used in the FQDN (Fully Qualified Domain Name) for this instance. The *domain* setting will be used in conjunction with the instance name to form the FQDN.

**location** Images to build an instance can be found using the *--list-locations* option:

```
# salt-cloud --list-location my-softlayer
```

**max\_net\_speed** Specifies the connection speed for the instance's network components. This setting is optional. By default, this is set to 10.

**public\_vlan** If it is necessary for an instance to be created within a specific frontend VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the *list\_vlans* function, as described below. This setting is optional.

**private\_vlan** If it is necessary for an instance to be created within a specific backend VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the *list\_vlans* function, as described below. This setting is optional.

**private\_network** If a server is to only be used internally, meaning it does not have a public VLAN associated with it, this value would be set to True. This setting is optional. The default is False.

**private\_ssh** Whether to run the deploy script on the server using the public IP address or the private IP address. If set to True, Salt Cloud will attempt to SSH into the new server using the private IP address. The default is False. This setting is optional.

**global\_identifier** When creating an instance using a custom template, this option is set to the corresponding value obtained using the `list_custom_images` function. This option will not be used if an `image` is set, and if an `image` is not set, it is required.

The profile can be realized now with a salt command:

```
# salt-cloud -p base_softlayer_ubuntu myserver
```

Using the above configuration, this will create `myserver.example.com`.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt 'myserver.example.com' test.ping
```

## Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles`:

```
base_softlayer_hw_centos:
  provider: my-softlayer-hw
  # CentOS 6.0 - Minimal Install (64 bit)
  image: 13963
  # 2 x 2.0 GHz Core Bare Metal Instance - 2 GB Ram
  size: 1921
  # 500GB SATA II
  hdd: 1267
  # San Jose 01
  location: 168642
  domain: example.com
  # Optional
  vlan: 396
  port_speed: 273
  bandwidth: 248
```

Most of the above items are required; optional items are specified below.

**image** Images to build an instance can be found using the `--list-images` option:

```
# salt-cloud --list-images my-softlayer-hw
```

A list of `id`'s and `names` will be provided. The `name` will describe the operating system and architecture. The `id` will be the setting to be used in the profile.

**size** Sizes to build an instance can be found using the `--list-sizes` option:

```
# salt-cloud --list-sizes my-softlayer-hw
```

A list of *id*'s and names will be provided. The *name* will describe the speed and quantity of CPU cores, and the amount of memory that the hardware will contain. The *id* will be the setting to be used in the profile.

**hdd** There is currently only one size of hard disk drive (HDD) that is available for hardware instances on SoftLayer:

```
1267: 500GB SATA II
```

The *hdd* setting in the profile should be 1267. Other sizes may be added in the future.

**location** Locations to build an instance can be found using the `--list-images` option:

```
# salt-cloud --list-locations my-softlayer-hw
```

A list of IDs and names will be provided. The *location* will describe the location in human terms. The *id* will be the setting to be used in the profile.

**domain** The domain name that will be used in the FQDN (Fully Qualified Domain Name) for this instance. The *domain* setting will be used in conjunction with the instance name to form the FQDN.

**vlan** If it is necessary for an instance to be created within a specific VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the `list_vlans` function, as described below.

**port\_speed** Specifies the speed for the instance's network port. This setting refers to an ID within the SoftLayer API, which sets the port speed. This setting is optional. The default is 273, or, 100 Mbps Public & Private Networks. The following settings are available:

- 273: 100 Mbps Public & Private Networks
- 274: 1 Gbps Public & Private Networks
- 21509: 10 Mbps Dual Public & Private Networks (up to 20 Mbps)
- 21513: 100 Mbps Dual Public & Private Networks (up to 200 Mbps)
- 2314: 1 Gbps Dual Public & Private Networks (up to 2 Gbps)
- 272: 10 Mbps Public & Private Networks

**bandwidth** Specifies the network bandwidth available for the instance. This setting refers to an ID within the SoftLayer API, which sets the bandwidth. This setting is optional. The default is 248, or, 5000 GB Bandwidth. The following settings are available:

- 248: 5000 GB Bandwidth
- 129: 6000 GB Bandwidth
- 130: 8000 GB Bandwidth
- 131: 10000 GB Bandwidth
- 36: Unlimited Bandwidth (10 Mbps Uplink)
- 125: Unlimited Bandwidth (100 Mbps Uplink)

## Actions

The following actions are currently supported by the SoftLayer Salt Cloud driver.

### show\_instance

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
$ salt-cloud -a show_instance myinstance
```

## Functions

The following functions are currently supported by the SoftLayer Salt Cloud driver.

### list\_vlans

This function lists all VLANs associated with the account, and all known data from the SoftLayer API concerning those VLANs.

```
$ salt-cloud -f list_vlans my-softlayer
$ salt-cloud -f list_vlans my-softlayer-hw
```

The *id* returned in this list is necessary for the *vlan* option when creating an instance.

### list\_custom\_images

This function lists any custom templates associated with the account, that can be used to create a new instance.

```
$ salt-cloud -f list_custom_images my-softlayer
```

The *globalIdentifier* returned in this list is necessary for the *global\_identifier* option when creating an image using a custom template.

## Optional Products for SoftLayer HW

The `softlayer_hw` provider supports the ability to add optional products, which are supported by SoftLayer's API. These products each have an ID associated with them, that can be passed into Salt Cloud with the *optional\_products* option:

```
softlayer_hw_test:
  provider: my-softlayer-hw
  # CentOS 6.0 - Minimal Install (64 bit)
  image: 13963
  # 2 x 2.0 GHz Core Bare Metal Instance - 2 GB Ram
  size: 1921
  # 500GB SATA II
  hdd: 1267
  # San Jose 01
  location: 168642
  domain: example.com
```

```
optional_products:  
  # MySQL for Linux  
  - id: 28  
  # Business Continuation Insurance  
  - id: 104
```

These values can be manually obtained by looking at the source of an order page on the SoftLayer web interface. For convenience, many of these values are listed here:

#### Public Secondary IP Addresses

- 22: 4 Public IP Addresses
- 23: 8 Public IP Addresses

#### Primary IPv6 Addresses

- 17129: 1 IPv6 Address

#### Public Static IPv6 Addresses

- 1481: /64 Block Static Public IPv6 Addresses

#### OS-Specific Addon

- 17139: XenServer Advanced for XenServer 6.x
- 17141: XenServer Enterprise for XenServer 6.x
- 2334: XenServer Advanced for XenServer 5.6
- 2335: XenServer Enterprise for XenServer 5.6
- 13915: Microsoft WebMatrix
- 21276: VMware vCenter 5.1 Standard

#### Control Panel Software

- 121: cPanel/WHM with Fantastico and RVskin
- 20778: Parallels Plesk Panel 11 (Linux) 100 Domain w/ Power Pack
- 20786: Parallels Plesk Panel 11 (Windows) 100 Domain w/ Power Pack
- 20787: Parallels Plesk Panel 11 (Linux) Unlimited Domain w/ Power Pack
- 20792: Parallels Plesk Panel 11 (Windows) Unlimited Domain w/ Power Pack
- 2340: Parallels Plesk Panel 10 (Linux) 100 Domain w/ Power Pack
- 2339: Parallels Plesk Panel 10 (Linux) Unlimited Domain w/ Power Pack
- 13704: Parallels Plesk Panel 10 (Windows) Unlimited Domain w/ Power Pack

### **Database Software**

- 29: MySQL 5.0 for Windows
- 28: MySQL for Linux
- 21501: Riak 1.x
- 20893: MongoDB
- 30: Microsoft SQL Server 2005 Express
- 92: Microsoft SQL Server 2005 Workgroup
- 90: Microsoft SQL Server 2005 Standard
- 94: Microsoft SQL Server 2005 Enterprise
- 1330: Microsoft SQL Server 2008 Express
- 1340: Microsoft SQL Server 2008 Web
- 1337: Microsoft SQL Server 2008 Workgroup
- 1334: Microsoft SQL Server 2008 Standard
- 1331: Microsoft SQL Server 2008 Enterprise
- 2179: Microsoft SQL Server 2008 Express R2
- 2173: Microsoft SQL Server 2008 Web R2
- 2183: Microsoft SQL Server 2008 Workgroup R2
- 2180: Microsoft SQL Server 2008 Standard R2
- 2176: Microsoft SQL Server 2008 Enterprise R2

### **Anti-Virus & Spyware Protection**

- 594: McAfee VirusScan Anti-Virus - Windows
- 414: McAfee Total Protection - Windows

### **Insurance**

- 104: Business Continuance Insurance

### **Monitoring**

- 55: Host Ping
- 56: Host Ping and TCP Service Monitoring

### **Notification**

- 57: Email and Ticket

### Advanced Monitoring

- 2302: Monitoring Package - Basic
- 2303: Monitoring Package - Advanced
- 2304: Monitoring Package - Premium Application

### Response

- 58: Automated Notification
- 59: Automated Reboot from Monitoring
- 60: 24x7x365 NOC Monitoring, Notification, and Response

### Intrusion Detection & Protection

- 413: McAfee Host Intrusion Protection w/Reporting

### Hardware & Software Firewalls

- 411: APF Software Firewall for Linux
- 894: Microsoft Windows Firewall
- 410: 10Mbps Hardware Firewall
- 409: 100Mbps Hardware Firewall
- 408: 1000Mbps Hardware Firewall

## 23.5.17 Getting Started with VEXXHOST

VEXXHOST is an cloud computing provider which provides [Canadian cloud computing](#) services which are based in Montral and uses the libcloud OpenStack driver. VEXXHOST currently runs the Havana release of OpenStack. When provisioning new instances, they automatically get a public IP and private IP address. Therefore, you do not need to assign a floating IP to access your instance once it's booted.

### Cloud Provider Configuration

To use the *openstack* driver for the VEXXHOST public cloud, you will need to set up the cloud provider configuration file as in the example below:

`/etc/salt/cloud.providers.d/vexxhost.conf`: In order to use the VEXXHOST public cloud, you will need to setup a cloud provider configuration file as in the example below which uses the OpenStack driver.

```
vexxhost:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure VEXXHOST using the OpenStack plugin
  #
```

```
identity_url: http://auth.api.thenebulacloud.com:5000/v2.0/tokens
compute_name: nova

# Set the compute region:
#
compute_region: na-yul-nhs1

# Configure VEXXHOST authentication credentials
#
user: your-tenant-id
password: your-api-key
tenant: your-tenant-name

# keys to allow connection to the instance launched
#
ssh_key_name: yourkey
ssh_key_file: /path/to/key/yourkey.priv

provider: openstack
```

## Authentication

All of the authentication fields that you need can be found by logging into your VEXXHOST customer center. Once you've logged in, you will need to click on "CloudConsole" and then click on "API Credentials".

## Cloud Profile Configuration

In order to get the correct image UUID and the instance type to use in the cloud profile, you can run the following command respectively:

```
# salt-cloud --list-images=vexxhost-config
# salt-cloud --list-sizes=vexxhost-config
```

Once you have that, you can go ahead and create a new cloud profile. This profile will build an Ubuntu 12.04 LTS *nb.2G* instance.

`/etc/salt/cloud.profiles.d/vh_ubuntu1204_2G.conf:`

```
vh_ubuntu1204_2G:
  provider: vexxhost
  image: 4051139f-750d-4d72-8ef0-074f2ccc7e5a
  size: nb.2G
```

## Provision an instance

To create an instance based on the sample profile that we created above, you can run the following `salt-cloud` command.

```
# salt-cloud -p vh_ubuntu1204_2G vh_instance1
```

Typically, instances are provisioned in under 30 seconds on the VEXXHOST public cloud. After the instance provisions, it will be set up a minion and then return all the instance information once it's complete.

Once the instance has been setup, you can test connectivity to it by running the following command:

```
# salt vh_instance1 test.ping
```

You can now continue to provision new instances and they will all automatically be set up as minions of the master you've defined in the configuration file.

### 23.5.18 Getting Started With vSphere

**Note:** Deprecated since version Carbon: The *vsphere* cloud driver has been deprecated in favor of the *vmware* cloud driver and will be removed in Salt Carbon. Please refer to [Getting started with VMware](#) instead to get started with the configuration.

VMware vSphere is a management platform for virtual infrastructure and cloud computing.

#### Dependencies

The vSphere module for Salt Cloud requires the PySphere package, which is available at PyPI:

<https://pypi.python.org/pypi/pysphere>

This package can be installed using *pip* or *easy\_install*:

```
# pip install pysphere
# easy_install pysphere
```

#### Configuration

Set up the cloud config at `/etc/salt/cloud.providers` or in the `/etc/salt/cloud.providers.d/` directory:

```
my-vsphere-config:
  provider: vsphere
  # Set the vSphere access credentials
  user: marco
  password: polo
  # Set the URL of your vSphere server
  url: 'vsphere.example.com'
```

#### Profiles

##### Cloud Profiles

vSphere uses a Managed Object Reference to identify objects located in vCenter. The MOR ID's are used when configuring a vSphere cloud profile. Use the following reference when locating the MOR's for the cloud profile.

<http://kb.vmware.com/selfservice/microsites/search.do?cmd=displayKC&docType=kc&externalId=1017126&sliceId=1&docTypeID=D>

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d` directory:

```
vsphere-centos:
  provider: my-vsphere-config
  image: centos
  # Optional
```

```
datastore: datastore-15
resourcepool: resgroup-8
folder: salt-cloud
host: host-9
template: False
```

**provider** Enter the name that was specified when the cloud provider profile was created.

**image** Images available to build an instance can be found using the `--list-images` option:

```
# salt-cloud --list-images my-vsphere-config
```

**datastore** The MOR of the datastore where the virtual machine should be located. If not specified, the current datastore is used.

**resourcepool** The MOR of the resourcepool to be used for the new vm. If not set, it will use the same resourcepool as the original vm.

**folder** Name of the folder that will contain the new VM. If not set, the VM will be added to the folder the original VM belongs to.

**host** The MOR of the host where the vm should be registered.

**If not specified:**

- if resourcepool is not specified, the current host is used.
- if resourcepool is specified, and the target pool represents a stand-alone host, the host is used.
- if resourcepool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
- if resourcepool is specified, and the target pool represents a cluster without DRS enabled, an `InvalidArgument` exception will be thrown.

**template** Specifies whether or not the new virtual machine should be marked as a template. Default is `False`.

## 23.6 Miscellaneous Options

### 23.6.1 Miscellaneous Salt Cloud Options

This page describes various miscellaneous options available in Salt Cloud

#### Deploy Script Arguments

Custom deploy scripts are unlikely to need custom arguments to be passed to them, but `salt-bootstrap` has been extended quite a bit, and this may be necessary. `script_args` can be specified in either the profile or the map file, to pass arguments to the deploy script:

```
ec2-amazon:
  provider: ec2
  image: ami-1624987f
  size: t1.micro
  ssh_username: ec2-user
  script: bootstrap-salt
  script_args: -c /tmp/
```

This has also been tested to work with pipes, if needed:

```
script_args: | head
```

### Selecting the File Transport

By default, Salt Cloud uses SFTP to transfer files to Linux hosts. However, if SFTP is not available, or specific SCP functionality is needed, Salt Cloud can be configured to use SCP instead.

```
file_transport: sftp
file_transport: scp
```

### Sync After Install

Salt allows users to create custom modules, grains, and states which can be synchronised to minions to extend Salt with further functionality.

This option will inform Salt Cloud to synchronise your custom modules, grains, states or all these to the minion just after it has been created. For this to happen, the following line needs to be added to the main cloud configuration file:

```
sync_after_install: all
```

The available options for this setting are:

```
modules
grains
states
all
```

### Setting up New Salt Masters

It has become increasingly common for users to set up multi-hierarchical infrastructures using Salt Cloud. This sometimes involves setting up an instance to be a master in addition to a minion. With that in mind, you can now lay down master configuration on a machine by specifying master options in the profile or map file.

```
make_master: True
```

This will cause Salt Cloud to generate master keys for the instance, and tell salt-bootstrap to install the salt-master package, in addition to the salt-minion package.

The default master configuration is usually appropriate for most users, and will not be changed unless specific master configuration has been added to the profile or map:

```
master:
  user: root
  interface: 0.0.0.0
```

## Delete SSH Keys

When Salt Cloud deploys an instance, the SSH pub key for the instance is added to the `known_hosts` file for the user that ran the `salt-cloud` command. When an instance is deployed, a cloud provider generally recycles the IP address for the instance. When Salt Cloud attempts to deploy an instance using a recycled IP address that has previously been accessed from the same machine, the old key in the `known_hosts` file will cause a conflict.

In order to mitigate this issue, Salt Cloud can be configured to remove old keys from the `known_hosts` file when destroying the node. In order to do this, the following line needs to be added to the main cloud configuration file:

```
delete_sshkeys: True
```

## Keeping /tmp/ Files

When Salt Cloud deploys an instance, it uploads temporary files to `/tmp/` for `salt-bootstrap` to put in place. After the script has run, they are deleted. To keep these files around (mostly for debugging purposes), the `--keep-tmp` option can be added:

```
salt-cloud -p myprofile mymachine --keep-tmp
```

For those wondering why `/tmp/` was used instead of `/root/`, this had to be done for images which require the use of `sudo`, and therefore do not allow remote root logins, even for file transfers (which makes `/root/` unavailable).

## Hide Output From Minion Install

By default Salt Cloud will stream the output from the minion deploy script directly to `STDOUT`. Although this can be very useful, in certain cases you may wish to switch this off. The following config option is there to enable or disable this output:

```
display_ssh_output: False
```

## Connection Timeout

There are several stages when deploying Salt where Salt Cloud needs to wait for something to happen. The VM getting its IP address, the VM's SSH port is available, etc.

If you find that the Salt Cloud defaults are not enough and your deployment fails because Salt Cloud did not wait long enough, there are some settings you can tweak.

---

### Note

All settings should be provided in lowercase All values should be provided in seconds

---

You can tweak these settings globally, per cloud provider, or event per profile definition.

### `wait_for_ip_timeout`

The amount of time Salt Cloud should wait for a VM to start and get an IP back from the cloud provider. Default: 5 minutes.

**wait\_for\_ip\_interval**

The amount of time Salt Cloud should sleep while querying for the VM's IP. Default: 5 seconds.

**ssh\_connect\_timeout**

The amount of time Salt Cloud should wait for a successful SSH connection to the VM. Default: 5 minutes.

**wait\_for\_passwd\_timeout**

The amount of time until an ssh connection can be established via password or ssh key. Default 15 seconds.

**wait\_for\_passwd\_maxtries**

The number of attempts to connect to the VM until we abandon. Default 15 attempts

**wait\_for\_fun\_timeout**

Some cloud drivers check for an available IP or a successful SSH connection using a function, namely, SoftLayer, and SoftLayer-HW. So, the amount of time Salt Cloud should retry such functions before failing. Default: 5 minutes.

**wait\_for\_spot\_timeout**

The amount of time Salt Cloud should wait before an EC2 Spot instance is available. This setting is only available for the EC2 cloud driver.

**Salt Cloud Cache**

Salt Cloud can maintain a cache of node data, for supported providers. The following options manage this functionality.

**update\_cachedir**

On supported cloud providers, whether or not to maintain a cache of nodes returned from a `--full-query`. The data will be stored in `msgpack` format under `<SALT_CACHEDIR>/cloud/active/<DRIVER>/<PROVIDER>/<NODE_NAME>.p`. This setting can be True or False.

**diff\_cache\_events**

When the cloud cachedir is being managed, if differences are encountered between the data that is returned live from the cloud provider and the data in the cache, fire events which describe the changes. This setting can be True or False.

Some of these events will contain data which describe a node. Because some of the fields returned may contain sensitive data, the `cache_event_strip_fields` configuration option exists to strip those fields from the event return.

```
cache_event_strip_fields:  
- password  
- priv_key
```

The following are events that can be fired based on this data.

**salt/cloud/minionid/cache\_node\_new** A new node was found on the cloud provider which was not listed in the cloud cachedir. A dict describing the new node will be contained in the event.

**salt/cloud/minionid/cache\_node\_missing** A node that was previously listed in the cloud cachedir is no longer available on the cloud provider.

**salt/cloud/minionid/cache\_node\_diff** One or more pieces of data in the cloud cachedir has changed on the cloud provider. A dict containing both the old and the new data will be contained in the event.

### SSH Known Hosts

Normally when bootstrapping a VM, salt-cloud will ignore the SSH host key. This is because it does not know what the host key is before starting (because it doesn't exist yet). If strict host key checking is turned on without the key in the `known_hosts` file, then the host will never be available, and cannot be bootstrapped.

If a provider is able to determine the host key before trying to bootstrap it, that provider's driver can add it to the `known_hosts` file, and then turn on strict host key checking. This can be set up in the main cloud configuration file (normally `/etc/salt/cloud`) or in the provider-specific configuration file:

```
known_hosts_file: /path/to/.ssh/known_hosts
```

If this is not set, it will default to `/dev/null`, and strict host key checking will be turned off.

It is highly recommended that this option is *not* set, unless the user has verified that the provider supports this functionality, and that the image being used is capable of providing the necessary information. At this time, only the EC2 driver supports this functionality.

### SSH Agent

New in version 2015.5.0.

If the ssh key is not stored on the server salt-cloud is being run on, set `ssh_agent`, and salt-cloud will use the forwarded ssh-agent to authenticate.

```
ssh_agent: True
```

### File Map Upload

New in version 2014.7.0.

The `file_map` option allows an arbitrary group of files to be uploaded to the target system before running the deploy script. This functionality requires a provider uses `salt.utils.cloud.bootstrap()`, which is currently limited to the `ec2`, `gce`, `openstack` and `nova` drivers.

The `file_map` can be configured globally in `/etc/salt/cloud`, or in any cloud provider or profile file. For example, to upload an extra package or a custom deploy script, a cloud profile using `file_map` might look like:

```
ubuntu14:
  provider: ec2-config
  image: ami-98aa1cf0
  size: t1.micro
  ssh_username: root
  securitygroup: default
  file_map:
    /local/path/to/custom/script: /remote/path/to/use/custom/script
    /local/path/to/package: /remote/path/to/store/package
```

## 23.7 Troubleshooting Steps

### 23.7.1 Troubleshooting Salt Cloud

This page describes various steps for troubleshooting problems that may arise while using Salt Cloud.

#### Virtual Machines Are Created, But Do Not Respond

Are TCP ports 4505 and 4506 open on the master? This is easy to overlook on new masters. Information on how to open firewall ports on various platforms can be found [here](#).

#### Generic Troubleshooting Steps

This section describes a set of instructions that are useful to a large number of situations, and are likely to solve most issues that arise.

---

#### Version Compatibility

One of the most common issues that Salt Cloud users run into is import errors. These are often caused by version compatibility issues with Salt.

Salt 0.16.x works with Salt Cloud 0.8.9 or greater.

Salt 0.17.x requires Salt Cloud 0.8.11.

Releases after 0.17.x (0.18 or greater) should not encounter issues as Salt Cloud has been merged into Salt itself.

---

#### Debug Mode

Frequently, running Salt Cloud in debug mode will reveal information about a deployment which would otherwise not be obvious:

```
salt-cloud -p myprofile myinstance -l debug
```

Keep in mind that a number of messages will appear that look at first like errors, but are in fact intended to give developers factual information to assist in debugging. A number of messages that appear will be for cloud providers that you do not have configured; in these cases, the message usually is intended to confirm that they are not configured.

## Salt Bootstrap

By default, Salt Cloud uses the Salt Bootstrap script to provision instances:

This script is packaged with Salt Cloud, but may be updated without updating the Salt package:

```
salt-cloud -u
```

## The Bootstrap Log

If the default deploy script was used, there should be a file in the `/tmp/` directory called `bootstrap-salt.log`. This file contains the full output from the deployment, including any errors that may have occurred.

## Keeping Temp Files

Salt Cloud uploads minion-specific files to instances once they are available via SSH, and then executes a deploy script to put them into the correct place and install Salt. The `--keep-tmp` option will instruct Salt Cloud not to remove those files when finished with them, so that the user may inspect them for problems:

```
salt-cloud -p myprofile myinstance --keep-tmp
```

By default, Salt Cloud will create a directory on the target instance called `/tmp/.saltcloud/`. This directory should be owned by the user that is to execute the deploy script, and should have permissions of `0700`.

Most cloud providers are configured to use `root` as the default initial user for deployment, and as such, this directory and all files in it should be owned by the `root` user.

The `/tmp/.saltcloud/` directory should the following files:

- A `deploy.sh` script. This script should have permissions of `0755`.
- A `.pem` and `.pub` key named after the minion. The `.pem` file should have permissions of `0600`. Ensure that the `.pem` and `.pub` files have been properly copied to the `/etc/salt/pki/minion/` directory.
- A file called `minion`. This file should have been copied to the `/etc/salt/` directory.
- Optionally, a file called `grains`. This file, if present, should have been copied to the `/etc/salt/` directory.

## Unprivileged Primary Users

Some providers, most notably EC2, are configured with a different primary user. Some common examples are `ec2-user`, `ubuntu`, `fedora`, and `bitnami`. In these cases, the `/tmp/.saltcloud/` directory and all files in it should be owned by this user.

Some providers, such as EC2, are configured to not require these users to provide a password when using the `sudo` command. Because it is more secure to require `sudo` users to provide a password, other providers are configured that way.

If this instance is required to provide a password, it needs to be configured in Salt Cloud. A password for `sudo` use may be added to either the provider configuration or the profile configuration:

```
sudo_password: mypassword
```

### **/tmp/ is Mounted as noexec**

It is more secure to mount the `/tmp/` directory with a `noexec` option. This is uncommon on most cloud providers, but very common in private environments. To see if the `/tmp/` directory is mounted this way, run the following command:

```
mount | grep tmp
```

The if the output of this command includes a line that looks like this, then the `/tmp/` directory is mounted as `noexec`:

```
tmpfs on /tmp type tmpfs (rw,noexec)
```

If this is the case, then the `deploy_command` will need to be changed in order to run the deploy script through the `sh` command, rather than trying to execute it directly. This may be specified in either the provider or the profile config:

```
deploy_command: sh /tmp/.saltcloud/deploy.sh
```

Please note that by default, Salt Cloud will place its files in a directory called `/tmp/.saltcloud/`. This may be also be changed in the provider or profile configuration:

```
tmp_dir: /tmp/.saltcloud/
```

If this directory is changed, then the `deploy_command` need to be changed in order to reflect the `tmp_dir` configuration.

### **Executing the Deploy Script Manually**

If all of the files needed for deployment were successfully uploaded to the correct locations, and contain the correct permissions and ownerships, the deploy script may be executed manually in order to check for other issues:

```
cd /tmp/.saltcloud/
./deploy.sh
```

## **23.8 Extending Salt Cloud**

### **23.8.1 Writing Cloud Provider Modules**

Salt Cloud runs on a module system similar to the main Salt project. The modules inside `saltcloud` exist in the `salt/cloud/clouds` directory of the salt source.

There are two basic types of cloud modules. If a cloud provider is supported by `libcloud`, then using it is the fastest route to getting a module written. The Apache Libcloud project is located at:

<http://libcloud.apache.org/>

Not every cloud provider is supported by `libcloud`. Additionally, not every feature in a supported cloud provider is necessary supported by `libcloud`. In either of these cases, a module can be created which does not rely on `libcloud`.

#### **All Modules**

The following functions are required by all modules, whether or not they are based on `libcloud`.

### The `__virtual__()` Function

This function determines whether or not to make this cloud module available upon execution. Most often, it uses `get_configured_provider()` to determine if the necessary configuration has been set up. It may also check for necessary imports, to decide whether to load the module. In most cases, it will return a `True` or `False` value. If the name of the driver used does not match the filename, then that name should be returned instead of `True`. An example of this may be seen in the Azure module:

<https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/msazure.py>

### The `get_configured_provider()` Function

This function uses `config.is_provider_configured()` to determine whether all required information for this driver has been configured. The last value in the list of required settings should be followed by a comma.

## Libcloud Based Modules

Writing a cloud module based on libcloud has two major advantages. First of all, much of the work has already been done by the libcloud project. Second, most of the functions necessary to Salt have already been added to the Salt Cloud project.

### The `create()` Function

The most important function that does need to be manually written is the `create()` function. This is what is used to request a virtual machine to be created by the cloud provider, wait for it to become available, and then (optionally) log in and install Salt on it.

A good example to follow for writing a cloud provider module based on libcloud is the module provided for Linode:

<https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/linode.py>

The basic flow of a `create()` function is as follows:

- Send a request to the cloud provider to create a virtual machine.
- Wait for the virtual machine to become available.
- Generate kwargs to be used to deploy Salt.
- Log into the virtual machine and deploy Salt.
- Return a data structure that describes the newly-created virtual machine.

At various points throughout this function, events may be fired on the Salt event bus. Four of these events, which are described below, are required. Other events may be added by the user, where appropriate.

When the `create()` function is called, it is passed a data structure called `vm_`. This dict contains a composite of information describing the virtual machine to be created. A dict called `__opts__` is also provided by Salt, which contains the options used to run Salt Cloud, as well as a set of configuration and environment variables.

The first thing the `create()` function must do is fire an event stating that it has started the create process. This event is tagged `salt/cloud/<vm name>/creating`. The payload contains the names of the VM, profile and provider.

A set of kwargs is then usually created, to describe the parameters required by the cloud provider to request the virtual machine.

An event is then fired to state that a virtual machine is about to be requested. It is tagged as `salt/cloud/<vm name>/requesting`. The payload contains most or all of the parameters that will be sent to the cloud provider. Any private information (such as passwords) should not be sent in the event.

After a request is made, a set of deploy kwargs will be generated. These will be used to install Salt on the target machine. Windows options are supported at this point, and should be generated, even if the cloud provider does not currently support Windows. This will save time in the future if the provider does eventually decide to support Windows.

An event is then fired to state that the deploy process is about to begin. This event is tagged `salt/cloud/<vm name>/deploying`. The payload for the event will contain a set of deploy kwargs, useful for debugging purposes. Any private data, including passwords and keys (including public keys) should be stripped from the deploy kwargs before the event is fired.

If any Windows options have been passed in, the `salt.utils.cloud.deploy_windows()` function will be called. Otherwise, it will be assumed that the target is a Linux or Unix machine, and the `salt.utils.cloud.deploy_script()` will be called.

Both of these functions will wait for the target machine to become available, then the necessary port to log in, then a successful login that can be used to install Salt. Minion configuration and keys will then be uploaded to a temporary directory on the target by the appropriate function. On a Windows target, the Windows Minion Installer will be run in silent mode. On a Linux/Unix target, a deploy script (`bootstrap-salt.sh`, by default) will be run, which will auto-detect the operating system, and install Salt using its native package manager. These do not need to be handled by the developer in the cloud module.

The `salt.utils.cloud.validate_windows_cred()` function has been extended to take the number of retries and `retry_delay` parameters in case a specific cloud provider has a delay between providing the Windows credentials and the credentials being available for use. In their `create()` function, or as a sub-function called during the creation process, developers should use the `win_deploy_auth_retries` and `win_deploy_auth_retry_delay` parameters from the provider configuration to allow the end-user the ability to customize the number of tries and delay between tries for their particular provider.

After the appropriate deploy function completes, a final event is fired which describes the virtual machine that has just been created. This event is tagged `salt/cloud/<vm name>/created`. The payload contains the names of the VM, profile, and provider.

Finally, a dict (queried from the provider) which describes the new virtual machine is returned to the user. Because this data is not fired on the event bus it can, and should, return any passwords that were returned by the cloud provider. In some cases (for example, Rackspace), this is the only time that the password can be queried by the user; post-creation queries may not contain password information (depending upon the provider).

### The libcloudfuncs Functions

A number of other functions are required for all cloud providers. However, with libcloud-based modules, these are all provided for free by the libcloudfuncs library. The following two lines set up the imports:

```
from salt.cloud.libcloudfuncs import * # pylint: disable=W0614,W0401
from salt.utils import namespaced_function
```

And then a series of declarations will make the necessary functions available within the cloud module.

```
get_size = namespaced_function(get_size, globals())
get_image = namespaced_function(get_image, globals())
avail_locations = namespaced_function(avail_locations, globals())
avail_images = namespaced_function(avail_images, globals())
avail_sizes = namespaced_function(avail_sizes, globals())
script = namespaced_function(script, globals())
destroy = namespaced_function(destroy, globals())
```

```
list_nodes = namespaced_function(list_nodes, globals())
list_nodes_full = namespaced_function(list_nodes_full, globals())
list_nodes_select = namespaced_function(list_nodes_select, globals())
show_instance = namespaced_function(show_instance, globals())
```

If necessary, these functions may be replaced by removing the appropriate declaration line, and then adding the function as normal.

These functions are required for all cloud modules, and are described in detail in the next section.

### Non-Libcloud Based Modules

In some cases, using libcloud is not an option. This may be because libcloud has not yet included the necessary driver itself, or it may be that the driver that is included with libcloud does not contain all of the necessary features required by the developer. When this is the case, some or all of the functions in `libcloudfuncs` may be replaced. If they are all replaced, the libcloud imports should be absent from the Salt Cloud module.

A good example of a non-libcloud provider is the DigitalOcean module:

[https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/digital\\_ocean.py](https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/digital_ocean.py)

### The `create()` Function

The `create()` function must be created as described in the libcloud-based module documentation.

### The `get_size()` Function

This function is only necessary for libcloud-based modules, and does not need to exist otherwise.

### The `get_image()` Function

This function is only necessary for libcloud-based modules, and does not need to exist otherwise.

### The `avail_locations()` Function

This function returns a list of locations available, if the cloud provider uses multiple data centers. It is not necessary if the cloud provider only uses one data center. It is normally called using the `--list-locations` option.

```
salt-cloud --list-locations my-cloud-provider
```

### The `avail_images()` Function

This function returns a list of images available for this cloud provider. There are not currently any known cloud providers that do not provide this functionality, though they may refer to images by a different name (for example, `templates`). It is normally called using the `--list-images` option.

```
salt-cloud --list-images my-cloud-provider
```

### The `avail_sizes()` Function

This function returns a list of sizes available for this cloud provider. Generally, this refers to a combination of RAM, CPU, and/or disk space. This functionality may not be present on some cloud providers. For example, the Parallels module breaks down RAM, CPU, and disk space into separate options, whereas in other providers, these options are baked into the image. It is normally called using the `--list-sizes` option.

```
salt-cloud --list-sizes my-cloud-provider
```

### The `script()` Function

This function builds the deploy script to be used on the remote machine. It is likely to be moved into the `salt.utils.cloud` library in the near future, as it is very generic and can usually be copied wholesale from another module. An excellent example is in the Azure driver.

### The `destroy()` Function

This function irreversibly destroys a virtual machine on the cloud provider. Before doing so, it should fire an event on the Salt event bus. The tag for this event is `salt/cloud/<vm name>/destroying`. Once the virtual machine has been destroyed, another event is fired. The tag for that event is `salt/cloud/<vm name>/destroyed`.

This function is normally called with the `-d` options:

```
salt-cloud -d myinstance
```

### The `list_nodes()` Function

This function returns a list of nodes available on this cloud provider, using the following fields:

- `id` (str)
- `image` (str)
- `size` (str)
- `state` (str)
- `private_ips` (list)
- `public_ips` (list)

No other fields should be returned in this function, and all of these fields should be returned, even if empty. The `private_ips` and `public_ips` fields should always be of a list type, even if empty, and the other fields should always be of a str type. This function is normally called with the `-Q` option:

```
salt-cloud -Q
```

### The `list_nodes_full()` Function

All information available about all nodes should be returned in this function. The fields in the `list_nodes()` function should also be returned, even if they would not normally be provided by the cloud provider. This is because some functions both within Salt and 3rd party will break if an expected field is not present. This function is normally called with the `-F` option:

```
salt-cloud -F
```

### The `list_nodes_select()` Function

This function returns only the fields specified in the `query.selection` option in `/etc/salt/cloud`. Because this function is so generic, all of the heavy lifting has been moved into the `salt.utils.cloud` library.

A function to call `list_nodes_select()` still needs to be present. In general, the following code can be used as-is:

```
def list_nodes_select(call=None):
    """
    Return a list of the VMs that are on the provider, with select fields
    """
    return salt.utils.cloud.list_nodes_select(
        list_nodes_full('function'), __opts__['query.selection'], call,
    )
```

However, depending on the cloud provider, additional variables may be required. For instance, some modules use a `conn` object, or may need to pass other options into `list_nodes_full()`. In this case, be sure to update the function appropriately:

```
def list_nodes_select(conn=None, call=None):
    """
    Return a list of the VMs that are on the provider, with select fields
    """
    if not conn:
        conn = get_conn() # pylint: disable=E0602

    return salt.utils.cloud.list_nodes_select(
        list_nodes_full(conn, 'function'),
        __opts__['query.selection'],
        call,
    )
```

This function is normally called with the `-S` option:

```
salt-cloud -S
```

### The `show_instance()` Function

This function is used to display all of the information about a single node that is available from the cloud provider. The simplest way to provide this is usually to call `list_nodes_full()`, and return just the data for the requested node. It is normally called as an action:

```
salt-cloud -a show_instance myinstance
```

## Actions and Functions

Extra functionality may be added to a cloud provider in the form of an `--action` or a `--function`. Actions are performed against a cloud instance/virtual machine, and functions are performed against a cloud provider.

## Actions

Actions are calls that are performed against a specific instance or virtual machine. The `show_instance` action should be available in all cloud modules. Actions are normally called with the `-a` option:

```
salt-cloud -a show_instance myinstance
```

Actions must accept a `name` as a first argument, may optionally support any number of kwargs as appropriate, and must accept an argument of `call`, with a default of `None`.

Before performing any other work, an action should normally verify that it has been called correctly. It may then perform the desired feature, and return useful information to the user. A basic action looks like:

```
def show_instance(name, call=None):
    """
    Show the details from EC2 concerning an AMI
    """
    if call != 'action':
        raise SaltCloudSystemExit(
            'The show_instance action must be called with -a or --action.'
        )

    return _get_node(name)
```

Please note that generic kwargs, if used, are passed through to actions as `kwargs` and not `**kwargs`. An example of this is seen in the Functions section.

## Functions

Functions are called that are performed against a specific cloud provider. An optional function that is often useful is `show_image`, which describes an image in detail. Functions are normally called with the `-f` option:

```
salt-cloud -f show_image my-cloud-provider image='Ubuntu 13.10 64-bit'
```

A function may accept any number of kwargs as appropriate, and must accept an argument of `call` with a default of `None`.

Before performing any other work, a function should normally verify that it has been called correctly. It may then perform the desired feature, and return useful information to the user. A basic function looks like:

```
def show_image(kwargs, call=None):
    """
    Show the details from EC2 concerning an AMI
    """
    if call != 'function':
        raise SaltCloudSystemExit(
            'The show_image action must be called with -f or --function.'
        )

    params = {'ImageId.1': kwargs['image'],
              'Action': 'DescribeImages'}
    result = query(params)
    log.info(result)

    return result
```

Take note that generic kwargs are passed through to functions as `kwargs` and not `**kwargs`.

## 23.8.2 OS Support for Cloud VMs

Salt Cloud works primarily by executing a script on the virtual machines as soon as they become available. The script that is executed is referenced in the cloud profile as the `script`. In older versions, this was the `os` argument. This was changed in 0.8.2.

A number of legacy scripts exist in the `deploy` directory in the saltcloud source tree. The preferred method is currently to use the `salt-bootstrap` script. A stable version is included with each release tarball starting with 0.8.4. The most updated version can be found at:

<https://github.com/saltstack/salt-bootstrap>

If you do not specify a script argument, this script will be used at the default.

If the Salt Bootstrap script does not meet your needs, you may write your own. The script should be written in bash and is a Jinja template. Deploy scripts need to execute a number of functions to do a complete salt setup. These functions include:

1. Install the salt minion. If this can be done via system packages this method is HIGHLY preferred.
2. Add the salt minion keys before the minion is started for the first time. The minion keys are available as strings that can be copied into place in the Jinja template under the dict named `vm`.
3. Start the salt-minion daemon and enable it at startup time.
4. Set up the minion configuration file from the `minion` data available in the Jinja template.

A good, well commented, example of this process is the Fedora deployment script:

<https://github.com/saltstack/salt-cloud/blob/master/saltcloud/deploy/Fedora.sh>

A number of legacy deploy scripts are included with the release tarball. None of them are as functional or complete as Salt Bootstrap, and are still included for academic purposes.

### Other Generic Deploy Scripts

If you want to be assured of always using the latest Salt Bootstrap script, there are a few generic templates available in the `deploy` directory of your saltcloud source tree:

```
curl-bootstrap
curl-bootstrap-git
python-bootstrap
wget-bootstrap
wget-bootstrap-git
```

These are example scripts which were designed to be customized, adapted, and refit to meet your needs. One important use of them is to pass options to the `salt-bootstrap` script, such as updating to specific git tags.

### Post-Deploy Commands

Once a minion has been deployed, it has the option to run a salt command. Normally, this would be the `state.apply`, which would finish provisioning the VM. Another common option (for testing) is to use `test.ping`. This is configured in the main cloud config file:

```
start_action: state.apply
```

This is currently considered to be experimental functionality, and may not work well with all providers. If you experience problems with Salt Cloud hanging after Salt is deployed, consider using Startup States instead:

<http://docs.saltstack.com/ref/states/startup.html>

## Skipping the Deploy Script

For whatever reason, you may want to skip the deploy script altogether. This results in a VM being spun up much faster, with absolutely no configuration. This can be set from the command line:

```
salt-cloud --no-deploy -p micro_aws my_instance
```

Or it can be set from the main cloud config file:

```
deploy: False
```

Or it can be set from the provider's configuration:

```
RACKSPACE.user: example_user
RACKSPACE.apikey: 123984bjjas87034
RACKSPACE.deploy: False
```

Or even on the VM's profile settings:

```
ubuntu_aws:
  provider: aws
  image: ami-7e2da54e
  size: t1.micro
  deploy: False
```

The default for deploy is True.

In the profile, you may also set the script option to None:

```
script: None
```

This is the slowest option, since it still uploads the None deploy script and executes it.

## Updating Salt Bootstrap

Salt Bootstrap can be updated automatically with salt-cloud:

```
salt-cloud -u
salt-cloud --update-bootstrap
```

Bear in mind that this updates to the latest (unstable) version, so use with caution.

## Keeping /tmp/ Files

When Salt Cloud deploys an instance, it uploads temporary files to /tmp/ for salt-bootstrap to put in place. After the script has run, they are deleted. To keep these files around (mostly for debugging purposes), the --keep-tmp option can be added:

```
salt-cloud -p myprofile mymachine --keep-tmp
```

For those wondering why /tmp/ was used instead of /root/, this had to be done for images which require the use of sudo, and therefore do not allow remote root logins, even for file transfers (which makes /root/ unavailable).

## Deploy Script Arguments

Custom deploy scripts are unlikely to need custom arguments to be passed to them, but salt-bootstrap has been extended quite a bit, and this may be necessary. `script_args` can be specified in either the profile or the map file, to pass arguments to the deploy script:

```
aws-amazon:
  provider: aws
  image: ami-1624987f
  size: t1.micro
  ssh_username: ec2-user
  script: bootstrap-salt
  script_args: -c /tmp/
```

This has also been tested to work with pipes, if needed:

```
script_args: | head
```

## 23.9 Using Salt Cloud from Salt

### 23.9.1 Using the Salt Modules for Cloud

In addition to the `salt-cloud` command, Salt Cloud can be called from Salt, in a variety of different ways. Most users will be interested in either the execution module or the state module, but it is also possible to call Salt Cloud as a runner.

Because the actual work will be performed on a remote minion, the normal Salt Cloud configuration must exist on any target minion that needs to execute a Salt Cloud command. Because Salt Cloud now supports breaking out configuration into individual files, the configuration is easily managed using Salt's own `file.managed` state function. For example, the following directories allow this configuration to be managed easily:

```
/etc/salt/cloud.providers.d/
/etc/salt/cloud.profiles.d/
```

### Minion Keys

Keep in mind that when creating minions, Salt Cloud will create public and private minion keys, upload them to the minion, and place the public key on the machine that created the minion. It will *not* attempt to place any public minion keys on the master, unless the minion which was used to create the instance is also the Salt Master. This is because granting arbitrary minions access to modify keys on the master is a serious security risk, and must be avoided.

### Execution Module

The `cloud` module is available to use from the command line. At the moment, almost every standard Salt Cloud feature is available to use. The following commands are available:

#### `list_images`

This command is designed to show images that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). Listing images requires a provider to be configured, and specified:

```
salt myminion cloud.list_images my-cloud-provider
```

### list\_sizes

This command is designed to show sizes that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). This command is not available for all cloud providers; see the provider-specific documentation for details. Listing sizes requires a provider to be configured, and specified:

```
salt myminion cloud.list_sizes my-cloud-provider
```

### list\_locations

This command is designed to show locations that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). This command is not available for all cloud providers; see the provider-specific documentation for details. Listing locations requires a provider to be configured, and specified:

```
salt myminion cloud.list_locations my-cloud-provider
```

### query

This command is used to query all configured cloud providers, and display all instances associated with those accounts. By default, it will run a standard query, returning the following fields:

**id** The name or ID of the instance, as used by the cloud provider.

**image** The disk image that was used to create this instance.

**private\_ips** Any public IP addresses currently assigned to this instance.

**public\_ips** Any private IP addresses currently assigned to this instance.

**size** The size of the instance; can refer to RAM, CPU(s), disk space, etc., depending on the cloud provider.

**state** The running state of the instance; for example, `running`, `stopped`, `pending`, etc. This state is dependent upon the provider.

This command may also be used to perform a full query or a select query, as described below. The following usages are available:

```
salt myminion cloud.query
salt myminion cloud.query list_nodes
salt myminion cloud.query list_nodes_full
```

### full\_query

This command behaves like the `query` command, but lists all information concerning each instance as provided by the cloud provider, in addition to the fields returned by the `query` command.

```
salt myminion cloud.full_query
```

### select\_query

This command behaves like the `query` command, but only returned select fields as defined in the `/etc/salt/cloud` configuration file. A sample configuration for this section of the file might look like:

```
query.selection:  
- id  
- key_name
```

This configuration would only return the `id` and `key_name` fields, for those cloud providers that support those two fields. This would be called using the following command:

```
salt myminion cloud.select_query
```

### profile

This command is used to create an instance using a profile that is configured on the target minion. Please note that the profile must be configured before this command can be used with it.

```
salt myminion cloud.profile ec2-centos64-x64 my-new-instance
```

Please note that the execution module does *not* run in parallel mode. Using multiple minions to create instances can effectively perform parallel instance creation.

### create

This command is similar to the `profile` command, in that it is used to create a new instance. However, it does not require a profile to be pre-configured. Instead, all of the options that are normally configured in a profile are passed directly to Salt Cloud to create the instance:

```
salt myminion cloud.create my-ec2-config my-new-instance \  
  image=ami-1624987f size='t1.micro' ssh_username=ec2-user \  
  securitygroup=default delvol_on_destroy=True
```

Please note that the execution module does *not* run in parallel mode. Using multiple minions to create instances can effectively perform parallel instance creation.

### destroy

This command is used to destroy an instance or instances. This command will search all configured providers and remove any instance(s) which matches the name(s) passed in here. The results of this command are *non-reversible* and should be used with caution.

```
salt myminion cloud.destroy myinstance  
salt myminion cloud.destroy myinstance1,myinstance2
```

### action

This command implements both the `action` and the `function` commands used in the standard `salt-cloud` command. If one of the standard `action` commands is used, an instance name must be provided. If one of the standard `function` commands is used, a provider configuration must be named.

```
salt myminion cloud.action start instance=myinstance
salt myminion cloud.action show_image provider=my-ec2-config \
    image=ami-1624987f
```

The actions available are largely dependent upon the module for the specific cloud provider. The following actions are available for all cloud providers:

**list\_nodes** This is a direct call to the `query` function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

**list\_nodes\_select** This is a direct call to the `full_query` function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

**list\_nodes\_select** This is a direct call to the `select_query` function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

**show\_instance** This is a thin wrapper around `list_nodes`, which returns the full information about a single instance. An instance name must be provided.

## State Module

A subset of the execution module is available through the `cloud` state module. Not all functions are currently included, because there is currently insufficient code for them to perform statefully. For example, a command to create an instance may be issued with a series of options, but those options cannot currently be statefully managed. Additional states to manage these options will be released at a later time.

### cloud.present

This state will ensure that an instance is present inside a particular cloud provider. Any option that is normally specified in the `cloud.create` execution module and function may be declared here, but only the actual presence of the instance will be managed statefully.

```
my-instance-name:
  cloud.present:
    - provider: my-ec2-config
    - image: ami-1624987f
    - size: 't1.micro'
    - ssh_username: ec2-user
    - securitygroup: default
    - delvol_on_destroy: True
```

### cloud.profile

This state will ensure that an instance is present inside a particular cloud provider. This function calls the `cloud.profile` execution module and function, but as with `cloud.present`, only the actual presence of the instance will be managed statefully.

```
my-instance-name:
  cloud.profile:
    - profile: ec2-centos64-x64
```

## cloud.absent

This state will ensure that an instance (identified by name) does not exist in any of the cloud providers configured on the target minion. Please note that this state is *non-reversible* and may be considered especially destructive when issued as a cloud state.

```
my-instance-name:
  cloud.absent
```

## Runner Module

The `cloud` runner module is executed on the master, and performs actions using the configuration and Salt modules on the master itself. This means that any public minion keys will also be properly accepted by the master.

Using the functions in the runner module is no different than using those in the execution module, outside of the behavior described in the above paragraph. The following functions are available inside the runner:

- `list_images`
- `list_sizes`
- `list_locations`
- `query`
- `full_query`
- `select_query`
- `profile`
- `destroy`
- `action`

Outside of the standard usage of `salt-run` itself, commands are executed as usual:

```
salt-run cloud.profile ec2-centos64-x86_64 my-instance-name
```

## CloudClient

The execution, state, and runner modules ultimately all use the `CloudClient` library that ships with Salt. To use the `CloudClient` library locally (either on the master or a minion), create a client object and issue a command against it:

```
import salt.cloud
import pprint
client = salt.cloud.CloudClient('/etc/salt/cloud')
nodes = client.query()
pprint.pprint(nodes)
```

## 23.10 Feature Comparison

### 23.10.1 Feature Matrix

A number of features are available in most cloud providers, but not all are available everywhere. This may be because the feature isn't supported by the cloud provider itself, or it may only be that the feature has not yet been added to

Salt Cloud. In a handful of cases, it is because the feature does not make sense for a particular cloud provider (Saltify, for instance).

This matrix shows which features are available in which cloud providers, as far as Salt Cloud is concerned. This is not a comprehensive list of all features available in all cloud providers, and should not be used to make business decisions concerning choosing a cloud provider. In most cases, adding support for a feature to Salt Cloud requires only a little effort.

### Legacy Drivers

Both AWS and Rackspace are listed as ``Legacy''. This is because those drivers have been replaced by other drivers, which are generally the preferred method for working with those providers.

The EC2 driver should be used instead of the AWS driver, when possible. The OpenStack driver should be used instead of the Rackspace driver, unless the user is dealing with instances in ``the old cloud'' in Rackspace.

### Note for Developers

When adding new features to a particular cloud provider, please make sure to add the feature to this table. Additionally, if you notice a feature that is not properly listed here, pull requests to fix them is appreciated.

### Standard Features

These are features that are available for almost every provider.

	AWS (Legacy)	Cloud Stack	Digi- tal Ocean	EC2	GoGrid	Lib by En- t	Lin- ode	Open- Stack	Par- al- lels	Rackspace (Legacy)	Saltify	Soft- layer	Soft- layer Hard- ware	Aliyun
Query	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes		Yes	Yes	Yes
Full Query	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes		Yes	Yes	Yes
Selec- tive Query	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes		Yes	Yes	Yes
List Sizes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes		Yes	Yes	Yes
List Im- ages	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes		Yes	Yes	Yes
List Loca- tions	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes		Yes	Yes	Yes
create	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
de- stroy	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes		Yes	Yes	Yes

### Actions

These are features that are performed on a specific instance, and require an instance name to be passed in. For example:

```
# salt-cloud -a attach_volume ami.example.com
```

Actions	AWS (Legacy)	CloudStack	Digital Ocean	EC2	GoGrid	JoyEnt	Linode	OpenStack	Parallels	Rackspace (Legacy)	Saltify	Softlayer	Softlayer Hardware	Aliyun
attach_volume				Yes										
create_attach_volumes	Yes			Yes										
del_tags	Yes			Yes										
delvol_on_destroy				Yes										
detach_volume				Yes										
disable_term_protect	Yes			Yes										
enable_term_protect	Yes			Yes										
get_tags	Yes			Yes										
keepvol_on_destroy				Yes										
list_keypairs			Yes											
rename	Yes			Yes										
set_tags	Yes			Yes										
show_delvol_on_destroy				Yes										
show_instance			Yes	Yes				Yes			Yes	Yes	Yes	Yes
show_term_protect				Yes										
start	Yes			Yes		Yes		Yes						Yes
stop	Yes			Yes		Yes		Yes						Yes
take_action						Yes								

## Functions

These are features that are performed against a specific cloud provider, and require the name of the provider to be passed in. For example:

```
# salt-cloud -f list_images my_digitalocean
```

Functions	AWS (Legacy)	CloudStack	Digital Ocean	EC2	GoGrid	JoyEnt	Linode	OpenStack
block_device_mappings	Yes							
create_keypair				Yes				
create_volume				Yes				
delete_key						Yes		
delete_keypair				Yes				
delete_volume				Yes				
get_image			Yes			Yes		
get_ip		Yes						
get_key		Yes						
get_keyid			Yes					
get_keypair		Yes						
get_networkid		Yes						

Table 23.1 -- continued from previous page

Functions	AWS (Legacy)	CloudStack	Digital Ocean	EC2	GoGrid	JoyEnt	Linode	OpenStack
get_node						Yes		
get_password		Yes						
get_size			Yes			Yes		
get_spot_config				Yes				
get_subnetid				Yes				
iam_profile	Yes			Yes				
import_key						Yes		
key_list						Yes		
keyname	Yes			Yes				
list_availability_zones				Yes				
list_custom_images								
list_keys						Yes		
list_nodes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
list_nodes_full	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
list_nodes_select	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
list_vlans								
rackconnect								Yes
reboot				Yes		Yes		
reformat_node						Yes		
securitygroup	Yes			Yes				
securitygroupid				Yes				
show_image				Yes				
show_key						Yes		
show_keypair			Yes	Yes				
show_volume				Yes				

## 23.11 Tutorials

### 23.11.1 Using Salt Cloud with the Event Reactor

One of the most powerful features of the Salt framework is the Event Reactor. As the Reactor was in development, Salt Cloud was regularly updated to take advantage of the Reactor upon completion. As such, various aspects of both the creation and destruction of instances with Salt Cloud fire events to the Salt Master, which can be used by the Event Reactor.

#### Event Structure

As of this writing, all events in Salt Cloud have a tag, which includes the ID of the instance being managed, and a payload which describes the task that is currently being handled. A Salt Cloud tag looks like:

```
salt/cloud/<minion_id>/<task>
```

For instance, the first event fired when creating an instance named `web1` would look like:

```
salt/cloud/web1/creating
```

Assuming this instance is using the `ec2-centos` profile, which is in turn using the `ec2-config` provider, the payload for this tag would look like:

```
{'name': 'web1',  
 'profile': 'ec2-centos',  
 'provider': 'ec2-config'}
```

## Available Events

When an instance is created in Salt Cloud, whether by map, profile, or directly through an API, a minimum of five events are normally fired. More may be available, depending upon the cloud provider being used. Some of the common events are described below.

### `salt/cloud/<minion_id>/creating`

This event states simply that the process to create an instance has begun. At this point in time, no actual work has begun. The payload for this event includes:

name profile provider

### `salt/cloud/<minion_id>/requesting`

Salt Cloud is about to make a request to the cloud provider to create an instance. At this point, all of the variables required to make the request have been gathered, and the payload of the event will reflect those variables which do not normally pose a security risk. What is returned here is dependent upon the cloud provider. Some common variables are:

name image size location

### `salt/cloud/<minion_id>/querying`

The instance has been successfully requested, but the necessary information to log into the instance (such as IP address) is not yet available. This event marks the beginning of the process to wait for this information.

The payload for this event normally only includes the `instance_id`.

### `salt/cloud/<minion_id>/waiting_for_ssh`

The information required to log into the instance has been retrieved, but the instance is not necessarily ready to be accessed. Following this event, Salt Cloud will wait for the IP address to respond to a ping, then wait for the specified port (usually 22) to respond to a connection, and on Linux systems, for SSH to become available. Salt Cloud will attempt to issue the `date` command on the remote system, as a means to check for availability. If no `ssh_username` has been specified, a list of usernames (starting with `root`) will be attempted. If one or more usernames was configured for `ssh_username`, they will be added to the beginning of the list, in order.

The payload for this event normally only includes the `ip_address`.

### `salt/cloud/<minion_id>/deploying`

The necessary port has been detected as available, and now Salt Cloud can log into the instance, upload any files used for deployment, and run the deploy script. Once the script has completed, Salt Cloud will log back into the instance and remove any remaining files.

A number of variables are used to deploy instances, and the majority of these will be available in the payload. Any keys, passwords or other sensitive data will be scraped from the payload. Most of the variables returned will be related to the profile or provider config, and any default values that could have been changed in the profile or provider, but weren't.

`salt/cloud/<minion_id>/created`

The deploy sequence has completed, and the instance is now available, Salted, and ready for use. This event is the final task for Salt Cloud, before returning instance information to the user and exiting.

The payload for this event contains little more than the initial `creating` event. This event is required in all cloud providers.

### Configuring the Event Reactor

The Event Reactor is built into the Salt Master process, and as such is configured via the master configuration file. Normally this will be a YAML file located at `/etc/salt/master`. Additionally, master configuration items can be stored, in YAML format, inside the `/etc/salt/master.d/` directory.

These configuration items may be stored in either location; however, they may only be stored in one location. For organizational and security purposes, it may be best to create a single configuration file, which contains only Event Reactor configuration, at `/etc/salt/master.d/reactor`.

The Event Reactor uses a top-level configuration item called `reactor`. This block contains a list of tags to be watched for, each of which also includes a list of `sls` files. For instance:

```
reactor:
  - 'salt/minion/*/start':
    - '/srv/reactor/custom-reactor.sls'
  - 'salt/cloud/*/created':
    - '/srv/reactor/cloud-alert.sls'
  - 'salt/cloud/*/destroyed':
    - '/srv/reactor/cloud-destroy-alert.sls'
```

The above configuration configures reactors for three different tags: one which is fired when a minion process has started and is available to receive commands, one which is fired when a cloud instance has been created, and one which is fired when a cloud instance is destroyed.

Note that each tag contains a wildcard (\*) in it. For each of these tags, this will normally refer to a `minion_id`. This is not required of event tags, but is very common.

### Reactor SLS Files

Reactor `sls` files should be placed in the `/srv/reactor/` directory for consistency between environments, but this is not currently enforced by Salt.

Reactor `sls` files follow a similar format to other `sls` files in Salt. By default they are written in YAML and can be templated using Jinja, but since they are processed through Salt's rendering system, any available renderer (JSON, Mako, Cheetah, etc.) can be used.

As with other `sls` files, each stanza will start with a declaration ID, followed by the function to run, and then any arguments for that function. For example:

```
# /srv/reactor/cloud-alert.sls
new_instance_alert:
  cmd.pagerduty.create_event:
```

```

- tgt: alertserver
- kwarg:
  description: "New instance: {{ data['name'] }}"
  details: "New cloud instance created on {{ data['provider'] }}"
  service_key: 1626dead5ecafe46231e968eb1be29c4
  profile: my-pagerduty-account

```

When the Event Reactor receives an event notifying it that a new instance has been created, this `sls` will create a new incident in PagerDuty, using the configured PagerDuty account.

The declaration ID in this example is `new_instance_alert`. The function called is `cmd.pagerduty.create_event`. The `cmd` portion of this function specifies that an execution module and function will be called, in this case, the `pagerduty.create_event` function.

Because an execution module is specified, a target (`tgt`) must be specified on which to call the function. In this case, a minion called `alertserver` has been used. Any arguments passed through to the function are declared in the `kwarg` block.

### Example: Reactor-Based Highstate

When Salt Cloud creates an instance, by default it will install the Salt Minion onto the instance, along with any specified minion configuration, and automatically accept that minion's keys on the master. One of the configuration options that can be specified is `startup_states`, which is commonly set to `highstate`. This will tell the minion to immediately apply a *highstate*, as soon as it is able to do so.

This can present a problem with some system images on some cloud providers. For instance, Salt Cloud can be configured to log in as either the `root` user, or a user with `sudo` access. While some providers commonly use images that lock out remote `root` access and require a user with `sudo` privileges to log in (notably EC2, with their `ec2-user` login), most cloud providers fall back to `root` as the default login on all images, including for operating systems (such as Ubuntu) which normally disallow remote `root` login.

For users of these operating systems, it is understandable that a *highstate* would include configuration to block remote `root` logins again. However, Salt Cloud may not have finished cleaning up its deployment files by the time the minion process has started, and kicked off a *highstate* run. Users have reported errors from Salt Cloud getting locked out while trying to clean up after itself.

The goal of a startup state may be achieved using the Event Reactor. Because a minion fires an event when it is able to receive commands, this event can effectively be used inside the reactor system instead. The following will point the reactor system to the right `sls` file:

```

reactor:
- 'salt/cloud/*/created':
- '/srv/reactor/startup_highstate.sls'

```

And the following `sls` file will start a *highstate* run on the target minion:

```

# /srv/reactor/startup_highstate.sls
reactor_highstate:
  cmd.state.apply:
    - tgt: {{ data['name'] }}

```

Because this event will not be fired until Salt Cloud has cleaned up after itself, the *highstate* run will not step on salt-cloud's toes. And because every file on the minion is configurable, including `/etc/salt/minion`, the `startup_states` can still be configured for future minion restarts, if desired.

---

## netapi modules

---

### 24.1 Writing netapi modules

netapi modules, put simply, bind a port and start a service. They are purposefully open-ended and can be used to present a variety of external interfaces to Salt, and even present multiple interfaces at once.

See also:

*The full list of netapi modules*

#### 24.1.1 Configuration

All netapi configuration is done in the *Salt master config* and takes a form similar to the following:

```
rest_cherrypy:
  port: 8000
  debug: True
  ssl_cert: /etc/pki/tls/certs/localhost.crt
  ssl_key: /etc/pki/tls/certs/localhost.key
```

#### 24.1.2 The `__virtual__` function

Like all module types in Salt, netapi modules go through Salt's loader interface to determine if they should be loaded into memory and then executed.

The `__virtual__` function in the module makes this determination and should return `False` or a string that will serve as the name of the module. If the module raises an `ImportError` or any other errors, it will not be loaded.

#### 24.1.3 The `start` function

The `start()` function will be called for each netapi module that is loaded. This function should contain the server loop that actually starts the service. This is started in a multiprocess.

#### 24.1.4 Inline documentation

As with the rest of Salt, it is a best-practice to include liberal inline documentation in the form of a module docstring and docstrings on any classes, methods, and functions in your netapi module.

### 24.1.5 Loader “magic” methods

The loader makes the `__opts__` data structure available to any function in a `netapi` module.

## 24.2 Introduction to netapi modules

`netapi` modules provide API-centric access to Salt. Usually externally-facing services such as REST or WebSockets, XMPP, XMLRPC, etc.

In general `netapi` modules bind to a port and start a service. They are purposefully open-ended. A single module can be configured to run as well as multiple modules simultaneously.

`netapi` modules are enabled by adding configuration to your Salt Master config file and then starting the **salt-api** daemon. Check the docs for each module to see external requirements and configuration settings.

Communication with Salt and Salt satellite projects is done using Salt's own *Python API*. A list of available client interfaces is below.

---

### salt-api

Prior to Salt's 2014.7.0 release, `netapi` modules lived in the separate sister projected `salt-api`. That project has been merged into the main Salt project.

---

See also:

*The full list of netapi modules*

## 24.3 Client interfaces

Salt's client interfaces expose executing functions by crafting a dictionary of values that are mapped to function arguments. This allows calling functions simply by creating a data structure. (And this is exactly how much of Salt's own internals work!)

`class salt.netapi.NetapiClient(opts)`

Provide a uniform method of accessing the various client interfaces in Salt in the form of low-data data structures. For example:

```
>>> client = NetapiClient(__opts__)
>>> lowstate = {'client': 'local', 'tgt': '*', 'fun': 'test.ping', 'arg': ''}
>>> client.run(lowstate)
```

**local** (\*args, \*\*kwargs)

Run *execution modules* synchronously

See `salt.client.LocalClient.cmd()` for all available parameters.

Sends a command from the master to the targeted minions. This is the same interface that Salt's own CLI uses. Note the `arg` and `kwarg` parameters are sent down to the minion(s) and the given function, `fun`, is called with those parameters.

**Returns** Returns the result from the execution module

**local\_async** (\*args, \*\*kwargs)

Run *execution modules* asynchronously

Wraps `salt.client.LocalClient.run_job()`.

**Returns** job ID

**local\_batch** (*\*args*, *\*\*kwargs*)

Run *execution modules* against batches of minions

New in version 0.8.4.

Wraps `salt.client.LocalClient.cmd_batch()`

**Returns** Returns the result from the execution module for each batch of returns

**runner** (*fun*, *timeout=None*, *\*\*kwargs*)

Run *runner modules* <all-salt.runners> synchronously

Wraps `salt.runner.RunnerClient.cmd_sync()`.

Note that runner functions must be called using keyword arguments. Positional arguments are not supported.

**Returns** Returns the result from the runner module

**wheel** (*fun*, *\*\*kwargs*)

Run *wheel modules* synchronously

Wraps `salt.wheel.WheelClient.master_call()`.

Note that wheel functions must be called using keyword arguments. Positional arguments are not supported.

**Returns** Returns the result from the wheel module

---

## Salt Virt

---

The Salt Virt cloud controller capability was initially added to Salt in version 0.14.0 as an alpha technology.

The initial Salt Virt system supports core cloud operations:

- Virtual machine deployment
- Inspection of deployed VMs
- Virtual machine migration
- Network profiling
- Automatic VM integration with all aspects of Salt
- Image Pre-seeding

Many features are currently under development to enhance the capabilities of the Salt Virt systems.

---

**Note:** It is noteworthy that Salt was originally developed with the intent of using the Salt communication system as the backbone to a cloud controller. This means that the Salt Virt system is not an afterthought, simply a system that took the back seat to other development. The original attempt to develop the cloud control aspects of Salt was a project called butter. This project never took off, but was functional and proves the early viability of Salt to be a cloud controller.

---

### 25.1 Salt Virt Tutorial

A tutorial about how to get Salt Virt up and running has been added to the tutorial section:

[Cloud Controller Tutorial](#)

### 25.2 The Salt Virt Runner

The point of interaction with the cloud controller is the **virt** runner. The **virt** runner comes with routines to execute specific virtual machine routines.

Reference documentation for the virt runner is available with the runner module documentation:

[Virt Runner Reference](#)

## 25.3 Based on Live State Data

The Salt Virt system is based on using Salt to query live data about hypervisors and then using the data gathered to make decisions about cloud operations. This means that no external resources are required to run Salt Virt, and that the information gathered about the cloud is live and accurate.

## 25.4 Deploy from Network or Disk

### 25.4.1 Virtual Machine Disk Profiles

Salt Virt allows for the disks created for deployed virtual machines to be finely configured. The configuration is a simple data structure which is read from the `config.option` function, meaning that the configuration can be stored in the minion config file, the master config file, or the minion's pillar.

This configuration option is called `virt.disk`. The default `virt.disk` data structure looks like this:

```
virt.disk:
  default:
    - system:
      size: 8192
      format: qcow2
      model: virtio
```

---

**Note:** The format and model does not need to be defined, Salt will default to the optimal format used by the underlying hypervisor, in the case of kvm this it is `qcow2` and `virtio`.

---

This configuration sets up a disk profile called default. The default profile creates a single system disk on the virtual machine.

### Define More Profiles

Many environments will require more complex disk profiles and may require more than one profile, this can be easily accomplished:

```
virt.disk:
  default:
    - system:
      size: 8192
  database:
    - system:
      size: 8192
    - data:
      size: 30720
  web:
    - system:
      size: 1024
    - logs:
      size: 5120
```

This configuration allows for one of three profiles to be selected, allowing virtual machines to be created with different storage needs of the deployed vm.

## 25.4.2 Virtual Machine Network Profiles

Salt Virt allows for the network devices created for deployed virtual machines to be finely configured. The configuration is a simple data structure which is read from the `config.option` function, meaning that the configuration can be stored in the minion config file, the master config file, or the minion's pillar.

This configuration option is called `virt.nic`. By default the `virt.nic` option is empty but defaults to a data structure which looks like this:

```
virt.nic:
  default:
    eth0:
      bridge: br0
      model: virtio
```

**Note:** The model does not need to be defined, Salt will default to the optimal model used by the underlying hypervisor, in the case of kvm this model is **virtio**

This configuration sets up a network profile called default. The default profile creates a single Ethernet device on the virtual machine that is bridged to the hypervisor's `br0` interface. This default setup does not require setting up the `virt.nic` configuration, and is the reason why a default install only requires setting up the `br0` bridge device on the hypervisor.

### Define More Profiles

Many environments will require more complex network profiles and may require more than one profile, this can be easily accomplished:

```
virt.nic:
  dual:
    eth0:
      bridge: service_br
    eth1:
      bridge: storage_br
  single:
    eth0:
      bridge: service_br
  triple:
    eth0:
      bridge: service_br
    eth1:
      bridge: storage_br
    eth2:
      bridge: dmz_br
  all:
    eth0:
      bridge: service_br
    eth1:
      bridge: storage_br
    eth2:
      bridge: dmz_br
    eth3:
      bridge: database_br
  dmz:
    eth0:
      bridge: service_br
    eth1:
```

```
    bridge: dmz_br
database:
  eth0:
    bridge: service_br
  eth1:
    bridge: database_br
```

This configuration allows for one of six profiles to be selected, allowing virtual machines to be created which attach to different network depending on the needs of the deployed vm.

---

## Understanding YAML

---

The default renderer for SLS files is the YAML renderer. YAML is a markup language with many powerful features. However, Salt uses a small subset of YAML that maps over very commonly used data structures, like lists and dictionaries. It is the job of the YAML renderer to take the YAML data structure and compile it into a Python data structure for use by Salt.

Though YAML syntax may seem daunting and terse at first, there are only three very simple rules to remember when writing YAML for SLS files.

### 26.1 Rule One: Indentation

YAML uses a fixed indentation scheme to represent relationships between data layers. Salt requires that the indentation for each level consists of exactly two spaces. Do not use tabs.

### 26.2 Rule Two: Colons

Python dictionaries are, of course, simply key-value pairs. Users from other languages may recognize this data type as hashes or associative arrays.

Dictionary keys are represented in YAML as strings terminated by a trailing colon. Values are represented by either a string following the colon, separated by a space:

```
my_key: my_value
```

In Python, the above maps to:

```
{'my_key': 'my_value'}
```

Alternatively, a value can be associated with a key through indentation.

```
my_key:  
  my_value
```

---

**Note:** The above syntax is valid YAML but is uncommon in SLS files because most often, the value for a key is not singular but instead is a *list* of values.

---

In Python, the above maps to:

```
{'my_key': 'my_value'}
```

Dictionaries can be nested:

```
first_level_dict_key:  
  second_level_dict_key: value_in_second_level_dict
```

And in Python:

```
{  
    'first_level_dict_key': {  
        'second_level_dict_key': 'value_in_second_level_dict'  
    }  
}
```

## 26.3 Rule Three: Dashes

To represent lists of items, a single dash followed by a space is used. Multiple items are a part of the same list as a function of their having the same level of indentation.

```
- list_value_one  
- list_value_two  
- list_value_three
```

Lists can be the value of a key-value pair. This is quite common in Salt:

```
my_dictionary:  
  - list_value_one  
  - list_value_two  
  - list_value_three
```

In Python, the above maps to:

```
{'my_dictionary': ['list_value_one', 'list_value_two', 'list_value_three']}
```

## 26.4 Learning More

One easy way to learn more about how YAML gets rendered into Python data structures is to use an online YAML parser to see the Python output.

One excellent choice for experimenting with YAML parsing is: <http://yaml-online-parser.appspot.com/>

---

## Master Tops System

---

In 0.10.4 the *external\_nodes* system was upgraded to allow for modular subsystems to be used to generate the top file data for a *highstate* run on the master.

The old *external\_nodes* option has been removed. The master tops system contains a number of subsystems that are loaded via the Salt loader interfaces like modules, states, returners, runners, etc.

Using the new *master\_tops* option is simple:

```
master_tops:
  ext_nodes: cobbler-external-nodes
```

for [Cobbler](#) or:

```
master_tops:
  reclass:
    inventory_base_uri: /etc/reclass
    classes_uri: roles
```

for [Reclass](#).

It's also possible to create custom *master\_tops* modules. These modules must go in a subdirectory called *tops* in the *extension\_modules* directory. The *extension\_modules* directory is not defined by default (the default */srv/salt/\_modules* will NOT work as of this release)

Custom tops modules are written like any other execution module, see the source for the two modules above for examples of fully functional ones. Below is a degenerate example:

*/etc/salt/master:*

```
extension_modules: /srv/salt/modules
master_tops:
  customtop: True
```

*/srv/salt/modules/tops/customtop.py:*

```
import logging
import sys
# Define the module's virtual name
__virtualname__ = 'customtop'

log = logging.getLogger(__name__)

def __virtual__():
    return __virtualname__
```

```
def top(**kwargs):
    log.debug('Calling top in customtop')
    return {'base': ['test']}
```

*salt minion state.show\_top* should then display something like:

```
$ salt minion state.show_top

minion
-----
base:
  - test
```

## 28.1 Getting Started

Salt SSH is very easy to use, simply set up a basic *roster* file of the systems to connect to and run `salt-ssh` commands in a similar way as standard `salt` commands.

- Salt ssh is considered production ready in version 2014.7.0
- Python is required on the remote system (unless using the `-r` option to send raw ssh commands)
- On many systems, the `salt-ssh` executable will be in its own package, usually named `salt-ssh`
- The Salt SSH system does not supercede the standard Salt communication systems, it simply offers an SSH-based alternative that does not require ZeroMQ and a remote agent. Be aware that since all communication with Salt SSH is executed via SSH it is substantially slower than standard Salt with ZeroMQ.
- At the moment fileserver operations must be wrapped to ensure that the relevant files are delivered with the `salt-ssh` commands. The state module is an exception, which compiles the state run on the master, and in the process finds all the references to `salt://` paths and copies those files down in the same tarball as the state run. However, needed files server wrappers are still under development.

## 28.2 Salt SSH Roster

The roster system in Salt allows for remote minions to be easily defined.

**Note:** See the [Roster documentation](#) for more details.

Simply create the roster file, the default location is `/etc/salt/roster`:

```
web1: 192.168.42.1
```

This is a very basic roster file where a Salt ID is being assigned to an IP address. A more elaborate roster can be created:

```
web1:
  host: 192.168.42.1 # The IP addr or DNS hostname
  user: fred        # Remote executions will be executed as user fred
  passwd: foobarbaz # The password to use for login, if omitted, keys are used
  sudo: True        # Whether to sudo to root, not enabled by default
web2:
  host: 192.168.42.2
```

**Note:** sudo works only if NOPASSWD is set for user in /etc/sudoers: fred ALL=(ALL) NOPASSWD: ALL

---

## 28.3 Deploy ssh key for salt-ssh

By default, salt-ssh will generate key pairs for ssh, the default path will be /etc/salt/pki/master/ssh/salt-ssh.rsa. You can use ssh-copy-id, (the OpenSSH key deployment tool) to deploy keys to your servers.

```
ssh-copy-id -i /etc/salt/pki/master/ssh/salt-ssh.rsa.pub user@server.demo.com
```

One could also create a simple shell script, named salt-ssh-copy-id.sh as follows:

```
#!/bin/bash
if [ -z $1 ]; then
    echo $0 user@host.com
    exit 0
fi
ssh-copy-id -i /etc/salt/pki/master/ssh/salt-ssh.rsa.pub $1
```

**Note:** Be certain to chmod +x salt-ssh-copy-id.sh.

---

```
./salt-ssh-copy-id.sh user@server1.host.com
./salt-ssh-copy-id.sh user@server2.host.com
```

Once keys are successfully deployed, salt-ssh can be used to control them.

## 28.4 Calling Salt SSH

The salt-ssh command can be easily executed in the same way as a salt command:

```
salt-ssh '*' test.ping
```

Commands with salt-ssh follow the same syntax as the salt command.

The standard salt functions are available! The output is the same as salt and many of the same flags are available. Please see <http://docs.saltstack.com/ref/cli/salt-ssh.html> for all of the available options.

### 28.4.1 Raw Shell Calls

By default salt-ssh runs Salt execution modules on the remote system, but salt-ssh can also execute raw shell commands:

```
salt-ssh '*' -r 'ifconfig'
```

## 28.5 States Via Salt SSH

The Salt State system can also be used with salt-ssh. The state system abstracts the same interface to the user in salt-ssh as it does when using standard salt. The intent is that Salt Formulas defined for standard salt will work seamlessly with salt-ssh and vice-versa.

The standard Salt States walkthroughs function by simply replacing `salt` commands with `salt-ssh`.

## 28.6 Targeting with Salt SSH

Due to the fact that the targeting approach differs in `salt-ssh`, only `glob` and `regex` targets are supported as of this writing, the remaining target systems still need to be implemented.

## 28.7 Configuring Salt SSH

Salt SSH takes its configuration from a master configuration file. Normally, this file is in `/etc/salt/master`. If one wishes to use a customized configuration file, the `-c` option to Salt SSH facilitates passing in a directory to look inside for a configuration file named `master`.

### 28.7.1 Minion Config

New in version 2015.5.1.

Minion config options can be defined globally using the master configuration option `ssh_minion_opts`. It can also be defined on a per-target basis with the `minion_opts` entry in the roster.

## 28.8 Running Salt SSH as non-root user

By default, Salt read all the configuration from `/etc/salt/`. If you are running Salt SSH with a regular user you have to modify some paths or you will get `Permission denied` messages. You have to modify two parameters: `pki_dir` and `cachedir`. Those should point to a full path writable for the user.

It's recommended not to modify `/etc/salt` for this purpose. Create a private copy of `/etc/salt` for the user and run the command with `-c /new/config/path`.

## 28.9 Define CLI Options with Saltfile

If you are commonly passing in CLI options to `salt-ssh`, you can create a `Saltfile` to automatically use these options. This is common if you're managing several different salt projects on the same server.

So if you `cd` into a directory with a `Saltfile` with the following YAML contents:

```
salt-ssh:
  config_dir: path/to/config/dir
  max_procs: 30
  wipe_ssh: true
```

Instead of having to call `salt-ssh --config-dir=path/to/config/dir --max-procs=30 --wipe \* test.ping` you can call `salt-ssh \* test.ping`.

Boolean-style options should be specified in their YAML representation.

---

**Note:** The option keys specified must match the destination attributes for the options specified in the parser `salt.utils.parsers.SaltSSHOptionParser`. For example, in the case of the `--wipe` command line

option, its `dest` is configured to be `wipe_ssh` and thus this is what should be configured in the Saltfile. Using the names of flags for this option, being `wipe: true` or `w: true`, will not work.

---

## 28.10 Debugging salt-ssh

One common approach for debugging `salt-ssh` is to simply use the tarball that salt ships to the remote machine and call `salt-call` directly.

To determine the location of `salt-call`, simply run `salt-ssh` with the `-ldebug` flag and look for a line containing the string, `SALT_ARGV`. This contains the `salt-call` command that `salt-ssh` attempted to execute.

It is recommended that one modify this command a bit by removing the `-l quiet`, `--metadata` and `--output json` to get a better idea of what's going on on the target system.

---

## Salt Rosters

---

Salt rosters are pluggable systems added in Salt 0.17.0 to facilitate the `salt-ssh` system. The roster system was created because `salt-ssh` needs a means to identify which systems need to be targeted for execution.

**See also:**

*Full list of builtin roster modules*

---

**Note:** The Roster System is not needed or used in standard Salt because the master does not need to be initially aware of target systems, since the Salt Minion checks itself into the master.

---

Since the roster system is pluggable, it can be easily augmented to attach to any existing systems to gather information about what servers are presently available and should be attached to by `salt-ssh`. By default the roster file is located at `/etc/salt/roster`.

### 29.1 How Rosters Work

The roster system compiles a data structure internally referred to as `targets`. The `targets` is a list of target systems and attributes about how to connect to said systems. The only requirement for a roster module in Salt is to return the `targets` data structure.

#### 29.1.1 Targets Data

The information which can be stored in a roster `target` is the following:

```
<Salt ID>:      # The id to reference the target system with
host:          # The IP address or DNS name of the remote host
user:          # The user to log in as
passwd:        # The password to log in with

# Optional parameters
port:          # The target system's ssh port number
sudo:          # Boolean to run command via sudo
priv:          # File path to ssh private key, defaults to salt-ssh.rsa
timeout:       # Number of seconds to wait for response when establishing
                # an SSH connection
minion_opts:   # Dictionary of minion opts
```

## 30.1 Full list of builtin auth modules

<i>auto</i>	An ``Always Approved" eauth interface to test against, not intended for
<i>django</i>	Provide authentication using Django Web Framework
<i>keystone</i>	Provide authentication using OpenStack Keystone
<i>ldap</i>	Provide authentication using simple LDAP binds
<i>mysql</i>	Provide authentication using MySQL.
<i>pam</i>	Authenticate against PAM
<i>pki</i>	Authenticate via a PKI certificate.
<i>stormpath_mod</i>	Salt Stormpath Authentication
<i>yubico</i>	Provide authentication using YubiKey.

### 30.1.1 salt.auth.auto

An ``Always Approved" eauth interface to test against, not intended for production use

```

salt.auth.auto.auth(username, password)
    Authenticate!

```

### 30.1.2 salt.auth.django

Provide authentication using Django Web Framework

#### depends

- Django Web Framework

Django authentication depends on the presence of the django framework in the PYTHONPATH, the Django project's settings.py file being in the PYTHONPATH and accessible via the DJANGO\_SETTINGS\_MODULE environment variable.

Django auth can be defined like any other eauth module:

```

external_auth:
  django:
    fred:
      - .*
      - '@runner'

```

This will authenticate Fred via Django and allow him to run any execution module and all runners.

The authorization details can optionally be located inside the Django database. The relevant entry in the `models.py` file would look like this:

```
class SaltExternalAuthModel(models.Model):
    user_fk = models.ForeignKey(auth.User)
    minion_matcher = models.CharField()
    minion_fn = models.CharField()
```

The `external_auth` clause in the master config would then look like this:

```
external_auth:
  django:
    ^model: <fully-qualified reference to model class>
```

When a user attempts to authenticate via Django, Salt will import the package indicated via the keyword `^model`. That model must have the fields indicated above, though the model DOES NOT have to be named `'SaltExternalAuthModel'`.

```
salt.auth.django.auth(username, password)
    Simple Django auth
```

```
salt.auth.django.django_auth_setup()
```

```
salt.auth.django.retrieve_auth_entries(u=None)
```

#### Parameters

- **django\_auth\_class** -- Reference to the django model class for auth
- **u** -- Username to filter for

**Returns** Dictionary that can be slotted into the `__opts__` structure for eauth that designates the user associated ACL

Database records such as:

username	minion_or_fn_matcher	minion_fn
fred		test.ping
fred	server1	network.interfaces
fred	server1	raid.list
fred	server2	.*
guru	.*	
smartadmin	server1	.*

Should result in an eauth config such as:

```
fred:
  - test.ping
  - server1:
    - network.interfaces
    - raid.list
  - server2:
    - .*
guru:
  - .*
smartadmin:
  - server1:
    - .*
```

### 30.1.3 salt.auth.keystone

Provide authentication using OpenStack Keystone

#### depends

- keystoneclient Python module

`salt.auth.keystone.auth(username, password)`

Try and authenticate

`salt.auth.keystone.get_auth_url()`

Try and get the URL from the config, else return localhost

### 30.1.4 salt.auth.ldap

Provide authentication using simple LDAP binds

#### depends

- ldap Python module

`salt.auth.ldap.auth(username, password)`

Simple LDAP auth

`salt.auth.ldap.groups(username, **kwargs)`

Authenticate against an LDAP group

Behavior is highly dependent on if Active Directory is in use.

AD handles group membership very differently than OpenLDAP. See the [External Authentication](#) documentation for a thorough discussion of available parameters for customizing the search.

OpenLDAP allows you to search for all groups in the directory and returns members of those groups. Then we check against the username entered.

### 30.1.5 salt.auth.mysql

Provide authentication using MySQL.

When using MySQL as an authentication backend, you will need to create or use an existing table that has a username and a password column.

To get started, create a simple table that holds just a username and a password. The password field will hold a SHA256 checksum.

```
CREATE TABLE `users` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `username` varchar(25) DEFAULT NULL,
  `password` varchar(70) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=2 DEFAULT CHARSET=latin1;
```

To create a user within MySQL, execute the following statement.

```
INSERT INTO users VALUES (NULL, 'diana', SHA2('secret', 256))
```

```
mysql_auth:
  hostname: localhost
  database: SaltStack
  username: root
  password: letmein
  auth_sql: 'SELECT username FROM users WHERE username = "{0}" AND password = SHA2("{1}", 256)'
```

The `auth_sql` contains the SQL that will validate a user to ensure they are correctly authenticated. This is where you can specify other SQL queries to authenticate users.

Enable MySQL authentication.

```
external_auth:
  mysql:
    damian:
      - test.*
```

#### depends

- MySQL-python Python module

`salt.auth.mysql.auth(username, password)`

Authenticate using a MySQL user table

### 30.1.6 salt.auth.pam

Authenticate against PAM

Provides an authenticate function that will allow the caller to authenticate a user against the Pluggable Authentication Modules (PAM) on the system.

Implemented using ctypes, so no compilation is necessary.

There is one extra configuration option for pam. The `pam_service` that is authenticated against. This defaults to `login`

```
auth.pam.service: login
```

---

**Note:** PAM authentication will not work for the `root` user.

The Python interface to PAM does not support authenticating as `root`.

---

class `salt.auth.pam.PamConv`

Wrapper class for `pam_conv` structure

**appdata\_ptr**

Structure/Union member

**conv**

Structure/Union member

class `salt.auth.pam.PamHandle`

Wrapper class for `pam_handle_t`

**handle**

Structure/Union member

class `salt.auth.pam.PamMessage`

Wrapper class for `pam_message` structure

**msg**

Structure/Union member

**msg\_style**

Structure/Union member

**class salt.auth.pam.PamResponse**

Wrapper class for pam\_response structure

**resp**

Structure/Union member

**resp\_retcode**

Structure/Union member

**salt.auth.pam.auth**(*username*, *password*, *\*\*kwargs*)

Authenticate via pam

**salt.auth.pam.authenticate**(*username*, *password*)

Returns True if the given username and password authenticate for the given service. Returns False otherwise

*username*: the username to authenticate*password*: the password in plain text**salt.auth.pam.groups**(*username*, *\*args*, *\*\*kwargs*)

Retrieve groups for a given user for this auth provider

Uses system groups

### 30.1.7 salt.auth.pki

Authenticate via a PKI certificate.

**Note:** This module is Experimental and should be used with caution

Provides an authenticate function that will allow the caller to authenticate a user via their public cert against a pre-defined Certificate Authority.

TODO: Add a `ca_dir` option to configure a directory of CA files, a la Apache.**depends**

- pyOpenSSL module

**salt.auth.pki.auth**(*pem*, *\*\*kwargs*)

Returns True if the given user cert was issued by the CA. Returns False otherwise.

*pem*: a pem-encoded user public key (certificate)

Configure the CA cert in the master config file:

```
external_auth:
  pki:
    ca_file: /etc/pki/tls/ca_certs/trusted-ca.crt
```

### 30.1.8 salt.auth.stormpath\_mod

Salt Stormpath Authentication

Module to provide authentication using Stormpath as the backend.

**depends**

- stormpath-sdk Python module

**configuration** This module requires the development branch of the stormpath-sdk which can be found here: <https://github.com/stormpath/stormpath-sdk-python>

The following config items are required in the master config:

```
stormpath.api_key_file: <path/to/apiKey.properties>
stormpath.app_url: <Rest url of your Stormpath application>
```

Ensure that your apiKey.properties is readable by the user the Salt Master is running as, but not readable by other system users.

`salt.auth.stormpath_mod.auth` (*username, password*)  
Try and authenticate

### 30.1.9 salt.auth.yubico

Provide authentication using YubiKey.

New in version 2015.5.0.

**depends** yubico-client Python module

To get your YubiKey API key you will need to visit the website below.

<https://upgrade.yubico.com/getapikey/>

The resulting page will show the generated Client ID (aka AuthID or API ID) and the generated API key (Secret Key). Make a note of both and use these two values in your /etc/salt/master configuration.

/etc/salt/master

```
yubico_users:
  damian:
    id: 12345
    key: ABCDEFGHIJKLMNOPQRSTUVWXYZ
```

```
external_auth:
  yubico:
    damian:
      - test.*
```

Please wait five to ten minutes after generating the key before testing so that the API key will be updated on all the YubiCloud servers.

`salt.auth.yubico.auth` (*username, password*)  
Authenticate against yubico server

## 30.2 Command Line Reference

Salt can be controlled by a command line client by the root user on the Salt master. The Salt command line client uses the Salt client API to communicate with the Salt master server. The Salt client is straightforward and simple to use.

Using the Salt client commands can be easily sent to the minions.

Each of these commands accepts an explicit `--config` option to point to either the master or minion configuration file. If this option is not provided and the default configuration file does not exist then Salt falls back to use the environment variables `SALT_MASTER_CONFIG` and `SALT_MINION_CONFIG`.

See also:

[Configuration](#)

### 30.2.1 Using the Salt Command

The Salt command needs a few components to send information to the Salt minions. The target minions need to be defined, the function to call and any arguments the function requires.

#### Defining the Target Minions

The first argument passed to salt, defines the target minions, the target minions are accessed via their hostname. The default target type is a bash glob:

```
salt '*foo.com' sys.doc
```

Salt can also define the target minions with regular expressions:

```
salt -E '.*' cmd.run 'ls -l | grep foo'
```

Or to explicitly list hosts, salt can take a list:

```
salt -L foo.bar.baz,quo.qux cmd.run 'ps aux | grep foo'
```

#### More Powerful Targets

The simple target specifications, glob, regex, and list will cover many use cases, and for some will cover all use cases, but more powerful options exist.

#### Targeting with Grains

The Grains interface was built into Salt to allow minions to be targeted by system properties. So minions running on a particular operating system can be called to execute a function, or a specific kernel.

Calling via a grain is done by passing the `-G` option to salt, specifying a grain and a glob expression to match the value of the grain. The syntax for the target is the grain key followed by a globexpression: ``os:Arch*``.

```
salt -G 'os:Fedora' test.ping
```

Will return True from all of the minions running Fedora.

To discover what grains are available and what the values are, execute the `grains.items` salt function:

```
salt '*' grains.items
```

more info on using targeting with grains can be found [here](#).

## Targeting with Executions

As of 0.8.8 targeting with executions is still under heavy development and this documentation is written to reference the behavior of execution matching in the future.

Execution matching allows for a primary function to be executed, and then based on the return of the primary function the main function is executed.

Execution matching allows for matching minions based on any arbitrary running data on the minions.

## Compound Targeting

New in version 0.9.5.

Multiple target interfaces can be used in conjunction to determine the command targets. These targets can then be combined using and or or statements. This is well defined with an example:

```
salt -C 'G@os:Debian and webser* or E@db.*' test.ping
```

In this example any minion who's id starts with `webser` and is running Debian, or any minion who's id starts with `db` will be matched.

The type of matcher defaults to glob, but can be specified with the corresponding letter followed by the `@` symbol. In the above example a grain is used with `G@` as well as a regular expression with `E@`. The `webser*` target does not need to be prefaced with a target type specifier because it is a glob.

more info on using compound targeting can be found [here](#).

## Node Group Targeting

New in version 0.9.5.

For certain cases, it can be convenient to have a predefined group of minions on which to execute commands. This can be accomplished using what are called *nodegroups*. Nodegroups allow for predefined compound targets to be declared in the master configuration file, as a sort of shorthand for having to type out complicated compound expressions.

```
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com and bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
  group3: 'G@os:Debian and N@group1'
```

## Calling the Function

The function to call on the specified target is placed after the target specification.

New in version 0.9.8.

Functions may also accept arguments, space-delimited:

```
salt '*' cmd.exec_code python 'import sys; print sys.version'
```

Optional, keyword arguments are also supported:

```
salt '*' pip.install salt timeout=5 upgrade=True
```

They are always in the form of `kwarg=argument`.

Arguments are formatted as YAML:

```
salt '*' cmd.run 'echo "Hello: $FIRST_NAME"' env='{FIRST_NAME: "Joe"}'
```

Note: dictionaries must have curly braces around them (like the `env` keyword argument above). This was changed in 0.15.1: in the above example, the first argument used to be parsed as the dictionary `{'echo "Hello: $FIRST_NAME"'}`. This was generally not the expected behavior.

If you want to test what parameters are actually passed to a module, use the `test.arg_repr` command:

```
salt '*' test.arg_repr 'echo "Hello: $FIRST_NAME"' env='{FIRST_NAME: "Joe"}'
```

### Finding available minion functions

The Salt functions are self documenting, all of the function documentation can be retrieved from the minions via the `sys.doc()` function:

```
salt '*' sys.doc
```

### Compound Command Execution

If a series of commands needs to be sent to a single target specification then the commands can be sent in a single publish. This can make gathering groups of information faster, and lowers the stress on the network for repeated commands.

Compound command execution works by sending a list of functions and arguments instead of sending a single function and argument. The functions are executed on the minion in the order they are defined on the command line, and then the data from all of the commands are returned in a dictionary. This means that the set of commands are called in a predictable way, and the returned data can be easily interpreted.

Executing compound commands if done by passing a comma delimited list of functions, followed by a comma delimited list of arguments:

```
salt '*' cmd.run, test.ping, test.echo 'cat /proc/cpuinfo', , foo
```

The trick to look out for here, is that if a function is being passed no arguments, then there needs to be a placeholder for the absent arguments. This is why in the above example, there are two commas right next to each other. `test.ping` takes no arguments, so we need to add another comma, otherwise Salt would attempt to pass `foo` to `test.ping`.

If you need to pass arguments that include commas, then make sure you add spaces around the commas that separate arguments. For example:

```
salt '*' cmd.run, test.ping, test.echo 'echo "1,2,3"' , , foo
```

You may change the arguments separator using the `--args-separator` option:

```
salt --args-separator=: '*' some.fun, test.echo params with , comma :: foo
```

## 30.2.2 CLI Completion

Shell completion scripts for the Salt CLI are available in the `pkg` Salt [source directory](#).

### 30.2.3 salt-call

#### salt-call

##### Synopsis

```
salt-call [options]
```

##### Description

The salt-call command is used to run module functions locally on a minion instead of executing them from the master. Salt-call is used to run a *Standalone Minion*, and was originally created for *troubleshooting*.

The Salt Master is contacted to retrieve state files and other resources during execution unless the `--local` option is specified.

---

**Note:** `salt-call` commands execute from the current user's shell context, while `salt` commands execute from the system's default context.

---

##### Options

###### **--version**

Print the version of Salt that is running.

###### **--versions-report**

Show program's dependencies and version number, and then exit

###### **-h, --help**

Show the help message and exit

###### **-c CONFIG\_DIR, --config-dir=CONFIG\_dir**

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

###### **--hard-crash**

Raise any original exception rather than exiting gracefully Default: False

###### **-g, --grains**

Return the information generated by the Salt grains

###### **-m MODULE\_DIRS, --module-dirs=MODULE\_DIRS**

Specify an additional directory to pull modules from. Multiple directories can be provided by passing `-m` `/--module-dirs` multiple times.

###### **-d, --doc, --documentation**

Return the documentation for the specified module or for all modules if none are specified

###### **--master=MASTER**

Specify the master to use. The minion must be authenticated with the master. If this option is omitted, the master options from the minion config will be used. If multi masters are set up the first listed master that responds will be used.

###### **--return RETURNER**

Set salt-call to pass the return data to one or many returner interfaces. To use many returner interfaces specify a comma delimited list of returners.

**--local**

Run salt-call locally, as if there was no master running.

**--file-root=FILE\_ROOT**

Set this directory as the base file root.

**--pillar-root=PILLAR\_ROOT**

Set this directory as the base pillar root.

**--retcode-passthrough**

Exit with the salt call retcode and not the salt binary retcode

**--metadata**

Print out the execution metadata as well as the return. This will print out the outputter data, the return code, etc.

**--id=ID**

Specify the minion id to use. If this option is omitted, the id option from the minion config will be used.

**--skip-grains**

Do not load grains.

**--refresh-grains-cache**

Force a refresh of the grains cache

**Logging Options** Logging options which override any settings defined on the configuration files.

**-l LOG\_LEVEL, --log-level=LOG\_LEVEL**

Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: info.

**--log-file=LOG\_FILE**

Log file path. Default: /var/log/salt/minion.

**--log-file-level=LOG\_LEVEL\_LOGFILE**

Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: info.

**Output Options****--out**

Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:

grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputters are formatted only for data returned from specific functions; for instance, the `grains` outputter will not work for non-grains data.

If an outputter is used that does not support the data passed into it, then Salt will fall back on the `pprint` outputter and display the return data using the Python `pprint` standard library module.

---

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use `--static` as well.

---

**--out-indent OUTPUT\_INDENT, --output-indent OUTPUT\_INDENT**

Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.

**--out-file=OUTPUT\_FILE, --output-file=OUTPUT\_FILE**

Write the output to the specified file.

**--no-color**

Disable all colored output

**--force-color**

Force colored output

---

**Note:** When using colored output the color codes are as follows:

green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

---

*salt(1) salt-master(1) salt-minion(1)*

## 30.2.4 salt

### salt

#### Synopsis

```
salt '*' [ options ] sys.doc
```

```
salt -E '*' [ options ] sys.doc cmd
```

```
salt -G 'os:Arch.*' [ options ] test.ping
```

```
salt -C 'G@os:Arch.* and webserv*' or G@kernel:FreeBSD' [ options ] test.ping
```

#### Description

Salt allows for commands to be executed across a swath of remote systems in parallel. This means that remote systems can be both controlled and queried with ease.

#### Options

**--version**

Print the version of Salt that is running.

**--versions-report**

Show program's dependencies and version number, and then exit

**-h, --help**

Show the help message and exit

**-c CONFIG\_DIR, --config-dir=CONFIG\_dir**

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

- t** TIMEOUT, **--timeout=TIMEOUT**  
The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 5
- s, --static**  
By default as of version 0.9.8 the salt command returns data to the console as it is received from minions, but previous releases would return data only after all data was received. Use the static option to only return the data with a hard timeout and after all minions have returned. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole.
- async**  
Instead of waiting for the job to run on minions only print the job id of the started execution and complete.
- state-output=STATE\_OUTPUT**  
New in version 0.17.  
Override the configured `state_output` value for minion output. One of `full`, `terse`, `mixed`, `changes` or `filter`. Default: `full`.
- subset=SUBSET**  
Execute the routine on a random subset of the targeted minions. The minions will be verified that they have the named function before executing.
- v** VERBOSE, **--verbose**  
Turn on verbosity for the salt call, this will cause the salt command to print out extra data like the job id.
- hide-timeout**  
Instead of showing the return data for all minions. This option prints only the online minions which could be reached.
- b** BATCH, **--batch-size=BATCH**  
Instead of executing on all targeted minions at once, execute on a progressive set of minions. This option takes an argument in the form of an explicit number of minions to execute at once, or a percentage of minions to execute on.
- a** EAUTH, **--auth=EAUTH**  
Pass in an external authentication medium to validate against. The credentials will be prompted for. The options are *auto*, *keystone*, *ldap*, *pam*, and *stormpath*. Can be used with the `-T` option.
- T, --make-token**  
Used in conjunction with the `-a` option. This creates a token that allows for the authenticated user to send commands without needing to re-authenticate.
- return=RETURNER**  
Choose an alternative returner to call on the minion, if an alternative returner is used then the return will not come back to the command line but will be sent to the specified return system. The options are *carbon*, *cassandra*, *couchbase*, *couchdb*, *elasticsearch*, *etcd*, *hipchat*, *local*, *local\_cache*, *memcache*, *mongo*, *mysql*, *odbc*, *postgres*, *redis*, *sentry*, *slack*, *sms*, *smtp*, *sqlite3*, *syslog*, and *xmpp*.
- d, --doc, --documentation**  
Return the documentation for the module functions available on the minions
- args-separator=ARGS\_SEPARATOR**  
Set the special argument used as a delimiter between command arguments of compound commands. This is useful when one wants to pass commas as arguments to some of the commands in a compound command.

**Logging Options** Logging options which override any settings defined on the configuration files.

- l LOG\_LEVEL, --log-level=LOG\_LEVEL**  
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.
- log-file=LOG\_FILE**  
Log file path. Default: /var/log/salt/master.
- log-file-level=LOG\_LEVEL\_LOGFILE**  
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

#### Target Selection

- E, --pcre**  
The target expression will be interpreted as a PCRE regular expression rather than a shell glob.
- L, --list**  
The target expression will be interpreted as a comma-delimited list; example: server1.foo.bar,server2.foo.bar,example7.who.qux
- G, --grain**  
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of '<grain value>:<glob expression>'; example: 'os:Arch\*'   
  
This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular expression matching with grains, use the --grain-pcre option.
- grain-pcre**  
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of '<grain value>:< regular expression>'; example: 'os:Arch.\*'
- N, --nodegroup**  
Use a predefined compound target defined in the Salt master configuration file.
- R, --range**  
Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions look like %cluster.   
  
Using the Range option requires that a range server is set up and the location of the range server is referenced in the master configuration file.
- C, --compound**  
Utilize many target definitions to make the call very granular. This option takes a group of targets separated by and or or. The default matcher is a glob as usual. If something other than a glob is used, preface it with the letter denoting the type; example: 'webserv\*' and G@os:Debian or E@db\*' Make sure that the compound target is encapsulated in quotes.
- I, --pillar**  
Instead of using shell globs to evaluate the target, use a pillar value to identify targets. The syntax for the target is the pillar key followed by a glob expression: ''role:production\*''
- S, --ipcidr**  
Match based on Subnet (CIDR notation) or IPv4 address.

#### Output Options

- out**  
Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:  
  
grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputters are formatted only for data returned from specific functions; for instance, the `grains` outputter will not work for non-grains data.

If an outputter is used that does not support the data passed into it, then Salt will fall back on the `pprint` outputter and display the return data using the Python `pprint` standard library module.

---

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use `--static` as well.

---

**--out-indent** OUTPUT\_INDENT, **--output-indent** OUTPUT\_INDENT

Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.

**--out-file=OUTPUT\_FILE**, **--output-file=OUTPUT\_FILE**

Write the output to the specified file.

**--no-color**

Disable all colored output

**--force-color**

Force colored output

---

**Note:** When using colored output the color codes are as follows:

green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

---

## 30.2.5 salt-cloud

## 30.2.6 salt-cp

### salt-cp

Copy a file to a set of systems

#### Synopsis

```
salt-cp '*' [ options ] SOURCE DEST
salt-cp -E '*' [ options ] SOURCE DEST
salt-cp -G 'os:Arch.*' [ options ] SOURCE DEST
```

#### Description

Salt copy copies a local file out to all of the Salt minions matched by the given target.

## Options

### **--version**

Print the version of Salt that is running.

### **--versions-report**

Show program's dependencies and version number, and then exit

### **-h, --help**

Show the help message and exit

### **-c CONFIG\_DIR, --config-dir=CONFIG\_dir**

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

### **-t TIMEOUT, --timeout=TIMEOUT**

The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 5

**Logging Options** Logging options which override any settings defined on the configuration files.

### **-l LOG\_LEVEL, --log-level=LOG\_LEVEL**

Console logging log level. One of `all`, `garbage`, `trace`, `debug`, `info`, `warning`, `error`, `quiet`. Default: `warning`.

### **--log-file=LOG\_FILE**

Log file path. Default: `/var/log/salt/master`.

### **--log-file-level=LOG\_LEVEL\_LOGFILE**

Logfile logging log level. One of `all`, `garbage`, `trace`, `debug`, `info`, `warning`, `error`, `quiet`. Default: `warning`.

## Target Selection

### **-E, --pcre**

The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

### **-L, --list**

The target expression will be interpreted as a comma-delimited list; example: `server1.foo.bar,server2.foo.bar,example7.quo.qux`

### **-G, --grain**

The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<glob expression>`; example: ``os:Arch*``

This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular expression matching with grains, use the `--grain-pcre` option.

### **--grain-pcre**

The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:< regular expression>`; example: ``os:Arch.*``

### **-N, --nodegroup**

Use a predefined compound target defined in the Salt master configuration file.

### **-R, --range**

Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions look like `%cluster`.

Using the Range option requires that a range server is set up and the location of the range server is referenced in the master configuration file.

*salt(1) salt-master(1) salt-minion(1)*

### 30.2.7 salt-key

#### salt-key

##### Synopsis

```
salt-key [ options ]
```

##### Description

Salt-key executes simple management of Salt server public keys used for authentication.

On initial connection, a Salt minion sends its public key to the Salt master. This key must be accepted using the `salt-key` command on the Salt master.

Salt minion keys can be in one of the following states:

- **unaccepted:** key is waiting to be accepted.
- **accepted:** key was accepted and the minion can communicate with the Salt master.
- **rejected:** key was rejected using the `salt-key` command. In this state the minion does not receive any communication from the Salt master.
- **denied:** key was rejected automatically by the Salt master. This occurs when a minion has a duplicate ID, or when a minion was rebuilt or had new keys generated and the previous key was not deleted from the Salt master. In this state the minion does not receive any communication from the Salt master.

To change the state of a minion key, use `-d` to delete the key and then accept or reject the key.

##### Options

###### **--version**

Print the version of Salt that is running.

###### **--versions-report**

Show program's dependencies and version number, and then exit

###### **-h, --help**

Show the help message and exit

###### **-c** CONFIG\_DIR, **--config-dir**=CONFIG\_dir

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

###### **-u** USER, **--user**=USER

Specify user to run salt-key

###### **--hard-crash**

Raise any original exception rather than exiting gracefully. Default is False.

**-q, --quiet**

Suppress output

**-y, --yes**

Answer 'Yes' to all questions presented, defaults to False

**--rotate-aes-key=ROTATE\_AES\_KEY**

Setting this to False prevents the master from refreshing the key session when keys are deleted or rejected, this lowers the security of the key deletion/rejection operation. Default is True.

**Logging Options** Logging options which override any settings defined on the configuration files.

**--log-file=LOG\_FILE**

Log file path. Default: /var/log/salt/minion.

**--log-file-level=LOG\_LEVEL\_LOGFILE**

Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

**Output Options**

**--out**

Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:

grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputters are formatted only for data returned from specific functions; for instance, the `grains` outputter will not work for non-grains data.

If an outputter is used that does not support the data passed into it, then Salt will fall back on the `pprint` outputter and display the return data using the Python `pprint` standard library module.

---

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use `--static` as well.

---

**--out-indent OUTPUT\_INDENT, --output-indent OUTPUT\_INDENT**

Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.

**--out-file=OUTPUT\_FILE, --output-file=OUTPUT\_FILE**

Write the output to the specified file.

**--no-color**

Disable all colored output

**--force-color**

Force colored output

---

**Note:** When using colored output the color codes are as follows:

green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

---

**Actions**

- l** ARG, **--list=ARG**  
List the public keys. The args `pre`, `un`, and `unaccepted` will list unaccepted/unsigned keys. `acc` or `accepted` will list accepted/signed keys. `rej` or `rejected` will list rejected keys. Finally, `all` will list all keys.
- L**, **--list-all**  
List all public keys. (Deprecated: use `--list all`)
- a** ACCEPT, **--accept=ACCEPT**  
Accept the specified public key (use `--include-all` to match rejected keys in addition to pending keys). Globs are supported.
- A**, **--accept-all**  
Accepts all pending keys.
- r** REJECT, **--reject=REJECT**  
Reject the specified public key (use `--include-all` to match accepted keys in addition to pending keys). Globs are supported.
- R**, **--reject-all**  
Rejects all pending keys.
- include-all**  
Include non-pending keys when accepting/rejecting.
- p** PRINT, **--print=PRINT**  
Print the specified public key.
- P**, **--print-all**  
Print all public keys
- d** DELETE, **--delete=DELETE**  
Delete the specified key. Globs are supported.
- D**, **--delete-all**  
Delete all keys.
- f** FINGER, **--finger=FINGER**  
Print the specified key's fingerprint.
- F**, **--finger-all**  
Print all keys' fingerprints.

#### Key Generation Options

- gen-keys=GEN\_KEYS**  
Set a name to generate a keypair for use with salt
- gen-keys-dir=GEN\_KEYS\_DIR**  
Set the directory to save the generated keypair. Only works with `'gen_keys_dir'` option; default is the current directory.
- keysize=KEYSIZE**  
Set the keysize for the generated key, only works with the `'--gen-keys'` option, the key size must be 2048 or higher, otherwise it will be rounded up to 2048. The default is 2048.
- gen-signature**  
Create a signature file of the master's public-key named `master_pubkey_signature`. The signature can be sent to a minion in the master's `auth-reply` and enables the minion to verify the master's public-key cryptographically. This requires a new signing-key-pair which can be auto-created with the `--auto-create` parameter.
- priv=PRIV**  
The private-key file to create a signature with

- signature-path**=SIGNATURE\_PATH  
The path where the signature file should be written
- pub**=PUB  
The public-key file to create a signature for
- auto-create**  
Auto-create a signing key-pair if it does not yet exist

## 30.2.8 salt-master

### salt-master

The Salt master daemon, used to control the Salt minions

#### Synopsis

```
salt-master [ options ]
```

#### Description

The master daemon controls the Salt minions

#### Options

- version**  
Print the version of Salt that is running.
- versions-report**  
Show program's dependencies and version number, and then exit
- h, --help**  
Show the help message and exit
- c** CONFIG\_DIR, **--config-dir**=CONFIG\_dir  
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.
- u** USER, **--user**=USER  
Specify user to run salt-master
- d, --daemon**  
Run salt-master as a daemon
- pid-file** PIDFILE  
Specify the location of the pidfile. Default: `/var/run/salt-master.pid`

**Logging Options** Logging options which override any settings defined on the configuration files.

**-l LOG\_LEVEL, --log-level=LOG\_LEVEL**

Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

**--log-file=LOG\_FILE**

Log file path. Default: /var/log/salt/master.

**--log-file-level=LOG\_LEVEL\_LOGFILE**

Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

## 30.2.9 salt-minion

### salt-minion

The Salt minion daemon, receives commands from a remote Salt master.

#### Synopsis

```
salt-minion [ options ]
```

#### Description

The Salt minion receives commands from the central Salt master and replies with the results of said commands.

#### Options

**--version**

Print the version of Salt that is running.

**--versions-report**

Show program's dependencies and version number, and then exit

**-h, --help**

Show the help message and exit

**-c CONFIG\_DIR, --config-dir=CONFIG\_dir**

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

**-u USER, --user=USER**

Specify user to run salt-minion

**-d, --daemon**

Run salt-minion as a daemon

**--pid-file** PIDFILE

Specify the location of the pidfile. Default: `/var/run/salt-minion.pid`

**Logging Options** Logging options which override any settings defined on the configuration files.

**-l** LOG\_LEVEL, **--log-level**=LOG\_LEVEL

Console logging log level. One of `all`, `garbage`, `trace`, `debug`, `info`, `warning`, `error`, `quiet`. Default: `warning`.

**--log-file**=LOG\_FILE

Log file path. Default: `/var/log/salt/minion`.

**--log-file-level**=LOG\_LEVEL\_LOGFILE

Logfile logging log level. One of `all`, `garbage`, `trace`, `debug`, `info`, `warning`, `error`, `quiet`. Default: `warning`.

### 30.2.10 salt-run

#### **salt-run**

Execute a Salt runner

#### Synopsis

```
salt-run RUNNER
```

#### Description

`salt-run` is the frontend command for executing Salt Runners. Salt runners are simple modules used to execute convenience functions on the master

#### Options

**--version**

Print the version of Salt that is running.

**--versions-report**

Show program's dependencies and version number, and then exit

**-h, --help**

Show the help message and exit

**-c** CONFIG\_DIR, **--config-dir**=CONFIG\_dir

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

**-t** TIMEOUT, **--timeout**=TIMEOUT

The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 1

**--hard-crash**

Raise any original exception rather than exiting gracefully. Default is False.

**-d**, **--doc**, **--documentation**

Display documentation for runners, pass a module or a runner to see documentation on only that module/runner.

**Logging Options** Logging options which override any settings defined on the configuration files.

**-l** LOG\_LEVEL, **--log-level**=LOG\_LEVEL

Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

**--log-file**=LOG\_FILE

Log file path. Default: /var/log/salt/master.

**--log-file-level**=LOG\_LEVEL\_LOGFILE

Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

### 30.2.11 salt-ssh

#### salt-ssh

##### Synopsis

```

salt-ssh '*' [ options ] sys.doc
salt-ssh -E '.*' [ options ] sys.doc cmd

```

##### Description

Salt SSH allows for salt routines to be executed using only SSH for transport

##### Options

**-r**, **--raw**, **--raw-shell**

Execute a raw shell command.

**--priv**

Specify the SSH private key file to be used for authentication.

**--roster**

Define which roster system to use, this defines if a database backend, scanner, or custom roster system is used. Default is the flat file roster.

**--roster-file**

Define an alternative location for the default roster file location. The default roster file is called `roster` and is found in the same directory as the master config file.

New in version 2014.1.0.

**--refresh, --refresh-cache**

Force a refresh of the master side data cache of the target's data. This is needed if a target's grains have been changed and the auto refresh timeframe has not been reached.

**--max-procs**

Set the number of concurrent minions to communicate with. This value defines how many processes are opened up at a time to manage connections, the more running process the faster communication should be, default is 25.

**-i, --ignore-host-keys**

Ignore the ssh host keys which by default are honored and connections would ask for approval.

**--passwd**

Set the default password to attempt to use when authenticating.

**--key-deploy**

Set this flag to attempt to deploy the authorized ssh key with all minions. This combined with `--passwd` can make initial deployment of keys very fast and easy.

**--version**

Print the version of Salt that is running.

**--versions-report**

Show program's dependencies and version number, and then exit

**-h, --help**

Show the help message and exit

**-c CONFIG\_DIR, --config-dir=CONFIG\_dir**

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

**Target Selection****-E, --pcre**

The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

**-L, --list**

The target expression will be interpreted as a comma-delimited list; example: `server1.foo.bar,server2.foo.bar,example7.quo.qux`

**-G, --grain**

The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<glob expression>`; example: ``os:Arch*`

This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular expression matching with grains, use the `--grain-pcre` option.

**--grain-pcre**

The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<regular expression>`; example: ``os:Arch.*`

**-N, --nodegroup**

Use a predefined compound target defined in the Salt master configuration file.

**-R, --range**

Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions look like `%cluster`.

Using the Range option requires that a range server is set up and the location of the range server is referenced in the master configuration file.

**Logging Options** Logging options which override any settings defined on the configuration files.

**-l LOG\_LEVEL, --log-level=LOG\_LEVEL**

Console logging log level. One of `all`, `garbage`, `trace`, `debug`, `info`, `warning`, `error`, `quiet`. Default: `warning`.

**--log-file=LOG\_FILE**

Log file path. Default: `/var/log/salt/ssh`.

**--log-file-level=LOG\_LEVEL\_LOGFILE**

Logfile logging log level. One of `all`, `garbage`, `trace`, `debug`, `info`, `warning`, `error`, `quiet`. Default: `warning`.

**Output Options****--out**

Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:

`grains`, `highstate`, `json`, `key`, `overstatestage`, `pprint`, `raw`, `txt`, `yaml`

Some outputters are formatted only for data returned from specific functions; for instance, the `grains` outputter will not work for non-grains data.

If an outputter is used that does not support the data passed into it, then Salt will fall back on the `pprint` outputter and display the return data using the Python `pprint` standard library module.

---

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the `static` option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use `--static` as well.

---

**--out-indent OUTPUT\_INDENT, --output-indent OUTPUT\_INDENT**

Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.

**--out-file=OUTPUT\_FILE, --output-file=OUTPUT\_FILE**

Write the output to the specified file.

**--no-color**

Disable all colored output

**--force-color**

Force colored output

---

**Note:** When using colored output the color codes are as follows:

`green` denotes success, `red` denotes failure, `blue` denotes changes and success and `yellow` denotes a expected future change in configuration.

---

### 30.2.12 salt-syndic

#### salt-syndic

The Salt syndic daemon, a special minion that passes through commands from a higher master

#### Synopsis

```
salt-syndic [ options ]
```

#### Description

The Salt syndic daemon, a special minion that passes through commands from a higher master.

#### Options

**--version**

Print the version of Salt that is running.

**--versions-report**

Show program's dependencies and version number, and then exit

**-h, --help**

Show the help message and exit

**-c** CONFIG\_DIR, **--config-dir**=CONFIG\_dir

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

**-u** USER, **--user**=USER

Specify user to run salt-syndic

**-d, --daemon**

Run salt-syndic as a daemon

**--pid-file** PIDFILE

Specify the location of the pidfile. Default: `/var/run/salt-syndic.pid`

**Logging Options** Logging options which override any settings defined on the configuration files.

**-l** LOG\_LEVEL, **--log-level**=LOG\_LEVEL

Console logging log level. One of `all`, `garbage`, `trace`, `debug`, `info`, `warning`, `error`, `quiet`. Default: `warning`.

**--log-file**=LOG\_FILE

Log file path. Default: `/var/log/salt/master`.

**--log-file-level=LOG\_LEVEL\_LOGFILE**

Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

### 30.2.13 salt-api

#### salt-api

Start interfaces used to remotely connect to the salt master

#### Synopsis

```
salt-api
```

#### Description

The Salt API system manages network api connectors for the Salt Master

#### Options

##### **--version**

Print the version of Salt that is running.

##### **--versions-report**

Show program's dependencies and version number, and then exit

##### **-h, --help**

Show the help message and exit

##### **-c CONFIG\_DIR, --config-dir=CONFIG\_dir**

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

##### **-d, --daemon**

Run the salt-api as a daemon

##### **--pid-file=PIDFILE**

Specify the location of the pidfile. Default: `/var/run/salt-api.pid`

**Logging Options** Logging options which override any settings defined on the configuration files.

##### **-l LOG\_LEVEL, --log-level=LOG\_LEVEL**

Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

##### **--log-file=LOG\_FILE**

Log file path. Default: `/var/log/salt/api`.

**--log-file-level=LOG\_LEVEL\_LOGFILE**

Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

`salt-api(7)` `salt(7)` `salt-master(1)`

## 30.3 Client ACL system

The salt client ACL system is a means to allow system users other than root to have access to execute select salt commands on minions from the master.

The client ACL system is configured in the master configuration file via the `client_acl` configuration option. Under the `client_acl` configuration option the users open to send commands are specified and then a list of regular expressions which specify the minion functions which will be made available to specified user. This configuration is much like the `peer` configuration:

```
client_acl:
  # Allow thatch to execute anything.
  thatch:
    - .*
  # Allow fred to use test and pkg, but only on "web*" minions.
  fred:
    - web*:
      - test.*
      - pkg.*
```

### 30.3.1 Permission Issues

Directories required for `client_acl` must be modified to be readable by the users specified:

```
chmod 755 /var/cache/salt /var/cache/salt/master /var/cache/salt/master/jobs /var/run/salt /var/run/s
```

**Note:** In addition to the changes above you will also need to modify the permissions of `/var/log/salt` and the existing log file to be writable by the user(s) which will be running the commands. If you do not wish to do this then you must disable logging or Salt will generate errors as it cannot write to the logs as the system users.

If you are upgrading from earlier versions of salt you must also remove any existing user keys and re-start the Salt master:

```
rm /var/cache/salt/*.key
service salt-master restart
```

## 30.4 Python client API

Salt provides several entry points for interfacing with Python applications. These entry points are often referred to as `*Client()` APIs. Each client accesses different parts of Salt, either from the master or from a minion. Each client is detailed below.

See also:

There are many ways to access Salt programmatically.

Salt can be used from CLI scripts as well as via a REST interface.

See Salt's *outputter system* to retrieve structured data from Salt as JSON, or as shell-friendly text, or many other formats.

See the *state.event* runner to utilize Salt's event bus from shell scripts.

Salt's *netapi module* provides access to Salt externally via a REST interface. Review the *netapi module* documentation for more information.

### 30.4.1 Salt's opts dictionary

Some clients require access to Salt's *opts* dictionary. (The dictionary representation of the *master* or *minion* config files.)

A common pattern for fetching the *opts* dictionary is to defer to environment variables if they exist or otherwise fetch the config from the default location.

```
salt.config.client_config(path, env_var='SALT_CLIENT_CONFIG', defaults=None)
    Load Master configuration data
```

Usage:

```
import salt.config
master_opts = salt.config.client_config('/etc/salt/master')
```

Returns a dictionary of the Salt Master configuration file with necessary options needed to communicate with a locally-running Salt Master daemon. This function searches for client specific configurations and adds them to the data from the master configuration.

This is useful for master-side operations like *LocalClient*.

```
salt.config.minion_config(path, env_var='SALT_MINION_CONFIG', defaults=None,
                        cache_minion_id=False)
    Reads in the minion configuration file and sets up special options
```

This is useful for Minion-side operations, such as the *Caller* class, and manually running the loader interface.

```
import salt.client
minion_opts = salt.config.minion_config('/etc/salt/minion')
```

### 30.4.2 Salt's Loader Interface

Modules in the Salt ecosystem are loaded into memory using a custom loader system. This allows modules to have conditional requirements (OS, OS version, installed libraries, etc) and allows Salt to inject special variables (*\_\_salt\_\_*, *\_\_opts\_\_*, etc).

Most modules can be manually loaded. This is often useful in third-party Python apps or when writing tests. However some modules require and expect a full, running Salt system underneath. Notably modules that facilitate master-to-minion communication such as the *mine*, *publish*, and *peer* execution modules. The error *KeyError: 'master\_uri'* is a likely indicator for this situation. In those instances use the *Caller* class to execute those modules instead.

Each module type has a corresponding loader function.

```
salt.loader.minion_mods(opts, context=None, whitelist=None, include_errors=False, initial_load=False,
                       loaded_base_name=None)
    Load execution modules
```

Returns a dictionary of execution modules appropriate for the current system by evaluating the `__virtual__()` function in each module.

```
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
__grains__ = salt.loader.grains(__opts__)
__opts__['grains'] = __grains__
__salt__ = salt.loader.minion_mods(__opts__)
__salt__['test.ping']()
```

`salt.loader.raw_mod(opts, name, functions, mod='modules')`  
Returns a single module loaded raw and bypassing the `__virtual__` function

```
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
testmod = salt.loader.raw_mod(__opts__, 'test', None)
testmod['test.ping']()
```

`salt.loader.states(opts, functions, whitelist=None)`  
Returns the state modules

```
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
statemods = salt.loader.states(__opts__, None)
```

`salt.loader.grains(opts, force_refresh=False)`  
Return the functions for the dynamic grains and the values for the static grains.

```
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
__grains__ = salt.loader.grains(__opts__)
print __grains__['id']
```

### 30.4.3 Salt's Client Interfaces

#### LocalClient

`class salt.client.LocalClient(c_path='/etc/salt/master', mopts=None, skip_perm_errors=False)`

The interface used by the **salt** CLI tool on the Salt Master

`LocalClient` is used to send a command to Salt minions to execute *execution modules* and return the results to the Salt Master.

Importing and using `LocalClient` must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as. (Unless *external\_auth* is configured and authentication credentials are included in the execution).

```
import salt.client
```

```
local = salt.client.LocalClient()
local.cmd('*', 'test.fib', [10])
```

**cmd**(*tgt, fun, arg=(), timeout=None, expr\_form='glob', ret='', jid='', kwarg=None, \*\*kwargs*)  
Synchronously execute a command on targeted minions

The cmd method will execute and wait for the timeout period for all minions to reply, then it will return all minion data at once.

```
>>> import salt.client
>>> local = salt.client.LocalClient()
>>> local.cmd('*', 'cmd.run', ['whoami'])
{'jerry': 'root'}
```

With extra keyword arguments for the command function to be run:

```
local.cmd('*', 'test.arg', ['arg1', 'arg2'], kwarg={'foo': 'bar'})
```

Compound commands can be used for multiple executions in a single publish. Function names and function arguments are provided in separate lists but the index values must correlate and an empty list must be used if no arguments are required.

```
>>> local.cmd('*', [
    'grains.items',
    'sys.doc',
    'cmd.run',
],
 [
    [],
    [],
    ['uptime'],
])
```

### Parameters

- **tgt** (*string or list*) -- Which minions to target for the execution. Default is shell glob. Modified by the *expr\_form* option.
- **fun** (*string or list of strings*) -- The module and function to call on the specified minions of the form *module.function*. For example *test.ping* or *grains.items*.

**Compound commands** Multiple functions may be called in a single publish by passing a list of commands. This can dramatically lower overhead and speed up the application communicating with Salt.

This requires that the *arg* param is a list of lists. The *fun* list and the *arg* list must correlate by index meaning a function that does not take arguments must still have a corresponding empty list at the expected index.

- **arg** (*list or list-of-lists*) -- A list of arguments to pass to the remote function. If the function takes no arguments *arg* may be omitted except when executing a compound command.
- **timeout** -- Seconds to wait after the last minion returns but before all minions return.
- **expr\_form** -- The type of *tgt*. Allowed values:
  - *glob* - Bash glob completion - Default
  - *pcr* - Perl style regular expression

- `list` - Python list of hosts
  - `grain` - Match based on a grain comparison
  - `grain_pcre` - Grain comparison with a regex
  - `pillar` - Pillar data comparison
  - `pillar_pcre` - Pillar data comparison with a regex
  - `nodegroup` - Match on nodegroup
  - `range` - Use a Range server for matching
  - `compound` - Pass a compound match string
- **ret** -- The returner to use. The value passed can be single returner, or a comma delimited list of returners to call in order on the minions
  - **kwarg** -- A dictionary with keyword arguments for the function.
  - **kwargs** -- Optional keyword arguments. Authentication credentials may be passed when using `external_auth`.

For example: `local.cmd('*', 'test.ping', username='saltdev', password='saltdev', eauth='pam')`. Or: `local.cmd('*', 'test.ping', token='5871821ea51754fdcea8153c1c745433')`

**Returns** A dictionary with the result of the execution, keyed by minion ID. A compound command will return a sub-dictionary keyed by function name.

**cmd\_async** (*tgt, fun, arg=(), expr\_form='glob', ret='', jid='', kwarg=None, \*\*kwargs*)  
Asynchronously send a command to connected minions

The function signature is the same as `cmd()` with the following exceptions.

**Returns** A job ID or 0 on failure.

```
>>> local.cmd_async('*', 'test.sleep', [300])
'20131219215921857715'
```

**cmd\_batch** (*tgt, fun, arg=(), expr\_form='glob', ret='', kwarg=None, batch='10%', \*\*kwargs*)  
Iteratively execute a command on subsets of minions at a time

The function signature is the same as `cmd()` with the following exceptions.

**Parameters batch** -- The batch identifier of systems to execute on

**Returns** A generator of minion returns

```
>>> returns = local.cmd_batch('*', 'state.highstate', bat='10%')
>>> for ret in returns:
...     print(ret)
{'jerry': {...}}
{'dave': {...}}
{'stewart': {...}}
```

**cmd\_iter** (*tgt, fun, arg=(), timeout=None, expr\_form='glob', ret='', kwarg=None, \*\*kwargs*)  
Yields the individual minion returns as they come in

The function signature is the same as `cmd()` with the following exceptions.

**Returns** A generator yielding the individual minion returns

```
>>> ret = local.cmd_iter('*', 'test.ping')
>>> for i in ret:
...     print(i)
{'jerry': {'ret': True}}
{'dave': {'ret': True}}
{'stewart': {'ret': True}}
```

**cmd\_iter\_no\_block**(*tgt, fun, arg=(), timeout=None, expr\_form='glob', ret='', kwarg=None, \*\*kwargs*)

Yields the individual minion returns as they come in, or `None` when no returns are available.

The function signature is the same as `cmd()` with the following exceptions.

**Returns** A generator yielding the individual minion returns, or `None` when no returns are available. This allows for actions to be injected in between minion returns.

```
>>> ret = local.cmd_iter_no_block('*', 'test.ping')
>>> for i in ret:
...     print(i)
None
{'jerry': {'ret': True}}
{'dave': {'ret': True}}
None
{'stewart': {'ret': True}}
```

**cmd\_subset**(*tgt, fun, arg=(), expr\_form='glob', ret='', kwarg=None, sub=3, cli=False, progress=False, \*\*kwargs*)

Execute a command on a random subset of the targeted systems

The function signature is the same as `cmd()` with the following exceptions.

**Parameters** **sub** -- The number of systems to execute on

```
>>> SLC.cmd_subset('*', 'test.ping', sub=1)
{'jerry': True}
```

**get\_cli\_returns**(*jid, minions, timeout=None, tgt='\*', tgt\_type='glob', verbose=False, show\_jid=False, \*\*kwargs*)

Starts a watcher looking at the return data for a specified JID

**Returns** all of the information for the JID

**get\_event\_iter\_returns**(*jid, minions, timeout=None*)

Gather the return data from the event system, break hard when timeout is reached.

**run\_job**(*tgt, fun, arg=(), expr\_form='glob', ret='', timeout=None, jid='', kwarg=None, \*\*kwargs*)

Asynchronously send a command to connected minions

Prep the job directory and publish a command to any targeted minions.

**Returns** A dictionary of (validated) `pub_data` or an empty dictionary on failure. The `pub_data` contains the job ID and a list of all minions that are expected to return data.

```
>>> local.run_job('*', 'test.sleep', [300])
{'jid': '20131219215650131543', 'minions': ['jerry']}
```

## Salt Caller

`class salt.client.Caller(c_path='/etc/salt/minion', mopts=None)`

Caller is the same interface used by the **salt-call** command-line tool on the Salt Minion.

Importing and using `Caller` must be done on the same machine as a Salt Minion and it must be done using the same user that the Salt Minion is running as.

Usage:

```
import salt.client
caller = salt.client.Caller()
caller.function('test.ping')

# Or call objects directly
caller.sminion.functions['cmd.run']('ls -l')
```

Note, a running master or minion daemon is not required to use this class. Running `salt-call --local` simply sets `file_client` to `'local'`. The same can be achieved at the Python level by including that setting in a minion config file.

Instantiate a new `Caller()` instance using a file system path to the minion config file:

```
caller = salt.client.Caller('/path/to/custom/minion_config')
caller.sminion.functions['grains.items']()
```

Instantiate a new `Caller()` instance using a dictionary of the minion config:

New in version 2014.7.0: Pass the minion config as a dictionary.

```
import salt.client
import salt.config

opts = salt.config.minion_config('/etc/salt/minion')
opts['file_client'] = 'local'
caller = salt.client.Caller(mopts=opts)
caller.sminion.functions['grains.items']()
```

**function** (*fun*, \**args*, \*\**kwargs*)  
Call a single salt function

## RunnerClient

class `salt.runner.RunnerClient` (*opts*)

The interface used by the `salt-run` CLI tool on the Salt Master

It executes *runner modules* which run on the Salt Master.

Importing and using `RunnerClient` must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as.

Salt's `external_auth` can be used to authenticate calls. The `eauth` user must be authorized to execute runner modules: (`@runner`). Only the `master_call()` below supports `eauth`.

**async** (*fun*, *low*, *user*='UNKNOWN')

Execute the function in a multiprocess and return the event tag to use to watch for the return

**cmd** (*fun*, *arg*=None, *pub\_data*=None, *kwarg*=None)

Execute a function

```
>>> opts = salt.config.master_config('/etc/salt/master')
>>> runner = salt.runner.RunnerClient(opts)
>>> runner.cmd('jobs.list_jobs', [])
{
  '20131219215650131543': {
```

```

        'Arguments': [300],
        'Function': 'test.sleep',
        'StartTime': '2013, Dec 19 21:56:50.131543',
        'Target': '*',
        'Target-type': 'glob',
        'User': 'saltdev'
    },
    '20131219215921857715': {
        'Arguments': [300],
        'Function': 'test.sleep',
        'StartTime': '2013, Dec 19 21:59:21.857715',
        'Target': '*',
        'Target-type': 'glob',
        'User': 'saltdev'
    },
}

```

**cmd\_async** (*low*)

Execute a runner function asynchronously; eauth is respected

This function requires that *external\_auth* is configured and the user is authorized to execute runner functions: (@runner).

```

runner.eauth_async({
    'fun': 'jobs.list_jobs',
    'username': 'saltdev',
    'password': 'saltdev',
    'eauth': 'pam',
})

```

**cmd\_sync** (*low, timeout=None*)

Execute a runner function synchronously; eauth is respected

This function requires that *external\_auth* is configured and the user is authorized to execute runner functions: (@runner).

```

runner.eauth_sync({
    'fun': 'jobs.list_jobs',
    'username': 'saltdev',
    'password': 'saltdev',
    'eauth': 'pam',
})

```

**WheelClient**

class salt.wheel.**WheelClient** (*opts=None*)

An interface to Salt's wheel modules

*Wheel modules* interact with various parts of the Salt Master.

Importing and using **WheelClient** must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as. Unless *external\_auth* is configured and the user is authorized to execute wheel functions: (@wheel).

Usage:

```

import salt.config
import salt.wheel

```

```
opts = salt.config.master_config('/etc/salt/master')
wheel = salt.wheel.WheelClient(opts)
```

**async** (*fun*, *low*, *user*='UNKNOWN')

Execute the function in a multiprocess and return the event tag to use to watch for the return

**cmd** (*fun*, *arg*=None, *pub\_data*=None, *kwarg*=None)

Execute a function

```
>>> wheel.cmd('key.finger', ['jerry'])
{'minions': {'jerry': '5d:f6:79:43:5e:d4:42:3f:57:b8:45:a8:7e:a4:6e:ca'}}
```

**cmd\_async** (*low*)

Execute a function asynchronously; eauth is respected

This function requires that *external\_auth* is configured and the user is authorized

```
>>> wheel.cmd_async({
    'fun': 'key.finger',
    'match': 'jerry',
    'eauth': 'auto',
    'username': 'saltdev',
    'password': 'saltdev',
})
{'jid': '20131219224744416681', 'tag': 'salt/wheel/20131219224744416681'}
```

**cmd\_sync** (*low*, *timeout*=None)

Execute a wheel function synchronously; eauth is respected

This function requires that *external\_auth* is configured and the user is authorized to execute runner functions: (@wheel).

```
>>> wheel.cmd_sync({
    'fun': 'key.finger',
    'match': 'jerry',
    'eauth': 'auto',
    'username': 'saltdev',
    'password': 'saltdev',
})
{'minions': {'jerry': '5d:f6:79:43:5e:d4:42:3f:57:b8:45:a8:7e:a4:6e:ca'}}
```

## CloudClient

**class** salt.cloud.**CloudClient** (*path*=None, *opts*=None, *config\_dir*=None, *pillars*=None)

The client class to wrap cloud interactions

**action** (*fun*=None, *cloudmap*=None, *names*=None, *provider*=None, *instance*=None, *kwargs*=None)

Execute a single action via the cloud plugin backend

Examples:

```
client.action(fun='show_instance', names=['myinstance'])
client.action(fun='show_image', provider='my-ec2-config',
    kwargs={'image': 'ami-10314d79'})
)
```

**create** (*provider*, *names*, *\*\*kwargs*)

Create the named VMs, without using a profile

Example:

```
client.create(names=['myinstance'], provider='my-ec2-config',
             kwargs={'image': 'ami-1624987f', 'size': 't1.micro',
                    'ssh_username': 'ec2-user', 'securitygroup': 'default',
                    'delvol_on_destroy': True})
```

**destroy**(*names*)

Destroy the named VMs

**extra\_action**(*names, provider, action, \*\*kwargs*)

Perform actions with block storage devices

Example:

```
client.extra_action(names=['myblock'], action='volume_create',
                  provider='my-nova', kwargs={'voltype': 'SSD', 'size': 1000}
                  )
client.extra_action(names=['salt-net'], action='network_create',
                  provider='my-nova', kwargs={'cidr': '192.168.100.0/24'})
)
```

**full\_query**(*query\_type='list\_nodes\_full'*)

Query all instance information

**list\_images**(*provider=None*)

List all available images in configured cloud systems

**list\_locations**(*provider=None*)

List all available locations in configured cloud systems

**list\_sizes**(*provider=None*)

List all available sizes in configured cloud systems

**low**(*fun, low*)

Pass the cloud function and low data structure to run

**map\_run**(*path, \*\*kwargs*)

Pass in a location for a map to execute

**min\_query**(*query\_type='list\_nodes\_min'*)

Query select instance information

**profile**(*profile, names, vm\_overrides=None, \*\*kwargs*)

Pass in a profile to create, names is a list of vm names to allocate

vm\_overrides is a special dict that will be per node options overrides

Example:

```
>>> client= salt.cloud.CloudClient(path='/etc/salt/cloud')
>>> client.profile('do_512_git', names=['minion01',])
{'minion01': {u'backups_active': 'False',
              u'created_at': '2014-09-04T18:10:15Z',
              u'droplet': {u'event_id': 31000502,
                           u'id': 2530006,
                           u'image_id': 5140006,
                           u'name': u'minion01',
                           u'size_id': 66},
              u'id': '2530006',
              u'image_id': '5140006',
              u'ip_address': '107.XXX.XXX.XXX',
```

```
u'locked': 'True',
u'name': 'minion01',
u'private_ip_address': None,
u'region_id': '4',
u'size_id': '66',
u'status': 'new']}]}
```

**query** (*query\_type='list\_nodes'*)

Query basic instance information

**select\_query** (*query\_type='list\_nodes\_select'*)

Query select instance information

## SSHClient

class salt.client.ssh.client.**SSHClient** (*c\_path='/etc/salt/master', mopts=None*)

Create a client object for executing routines via the salt-ssh backend

New in version 2015.5.0.

**cmd** (*tgt, fun, arg=(), timeout=None, expr\_form='glob', kwarg=None, \*\*kwargs*)

Execute a single command via the salt-ssh subsystem and return all routines at once

New in version 2015.5.0.

**cmd\_iter** (*tgt, fun, arg=(), timeout=None, expr\_form='glob', ret='', kwarg=None, \*\*kwargs*)

Execute a single command via the salt-ssh subsystem and return a generator

New in version 2015.5.0.

## 30.5 Full list of Salt Cloud modules

<i>aliyun</i>	AliYun ECS Cloud Module
<i>botocore_aws</i>	The AWS Cloud Module
<i>cloudstack</i>	CloudStack Cloud Module
<i>digital_ocean</i>	DigitalOcean Cloud Module
<i>digital_ocean_v2</i>	DigitalOcean Cloud Module v2
<i>ec2</i>	The EC2 Cloud Module
<i>gce</i>	Copyright 2013 Google Inc.
<i>gogrid</i>	GoGrid Cloud Module
<i>joyent</i>	Joyent Cloud Module
<i>libcloud_aws</i>	The AWS Cloud Module
<i>linode</i>	Linode Cloud Module using Apache Libcloud OR linode-python bindings
<i>lxc</i>	Install Salt on an LXC Container
<i>msazure</i>	Azure Cloud Module
<i>nova</i>	OpenStack Nova Cloud Module
<i>opennebula</i>	OpenNebula Cloud Module
<i>openstack</i>	OpenStack Cloud Module
<i>parallels</i>	Parallels Cloud Module
<i>proxmox</i>	Proxmox Cloud Module
<i>pyrax</i>	Pyrax Cloud Module
<i>rackspace</i>	Rackspace Cloud Module

Table 30.2 -- continued from previous page

<code>saltify</code>	Saltify Module ===== The Saltify module is designed to install Salt on a remote machine, virt
<code>softlayer</code>	SoftLayer Cloud Module
<code>softlayer_hw</code>	SoftLayer HW Cloud Module
<code>vsphere</code>	vSphere Cloud Module

### 30.5.1 salt.cloud.clouds.aliyun

#### AliYun ECS Cloud Module

New in version 2014.7.0.

The Aliyun cloud module is used to control access to the aliyun ECS. <http://www.aliyun.com/>

Use of this module requires the `id` and `key` parameter to be set. Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/aliyun.conf`:

```
my-aliyun-config:
# aliyun Access Key ID
id: wFGEwgregeqw3435gDger
# aliyun Access Key Secret
key: GDE43t43REGTrkilg43934t34qT43t4dgegerGEgg
location: cn-qingdao
provider: aliyun
```

**depends** requests

`salt.cloud.clouds.aliyun.avail_images` (*kwargs=None, call=None*)

Return a list of the images that are on the provider

`salt.cloud.clouds.aliyun.avail_locations` (*call=None*)

Return a dict of all available VM locations on the cloud provider with relevant data

`salt.cloud.clouds.aliyun.avail_sizes` (*call=None*)

Return a list of the image sizes that are on the provider

`salt.cloud.clouds.aliyun.create` (*vm\_*)

Create a single VM from a data dict

`salt.cloud.clouds.aliyun.create_node` (*kwargs*)

Convenience function to make the rest api call for node creation.

`salt.cloud.clouds.aliyun.destroy` (*name, call=None*)

Destroy a node.

CLI Example:

```
salt-cloud -a destroy myinstance
salt-cloud -d myinstance
```

`salt.cloud.clouds.aliyun.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.aliyun.get_image` (*vm\_*)

Return the image object to use

`salt.cloud.clouds.aliyun.get_location` (*vm\_=None*)

Return the aliyun region to use, in this order:

- CLI parameter

- VM parameter
- Cloud profile setting

`salt.cloud.clouds.aliyun.get_securitygroup(vm_)`

Return the security group

`salt.cloud.clouds.aliyun.get_size(vm_)`

Return the VM's size. Used by `create_node()`.

`salt.cloud.clouds.aliyun.list_availability_zones(call=None)`

List all availability zones in the current region

`salt.cloud.clouds.aliyun.list_monitor_data(kwargs=None, call=None)`

Get monitor data of the instance. If instance name is missing, will show all the instance monitor data on the region.

CLI Examples:

```
salt-cloud -f list_monitor_data aliyun
salt-cloud -f list_monitor_data aliyun name=AY14051311071990225bd
```

`salt.cloud.clouds.aliyun.list_nodes(call=None)`

Return a list of the VMs that are on the provider

`salt.cloud.clouds.aliyun.list_nodes_full(call=None)`

Return a list of the VMs that are on the provider

`salt.cloud.clouds.aliyun.list_nodes_min(call=None)`

Return a list of the VMs that are on the provider. Only a list of VM names, and their state, is returned. This is the minimum amount of information needed to check for existing VMs.

`salt.cloud.clouds.aliyun.list_nodes_select(call=None)`

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.aliyun.list_securitygroup(call=None)`

Return a list of security group

`salt.cloud.clouds.aliyun.query(params=None)`

Make a web call to aliyun ECS REST API

`salt.cloud.clouds.aliyun.reboot(name, call=None)`

Reboot a node

CLI Examples:

```
salt-cloud -a reboot myinstance
```

`salt.cloud.clouds.aliyun.script(vm_)`

Return the script deployment object

`salt.cloud.clouds.aliyun.show_disk(name, call=None)`

Show the disk details of the instance

CLI Examples:

```
salt-cloud -a show_disk aliyun myinstance
```

`salt.cloud.clouds.aliyun.show_image(kwargs, call=None)`

Show the details from aliyun image

`salt.cloud.clouds.aliyun.show_instance(name, call=None)`

Show the details from aliyun instance

`salt.cloud.clouds.aliyun.start(name, call=None)`

Start a node

CLI Examples:

```
salt-cloud -a start myinstance
```

`salt.cloud.clouds.aliyun.stop(name, force=False, call=None)`

Stop a node

CLI Examples:

```
salt-cloud -a stop myinstance
salt-cloud -a stop myinstance force=True
```

### 30.5.2 salt.cloud.clouds.botocore\_aws

#### The AWS Cloud Module

The AWS cloud module is used to interact with the Amazon Web Services system.

This module has been replaced by the EC2 cloud module, and is no longer supported. The documentation shown here is for reference only; it is highly recommended to change all usages of this driver over to the EC2 driver.

If this driver is still needed, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/aws.conf`:

```
my-aws-botocore-config:
  # The AWS API authentication id
  id: GKTADJGHEIQSXMKKRBJ08H
  # The AWS API authentication key
  key: askdjghsdfjkghWupUjasdfklkfklgsdfjajkgghs
  # The ssh keyname to use
  keyname: default
  # The amazon security group
  securitygroup: ssh_open
  # The location of the private key which corresponds to the keyname
  private_key: /root/default.pem
  provider: aws
```

`salt.cloud.clouds.botocore_aws.disable_term_protect(name, call=None)`

Disable termination protection on a node

CLI Example:

```
salt-cloud -a disable_term_protect mymachine
```

`salt.cloud.clouds.botocore_aws.enable_term_protect(name, call=None)`

Enable termination protection on a node

CLI Example:

```
salt-cloud -a enable_term_protect mymachine
```

`salt.cloud.clouds.botocore_aws.get_configured_provider()`

Return the first configured instance.

### 30.5.3 salt.cloud.clouds.cloudstack

#### CloudStack Cloud Module

The CloudStack cloud module is used to control access to a CloudStack based Public Cloud.

**depends** libcloud >= 0.15

Use of this module requires the `apikey`, `secretkey`, `host` and `path` parameters.

```
my-cloudstack-cloud-config:
  apikey: <your api key >
  secretkey: <your secret key >
  host: localhost
  path: /client/api
  provider: cloudstack
```

`salt.cloud.clouds.cloudstack.avail_images` (*conn=None, call=None*)

Return a dict of all available VM images on the cloud provider with relevant data

`salt.cloud.clouds.cloudstack.avail_locations` (*conn=None, call=None*)

Return a dict of all available VM locations on the cloud provider with relevant data

`salt.cloud.clouds.cloudstack.avail_sizes` (*conn=None, call=None*)

Return a dict of all available VM images on the cloud provider with relevant data

`salt.cloud.clouds.cloudstack.block_device_mappings` (*vm\_*)

Return the block device mapping:

```
[{'DeviceName': '/dev/sdb', 'VirtualName': 'ephemeral0'},
 {'DeviceName': '/dev/sdc', 'VirtualName': 'ephemeral1'}]
```

`salt.cloud.clouds.cloudstack.create` (*vm\_*)

Create a single VM from a data dict

`salt.cloud.clouds.cloudstack.destroy` (*name, conn=None, call=None*)

Delete a single VM, and all of its volumes

`salt.cloud.clouds.cloudstack.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.cloudstack.get_conn` ()

Return a conn object for the passed VM data

`salt.cloud.clouds.cloudstack.get_image` (*conn, vm\_*)

Return the image object to use

`salt.cloud.clouds.cloudstack.get_ip` (*data*)

Return the IP address of the VM If the VM has public IP as defined by libcloud module then use it Otherwise try to extract the private IP and use that one.

`salt.cloud.clouds.cloudstack.get_key` ()

Returns the ssh private key for VM access

`salt.cloud.clouds.cloudstack.get_keypair` (*vm\_*)

Return the keypair to use

`salt.cloud.clouds.cloudstack.get_location` (*conn, vm\_*)

Return the node location to use

`salt.cloud.clouds.cloudstack.get_networkid` (*vm\_*)

Return the networkid to use, only valid for Advanced Zone

`salt.cloud.clouds.cloudstack.get_node(conn, name)`  
Return a libcloud node for the named VM

`salt.cloud.clouds.cloudstack.get_password(vm_)`  
Return the password to use

`salt.cloud.clouds.cloudstack.get_project(conn, vm_)`  
Return the project to use.

`salt.cloud.clouds.cloudstack.get_size(conn, vm_)`  
Return the VM's size object

`salt.cloud.clouds.cloudstack.list_nodes(conn=None, call=None)`  
Return a list of the VMs that are on the provider

`salt.cloud.clouds.cloudstack.list_nodes_full(conn=None, call=None)`  
Return a list of the VMs that are on the provider, with all fields

`salt.cloud.clouds.cloudstack.list_nodes_select(conn=None, call=None)`  
Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.cloudstack.script(vm_)`  
Return the script deployment object

`salt.cloud.clouds.cloudstack.show_instance(name, call=None)`  
Show the details from the provider concerning an instance

### 30.5.4 salt.cloud.clouds.digital\_ocean

#### DigitalOcean Cloud Module

The DigitalOcean cloud module is used to control access to the DigitalOcean VPS system.

---

**Note:** Due to Digital Ocean deprecating its original API, this salt-cloud driver for Digital Ocean will be deprecated in Salt Beryllium. The `digital_ocean_v2` driver that is currently available on all 2015.5.x releases will be used instead. Starting in Beryllium, the `digital_ocean_v2.py` driver will be renamed to `digital_ocean.py` and this driver will be removed. Please convert any original `digital_ocean` provider configs to use the new `digital_ocean_v2` provider configs.

---

Use of this module only requires the `api_key` parameter to be set. Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/digital_ocean.conf`:

```
my-digital-ocean-config:
  # DigitalOcean account keys
  client_key: wFGEwgregeqw3435gDger
  api_key: GDE43t43REGTrkilg43934t34qT43t4dgegerGEgg
  provider: digital_ocean
```

**depends** requests

`salt.cloud.clouds.digital_ocean.avail_images(call=None)`  
Return a list of the images that are on the provider

`salt.cloud.clouds.digital_ocean.avail_locations(call=None)`  
Return a dict of all available VM locations on the cloud provider with relevant data

`salt.cloud.clouds.digital_ocean.avail_sizes(call=None)`  
Return a list of the image sizes that are on the provider

`salt.cloud.clouds.digital_ocean.create(vm_)`

Create a single VM from a data dict

`salt.cloud.clouds.digital_ocean.create_node(args)`

Create a node

`salt.cloud.clouds.digital_ocean.destroy(name, call=None)`

Destroy a node. Will check termination protection and warn if enabled.

CLI Example:

```
salt-cloud --destroy mymachine
```

`salt.cloud.clouds.digital_ocean.get_configured_provider()`

Return the first configured instance.

`salt.cloud.clouds.digital_ocean.get_image(vm_)`

Return the image object to use

`salt.cloud.clouds.digital_ocean.get_keyid(keyname)`

Return the ID of the keyname

`salt.cloud.clouds.digital_ocean.get_location(vm_)`

Return the VM's location

`salt.cloud.clouds.digital_ocean.get_size(vm_)`

Return the VM's size. Used by `create_node()`.

`salt.cloud.clouds.digital_ocean.list_keypairs(call=None)`

Return a dict of all available VM locations on the cloud provider with relevant data

`salt.cloud.clouds.digital_ocean.list_nodes(call=None)`

Return a list of the VMs that are on the provider

`salt.cloud.clouds.digital_ocean.list_nodes_full(call=None)`

Return a list of the VMs that are on the provider

`salt.cloud.clouds.digital_ocean.list_nodes_select(call=None)`

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.digital_ocean.query(method='droplets', droplet_id=None, command=None, args=None)`

Make a web call to DigitalOcean

`salt.cloud.clouds.digital_ocean.script(vm_)`

Return the script deployment object

`salt.cloud.clouds.digital_ocean.show_instance(name, call=None)`

Show the details from DigitalOcean concerning a droplet

`salt.cloud.clouds.digital_ocean.show_keypair(kwargs=None, call=None)`

Show the details of an SSH keypair

### 30.5.5 salt.cloud.clouds.digital\_ocean\_v2

#### DigitalOcean Cloud Module v2

The DigitalOcean cloud module is used to control access to the DigitalOcean VPS system.

Use of this module only requires the `personal_access_token` parameter to be set. Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/digital_ocean.conf`:

```
my-digital-ocean-config:
  personal_access_token: xxx
  provider: digital_ocean
```

**depends** requests

**salt.cloud.clouds.digital\_ocean\_v2.avail\_images** (*call=None*)

Return a list of the images that are on the provider

**salt.cloud.clouds.digital\_ocean\_v2.avail\_locations** (*call=None*)

Return a dict of all available VM locations on the cloud provider with relevant data

**salt.cloud.clouds.digital\_ocean\_v2.avail\_sizes** (*call=None*)

Return a list of the image sizes that are on the provider

**salt.cloud.clouds.digital\_ocean\_v2.create** (*vm\_*)

Create a single VM from a data dict

**salt.cloud.clouds.digital\_ocean\_v2.create\_dns\_record** (*hostname, ip\_address*)

Creates a DNS record for the given hostname if the domain is managed with DO.

**salt.cloud.clouds.digital\_ocean\_v2.create\_node** (*args*)

Create a node

**salt.cloud.clouds.digital\_ocean\_v2.delete\_dns\_record** (*hostname*)

Deletes a DNS for the given hostname if the domain is managed with DO.

**salt.cloud.clouds.digital\_ocean\_v2.destroy** (*name, call=None*)

Destroy a node. Will check termination protection and warn if enabled.

CLI Example:

```
salt-cloud --destroy mymachine
```

**salt.cloud.clouds.digital\_ocean\_v2.get\_configured\_provider** ()

Return the first configured instance.

**salt.cloud.clouds.digital\_ocean\_v2.get\_image** (*vm\_*)

Return the image object to use

**salt.cloud.clouds.digital\_ocean\_v2.get\_keyid** (*keyname*)

Return the ID of the keyname

**salt.cloud.clouds.digital\_ocean\_v2.get\_location** (*vm\_*)

Return the VM's location

**salt.cloud.clouds.digital\_ocean\_v2.get\_size** (*vm\_*)

Return the VM's size. Used by `create_node()`.

**salt.cloud.clouds.digital\_ocean\_v2.list\_keypairs** (*call=None*)

Return a dict of all available VM locations on the cloud provider with relevant data

**salt.cloud.clouds.digital\_ocean\_v2.list\_nodes** (*call=None*)

Return a list of the VMs that are on the provider

**salt.cloud.clouds.digital\_ocean\_v2.list\_nodes\_full** (*call=None, forOutput=True*)

Return a list of the VMs that are on the provider

**salt.cloud.clouds.digital\_ocean\_v2.list\_nodes\_select** (*call=None*)

Return a list of the VMs that are on the provider, with select fields

```
salt.cloud.clouds.digital_ocean_v2.query(method='droplets', droplet_id=None, com-
                                         mand=None, args=None, http_method='get')
```

Make a web call to DigitalOcean

```
salt.cloud.clouds.digital_ocean_v2.script(vm_)
```

Return the script deployment object

```
salt.cloud.clouds.digital_ocean_v2.show_instance(name, call=None)
```

Show the details from DigitalOcean concerning a droplet

```
salt.cloud.clouds.digital_ocean_v2.show_keypair(kwargs=None, call=None)
```

Show the details of an SSH keypair

### 30.5.6 salt.cloud.clouds.ec2

#### The EC2 Cloud Module

The EC2 cloud module is used to interact with the Amazon Elastic Cloud Computing.

To use the EC2 cloud module, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/ec2.conf`:

```
my-ec2-config:
# The EC2 API authentication id, set this and/or key to
# 'use-instance-role-credentials' to use the instance role credentials
# from the meta-data if running on an AWS instance
id: GKTADJGHEIQSXMKKRBJ08H
# The EC2 API authentication key, set this and/or id to
# 'use-instance-role-credentials' to use the instance role credentials
# from the meta-data if running on an AWS instance
key: askdjghsdfjkghWupUjasdfklkfjlsdfjajkghs
# The ssh keyname to use
keyname: default
# The amazon security group
securitygroup: ssh_open
# The location of the private key which corresponds to the keyname
private_key: /root/default.pem

# Be default, service_url is set to amazonaws.com. If you are using this
# driver for something other than Amazon EC2, change it here:
service_url: amazonaws.com

# The endpoint that is ultimately used is usually formed using the region
# and the service_url. If you would like to override that entirely, you
# can explicitly define the endpoint:
endpoint: myendpoint.example.com:1138/services/Cloud

# SSH Gateways can be used with this provider. Gateways can be used
# when a salt-master is not on the same private network as the instance
# that is being deployed.

# Defaults to None
# Required
ssh_gateway: gateway.example.com

# Defaults to port 22
# Optional
ssh_gateway_port: 22
```

```

# Defaults to root
# Optional
ssh_gateway_username: root

# One authentication method is required. If both
# are specified, Private key wins.

# Private key defaults to None
ssh_gateway_private_key: /path/to/key.pem

# Password defaults to None
ssh_gateway_password: ExamplePasswordHere

# Pass userdata to the instance to be created
userdata_file: /etc/salt/my-userdata-file

provider: ec2

```

**depends** requests

**salt.cloud.clouds.ec2.attach\_volume** (*name=None*, *kwargs=None*, *instance\_id=None*, *call=None*)

Attach a volume to an instance

**salt.cloud.clouds.ec2.avail\_images** (*kwargs=None*, *call=None*)

Return a dict of all available VM images on the cloud provider.

**salt.cloud.clouds.ec2.avail\_locations** (*call=None*)

List all available locations

**salt.cloud.clouds.ec2.avail\_sizes** (*call=None*)

Return a dict of all available VM sizes on the cloud provider with relevant data. Latest version can be found at:

<http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/instance-types.html>

**salt.cloud.clouds.ec2.block\_device\_mappings** (*vm\_*)

Return the block device mapping:

```
[{'DeviceName': '/dev/sdb', 'VirtualName': 'ephemeral0'},
 {'DeviceName': '/dev/sdc', 'VirtualName': 'ephemeral1'}]
```

**salt.cloud.clouds.ec2.copy\_snapshot** (*kwargs=None*, *call=None*)

Copy a snapshot

**salt.cloud.clouds.ec2.create** (*vm\_=None*, *call=None*)

Create a single VM from a data dict

**salt.cloud.clouds.ec2.create\_attach\_volumes** (*name*, *kwargs*, *call=None*, *wait\_to\_finish=True*)

Create and attach volumes to created node

**salt.cloud.clouds.ec2.create\_keypair** (*kwargs=None*, *call=None*)

Create an SSH keypair

**salt.cloud.clouds.ec2.create\_snapshot** (*kwargs=None*, *call=None*, *wait\_to\_finish=False*)

Create a snapshot.

**volume\_id** The ID of the Volume from which to create a snapshot.

**description** The optional description of the snapshot.

CLI Example:

```
salt-cloud -f create_snapshot my-ec2-config volume_id=vol-351d8826
salt-cloud -f create_snapshot my-ec2-config volume_id=vol-351d8826 \
    description="My Snapshot Description"
```

`salt.cloud.clouds.ec2.create_volume` (*kwargs=None, call=None, wait\_to\_finish=False*)

Create a volume

CLI Examples:

```
salt-cloud -f create_volume my-ec2-config zone=us-east-1b
salt-cloud -f create_volume my-ec2-config zone=us-east-1b tags='{ "tag1": "val1", "tag2": "val2" }
```

`salt.cloud.clouds.ec2.del_tags` (*name=None, kwargs=None, call=None, instance\_id=None, resource\_id=None*)

Delete tags for a resource. Normally a VM name or instance\_id is passed in, but a resource\_id may be passed instead. If both are passed in, the instance\_id will be used.

CLI Examples:

```
salt-cloud -a del_tags mymachine tags=mytag,
salt-cloud -a del_tags mymachine tags=tag1,tag2,tag3
salt-cloud -a del_tags resource_id=vol-3267ab32 tags=tag1,tag2,tag3
```

`salt.cloud.clouds.ec2.delete_keypair` (*kwargs=None, call=None*)

Delete an SSH keypair

`salt.cloud.clouds.ec2.delete_snapshot` (*kwargs=None, call=None*)

Delete a snapshot

`salt.cloud.clouds.ec2.delete_volume` (*name=None, kwargs=None, instance\_id=None, call=None*)

Delete a volume

`salt.cloud.clouds.ec2.delvol_on_destroy` (*name, kwargs=None, call=None*)

Delete all/specified EBS volumes upon instance termination

CLI Example:

```
salt-cloud -a delvol_on_destroy mymachine
```

`salt.cloud.clouds.ec2.describe_snapshots` (*kwargs=None, call=None*)

Describe a snapshot (or snapshots)

**snapshot\_id** One or more snapshot IDs. Multiple IDs must be separated by "".

**owner** Return the snapshots owned by the specified owner. Valid values include: self, amazon, <AWS Account ID>. Multiple values must be separated by "".

**restorable\_by** One or more AWS accounts IDs that can create volumes from the snapshot. Multiple aws account IDs must be separated by "".

TODO: Add all of the filters.

`salt.cloud.clouds.ec2.describe_volumes` (*kwargs=None, call=None*)

Describe a volume (or volumes)

**volume\_id** One or more volume IDs. Multiple IDs must be separated by "".

TODO: Add all of the filters.

`salt.cloud.clouds.ec2.destroy` (*name, call=None*)

Destroy a node. Will check termination protection and warn if enabled.

CLI Example:

```
salt-cloud --destroy mymachine
```

`salt.cloud.clouds.ec2.detach_volume` (*name=None*, *kwargs=None*, *instance\_id=None*, *call=None*)

Detach a volume from an instance

`salt.cloud.clouds.ec2.disable_term_protect` (*name*, *call=None*)

Disable termination protection on a node

CLI Example:

```
salt-cloud -a disable_term_protect mymachine
```

`salt.cloud.clouds.ec2.enable_term_protect` (*name*, *call=None*)

Enable termination protection on a node

CLI Example:

```
salt-cloud -a enable_term_protect mymachine
```

`salt.cloud.clouds.ec2.get_availability_zone` (*vm\_*)

Return the availability zone to use

`salt.cloud.clouds.ec2.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.ec2.get_console_output` (*name=None*, *instance\_id=None*, *call=None*, *kwargs=None*)

Show the console output from the instance.

By default, returns decoded data, not the Base64-encoded data that is actually returned from the EC2 API.

`salt.cloud.clouds.ec2.get_location` (*vm\_=None*)

Return the EC2 region to use, in this order:

- CLI parameter
- VM parameter
- Cloud profile setting

`salt.cloud.clouds.ec2.get_password_data` (*name=None*, *kwargs=None*, *instance\_id=None*, *call=None*)

Return password data for a Windows instance.

By default only the encrypted password data will be returned. However, if a `key_file` is passed in, then a decrypted password will also be returned.

Note that the `key_file` references the private key that was used to generate the keypair associated with this instance. This private key will `_not_` be transmitted to Amazon; it is only used internally inside of Salt Cloud to decrypt data `_after_` it has been received from Amazon.

CLI Examples:

```
salt-cloud -a get_password_data mymachine
salt-cloud -a get_password_data mymachine key_file=/root/ec2key.pem
```

Note: PKCS1\_v1\_5 was added in PyCrypto 2.5

`salt.cloud.clouds.ec2.get_placementgroup` (*vm\_*)

Returns the PlacementGroup to use

`salt.cloud.clouds.ec2.get_provider`(*vm=None*)

Extract the provider name from vm

`salt.cloud.clouds.ec2.get_salt_interface`(*vm\_*)

Return the salt\_interface type to connect to. Either 'public\_ips' (default) or 'private\_ips'.

`salt.cloud.clouds.ec2.get_spot_config`(*vm\_*)

Returns the spot instance configuration for the provided vm

`salt.cloud.clouds.ec2.get_ssh_gateway_config`(*vm\_*)

Return the ssh\_gateway configuration.

`salt.cloud.clouds.ec2.get_subnetid`(*vm\_*)

Returns the SubnetId to use

`salt.cloud.clouds.ec2.get_tags`(*name=None, instance\_id=None, call=None, location=None, kwargs=None, resource\_id=None*)

Retrieve tags for a resource. Normally a VM name or instance\_id is passed in, but a resource\_id may be passed instead. If both are passed in, the instance\_id will be used.

CLI Examples:

```
salt-cloud -a get_tags mymachine
salt-cloud -a get_tags resource_id=vol-3267ab32
```

`salt.cloud.clouds.ec2.get_tenancy`(*vm\_*)

Returns the Tenancy to use.

Can be "dedicated" or "default". Cannot be present for spot instances.

`salt.cloud.clouds.ec2.iam_profile`(*vm\_*)

Return the IAM profile.

The IAM instance profile to associate with the instances. This is either the Amazon Resource Name (ARN) of the instance profile or the name of the role.

Type: String

Default: None

Required: No

Example: arn:aws:iam::111111111111:instance-profile/s3access

Example: s3access

`salt.cloud.clouds.ec2.keepvol_on_destroy`(*name, kwargs=None, call=None*)

Do not delete all/specified EBS volumes upon instance termination

CLI Example:

```
salt-cloud -a keepvol_on_destroy mymachine
```

`salt.cloud.clouds.ec2.keyname`(*vm\_*)

Return the keyname

`salt.cloud.clouds.ec2.list_nodes`(*call=None*)

Return a list of the VMs that are on the provider

`salt.cloud.clouds.ec2.list_nodes_full`(*location=None, call=None*)

Return a list of the VMs that are on the provider

`salt.cloud.clouds.ec2.list_nodes_min`(*location=None, call=None*)

Return a list of the VMs that are on the provider. Only a list of VM names, and their state, is returned. This is the minimum amount of information needed to check for existing VMs.

`salt.cloud.clouds.ec2.list_nodes_select` (*call=None*)  
Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.ec2.optimize_providers` (*providers*)  
Return an optimized list of providers.

We want to reduce the duplication of querying the same region.

If a provider is using the same credentials for the same region the same data will be returned for each provider, thus causing un-wanted duplicate data and API calls to EC2.

`salt.cloud.clouds.ec2.query` (*params=None, setname=None, requesturl=None, location=None, return\_url=False, return\_root=False*)

`salt.cloud.clouds.ec2.query_instance` (*vm\_=None, call=None*)  
Query an instance upon creation from the EC2 API

`salt.cloud.clouds.ec2.queue_instances` (*instances*)  
Queue a set of instances to be provisioned later. Expects a list.

Currently this only queries node data, and then places it in the cloud cache (if configured). If the salt-cloud-reactor is being used, these instances will be automatically provisioned using that.

For more information about the salt-cloud-reactor, see:

<https://github.com/saltstack-formulas/salt-cloud-reactor>

`salt.cloud.clouds.ec2.reboot` (*name, call=None*)  
Reboot a node.

CLI Example:

```
salt-cloud -a reboot mymachine
```

`salt.cloud.clouds.ec2.rename` (*name, kwargs, call=None*)  
Properly rename a node. Pass in the new name as ``new name``.

CLI Example:

```
salt-cloud -a rename mymachine newname=yourmachine
```

`salt.cloud.clouds.ec2.request_instance` (*vm\_=None, call=None*)  
Put together all of the information necessary to request an instance on EC2, and then fire off the request the instance.

Returns data about the instance

`salt.cloud.clouds.ec2.script` (*vm\_*)  
Return the script deployment object

`salt.cloud.clouds.ec2.securitygroup` (*vm\_*)  
Return the security group

`salt.cloud.clouds.ec2.securitygroupid` (*vm\_*)  
Returns the SecurityGroupId

`salt.cloud.clouds.ec2.set_tags` (*name=None, tags=None, call=None, location=None, instance\_id=None, resource\_id=None, kwargs=None*)  
Set tags for a resource. Normally a VM name or instance\_id is passed in, but a resource\_id may be passed instead. If both are passed in, the instance\_id will be used.

CLI Examples:

```
salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'
salt-cloud -a set_tags resource_id=vol-3267ab32 tag=somestuff
```

`salt.cloud.clouds.ec2.show_delvol_on_destroy` (*name*, *kwargs=None*, *call=None*)

Do not delete all/specified EBS volumes upon instance termination

CLI Example:

```
salt-cloud -a show_delvol_on_destroy mymachine
```

`salt.cloud.clouds.ec2.show_image` (*kwargs*, *call=None*)

Show the details from EC2 concerning an AMI

`salt.cloud.clouds.ec2.show_instance` (*name=None*, *instance\_id=None*, *call=None*, *kwargs=None*)

Show the details from EC2 concerning an AMI.

Can be called as an action (which requires a name):

```
salt-cloud -a show_instance myinstance
```

...or as a function (which requires either a name or instance\_id):

```
salt-cloud -f show_instance my-ec2 name=myinstance
salt-cloud -f show_instance my-ec2 instance_id=i-d34db33f
```

`salt.cloud.clouds.ec2.show_keypair` (*kwargs=None*, *call=None*)

Show the details of an SSH keypair

`salt.cloud.clouds.ec2.show_term_protect` (*name=None*, *instance\_id=None*, *call=None*, *quiet=False*)

Show the details from EC2 concerning an AMI

`salt.cloud.clouds.ec2.show_volume` (*kwargs=None*, *call=None*)

Wrapper around describe\_volumes. Here just to keep functionality. Might be depreciated later.

`salt.cloud.clouds.ec2.sign` (*key*, *msg*)

`salt.cloud.clouds.ec2.ssh_interface` (*vm\_*)

Return the ssh\_interface type to connect to. Either 'public\_ips' (default) or 'private\_ips'.

`salt.cloud.clouds.ec2.start` (*name*, *call=None*)

Start a node

`salt.cloud.clouds.ec2.stop` (*name*, *call=None*)

Stop a node

`salt.cloud.clouds.ec2.wait_for_instance` (*vm\_=None*, *data=None*, *ip\_address=None*, *display\_ssh\_output=True*, *call=None*)

Wait for an instance upon creation from the EC2 API, to become available

## Google Compute Engine Module

The Google Compute Engine module. This module interfaces with Google Compute Engine. To authenticate to GCE, you will need to create a Service Account.

### Setting up Service Account Authentication:

- Go to the Cloud Console at: <https://cloud.google.com/console>.
- Create or navigate to your desired Project.
- Make sure Google Compute Engine service is enabled under the Services section.
- Go to ``APIs and auth'' section, and then the ``Credentials'' link.
- Click the ``CREATE NEW CLIENT ID'' button.
- Select ``Service Account'' and click ``Create Client ID'' button.
- This will automatically download a .json file; ignore it.
- Look for a new ``Service Account'' section in the page, click on the ``Generate New P12 key'' button
- Copy the Email Address for inclusion in your /etc/salt/cloud file in the `service\_account\_email\_address' setting.
- Download the Private Key
- The key that you download is a PKCS12 key. It needs to be converted to the PEM format.
- Convert the key using OpenSSL (the default password is `notasecret'): `C{openssl pkcs12 -in PRIVKEY.p12 -passin pass:notasecret -nodes -nocerts | openssl rsa -out ~/PRIVKEY.pem}`
- Add the full path name of the converted private key to your /etc/salt/cloud file as `service\_account\_private\_key' setting.
- Consider using a more secure location for your private key.

```
my-gce-config:
  # The Google Cloud Platform Project ID
  project: "my-project-id"
  # The Service Account client ID
  service_account_email_address: 1234567890@developer.gserviceaccount.com
  # The location of the private key (PEM format)
  service_account_private_key: /home/erjohnso/PRIVKEY.pem
  provider: gce
  # Specify whether to use public or private IP for deploy script.
  # Valid options are:
  #   private_ips - The salt-master is also hosted with GCE
  #   public_ips - The salt-master is hosted outside of GCE
  ssh_interface: public_ips
```

**maintainer** Eric Johnson <erjohnso@google.com>

**maturity** new

**depends** libcloud >= 0.14.1

**depends** pycrypto >= 2.1

`salt.cloud.clouds.gce.attach_disk` (*name=None, kwargs=None, call=None*)

Attach an existing disk to an existing instance.

CLI Example:

```
salt-cloud -a attach_disk myinstance disk_name=mydisk mode=READ_WRITE
```

`salt.cloud.clouds.gce.attach_lb` (*kwargs=None, call=None*)

Add an existing node/member to an existing load-balancer configuration.

CLI Example:

```
salt-cloud -f attach_lb gce name=lb member=myinstance
```

`salt.cloud.clouds.gce.avail_images` (*conn=None*)

Return a dict of all available VM images on the cloud provider with relevant data

Note that for GCE, there are custom images within the project, but the generic images are in other projects. This returns a dict of images in the project plus images in `debian-cloud` and `centos-cloud` (If there is overlap in names, the one in the current project is used.)

`salt.cloud.clouds.gce.avail_locations` (*conn=None, call=None*)

Return a dict of all available VM locations on the cloud provider with relevant data

`salt.cloud.clouds.gce.avail_sizes` (*conn=None*)

Return a dict of available instances sizes (a.k.a machine types) and convert them to something more serializable.

`salt.cloud.clouds.gce.create` (*vm\_=None, call=None*)

Create a single GCE instance from a data dict.

`salt.cloud.clouds.gce.create_address` (*kwargs=None, call=None*)

Create a static address in a region.

CLI Example:

```
salt-cloud -f create_address gce name=my-ip region=us-central1 address=IP
```

`salt.cloud.clouds.gce.create_disk` (*kwargs=None, call=None*)

Create a new persistent disk. Must specify *disk\_name* and *location*. Can also specify an *image* or *snapshot* but if neither of those are specified, a *size* (in GB) is required.

CLI Example:

```
salt-cloud -f create_disk gce disk_name=pd size=300 location=us-central1-b
```

`salt.cloud.clouds.gce.create_fwrule` (*kwargs=None, call=None*)

Create a GCE firewall rule. The `default` network is used if not specified.

CLI Example:

```
salt-cloud -f create_fwrule gce name=allow-http allow=tcp:80
```

`salt.cloud.clouds.gce.create_hc` (*kwargs=None, call=None*)

Create an HTTP health check configuration.

CLI Example:

```
salt-cloud -f create_hc gce name=hc path=/healthy port=80
```

`salt.cloud.clouds.gce.create_lb` (*kwargs=None, call=None*)

Create a load-balancer configuration.

CLI Example:

```
salt-cloud -f create_lb gce name=lb region=us-central1 ports=80
```

`salt.cloud.clouds.gce.create_network` (*kwargs=None, call=None*)  
Create a GCE network.

CLI Example:

```
salt-cloud -f create_network gce name=mynet cidr=10.10.10.0/24
```

`salt.cloud.clouds.gce.create_snapshot` (*kwargs=None, call=None*)  
Create a new disk snapshot. Must specify *name* and *disk\_name*.

CLI Example:

```
salt-cloud -f create_snapshot gce name=snap1 disk_name=pd
```

`salt.cloud.clouds.gce.delete_address` (*kwargs=None, call=None*)  
Permanently delete a static address.

CLI Example:

```
salt-cloud -f delete_address gce name=my-ip
```

`salt.cloud.clouds.gce.delete_disk` (*kwargs=None, call=None*)  
Permanently delete a persistent disk.

CLI Example:

```
salt-cloud -f delete_disk gce disk_name=pd
```

`salt.cloud.clouds.gce.delete_fwrule` (*kwargs=None, call=None*)  
Permanently delete a firewall rule.

CLI Example:

```
salt-cloud -f delete_fwrule gce name=allow-http
```

`salt.cloud.clouds.gce.delete_hc` (*kwargs=None, call=None*)  
Permanently delete a health check.

CLI Example:

```
salt-cloud -f delete_hc gce name=hc
```

`salt.cloud.clouds.gce.delete_lb` (*kwargs=None, call=None*)  
Permanently delete a load-balancer.

CLI Example:

```
salt-cloud -f delete_lb gce name=lb
```

`salt.cloud.clouds.gce.delete_network` (*kwargs=None, call=None*)  
Permanently delete a network.

CLI Example:

```
salt-cloud -f delete_network gce name=mynet
```

`salt.cloud.clouds.gce.delete_snapshot` (*kwargs=None, call=None*)  
Permanently delete a disk snapshot.

CLI Example:

```
salt-cloud -f delete_snapshot gce name=disk-snap-1
```

`salt.cloud.clouds.gce.destroy`(*vm\_name*, *call=None*)

Call 'destroy' on the instance. Can be called with '-a destroy' or -d

CLI Example:

```
salt-cloud -a destroy myinstance1 myinstance2 ...
salt-cloud -d myinstance1 myinstance2 ...
```

`salt.cloud.clouds.gce.detach_disk`(*name=None*, *kwargs=None*, *call=None*)

Detach a disk from an instance.

CLI Example:

```
salt-cloud -a detach_disk myinstance disk_name=mydisk
```

`salt.cloud.clouds.gce.detach_lb`(*kwargs=None*, *call=None*)

Remove an existing node/member from an existing load-balancer configuration.

CLI Example:

```
salt-cloud -f detach_lb gce name=lb member=myinstance
```

`salt.cloud.clouds.gce.get_configured_provider`()

Return the first configured instance.

`salt.cloud.clouds.gce.get_conn`()

Return a conn object for the passed VM data

`salt.cloud.clouds.gce.get_lb_conn`(*gce\_driver=None*)

Return a load-balancer conn object

`salt.cloud.clouds.gce.list_nodes`(*conn=None*, *call=None*)

Return a list of the VMs that are on the provider

`salt.cloud.clouds.gce.list_nodes_full`(*conn=None*, *call=None*)

Return a list of the VMs that are on the provider, with all fields

`salt.cloud.clouds.gce.list_nodes_select`(*conn=None*, *call=None*)

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.gce.reboot`(*vm\_name*, *call=None*)

Call GCE 'reset' on the instance.

CLI Example:

```
salt-cloud -a reboot myinstance
```

`salt.cloud.clouds.gce.script`(*vm\_*)

Return the script deployment object

`salt.cloud.clouds.gce.show_address`(*kwargs=None*, *call=None*)

Show the details of an existing static address.

CLI Example:

```
salt-cloud -f show_address gce name=mynsAPSHOT region=us-central1
```

`salt.cloud.clouds.gce.show_disk`(*name=None*, *kwargs=None*, *call=None*)

Show the details of an existing disk.

CLI Example:

```
salt-cloud -a show_disk myinstance disk_name=mydisk
salt-cloud -f show_disk gce disk_name=mydisk
```

**salt.cloud.clouds.gce.show\_fwrule** (*kwargs=None, call=None*)  
Show the details of an existing firewall rule.

CLI Example:

```
salt-cloud -f show_fwrule gce name=allow-http
```

**salt.cloud.clouds.gce.show\_hc** (*kwargs=None, call=None*)  
Show the details of an existing health check.

CLI Example:

```
salt-cloud -f show_hc gce name=hc
```

**salt.cloud.clouds.gce.show\_instance** (*vm\_name, call=None*)  
Show the details of the existing instance.

**salt.cloud.clouds.gce.show\_lb** (*kwargs=None, call=None*)  
Show the details of an existing load-balancer.

CLI Example:

```
salt-cloud -f show_lb gce name=lb
```

**salt.cloud.clouds.gce.show\_network** (*kwargs=None, call=None*)  
Show the details of an existing network.

CLI Example:

```
salt-cloud -f show_network gce name=mynet
```

**salt.cloud.clouds.gce.show\_snapshot** (*kwargs=None, call=None*)  
Show the details of an existing snapshot.

CLI Example:

```
salt-cloud -f show_snapshot gce name=mynsnapshot
```

### 30.5.8 salt.cloud.clouds.gogrid

#### GoGrid Cloud Module

The GoGrid cloud module. This module interfaces with the gogrid public cloud service. To use Salt Cloud with GoGrid log into the GoGrid web interface and create an api key. Do this by clicking on "My Account" and then going to the API Keys tab.

**depends** libcloud >= 0.13.2

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/gogrid.conf`:

```
my-gogrid-config:
  # The generated api key to use
  apikey: asdff7896asdh789
  # The apikey's shared secret
  sharedsecret: saltybacon

  provider: gogrid
```

**Note:** A Note about using Map files with GoGrid:

Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the `-P` argument should not be used on maps referencing GoGrid instances.

---

`salt.cloud.clouds.gogrid.avail_images` (*conn=None, call=None*)

Return a dict of all available VM images on the cloud provider with relevant data

`salt.cloud.clouds.gogrid.avail_locations` (*conn=None, call=None*)

Return a dict of all available VM locations on the cloud provider with relevant data

`salt.cloud.clouds.gogrid.avail_sizes` (*conn=None, call=None*)

Return a dict of all available VM images on the cloud provider with relevant data

`salt.cloud.clouds.gogrid.create` (*vm\_*)

Create a single VM from a data dict

`salt.cloud.clouds.gogrid.destroy` (*name, conn=None, call=None*)

Delete a single VM

`salt.cloud.clouds.gogrid.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.gogrid.get_conn` ()

Return a conn object for the passed VM data

`salt.cloud.clouds.gogrid.get_image` (*conn, vm\_*)

Return the image object to use

`salt.cloud.clouds.gogrid.get_node` (*conn, name*)

Return a libcloud node for the named VM

`salt.cloud.clouds.gogrid.get_salt_interface` (*vm\_*)

Return the salt\_interface type to connect to. Either `'public_ips'` (default) or `'private_ips'`.

`salt.cloud.clouds.gogrid.get_size` (*conn, vm\_*)

Return the VM's size object

`salt.cloud.clouds.gogrid.list_nodes` (*conn=None, call=None*)

Return a list of the VMs that are on the provider

`salt.cloud.clouds.gogrid.list_nodes_full` (*conn=None, call=None*)

Return a list of the VMs that are on the provider, with all fields

`salt.cloud.clouds.gogrid.list_nodes_select` (*conn=None, call=None*)

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.gogrid.reboot` (*name, conn=None*)

Reboot a single VM

`salt.cloud.clouds.gogrid.script` (*vm\_*)

Return the script deployment object

`salt.cloud.clouds.gogrid.show_instance` (*name, call=None*)

Show the details from the provider concerning an instance

### 30.5.9 salt.cloud.clouds.joyent

#### Joyent Cloud Module

The Joyent Cloud module is used to interact with the Joyent cloud system.

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/joyent.conf`:

```
my-joyent-config:
  provider: joyent
  # The Joyent login user
  user: fred
  # The Joyent user's password
  password: saltybacon
  # The location of the ssh private key that can log into the new VM
  private_key: /root/mykey.pem
  # The name of the private key
  private_key: mykey
```

When creating your profiles for the joyent cloud, add the location attribute to the profile, this will automatically get picked up when performing tasks associated with that vm. An example profile might look like:

```
joyent_512:
  provider: my-joyent-config
  size: Extra Small 512 MB
  image: centos-6
  location: us-east-1
```

This driver can also be used with the Joyent SmartDataCenter project. More details can be found at:

Using SDC requires that an `api_host_suffix` is set. The default value for this is `.api.joyentcloud.com`. All characters, including the leading `.`, should be included:

```
api_host_suffix: .api.myhostname.com
```

**depends** PyCrypto

**salt.cloud.clouds.joyent.avail\_images** (*call=None*)

Get list of available images

CLI Example:

```
salt-cloud --list-images
```

Can use a custom URL for images. Default is:

```
image_url: images.joyent.com/image
```

**salt.cloud.clouds.joyent.avail\_locations** (*call=None*)

List all available locations

**salt.cloud.clouds.joyent.avail\_sizes** (*call=None*)

get list of available packages

CLI Example:

```
salt-cloud --list-sizes
```

**salt.cloud.clouds.joyent.create** (*vm\_*)

Create a single VM from a data dict

CLI Example:

```
salt-cloud -p profile_name vm_name
```

`salt.cloud.clouds.joyent.create_node(**kwargs)`  
convenience function to make the rest api call for node creation.

`salt.cloud.clouds.joyent.delete_key(kwarg=None, call=None)`  
List the keys available

CLI Example:

```
salt-cloud -f delete_key joyent keyname=mykey
```

`salt.cloud.clouds.joyent.destroy(name, call=None)`  
destroy a machine by name

#### Parameters

- **name** -- name given to the machine
- **call** -- call value in this case is `action`

**Returns** array of booleans , true if successfully stopped and true if successfully removed

CLI Example:

```
salt-cloud -d vm_name
```

`salt.cloud.clouds.joyent.get_configured_provider()`  
Return the first configured instance.

`salt.cloud.clouds.joyent.get_image(vm_)`  
Return the image object to use

`salt.cloud.clouds.joyent.get_location(vm_=None)`

Return the joyent data center to use, in this order:

- CLI parameter
- VM parameter
- Cloud profile setting

`salt.cloud.clouds.joyent.get_location_path(location='us-east-1',  
api_host_suffix='api.joyentcloud.com')`  
create url from location variable :param location: joyent data center location :return: url

`salt.cloud.clouds.joyent.get_node(name)`  
gets the node from the full node list by name :param name: name of the vm :return: node object

`salt.cloud.clouds.joyent.get_salt_interface(vm_)`  
Return the salt\_interface type to connect to. Either `public\_ips` (default) or `private\_ips`.

`salt.cloud.clouds.joyent.get_size(vm_)`  
Return the VM's size object

`salt.cloud.clouds.joyent.has_method(obj, method_name)`  
Find if the provided object has a specific method

`salt.cloud.clouds.joyent.import_key(kwarg=None, call=None)`  
List the keys available

CLI Example:

```
salt-cloud -f import_key joyent keyname=mykey keyfile=/tmp/mykey.pub
```

`salt.cloud.clouds.joyent.joyent_node_state(id_)`

Convert joyent returned state to state common to other data center return values for consistency

**Parameters** `id` -- joyent state value

**Returns** libcloudfuncs state value

`salt.cloud.clouds.joyent.key_list(items=None)`

convert list to dictionary using the key as the identifier :param items: array to iterate over :return: dictionary

`salt.cloud.clouds.joyent.list_keys(kwargs=None, call=None)`

List the keys available

`salt.cloud.clouds.joyent.list_nodes(full=False, call=None)`

list of nodes, keeping only a brief listing

CLI Example:

```
salt-cloud -Q
```

`salt.cloud.clouds.joyent.list_nodes_full(call=None)`

list of nodes, maintaining all content provided from joyent listings

CLI Example:

```
salt-cloud -F
```

`salt.cloud.clouds.joyent.list_nodes_select(call=None)`

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.joyent.query(action=None, command=None, args=None, method='GET', location=None, data=None)`

Make a web call to Joyent

`salt.cloud.clouds.joyent.query_instance(vm_=None, call=None)`

Query an instance upon creation from the Joyent API

`salt.cloud.clouds.joyent.reboot(name, call=None)`

reboot a machine by name :param name: name given to the machine :param call: call value in this case is 'action' :return: true if successful

CLI Example:

```
salt-cloud -a reboot vm_name
```

`salt.cloud.clouds.joyent.reformat_node(item=None, full=False)`

Reformat the returned data from joyent, determine public/private IPs and strip out fields if necessary to provide either full or brief content.

**Parameters**

- **item** -- node dictionary
- **full** -- full or brief output

**Returns** dict

`salt.cloud.clouds.joyent.show_instance(name, call=None)`

get details about a machine :param name: name given to the machine :param call: call value in this case is 'action' :return: machine information

CLI Example:

```
salt-cloud -a show_instance vm_name
```

`salt.cloud.clouds.joyent.show_key` (*kwargs=None, call=None*)  
List the keys available

`salt.cloud.clouds.joyent.ssh_interface` (*vm\_*)  
Return the ssh\_interface type to connect to. Either `'public_ips'` (default) or `'private_ips'`.

`salt.cloud.clouds.joyent.start` (*name, call=None*)  
start a machine by name :param name: name given to the machine :param call: call value in this case is `'action'`  
:return: true if successful

CLI Example:

```
salt-cloud -a start vm_name
```

`salt.cloud.clouds.joyent.stop` (*name, call=None*)  
stop a machine by name :param name: name given to the machine :param call: call value in this case is `'action'`  
:return: true if successful

CLI Example:

```
salt-cloud -a stop vm_name
```

`salt.cloud.clouds.joyent.take_action` (*name=None, call=None, command=None, data=None, method='GET', location='us-east-1'*)  
take action call used by start,stop, reboot :param name: name given to the machine :param call: call value in this case is `'action'` :command: api path :data: any data to be passed to the api, must be in json format :method: GET,POST,or DELETE :location: data center to execute the command on :return: true if successful

### 30.5.10 salt.cloud.clouds.libcloud\_aws

#### The AWS Cloud Module

The AWS cloud module is used to interact with the Amazon Web Services system.

This module has been replaced by the EC2 cloud module, and is no longer supported. The documentation shown here is for reference only; it is highly recommended to change all usages of this driver over to the EC2 driver.

If this driver is still needed, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/aws.conf`:

```
my-aws-config:
  # The AWS API authentication id
  id: GKTADJGHEIQSXMKKRBJ08H
  # The AWS API authentication key
  key: askdjghsdfjkghWupUjasdfklkfklgsdfjajkghs
  # The ssh keyname to use
  keyname: default
  # The amazon security group
  securitygroup: ssh_open
  # The location of the private key which corresponds to the keyname
  private_key: /root/default.pem

provider: aws
```

`salt.cloud.clouds.libcloud_aws.block_device_mappings` (*vm\_*)  
Return the block device mapping:

```
[{'DeviceName': '/dev/sdb', 'VirtualName': 'ephemeral0'},
 {'DeviceName': '/dev/sdc', 'VirtualName': 'ephemeral1'}]
```

`salt.cloud.clouds.libcloud_aws.create(vm_)`

Create a single VM from a data dict

`salt.cloud.clouds.libcloud_aws.create_attach_volumes(volumes, location, data)`

Create and attach volumes to created node

`salt.cloud.clouds.libcloud_aws.del_tags(name, kwargs, call=None)`

Delete tags for a node

CLI Example:

```
salt-cloud -a del_tags mymachine tag1,tag2,tag3
```

`salt.cloud.clouds.libcloud_aws.destroy(name)`

Wrap core libcloudfuncs destroy method, adding check for termination protection

`salt.cloud.clouds.libcloud_aws.get_availability_zone(conn, vm_)`

Return the availability zone to use

`salt.cloud.clouds.libcloud_aws.get_configured_provider()`

Return the first configured instance.

`salt.cloud.clouds.libcloud_aws.get_conn(**kwargs)`

Return a conn object for the passed VM data

`salt.cloud.clouds.libcloud_aws.get_location(vm_=None)`

Return the AWS region to use, in this order:

- CLI parameter
- Cloud profile setting
- Global salt-cloud config

`salt.cloud.clouds.libcloud_aws.get_salt_interface(vm_)`

Return the salt\_interface type to connect to. Either `public\_ips` (default) or `private\_ips`.

`salt.cloud.clouds.libcloud_aws.get_tags(name, call=None)`

Retrieve tags for a node

`salt.cloud.clouds.libcloud_aws.iam_profile(vm_)`

Return the IAM role

`salt.cloud.clouds.libcloud_aws.keyname(vm_)`

Return the keyname

`salt.cloud.clouds.libcloud_aws.rename(name, kwargs, call=None)`

Properly rename a node. Pass in the new name as ``new name``.

CLI Example:

```
salt-cloud -a rename mymachine newname=yourmachine
```

`salt.cloud.clouds.libcloud_aws.securitygroup(vm_)`

Return the security group

`salt.cloud.clouds.libcloud_aws.set_tags(name, tags, call=None)`

Set tags for a node

CLI Example:

```
salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'
```

`salt.cloud.clouds.libcloud_aws.ssh_interface`(*vm\_*)  
Return the `ssh_interface` type to connect to. Either `public_ips` (default) or `private_ips`.

`salt.cloud.clouds.libcloud_aws.ssh_username`(*vm\_*)  
Return the `ssh_username`. Defaults to `ec2-user`.

`salt.cloud.clouds.libcloud_aws.start`(*name*, *call=None*)  
Start a node

`salt.cloud.clouds.libcloud_aws.stop`(*name*, *call=None*)  
Stop a node

### 30.5.11 salt.cloud.clouds.linode

#### Linode Cloud Module using Apache Libcloud OR linode-python bindings

The Linode cloud module is used to control access to the Linode VPS system

Use of this module only requires the `apikey` parameter.

#### Dependencies

linode-python OR apache-libcloud

**linode-python** linode-python >= 1.1.1

SaltStack recommends installing `linode-python` if you're using a version of Python less than 2.7.9. You can install `linode-python` via `pip`:

```
pip install linode-python
```

---

**Note:** The `linode-python` driver will work with earlier versions of `linode-python`, but it is highly recommended to use a minimum version of 1.1.1. Earlier versions leak sensitive information into the debug logs.

---

**\*\* OR \*\***

**apache-libcloud** apache-libcloud >= 0.13.2

If your `salt-cloud` server runs on Python version 2.7.9 or Python >= 3.4, you can use the `libcloud` library to connect to Linode. For security reasons, Linode recently dropped support for TLSv1.0 and only supports TLS >= v1.1. Because of this reason, `libcloud` won't work for servers running older versions of Python or older versions of OpenSSL.

If your sever meets these requirements, you can install `libcloud` either via system packages or using `pip`:

```
pip install apache-libcloud
```

---

**Note:** RedHat/CentOS 7 backported the `ssl` stack from Python 2.7.9 to Python 2.7.5, so the `libcloud` library should work appropriately for those operating systems.

---

See [Issue #30341](#) for more information.

## Configuration

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/linode.conf`:

```
my-linode-config: # Linode account api key apikey: JVkbSJDGHSDKUKSDJfhsklfgjsjdkflhjsdffhgdgjenrtuin
provider: linode
```

When used with `linode-python`, this provider supports cloning existing Linodes. To clone, add a profile with a `clonefrom` key, and a `script_args`: `-C`.

`Clonefrom` should be the name of the that is the source for the clone. `script_args`: `-C` passes a `-C` to the bootstrap script, which only configures the minion and doesn't try to install a new copy of `salt-minion`. This way the minion gets new keys and the keys get pre-seeded on the master, and the `/etc/salt/minion` file has the right `'id'` declaration.

Cloning requires a post 2015-02-01 `salt-bootstrap`.

```
class salt.cloud.clouds.linode.NodeAuthPassword(password, generated=False)
```

A password to be used for authentication to a node.

```
class salt.cloud.clouds.linode.NodeAuthSSHKey(pubkey)
```

An SSH key to be installed for authentication to a node. This is the actual contents of the users ssh public key which will normally be installed as root's public key on the node. `>>> pubkey = `..!` # read from file >>> from libcloud.compute.base import NodeAuthSSHKey >>> k = NodeAuthSSHKey(pubkey) >>> k <NodeAuthSSHKey>`

```
salt.cloud.clouds.linode.boot(LinodeID=None, configid=None)
```

Execute a boot sequence on a linode

```
salt.cloud.clouds.linode.create(vm_)
```

Create a single VM from a data dict

```
salt.cloud.clouds.linode.create_config(vm_, LinodeID=None, root_disk_id=None, swap_disk_id=None)
```

Create a Linode Config

```
salt.cloud.clouds.linode.create_disk_from_distro(vm_=None, LinodeID=None, swapsize=None)
```

Create the disk for the linode

```
salt.cloud.clouds.linode.create_swap_disk(vm_=None, LinodeID=None, swapsize=None)
```

Create the disk for the linode

```
salt.cloud.clouds.linode.get_auth(vm_)
```

Return either `NodeAuthSSHKey` or `NodeAuthPassword`, preferring `NodeAuthSSHKey` if both are provided.

```
salt.cloud.clouds.linode.get_configured_provider()
```

Return the first configured instance.

```
salt.cloud.clouds.linode.get_conn()
```

Return a `conn` object for the passed VM data

```
salt.cloud.clouds.linode.get_kernels(conn=None)
```

Get Linode's list of kernels available

```
salt.cloud.clouds.linode.get_one_kernel(conn=None, name=None)
```

Return data on one kernel `name=None` returns latest kernel

```
salt.cloud.clouds.linode.get_password(vm_)
```

Return the password to use

`salt.cloud.clouds.linode.get_private_ip(vm_)`

Return True if a private ip address is requested

`salt.cloud.clouds.linode.get_pubkey(vm_)`

Return the SSH pubkey to use

`salt.cloud.clouds.linode.get_ssh_key_filename(vm_)`

Return path to filename if `get_auth()` returns a `NodeAuthSSHKey`.

`salt.cloud.clouds.linode.get_swap(vm_)`

Return the amount of swap space to use in MB

`salt.cloud.clouds.linode.remove_complex_types(dictionary)`

Linode-python is now returning some complex types that are not serializable by msgpack. Kill those.

`salt.cloud.clouds.linode.waitfor_job(conn=None, LinodeID=None, JobID=None, timeout=300, quiet=True)`

`salt.cloud.clouds.linode.waitfor_status(conn=None, LinodeID=None, status=None, timeout=300, quiet=True)`

Wait for a certain status

### 30.5.12 salt.cloud.clouds.lxc

#### Install Salt on an LXC Container

New in version 2014.7.0.

Please read *core config documentation*.

`salt.cloud.clouds.lxc.avail_images()`

`salt.cloud.clouds.lxc.create(vm_, call=None)`

Create an lxc Container. This function is idempotent and will try to either provision or finish the provision of an lxc container.

NOTE: Most of the initialization code has been moved and merged with the lxc runner and lxc.init functions

`salt.cloud.clouds.lxc.destroy(vm_, call=None)`

Destroy a lxc container

`salt.cloud.clouds.lxc.get_configured_provider(vm_=None)`

Return the contextual provider of None if no configured one can be found.

`salt.cloud.clouds.lxc.get_provider(name)`

`salt.cloud.clouds.lxc.list_nodes(conn=None, call=None)`

`salt.cloud.clouds.lxc.list_nodes_full(conn=None, call=None)`

`salt.cloud.clouds.lxc.list_nodes_select(call=None)`

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.lxc.show_instance(name, call=None)`

Show the details from the provider concerning an instance

### 30.5.13 salt.cloud.clouds.msazure

#### Azure Cloud Module

The Azure cloud module is used to control access to Microsoft Azure

**depends**

- [Microsoft Azure SDK for Python](#)

**configuration** Required provider parameters:

- `apikey`
- `certificate_path`
- `subscription_id`

A Management Certificate (.pem and .crt files) must be created and the .pem file placed on the same machine that salt-cloud is run from. Information on creating the pem file to use, and uploading the associated cer file can be found at:

<http://www.windowsazure.com/en-us/develop/python/how-to-guides/service-management/>

Example `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/azure.conf` configuration:

```
my-azure-config:
  provider: azure
  subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
  certificate_path: /etc/salt/azure.pem
  management_host: management.core.windows.net
```

`salt.cloud.clouds.msazure.avail_images` (*conn=None, call=None*)

List available images for Azure

`salt.cloud.clouds.msazure.avail_locations` (*conn=None, call=None*)

List available locations for Azure

`salt.cloud.clouds.msazure.avail_sizes` (*call=None*)

Because sizes are built into images with Azure, there will be no sizes to return here

`salt.cloud.clouds.msazure.create` (*vm\_*)

Create a single VM from a data dict

`salt.cloud.clouds.msazure.create_attach_volumes` (*name, kwargs, call=None, wait\_to\_finish=True*)

Create and attach volumes to created node

`salt.cloud.clouds.msazure.destroy` (*name, conn=None, call=None, kwargs=None*)

Destroy a VM

CLI Examples:

```
salt-cloud -d myminion
salt-cloud -a destroy myminion service_name=myservice
```

`salt.cloud.clouds.msazure.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.msazure.get_conn` ()

Return a conn object for the passed VM data

`salt.cloud.clouds.msazure.list_disks` (*conn=None, call=None*)

Destroy a VM

`salt.cloud.clouds.msazure.list_hosted_services` (*conn=None, call=None*)

List VMs on this Azure account, with full information

`salt.cloud.clouds.msazure.list_nodes` (*conn=None, call=None*)

List VMs on this Azure account

`salt.cloud.clouds.msazure.list_nodes_full` (*conn=None, call=None*)

List VMs on this Azure account, with full information

`salt.cloud.clouds.msazure.list_nodes_select` (*conn=None, call=None*)

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.msazure.list_storage_services` (*conn=None, call=None*)

List VMs on this Azure account, with full information

`salt.cloud.clouds.msazure.script` (*vm\_*)

Return the script deployment object

`salt.cloud.clouds.msazure.show_instance` (*name, call=None*)

Show the details from the provider concerning an instance

`salt.cloud.clouds.msazure.show_service` (*kwargs=None, conn=None, call=None*)

Show the details from the provider concerning an instance

### 30.5.14 salt.cloud.clouds.nova

#### OpenStack Nova Cloud Module

PLEASE NOTE: This module is currently in early development, and considered to be experimental and unstable. It is not recommended for production use. Unless you are actively developing code in this module, you should use the OpenStack module instead.

OpenStack is an open source project that is in use by a number a cloud providers, each of which have their own ways of using it.

The OpenStack Nova module for Salt Cloud was bootstrapped from the OpenStack module for Salt Cloud, which uses a libcloud-based connection. The Nova module is designed to use the nova and glance modules already built into Salt.

These modules use the Python novaclient and glanceclient libraries, respectively. In order to use this module, the proper salt configuration must also be in place. This can be specified in the master config, the minion config, a set of grains or a set of pillars.

```
my_openstack_profile:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
```

Note that there is currently a dependency upon netaddr. This can be installed on Debian-based systems by means of the python-netaddr package.

This module currently requires the latest develop branch of Salt to be installed.

This module has been tested to work with HP Cloud and Rackspace. See the documentation for specific options for either of these providers. These examples could be set up in the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/openstack.conf`:

```
my-openstack-config:
  # The ID of the minion that will execute the salt nova functions
  auth_minion: myminion
  # The name of the configuration profile to use on said minion
  config_profile: my_openstack_profile
```

```
ssh_key_name: mykey

provider: nova
userdata_file: /tmp/userdata.txt
```

For local installations that only use private IP address ranges, the following option may be useful. Using the old syntax:

Note: For api use, you will need an auth plugin. The base novaclient does not support apikeys, but some providers such as rackspace have extended keystone to accept them

```
my-openstack-config:
  # Ignore IP addresses on this network for bootstrap
  ignore_cidr: 192.168.50.0/24

my-nova:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/'
  compute_region: IAD
  user: myusername
  password: mypassword
  tenant: <userid>
  provider: nova

my-api:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/'
  compute_region: IAD
  user: myusername
  api_key: <api_key>
  os_auth_plugin: rackspace
  tenant: <userid>
  provider: nova
  networks:
    - net-id: 47a38ff2-fe21-4800-8604-42bd1848e743
    - net-id: 00000000-0000-0000-0000-000000000000
    - net-id: 11111111-1111-1111-1111-111111111111
```

Note: You must include the default net-ids when setting networks or the server will be created without the rest of the interfaces

Note: For rackconnect v3, rackconnectv3 needs to be specified with the rackconnect v3 cloud network as it's variable

`salt.cloud.clouds.nova.attach_volume` (*name*, *server\_name*, *device*='/dev/xvdb', *\*\*kwargs*)

Attach block volume

`salt.cloud.clouds.nova.avail_images` ()

Return a dict of all available VM images on the cloud provider.

`salt.cloud.clouds.nova.avail_locations` (*conn*=None, *call*=None)

Return a list of locations

`salt.cloud.clouds.nova.avail_sizes` ()

Return a dict of all available VM sizes on the cloud provider.

`salt.cloud.clouds.nova.create` (*vm\_*)

Create a single VM from a data dict

`salt.cloud.clouds.nova.create_attach_volumes` (*name*, *call*=None, *\*\*kwargs*)

Create and attach volumes to created node

`salt.cloud.clouds.nova.create_volume`(*name*, *size=100*, *snapshot=None*, *voltype=None*,  
\*\**kwargs*)  
Create block storage device

`salt.cloud.clouds.nova.destroy`(*name*, *conn=None*, *call=None*)  
Delete a single VM

`salt.cloud.clouds.nova.get_configured_provider`()  
Return the first configured instance.

`salt.cloud.clouds.nova.get_conn`()  
Return a conn object for the passed VM data

`salt.cloud.clouds.nova.get_image`(*conn*, *vm\_*)  
Return the image object to use

`salt.cloud.clouds.nova.get_salt_interface`(*vm\_*)  
Return the salt\_interface type to connect to. Either `public\_ips` (default) or `private\_ips`.

`salt.cloud.clouds.nova.get_size`(*conn*, *vm\_*)  
Return the VM's size object

`salt.cloud.clouds.nova.ignore_cidr`(*vm\_*, *ip*)  
Return True if we are to ignore the specified IP. Compatible with IPv4.

`salt.cloud.clouds.nova.list_nodes`(*call=None*, \*\**kwargs*)  
Return a list of the VMs that in this location

`salt.cloud.clouds.nova.list_nodes_full`(*call=None*, \*\**kwargs*)  
Return a list of the VMs that in this location

`salt.cloud.clouds.nova.list_nodes_select`(*call=None*)  
Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.nova.managedcloud`(*vm\_*)  
Determine if we should wait for the managed cloud automation before running. Either `False` (default) or `True`.

`salt.cloud.clouds.nova.network_create`(*name*, \*\**kwargs*)  
Create private networks

`salt.cloud.clouds.nova.network_list`(*call=None*, \*\**kwargs*)  
List private networks

`salt.cloud.clouds.nova.preferred_ip`(*vm\_*, *ips*)  
Return the preferred Internet protocol. Either `ipv4` (default) or `ipv6`.

`salt.cloud.clouds.nova.rackconnect`(*vm\_*)  
Determine if we should wait for rackconnect automation before running. Either `False` (default) or `True`.

`salt.cloud.clouds.nova.reboot`(*name*, *conn=None*)  
Reboot a single VM

`salt.cloud.clouds.nova.request_instance`(*vm\_=None*, *call=None*)  
Put together all of the information necessary to request an instance through Novaclient and then fire off the request the instance.  
  
Returns data about the instance

`salt.cloud.clouds.nova.script`(*vm\_*)  
Return the script deployment object

`salt.cloud.clouds.nova.show_instance`(*name*, *call=None*)  
Show the details from the provider concerning an instance

```

salt.cloud.clouds.nova.ssh_interface(vm_)
    Return the ssh_interface type to connect to. Either `public_ips' (default) or `private_ips'.

salt.cloud.clouds.nova.virtual_interface_create(name, net_name, **kwargs)
    Create private networks

salt.cloud.clouds.nova.virtual_interface_list(name, **kwargs)
    Create private networks

salt.cloud.clouds.nova.volume_attach(name, server_name, device='/dev/xvdb', **kwargs)
    Attach block volume

salt.cloud.clouds.nova.volume_create(name, size=100, snapshot=None, voltype=None,
                                     **kwargs)
    Create block storage device

salt.cloud.clouds.nova.volume_create_attach(name, call=None, **kwargs)
    Create and attach volumes to created node

salt.cloud.clouds.nova.volume_delete(name, **kwargs)
    Delete block storage device

salt.cloud.clouds.nova.volume_detach(name, **kwargs)
    Detach block volume

salt.cloud.clouds.nova.volume_list(**kwargs)
    List block devices

```

### 30.5.15 salt.cloud.clouds.opennebula

#### OpenNebula Cloud Module

The OpenNebula cloud module is used to control access to an OpenNebula cloud.

**depends** lxml

Use of this module requires the `xml_rpc`, `user` and `password` parameter to be set. Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/opennebula.conf`:

```

my-opennebula-config:
  xml_rpc: http://localhost:2633/RPC2
  user: oneadmin
  password: JHGhgsayu32jsa
  provider: opennebula

```

```

salt.cloud.clouds.opennebula.avail_images(call=None)
    Return a list of the templates that are on the provider

salt.cloud.clouds.opennebula.avail_locations(call=None)
    Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.opennebula.avail_sizes(call=None)
    Because sizes are built into templates with OpenNebula, there will be no sizes to return here

salt.cloud.clouds.opennebula.create(vm_)
    Create a single VM from a data dict

salt.cloud.clouds.opennebula.destroy(name, call=None)
    Destroy a node. Will check termination protection and warn if enabled.

CLI Example:

```

```
salt-cloud --destroy mymachine
```

**salt.cloud.clouds.opennebula.get\_configured\_provider()**  
Return the first configured instance.

**salt.cloud.clouds.opennebula.get\_image**(*vm\_*)  
Return the image object to use

**salt.cloud.clouds.opennebula.get\_location**(*vm\_*)  
Return the VM's location

**salt.cloud.clouds.opennebula.list\_nodes**(*call=None*)  
Return a list of the VMs that are on the provider

**salt.cloud.clouds.opennebula.list\_nodes\_full**(*call=None*)  
Return a list of the VMs that are on the provider

**salt.cloud.clouds.opennebula.list\_nodes\_select**(*call=None*)  
Return a list of the VMs that are on the provider, with select fields

**salt.cloud.clouds.opennebula.script**(*vm\_*)  
Return the script deployment object

**salt.cloud.clouds.opennebula.show\_instance**(*name, call=None*)  
Show the details from OpenNebula concerning a VM

### 30.5.16 salt.cloud.clouds.openstack

#### OpenStack Cloud Module

OpenStack is an open source project that is in use by a number a cloud providers, each of which have their own ways of using it.

**depends** libcloud >= 0.13.2

OpenStack provides a number of ways to authenticate. This module uses password- based authentication, using auth v2.0. It is likely to start supporting other methods of authentication provided by OpenStack in the future.

Note that there is currently a dependency upon netaddr. This can be installed on Debian-based systems by means of the python-netaddr package.

This module has been tested to work with HP Cloud and Rackspace. See the documentation for specific options for either of these providers. Some examples, using the old cloud configuration syntax, are provided below:

Set up in the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/openstack.conf`:

```
my-openstack-config:
  # The OpenStack identity service url
  identity_url: https://region-b.geo-1.identity.hpcloudsvc.com:35357/v2.0/
  # The OpenStack compute region
  compute_region: region-b.geo-1
  # The OpenStack compute service name
  compute_name: Compute
  # The OpenStack tenant name (not tenant ID)
  tenant: myuser-tenant1
  # The OpenStack user name
  user: myuser
  # The OpenStack keypair name
  ssh_key_name: mykey
```

```

# Skip SSL certificate validation
insecure: false
# The ssh key file
ssh_key_file: /path/to/keyfile/test.pem
# The OpenStack network UUIDs
networks:
  - fixed:
      - 4402cd51-37ee-435e-a966-8245956dc0e6
  - floating:
      - Ext-Net
files:
  /path/to/dest.txt:
    /local/path/to/src.txt
# Skips the service catalog API endpoint, and uses the following
base_url: http://192.168.1.101:3000/v2/12345
provider: openstack
userdata_file: /tmp/userdata.txt
# config_drive is required for userdata at rackspace
config_drive: True

```

For in-house Openstack Essex installation, libcloud needs the service\_type :

```

my-openstack-config:
  identity_url: 'http://control.openstack.example.org:5000/v2.0/'
  compute_name : Compute Service
  service_type : compute

```

Either a password or an API key must also be specified:

```

my-openstack-password-or-api-config:
# The OpenStack password
password: letmein
# The OpenStack API key
apikey: 901d3f579h23c8v73q9

```

Optionally, if you don't want to save plain-text password in your configuration file, you can use keyring:

```

my-openstack-keyring-config:
# The OpenStack password is stored in keyring
# don't forget to set the password by running something like:
# salt-cloud --set-password=myuser my-openstack-keyring-config
password: USE_KEYRING

```

For local installations that only use private IP address ranges, the following option may be useful. Using the old syntax:

```

my-openstack-config:
# Ignore IP addresses on this network for bootstrap
ignore_cidr: 192.168.50.0/24

```

It is possible to upload a small set of files (no more than 5, and nothing too large) to the remote server. Generally this should not be needed, as salt itself can upload to the server after it is spun up, with nowhere near the same restrictions.

```

my-openstack-config:
files:
  /path/to/dest.txt:
    /local/path/to/src.txt

```

Alternatively, one could use the private IP to connect by specifying:

```
my-openstack-config:
  ssh_interface: private_ips
```

`salt.cloud.clouds.openstack.avail_images` (*conn=None, call=None*)

Return a dict of all available VM images on the cloud provider with relevant data

`salt.cloud.clouds.openstack.avail_locations` (*conn=None, call=None*)

Return a dict of all available VM locations on the cloud provider with relevant data

`salt.cloud.clouds.openstack.avail_sizes` (*conn=None, call=None*)

Return a dict of all available VM images on the cloud provider with relevant data

`salt.cloud.clouds.openstack.create` (*vm\_*)

Create a single VM from a data dict

`salt.cloud.clouds.openstack.destroy` (*name, conn=None, call=None*)

Delete a single VM

`salt.cloud.clouds.openstack.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.openstack.get_conn` ()

Return a conn object for the passed VM data

`salt.cloud.clouds.openstack.get_image` (*conn, vm\_*)

Return the image object to use

`salt.cloud.clouds.openstack.get_node` (*conn, name*)

Return a libcloud node for the named VM

`salt.cloud.clouds.openstack.get_salt_interface` (*vm\_*)

Return the salt\_interface type to connect to. Either 'public\_ips' (default) or 'private\_ips'.

`salt.cloud.clouds.openstack.get_size` (*conn, vm\_*)

Return the VM's size object

`salt.cloud.clouds.openstack.ignore_cidr` (*vm\_, ip*)

Return True if we are to ignore the specified IP. Compatible with IPv4.

`salt.cloud.clouds.openstack.list_nodes` (*conn=None, call=None*)

Return a list of the VMs that are on the provider

`salt.cloud.clouds.openstack.list_nodes_full` (*conn=None, call=None*)

Return a list of the VMs that are on the provider, with all fields

`salt.cloud.clouds.openstack.list_nodes_select` (*conn=None, call=None*)

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.openstack.managedcloud` (*vm\_*)

Determine if we should wait for the managed cloud automation before running. Either 'False' (default) or 'True'.

`salt.cloud.clouds.openstack.networks` (*vm\_, kwargs=None*)

`salt.cloud.clouds.openstack.preferred_ip` (*vm\_, ips*)

Return the preferred Internet protocol. Either 'ipv4' (default) or 'ipv6'.

`salt.cloud.clouds.openstack.rackconnect` (*vm\_*)

Determine if we should wait for rackconnect automation before running. Either 'False' (default) or 'True'.

`salt.cloud.clouds.openstack.reboot` (*name, conn=None*)

Reboot a single VM

`salt.cloud.clouds.openstack.request_instance` (*vm\_=None, call=None*)

Put together all of the information necessary to request an instance on Openstack and then fire off the request the instance.

Returns data about the instance

`salt.cloud.clouds.openstack.script` (*vm\_*)

Return the script deployment object

`salt.cloud.clouds.openstack.show_instance` (*name, call=None*)

Show the details from the provider concerning an instance

`salt.cloud.clouds.openstack.ssh_interface` (*vm\_*)

Return the ssh\_interface type to connect to. Either `'public_ips'` (default) or `'private_ips'`.

### 30.5.17 salt.cloud.clouds.parallels

#### Parallels Cloud Module

The Parallels cloud module is used to control access to cloud providers using the Parallels VPS system.

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/parallels.c`

```
my-parallels-config:
  # Parallels account information
  user: myuser
  password: mypassword
  url: https://api.cloud.xmission.com:4465/paci/v1.0/
  provider: parallels
```

`salt.cloud.clouds.parallels.avail_images` (*call=None*)

Return a list of the images that are on the provider

`salt.cloud.clouds.parallels.create` (*vm\_*)

Create a single VM from a data dict

`salt.cloud.clouds.parallels.create_node` (*vm\_*)

Build and submit the XML to create a node

`salt.cloud.clouds.parallels.destroy` (*name, call=None*)

Destroy a node.

CLI Example:

```
salt-cloud --destroy mymachine
```

`salt.cloud.clouds.parallels.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.parallels.get_image` (*vm\_*)

Return the image object to use

`salt.cloud.clouds.parallels.list_nodes` (*call=None*)

Return a list of the VMs that are on the provider

`salt.cloud.clouds.parallels.list_nodes_full` (*call=None*)

Return a list of the VMs that are on the provider

`salt.cloud.clouds.parallels.list_nodes_select` (*call=None*)

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.parallels.query` (*action=None, command=None, args=None, method='GET', data=None*)

Make a web call to a Parallels provider

`salt.cloud.clouds.parallels.script` (*vm\_*)

Return the script deployment object

`salt.cloud.clouds.parallels.show_image` (*kwargs, call=None*)

Show the details from Parallels concerning an image

`salt.cloud.clouds.parallels.show_instance` (*name, call=None*)

Show the details from Parallels concerning an instance

`salt.cloud.clouds.parallels.start` (*name, call=None*)

Start a node.

CLI Example:

```
salt-cloud -a start mymachine
```

`salt.cloud.clouds.parallels.stop` (*name, call=None*)

Stop a node.

CLI Example:

```
salt-cloud -a stop mymachine
```

`salt.cloud.clouds.parallels.wait_until` (*name, state, timeout=300*)

Wait until a specific state has been reached on a node

### 30.5.18 salt.cloud.clouds.proxmox

#### Proxmox Cloud Module

New in version 2014.7.0.

The Proxmox cloud module is used to control access to cloud providers using the Proxmox system (KVM / OpenVZ).

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/proxmox.com`

```
my-proxmox-config:
  # Proxmox account information
  user: myuser@pam or myuser@pve
  password: mypassword
  url: hypervisor.domain.tld
  provider: proxmox
  verify_ssl: True
```

**maintainer** Frank Klaassen <frank@cloudright.nl>

**maturity** new

**depends** requests >= 2.2.1

**depends** IPy >= 0.81

`salt.cloud.clouds.proxmox.avail_images` (*call=None, location='local'*)

Return a list of the images that are on the provider

CLI Example:

```
salt-cloud --list-images my-proxmox-config
```

**salt.cloud.clouds.proxmox.avail\_locations**(*call=None*)

Return a list of the hypervisors (nodes) which this Proxmox PVE machine manages

CLI Example:

```
salt-cloud --list-locations my-proxmox-config
```

**salt.cloud.clouds.proxmox.create**(*vm\_*)

Create a single VM from a data dict

CLI Example:

```
salt-cloud -p proxmox-ubuntu vmhostname
```

**salt.cloud.clouds.proxmox.create\_node**(*vm\_*)

Build and submit the requestdata to create a new node

**salt.cloud.clouds.proxmox.destroy**(*name, call=None*)

Destroy a node.

CLI Example:

```
salt-cloud --destroy mymachine
```

**salt.cloud.clouds.proxmox.get\_configured\_provider**()

Return the first configured instance.

**salt.cloud.clouds.proxmox.get\_resources\_nodes**(*call=None, resFilter=None*)

Retrieve all hypervisors (nodes) available on this environment CLI Example:

```
salt-cloud -f get_resources_nodes my-proxmox-config
```

**salt.cloud.clouds.proxmox.get\_resources\_vms**(*call=None, resFilter=None, includeConfig=True*)

Retrieve all VMs available on this environment

CLI Example:

```
salt-cloud -f get_resources_vms my-proxmox-config
```

**salt.cloud.clouds.proxmox.get\_vm\_status**(*vmid=None, name=None*)

Get the status for a VM, either via the ID or the hostname

**salt.cloud.clouds.proxmox.get\_vmconfig**(*vmid, node=None, node\_type='openvz'*)

Get VM configuration

**salt.cloud.clouds.proxmox.list\_nodes**(*call=None*)

Return a list of the VMs that are managed by the provider

CLI Example:

```
salt-cloud -Q my-proxmox-config
```

**salt.cloud.clouds.proxmox.list\_nodes\_full**(*call=None*)

Return a list of the VMs that are on the provider

CLI Example:

```
salt-cloud -F my-proxmox-config
```

`salt.cloud.clouds.proxmox.list_nodes_select` (*call=None*)

Return a list of the VMs that are on the provider, with select fields

CLI Example:

```
salt-cloud -S my-proxmox-config
```

`salt.cloud.clouds.proxmox.query` (*conn\_type, option, post\_data=None*)

Execute the HTTP request to the API

`salt.cloud.clouds.proxmox.script` (*vm\_*)

Return the script deployment object

`salt.cloud.clouds.proxmox.set_vm_status` (*status, name=None, vmid=None*)

Convenience function for setting VM status

`salt.cloud.clouds.proxmox.show_instance` (*name, call=None*)

Show the details from Proxmox concerning an instance

`salt.cloud.clouds.proxmox.shutdown` (*name=None, vmid=None, call=None*)

Shutdown a node via ACPI.

CLI Example:

```
salt-cloud -a shutdown mymachine
```

`salt.cloud.clouds.proxmox.start` (*name, vmid=None, call=None*)

Start a node.

CLI Example:

```
salt-cloud -a start mymachine
```

`salt.cloud.clouds.proxmox.stop` (*name, vmid=None, call=None*)

Stop a node ("pulling the plug").

CLI Example:

```
salt-cloud -a stop mymachine
```

`salt.cloud.clouds.proxmox.wait_for_created` (*upid, timeout=300*)

Wait until a the vm has been created successfully

`salt.cloud.clouds.proxmox.wait_for_state` (*vmid, state, timeout=300*)

Wait until a specific state has been reached on a node

### 30.5.19 salt.cloud.clouds.pyrax

#### Pyrax Cloud Module

PLEASE NOTE: This module is currently in early development, and considered to be experimental and unstable. It is not recommended for production use. Unless you are actively developing code in this module, you should use the OpenStack module instead.

`salt.cloud.clouds.pyrax.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.pyrax.get_conn` (*conn\_type*)

Return a conn object for the passed VM data

`salt.cloud.clouds.pyrax.queues_create` (*call, kwargs*)

`salt.cloud.clouds.pyrax.queues_delete` (*call, kwargs*)

`salt.cloud.clouds.pyrax.queues_exists` (*call, kwargs*)

`salt.cloud.clouds.pyrax.queues_show` (*call, kwargs*)

### 30.5.20 salt.cloud.clouds.rackspace

#### Rackspace Cloud Module

The Rackspace cloud module. This module uses the preferred means to set up a libcloud based cloud module and should be used as the general template for setting up additional libcloud based modules.

**depends** libcloud >= 0.13.2

Please note that the *rackspace* driver is only intended for 1st gen instances, aka, "the old cloud" at Rackspace. It is required for 1st gen instances, but will *not* work with OpenStack-based instances. Unless you explicitly have a reason to use it, it is highly recommended that you use the *openstack* driver instead.

The rackspace cloud module interfaces with the Rackspace public cloud service and requires that two configuration parameters be set for use, `user` and `apikey`.

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/rackspace.conf`

```
my-rackspace-config:
  provider: rackspace
  # The Rackspace login user
  user: fred
  # The Rackspace user's apikey
  apikey: 901d3f579h23c8v73q9
```

`salt.cloud.clouds.rackspace.avail_images` (*conn=None, call=None*)

Return a dict of all available VM images on the cloud provider with relevant data

`salt.cloud.clouds.rackspace.avail_locations` (*conn=None, call=None*)

Return a dict of all available VM locations on the cloud provider with relevant data

`salt.cloud.clouds.rackspace.avail_sizes` (*conn=None, call=None*)

Return a dict of all available VM images on the cloud provider with relevant data

`salt.cloud.clouds.rackspace.create` (*vm\_*)

Create a single VM from a data dict

`salt.cloud.clouds.rackspace.destroy` (*name, conn=None, call=None*)

Delete a single VM

`salt.cloud.clouds.rackspace.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.rackspace.get_conn` ()

Return a conn object for the passed VM data

`salt.cloud.clouds.rackspace.get_image` (*conn, vm\_*)

Return the image object to use

`salt.cloud.clouds.rackspace.get_salt_interface` (*vm\_*)

Return the salt\_interface type to connect to. Either 'public\_ips' (default) or 'private\_ips'.

`salt.cloud.clouds.rackspace.get_size` (*conn, vm\_*)

Return the VM's size object

`salt.cloud.clouds.rackspace.list_nodes(conn=None, call=None)`

Return a list of the VMs that are on the provider

`salt.cloud.clouds.rackspace.list_nodes_full(conn=None, call=None)`

Return a list of the VMs that are on the provider, with all fields

`salt.cloud.clouds.rackspace.list_nodes_select(conn=None, call=None)`

Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.rackspace.preferred_ip(vm_, ips)`

Return the preferred Internet protocol. Either 'ipv4' (default) or 'ipv6'.

`salt.cloud.clouds.rackspace.script(vm_)`

Return the script deployment object

`salt.cloud.clouds.rackspace.show_instance(name, call=None)`

Show the details from the provider concerning an instance

`salt.cloud.clouds.rackspace.ssh_interface(vm_)`

Return the ssh\_interface type to connect to. Either 'public\_ips' (default) or 'private\_ips'.

### 30.5.21 salt.cloud.clouds.saltify

#### Saltify Module

The Saltify module is designed to install Salt on a remote machine, virtual or bare metal, using SSH. This module is useful for provisioning machines which are already installed, but not Salted.

Use of this module requires some configuration in cloud profile and provider files as described in the [Getting Started with Saltify](#) documentation.

`salt.cloud.clouds.saltify.create(vm_)`

Provision a single machine

`salt.cloud.clouds.saltify.get_configured_provider()`

Return the first configured instance.

`salt.cloud.clouds.saltify.list_nodes()`

Because this module is not specific to any cloud providers, there will be no nodes to list.

`salt.cloud.clouds.saltify.list_nodes_full()`

Because this module is not specific to any cloud providers, there will be no nodes to list.

`salt.cloud.clouds.saltify.list_nodes_select()`

Because this module is not specific to any cloud providers, there will be no nodes to list.

### 30.5.22 salt.cloud.clouds.softlayer

#### SoftLayer Cloud Module

The SoftLayer cloud module is used to control access to the SoftLayer VPS system.

Use of this module only requires the `apikey` parameter. Set up the cloud configuration at:

`/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/softlayer.conf`:

```
my-softlayer-config:
  # SoftLayer account api key
  user: MYLOGIN
```

```
apikey: JVkbSJDGHS DKUKSDJfhskdlfjgsjdkflhjl sdfffhgdgjenrtuin
provider: softlayer
```

The SoftLayer Python Library needs to be installed in order to use the SoftLayer salt.cloud modules. See: <https://pypi.python.org/pypi/SoftLayer>

**depends** softlayer

**salt.cloud.clouds.softlayer.avail\_images**(*call=None*)

Return a dict of all available VM images on the cloud provider.

**salt.cloud.clouds.softlayer.avail\_locations**(*call=None*)

List all available locations

**salt.cloud.clouds.softlayer.avail\_sizes**(*call=None*)

Return a dict of all available VM sizes on the cloud provider with relevant data. This data is provided in three dicts.

**salt.cloud.clouds.softlayer.create**(*vm\_*)

Create a single VM from a data dict

**salt.cloud.clouds.softlayer.destroy**(*name, call=None*)

Destroy a node.

CLI Example:

```
salt-cloud --destroy mymachine
```

**salt.cloud.clouds.softlayer.get\_configured\_provider**()

Return the first configured instance.

**salt.cloud.clouds.softlayer.get\_conn**(*service='SoftLayer\_Virtual\_Guest'*)

Return a conn object for the passed VM data

**salt.cloud.clouds.softlayer.get\_location**(*vm\_=None*)

**Return the location to use, in this order:**

- CLI parameter
- VM parameter
- Cloud profile setting

**salt.cloud.clouds.softlayer.list\_custom\_images**(*call=None*)

Return a dict of all custom VM images on the cloud provider.

**salt.cloud.clouds.softlayer.list\_nodes**(*call=None*)

Return a list of the VMs that are on the provider

**salt.cloud.clouds.softlayer.list\_nodes\_full**(*mask='mask[id]'; call=None*)

Return a list of the VMs that are on the provider

**salt.cloud.clouds.softlayer.list\_nodes\_select**(*call=None*)

Return a list of the VMs that are on the provider, with select fields

**salt.cloud.clouds.softlayer.list\_vlans**(*call=None*)

List all VLANs associated with the account

**salt.cloud.clouds.softlayer.script**(*vm\_*)

Return the script deployment object

**salt.cloud.clouds.softlayer.show\_instance**(*name, call=None*)

Show the details from SoftLayer concerning a guest

### 30.5.23 salt.cloud.clouds.softlayer\_hw

#### SoftLayer HW Cloud Module

The SoftLayer HW cloud module is used to control access to the SoftLayer hardware cloud system

Use of this module only requires the `apikey` parameter. Set up the cloud configuration at:

`/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/softlayer.conf`:

```
my-softlayer-config:
  # SoftLayer account api key
  user: MYLOGIN
  apikey: JVkbSJDGHSDKUKSDJfhsdklfjgsjdkflhjlsdffhgdgjenrtuin
  provider: softlayer_hw
```

The SoftLayer Python Library needs to be installed in order to use the SoftLayer salt.cloud modules. See: <https://pypi.python.org/pypi/SoftLayer>

**depends** softlayer

`salt.cloud.clouds.softlayer_hw.avail_images` (*call=None*)

Return a dict of all available VM images on the cloud provider.

`salt.cloud.clouds.softlayer_hw.avail_locations` (*call=None*)

List all available locations

`salt.cloud.clouds.softlayer_hw.avail_sizes` (*call=None*)

Return a dict of all available VM sizes on the cloud provider with relevant data. This data is provided in three dicts.

`salt.cloud.clouds.softlayer_hw.create` (*vm\_*)

Create a single VM from a data dict

`salt.cloud.clouds.softlayer_hw.destroy` (*name, call=None*)

Destroy a node.

CLI Example:

```
salt-cloud --destroy mymachine
```

`salt.cloud.clouds.softlayer_hw.get_configured_provider` ()

Return the first configured instance.

`salt.cloud.clouds.softlayer_hw.get_conn` (*service='SoftLayer\_Hardware'*)

Return a conn object for the passed VM data

`salt.cloud.clouds.softlayer_hw.get_location` (*vm\_=None*)

**Return the location to use, in this order:**

- CLI parameter
- VM parameter
- Cloud profile setting

`salt.cloud.clouds.softlayer_hw.list_nodes` (*call=None*)

Return a list of the VMs that are on the provider

```
salt.cloud.clouds.softlayer_hw.list_nodes_full(mask='mask[id, hostname, primaryI-
                                             pAddress, primaryBackendIpAddress,
                                             processorPhysicalCoreAmount, memo-
                                             ryCount]', call=None)
```

Return a list of the VMs that are on the provider

```
salt.cloud.clouds.softlayer_hw.list_nodes_select(call=None)
```

Return a list of the VMs that are on the provider, with select fields

```
salt.cloud.clouds.softlayer_hw.list_vlans(call=None)
```

List all VLANs associated with the account

```
salt.cloud.clouds.softlayer_hw.script(vm_)
```

Return the script deployment object

```
salt.cloud.clouds.softlayer_hw.show_instance(name, call=None)
```

Show the details from SoftLayer concerning a guest

### 30.5.24 salt.cloud.clouds.vsphere

#### vSphere Cloud Module

**Note:** Deprecated since version Carbon: The *vsphere* cloud driver has been deprecated in favor of the *vmware* cloud driver and will be removed in Salt Carbon. Please refer to [Getting started with VMware](#) to get started and convert your vsphere provider configurations to use the vmware driver.

The vSphere cloud module is used to control access to VMWare vSphere.

#### depends

- PySphere Python module >= 0.1.8

Note: Ensure python pysphere module is installed by running following one-liner check. The output should be 0.

```
python -c "import pysphere" ; echo $?
# if this fails install using
pip install https://pysphere.googlecode.com/files/pysphere-0.1.8.zip
```

Use of this module only requires a URL, username and password. Set up the cloud configuration at:

`/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/vsphere.conf`:

```
my-vsphere-config:
  provider: vsphere
  user: myuser
  password: verybadpass
  template_user: root
  template_password: mybadVMpassword
  url: 'https://10.1.1.1:443'
```

Note: Your URL may or may not look like any of the following, depending on how your VMWare installation is configured:

```
10.1.1.1
10.1.1.1:443
https://10.1.1.1:443
https://10.1.1.1:443/sdk
10.1.1.1:443/sdk
```

**folder** Name of the folder that will contain the new VM. If not set, the VM will be added to the folder the original VM belongs to.

**resourcepool** MOR of the resourcepool to be used for the new vm. If not set, it uses the same resourcepool than the original vm.

**datastore** MOR of the datastore where the virtual machine should be located. If not specified, the current datastore is used.

**host** MOR of the host where the virtual machine should be registered.

**Id not specified:**

- if resourcepool is not specified, current host is used.
- if resourcepool is specified, and the target pool represents a stand-alone host, the host is used.
- if resourcepool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
- if resourcepool is specified and the target pool represents a cluster without DRS enabled, an `InvalidArgument` exception will be thrown.

**template** Specifies whether or not the new virtual machine should be marked as a template. Default is `False`.

**template\_user** Specifies the user to access the VM. Should be

**template\_password** The password with which to access the VM.

**sudo** The user to access the VM with sudo privileges.

New in version 2015.5.2.

**sudo\_password** The password corresponding to the sudo user to access the VM with sudo privileges.

New in version 2015.5.2.

**salt.cloud.clouds.vsphere.avail\_images()**

Return a dict of all available VM images on the cloud provider.

**salt.cloud.clouds.vsphere.avail\_locations()**

Return a dict of all available VM locations on the cloud provider with relevant data

**salt.cloud.clouds.vsphere.create(vm\_)**

Create a single VM from a data dict

**salt.cloud.clouds.vsphere.destroy(name, call=None)**

Destroy a node.

CLI Example:

```
salt-cloud --destroy mymachine
```

**salt.cloud.clouds.vsphere.get\_configured\_provider()**

Return the first configured instance.

**salt.cloud.clouds.vsphere.get\_conn()**

Return a conn object for the passed VM data

**salt.cloud.clouds.vsphere.list\_clusters(kwargs=None, call=None)**

List the clusters for this VMware environment

**salt.cloud.clouds.vsphere.list\_datacenters(kwargs=None, call=None)**

List the data centers for this VMware environment

`salt.cloud.clouds.vsphere.list_datastores` (*kwargs=None, call=None*)  
List the datastores for this VMware environment

`salt.cloud.clouds.vsphere.list_folders` (*kwargs=None, call=None*)  
List the folders for this VMWare environment

`salt.cloud.clouds.vsphere.list_hosts` (*kwargs=None, call=None*)  
List the hosts for this VMware environment

`salt.cloud.clouds.vsphere.list_nodes` (*kwargs=None, call=None*)  
Return a list of the VMs that are on the provider, with basic fields

`salt.cloud.clouds.vsphere.list_nodes_full` (*kwargs=None, call=None*)  
Return a list of the VMs that are on the provider with full details

`salt.cloud.clouds.vsphere.list_nodes_min` (*kwargs=None, call=None*)  
Return a list of the nodes in the provider, with no details

`salt.cloud.clouds.vsphere.list_nodes_select` ()  
Return a list of the VMs that are on the provider, with select fields

`salt.cloud.clouds.vsphere.list_resourcepools` (*kwargs=None, call=None*)  
List the hosts for this VMware environment

`salt.cloud.clouds.vsphere.script` (*vm\_*)  
Return the script deployment object

`salt.cloud.clouds.vsphere.show_instance` (*name, call=None*)  
Show the details from vSphere concerning a guest

`salt.cloud.clouds.vsphere.wait_for_ip` (*vm\_*)

## 30.6 Configuration file examples

- *Example master configuration file*
- *Example minion configuration file*

### 30.6.1 Example master configuration file

```
##### Primary configuration settings #####
#####
# This configuration file is used to manage the behavior of the Salt Master.
# Values that are commented out but have an empty line after the comment are
# defaults that do not need to be set in the config. If there is no blank line
# after the comment then the value is presented as an example and is not the
# default.

# Per default, the master will automatically include all config files
# from master.d/*.conf (master.d is a directory in the same directory
# as the main master config file).
#default_include: master.d/*.conf

# The address of the interface to bind to:
#interface: 0.0.0.0
```

```
# Whether the master should listen for IPv6 connections. If this is set to True,
# the interface option must be adjusted, too. (For example: "interface: ':::')
#ipv6: False

# The tcp port used by the publisher:
#publish_port: 4505

# The user under which the salt master will run. Salt will update all
# permissions to allow the specified user to run the master. The exception is
# the job cache, which must be deleted if this user is changed. If the
# modified files cause conflicts, set verify_env to False.
#user: root

# Max open files
#
# Each minion connecting to the master uses AT LEAST one file descriptor, the
# master subscription connection. If enough minions connect you might start
# seeing on the console (and then salt-master crashes):
#   Too many open files (tcp_listener.cpp:335)
#   Aborted (core dumped)
#
# By default this value will be the one of `ulimit -Hn`, ie, the hard limit for
# max open files.
#
# If you wish to set a different value than the default one, uncomment and
# configure this setting. Remember that this value CANNOT be higher than the
# hard limit. Raising the hard limit depends on your OS and/or distribution,
# a good way to find the limit is to search the internet. For example:
#   raise max open files hard limit debian
#
#max_open_files: 100000

# The number of worker threads to start. These threads are used to manage
# return calls made from minions to the master. If the master seems to be
# running slowly, increase the number of threads. This setting can not be
# set lower than 3.
#worker_threads: 5

# The port used by the communication interface. The ret (return) port is the
# interface used for the file server, authentication, job returns, etc.
#ret_port: 4506

# Specify the location of the daemon process ID file:
#pidfile: /var/run/salt-master.pid

# The root directory prepended to these options: pki_dir, cachedir,
# sock_dir, log_file, autosign_file, autoreject_file, extension_modules,
# key_logfile, pidfile:
#root_dir: /

# Directory used to store public key data:
#pki_dir: /etc/salt/pki/master

# Directory to store job and cache data:
#cachedir: /var/cache/salt/master

# Directory for custom modules. This directory can contain subdirectories for
# each of Salt's module types such as "runners", "output", "wheel", "modules",
```

```
# "states", "returners", etc.
#extension_modules: <no default>

# Directory for custom modules. This directory can contain subdirectories for
# each of Salt's module types such as "runners", "output", "wheel", "modules",
# "states", "returners", etc.
# Like 'extension_modules' but can take an array of paths
#module_dirs: <no default>
# - /var/cache/salt/minion/extmods

# Verify and set permissions on configuration directories at startup:
#verify_env: True

# Set the number of hours to keep old job information in the job cache:
#keep_jobs: 24

# Set the default timeout for the salt command and api. The default is 5
# seconds.
#timeout: 5

# The loop_interval option controls the seconds for the master's maintenance
# process check cycle. This process updates file server backends, cleans the
# job cache and executes the scheduler.
#loop_interval: 60

# Set the default outputter used by the salt command. The default is "nested".
#output: nested

# Return minions that timeout when running commands like test.ping
#show_timeout: True

# By default, output is colored. To disable colored output, set the color value
# to False.
#color: True

# Do not strip off the colored output from nested results and state outputs
# (true by default).
# strip_colors: False

# To display a summary of the number of minions targeted, the number of
# minions returned, and the number of minions that did not return, set the
# cli_summary value to True. (False by default.)
#
#cli_summary: False

# Set the directory used to hold unix sockets:
#sock_dir: /var/run/salt/master

# The master can take a while to start up when lspci and/or dmidecode is used
# to populate the grains for the master. Enable if you want to see GPU hardware
# data for your master.
# enable_gpu_grains: False

# The master maintains a job cache. While this is a great addition, it can be
# a burden on the master for larger deployments (over 5000 minions).
# Disabling the job cache will make previously executed jobs unavailable to
# the jobs system and is not generally recommended.
#job_cache: True
```

```
# Cache minion grains and pillar data in the cachedir.
#minion_data_cache: True

# Store all returns in the given returner.
# Setting this option requires that any returner-specific configuration also
# be set. See various returners in salt/returners for details on required
# configuration values. (See also, event_return_queue below.)
#
#event_return: mysql

# On busy systems, enabling event_returns can cause a considerable load on
# the storage system for returners. Events can be queued on the master and
# stored in a batched fashion using a single transaction for multiple events.
# By default, events are not queued.
#event_return_queue: 0

# Only return events matching tags in a whitelist,
# event_return_whitelist:
#   - salt/master/a_tag
#   - salt/master/another_tag

# Store all event returns _except_ the tags in a blacklist.
# event_return_blacklist:
#   - salt/master/not_this_tag
#   - salt/master/or_this_one

# Passing very large events can cause the minion to consume large amounts of
# memory. This value tunes the maximum size of a message allowed onto the
# master event bus. The value is expressed in bytes.
#max_event_size: 1048576

# By default, the master AES key rotates every 24 hours. The next command
# following a key rotation will trigger a key refresh from the minion which may
# result in minions which do not respond to the first command after a key refresh.
#
# To tell the master to ping all minions immediately after an AES key refresh, set
# ping_on_rotate to True. This should mitigate the issue where a minion does not
# appear to initially respond after a key is rotated.
#
# Note that ping_on_rotate may cause high load on the master immediately after
# the key rotation event as minions reconnect. Consider this carefully if this
# salt master is managing a large number of minions.
#
# If disabled, it is recommended to handle this event by listening for the
# 'aes_key_rotate' event with the 'key' tag and acting appropriately.
# ping_on_rotate: False

# By default, the master deletes its cache of minion data when the key for that
# minion is removed. To preserve the cache after key deletion, set
# 'preserve_minion_cache' to True.
#
# WARNING: This may have security implications if compromised minions auth with
# a previous deleted minion ID.
#preserve_minion_cache: False

# If max_minions is used in large installations, the master might experience
# high-load situations because of having to check the number of connected
# minions for every authentication. This cache provides the minion-ids of
```

```

# all connected minions to all MWorker-processes and greatly improves the
# performance of max_minions.
# con_cache: False

# The master can include configuration from other files. To enable this,
# pass a list of paths to this option. The paths can be either relative or
# absolute; if relative, they are considered to be relative to the directory
# the main master configuration file lives in (this file). Paths can make use
# of shell-style globbing. If no files are matched by a path passed to this
# option, then the master will log a warning message.
#
# Include a config file from some other path:
# include: /etc/salt/extra_config
#
# Include config from several files and directories:
# include:
#   - /etc/salt/extra_config

#####      Security settings      #####
#####
# Enable "open mode", this mode still maintains encryption, but turns off
# authentication, this is only intended for highly secure environments or for
# the situation where your keys end up in a bad state. If you run in open mode
# you do so at your own risk!
#open_mode: False

# Enable auto_accept, this setting will automatically accept all incoming
# public keys from the minions. Note that this is insecure.
#auto_accept: False

# Time in minutes that a incoming public key with a matching name found in
# pki_dir/minion_autosign/keyid is automatically accepted. Expired autosign keys
# are removed when the master checks the minion_autosign directory.
# 0 equals no timeout
# autosign_timeout: 120

# If the autosign_file is specified, incoming keys specified in the
# autosign_file will be automatically accepted. This is insecure. Regular
# expressions as well as globbing lines are supported.
#autosign_file: /etc/salt/autosign.conf

# Works like autosign_file, but instead allows you to specify minion IDs for
# which keys will automatically be rejected. Will override both membership in
# the autosign_file and the auto_accept setting.
#autoreject_file: /etc/salt/autoreject.conf

# Enable permissive access to the salt keys. This allows you to run the
# master or minion as root, but have a non-root group be given access to
# your pki_dir. To make the access explicit, root must belong to the group
# you've given access to. This is potentially quite insecure. If an autosign_file
# is specified, enabling permissive_pki_access will allow group access to that
# specific file.
#permissive_pki_access: False

# Allow users on the master access to execute specific commands on minions.
# This setting should be treated with care since it opens up execution
# capabilities to non root users. By default this capability is completely

```

```
# disabled.
#client_acl:
#  larry:
#    - test.ping
#    - network.*
#
# Blacklist any of the following users or modules
#
# This example would blacklist all non sudo users, including root from
# running any commands. It would also blacklist any use of the "cmd"
# module. This is completely disabled by default.
#
#client_acl_blacklist:
#  users:
#    - root
#    - '^(?!sudo_).*\$$' # all non sudo users
#  modules:
#    - cmd

# Enforce client_acl & client_acl_blacklist when users have sudo
# access to the salt command.
#
#sudo_acl: False

# The external auth system uses the Salt auth modules to authenticate and
# validate users to access areas of the Salt system.
#external_auth:
#  pam:
#    fred:
#      - test.*
#
# Time (in seconds) for a newly generated token to live. Default: 12 hours
#token_expire: 43200

# Allow minions to push files to the master. This is disabled by default, for
# security purposes.
#file_recv: False

# Set a hard-limit on the size of the files that can be pushed to the master.
# It will be interpreted as megabytes. Default: 100
#file_recv_max_size: 100

# Signature verification on messages published from the master.
# This causes the master to cryptographically sign all messages published to its event
# bus, and minions then verify that signature before acting on the message.
#
# This is False by default.
#
# Note that to facilitate interoperability with masters and minions that are different
# versions, if sign_pub_messages is True but a message is received by a minion with
# no signature, it will still be accepted, and a warning message will be logged.
# Conversely, if sign_pub_messages is False, but a minion receives a signed
# message it will be accepted, the signature will not be checked, and a warning message
# will be logged. This behavior went away in Salt 2014.1.0 and these two situations
# will cause minion to throw an exception and drop the message.
# sign_pub_messages: False

#####      Salt-SSH Configuration      #####
```

```
#####

# Pass in an alternative location for the salt-ssh roster file
#roster_file: /etc/salt/roster

# Pass in minion option overrides that will be inserted into the SHIM for
# salt-ssh calls. The local minion config is not used for salt-ssh. Can be
# overridden on a per-minion basis in the roster (`minion_opts`)
#ssh_minion_opts:
# gpg_keydir: /root/gpg

#####   Master Module Management   #####
#####
# Manage how master side modules are loaded.

# Add any additional locations to look for master runners:
#runner_dirs: []

# Enable Cython for master side modules:
#cython_enable: False

#####   State System settings   #####
#####
# The state system uses a "top" file to tell the minions what environment to
# use and what modules to use. The state_top file is defined relative to the
# root of the base environment as defined in "File Server settings" below.
#state_top: top.sls

# The master_tops option replaces the external_nodes option by creating
# a pluggable system for the generation of external top data. The external_nodes
# option is deprecated by the master_tops option.
#
# To gain the capabilities of the classic external_nodes system, use the
# following configuration:
# master_tops:
#   ext_nodes: <Shell command which returns yaml>
#
#master_tops: {}

# The external_nodes option allows Salt to gather data that would normally be
# placed in a top file. The external_nodes option is the executable that will
# return the ENC data. Remember that Salt will look for external nodes AND top
# files and combine the results if both are enabled!
#external_nodes: None

# The renderer to use on the minions to render the state data
#renderer: yaml_jinja

# The Jinja renderer can strip extra carriage returns and whitespace
# See http://jinja.pocoo.org/docs/api/#high-level-api
#
# If this is set to True the first newline after a Jinja block is removed
# (block, not variable tag!). Defaults to False, corresponds to the Jinja
# environment init variable "trim_blocks".
#jinja_trim_blocks: False
#
# If this is set to True leading spaces and tabs are stripped from the start
```

```
# of a line to a block. Defaults to False, corresponds to the Jinja
# environment init variable "lstrip_blocks".
#jinja_lstrip_blocks: False

# The failhard option tells the minions to stop immediately after the first
# failure detected in the state execution, defaults to False
#failhard: False

# The state_verbose and state_output settings can be used to change the way
# state system data is printed to the display. By default all data is printed.
# The state_verbose setting can be set to True or False, when set to False
# all data that has a result of True and no changes will be suppressed.
#state_verbose: True

# The state_output setting changes if the output is the full multi line
# output for each changed state if set to 'full', but if set to 'terse'
# the output will be shortened to a single line. If set to 'mixed', the output
# will be terse unless a state failed, in which case that output will be full.
# If set to 'changes', the output will be full unless the state didn't change.
#state_output: full

# Automatically aggregate all states that have support for mod_aggregate by
# setting to 'True'. Or pass a list of state module names to automatically
# aggregate just those types.
#
# state_aggregate:
#   - pkg
#
#state_aggregate: False

# Send progress events as each function in a state run completes execution
# by setting to 'True'. Progress events are in the format
# 'salt/job/<JID>/prog/<MID>/<RUN NUM>'.
#state_events: False

#####      File Server settings      #####
#####

# Salt runs a lightweight file server written in zeromq to deliver files to
# minions. This file server is built into the master daemon and does not
# require a dedicated port.

# The file server works on environments passed to the master, each environment
# can have multiple root directories, the subdirectories in the multiple file
# roots cannot match, otherwise the downloaded files will not be able to be
# reliably ensured. A base environment is required to house the top file.
# Example:
# file_roots:
#   base:
#     - /srv/salt/
#   dev:
#     - /srv/salt/dev/services
#     - /srv/salt/dev/states
#   prod:
#     - /srv/salt/prod/services
#     - /srv/salt/prod/states
#
#file_roots:
#   base:
```

```
# - /srv/salt

# The hash_type is the hash to use when discovering the hash of a file on
# the master server. The default is md5, but sha1, sha224, sha256, sha384
# and sha512 are also supported.
#
# Prior to changing this value, the master should be stopped and all Salt
# caches should be cleared.
#hash_type: md5

# The buffer size in the file server can be adjusted here:
#file_buffer_size: 1048576

# A regular expression (or a list of expressions) that will be matched
# against the file path before syncing the modules and states to the minions.
# This includes files affected by the file.recurse state.
# For example, if you manage your custom modules and states in subversion
# and don't want all the '.svn' folders and content synced to your minions,
# you could set this to '/\.svn($|/)'. By default nothing is ignored.
#file_ignore_regex:
# - '/\.svn($|/)'
# - '/\.git($|/)'

# A file glob (or list of file globs) that will be matched against the file
# path before syncing the modules and states to the minions. This is similar
# to file_ignore_regex above, but works on globs instead of regex. By default
# nothing is ignored.
# file_ignore_glob:
# - '*.pyc'
# - '*/somefolder/*.bak'
# - '*.swp'

# File Server Backend
#
# Salt supports a modular fileservers backend system, this system allows
# the salt master to link directly to third party systems to gather and
# manage the files available to minions. Multiple backends can be
# configured and will be searched for the requested file in the order in which
# they are defined here. The default setting only enables the standard backend
# "roots" which uses the "file_roots" option.
#fileservers_backend:
# - roots
#
# To use multiple backends list them in the order they are searched:
#fileservers_backend:
# - git
# - roots
#
# Uncomment the line below if you do not want the file_server to follow
# symlinks when walking the filesystem tree. This is set to True
# by default. Currently this only applies to the default roots
# fileservers_backend.
#fileservers_followsymlinks: False
#
# Uncomment the line below if you do not want symlinks to be
# treated as the files they are pointing to. By default this is set to
# False. By uncommenting the line below, any detected symlink while listing
# files on the Master will not be returned to the Minion.
```

```

#fileserver_ignoresymlinks: True
#
# By default, the Salt fileserver recurses fully into all defined environments
# to attempt to find files. To limit this behavior so that the fileserver only
# traverses directories with SLS files and special Salt directories like _modules,
# enable the option below. This might be useful for installations where a file root
# has a very large number of files and performance is impacted. Default is False.
# fileserver_limit_traversal: False
#
# The fileserver can fire events off every time the fileserver is updated,
# these are disabled by default, but can be easily turned on by setting this
# flag to True
#fileserver_events: False

# Git File Server Backend Configuration
#
# Gitfs can be provided by one of two python modules: GitPython or pygit2. If
# using pygit2, both libgit2 and git must also be installed.
#gitfs_provider: gitpython
#
# When using the git fileserver backend at least one git remote needs to be
# defined. The user running the salt master will need read access to the repo.
#
# The repos will be searched in order to find the file requested by a client
# and the first repo to have the file will return it.
# When using the git backend branches and tags are translated into salt
# environments.
# Note: file:// repos will be treated as a remote, so refs you want used must
# exist in that repo as *local* refs.
#gitfs_remotes:
# - git://github.com/saltstack/salt-states.git
# - file:///var/git/saltmaster
#
# The gitfs_ssl_verify option specifies whether to ignore ssl certificate
# errors when contacting the gitfs backend. You might want to set this to
# false if you're using a git backend that uses a self-signed certificate but
# keep in mind that setting this flag to anything other than the default of True
# is a security concern, you may want to try using the ssh transport.
#gitfs_ssl_verify: True
#
# The gitfs_root option gives the ability to serve files from a subdirectory
# within the repository. The path is defined relative to the root of the
# repository and defaults to the repository root.
#gitfs_root: somefolder/otherfolder
#
#
#####          Pillar settings          #####
#####
# Salt Pillars allow for the building of global data that can be made selectively
# available to different minions based on minion grain filtering. The Salt
# Pillar is laid out in the same fashion as the file server, with environments,
# a top file and sls files. However, pillar data does not need to be in the
# highstate format, and is generally just key/value pairs.
#pillar_roots:
# base:
#   - /srv/pillar
#
#ext_pillar:

```

```

# - hiera: /etc/hiera.yaml
# - cmd_yaml: cat /etc/salt/yaml

# The ext_pillar_first option allows for external pillar sources to populate
# before file system pillar. This allows for targeting file system pillar from
# ext_pillar.
#ext_pillar_first: False

# The pillar_gitfs_ssl_verify option specifies whether to ignore ssl certificate
# errors when contacting the pillar gitfs backend. You might want to set this to
# false if you're using a git backend that uses a self-signed certificate but
# keep in mind that setting this flag to anything other than the default of True
# is a security concern, you may want to try using the ssh transport.
#pillar_gitfs_ssl_verify: True

# The pillar_opts option adds the master configuration file data to a dict in
# the pillar called "master". This is used to set simple configurations in the
# master config file that can then be used on minions.
#pillar_opts: False

# The pillar_safe_render_error option prevents the master from passing pillar
# render errors to the minion. This is set on by default because the error could
# contain templating data which would give that minion information it shouldn't
# have, like a password! When set true the error message will only show:
#   Rendering SLS 'my.sls' failed. Please see master log for details.
#pillar_safe_render_error: True

# The pillar_source_merging_strategy option allows you to configure merging strategy
# between different sources. It accepts four values: recurse, aggregate, overwrite,
# or smart. Recurse will merge recursively mapping of data. Aggregate instructs
# aggregation of elements between sources that use the #!yamlex renderer. Overwrite
# will overwrite elements according the order in which they are processed. This is
# behavior of the 2014.1 branch and earlier. Smart guesses the best strategy based
# on the "renderer" setting and is the default value.
#pillar_source_merging_strategy: smart

#####      Syndic settings      #####
#####
# The Salt syndic is used to pass commands through a master from a higher
# master. Using the syndic is simple, if this is a master that will have
# syndic servers(s) below it set the "order_masters" setting to True, if this
# is a master that will be running a syndic daemon for passthrough the
# "syndic_master" setting needs to be set to the location of the master server
# to receive commands from.

# Set the order_masters setting to True if this master will command lower
# masters' syndic interfaces.
#order_masters: False

# If this master will be running a salt syndic daemon, syndic_master tells
# this master where to receive commands from.
#syndic_master: masterofmaster

# This is the 'ret_port' of the MasterOfMaster:
#syndic_master_port: 4506

# PID file of the syndic daemon:

```

```
#syndic_pidfile: /var/run/salt-syndic.pid

# LOG file of the syndic daemon:
#syndic_log_file: syndic.log

#####      Peer Publish settings      #####
#####
# Salt minions can send commands to other minions, but only if the minion is
# allowed to. By default "Peer Publication" is disabled, and when enabled it
# is enabled for specific minions and specific commands. This allows secure
# compartmentalization of commands based on individual minions.

# The configuration uses regular expressions to match minions and then a list
# of regular expressions to match functions. The following will allow the
# minion authenticated as foo.example.com to execute functions from the test
# and pkg modules.
#peer:
#  foo.example.com:
#    - test.*
#    - pkg.*
#
# This will allow all minions to execute all commands:
#peer:
#  .*:
#    - .*
#
# This is not recommended, since it would allow anyone who gets root on any
# single minion to instantly have root on all of the minions!

# Minions can also be allowed to execute runners from the salt master.
# Since executing a runner from the minion could be considered a security risk,
# it needs to be enabled. This setting functions just like the peer setting
# except that it opens up runners instead of module functions.
#
# All peer runner support is turned off by default and must be enabled before
# using. This will enable all peer runners for all minions:
#peer_run:
#  .*:
#    - .*
#
# To enable just the manage.up runner for the minion foo.example.com:
#peer_run:
#  foo.example.com:
#    - manage.up
#
#####      Mine settings      #####
#####
# Restrict mine.get access from minions. By default any minion has a full access
# to get all mine data from master cache. In acl definion below, only pcre matches
# are allowed.
# mine_get:
#  .*:
#    - .*
#
# The example below enables minion foo.example.com to get 'network.interfaces' mine
# data only, minions web* to get all network.* and disk.* mine data and all other
```

```

# minions won't get any mine data.
# mine_get:
#   foo.example.com:
#     - network.interfaces
#   web.*:
#     - network.*
#     - disk.*

#####          Logging settings          #####
#####
# The location of the master log file
# The master log can be sent to a regular file, local path name, or network
# location. Remote logging works best when configured to use rsyslogd(8) (e.g.:
# `file:///dev/log`), with rsyslogd(8) configured for network logging. The URI
# format is: <file|udp|tcp>://<host|socketpath>:<port-if-required>/<log-facility>
#log_file: /var/log/salt/master
#log_file: file:///dev/log
#log_file: udp://loghost:10514

#log_file: /var/log/salt/master
#key_logfile: /var/log/salt/key

# The level of messages to send to the console.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
#
# The following log levels are considered INSECURE and may log sensitive data:
# ['garbage', 'trace', 'debug']
#
#log_level: warning

# The level of messages to send to the log file.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
# If using 'log_granular_levels' this must be set to the highest desired level.
#log_level_logfile: warning

# The date and time format used in log messages. Allowed date/time formatting
# can be seen here: http://docs.python.org/library/time.html#time.strftime
#log_datefmt: '%H:%M:%S'
#log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

# The format of the console logging messages. Allowed formatting options can
# be seen here: http://docs.python.org/library/logging.html#logrecord-attributes
#log_fmt_console: '%[(levelname)-8s] %(message)s'
#log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(%name)-17s][%(levelname)-8s] %(message)s'

# This can be used to control logging levels more specifically. This
# example sets the main salt library at the 'warning' level, but sets
# 'salt.modules' to log at the 'debug' level:
#   log_granular_levels:
#     'salt': 'warning'
#     'salt.modules': 'debug'
#
#log_granular_levels: {}

#####          Node Groups          #####
#####

```

```

# Node groups allow for logical groupings of minion nodes. A group consists of a group
# name and a compound target.
#nodegroups:
# group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com and bl*.domain.com'
# group2: 'G@os:Debian and foo.domain.com'

#####      Range Cluster settings      #####
#####
# The range server (and optional port) that serves your cluster information
# https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec
#
#range_server: range:80

#####      Windows Software Repo settings #####
#####
# Location of the repo on the master:
#win_repo: '/srv/salt/win/repo'
#
# Location of the master's repo cache file:
#win_repo_mastercachefile: '/srv/salt/win/repo/winrepo.p'
#
# List of git repositories to include with the local repo:
#win_gitrepos:
# - 'https://github.com/saltstack/salt-winrepo.git'

#####      Returner settings      #####
#####
# Which returner(s) will be used for minion's result:
#return: mysql

```

### 30.6.2 Example minion configuration file

```

##### Primary configuration settings #####
#####
# This configuration file is used to manage the behavior of the Salt Minion.
# With the exception of the location of the Salt Master Server, values that are
# commented out but have an empty line after the comment are defaults that need
# not be set in the config. If there is no blank line after the comment, the
# value is presented as an example and is not the default.

# Per default the minion will automatically include all config files
# from minion.d/*.conf (minion.d is a directory in the same directory
# as the main minion config file).
#default_include: minion.d/*.conf

# Set the location of the salt master server. If the master server cannot be
# resolved, then the minion will fail to start.
#master: salt

# If multiple masters are specified in the 'master' setting, the default behavior
# is to always try to connect to them in the order they are listed. If random_master is
# set to True, the order will be randomized instead. This can be helpful in distributing
# the load of many minions executing salt-call requests, for example, from a cron job.
# If only one master is listed, this setting is ignored and a warning will be logged.

```

```
# NOTE: If master_type is set to failover, use master_shuffle instead.
#random_master: False

# Use if master_type is set to failover.
#master_shuffle: False

# Minions can connect to multiple masters simultaneously (all masters
# are "hot"), or can be configured to failover if a master becomes
# unavailable. Multiple hot masters are configured by setting this
# value to "str". Failover masters can be requested by setting
# to "failover". MAKE SURE TO SET master_alive_interval if you are
# using failover.
# master_type: str

# Poll interval in seconds for checking if the master is still there. Only
# respected if master_type above is "failover". To disable the interval entirely,
# set the value to -1. (This may be necessary on machines which have high numbers
# of TCP connections, such as load balancers.)
# master_alive_interval: 30

# Set whether the minion should connect to the master via IPv6:
#ipv6: False

# Set the number of seconds to wait before attempting to resolve
# the master hostname if name resolution fails. Defaults to 30 seconds.
# Set to zero if the minion should shutdown and not retry.
# retry_dns: 30

# Set the port used by the master reply and authentication server.
#master_port: 4506

# The user to run salt.
#user: root

# Setting sudo_user will cause salt to run all execution modules under an sudo
# to the user given in sudo_user. The user under which the salt minion process
# itself runs will still be that provided in the user config above, but all
# execution modules run by the minion will be rerouted through sudo.
#sudo_user: saltdev

# Specify the location of the daemon process ID file.
#pidfile: /var/run/salt-minion.pid

# The root directory prepended to these options: pki_dir, cachedir, log_file,
# sock_dir, pidfile.
#root_dir: /

# The directory to store the pki information in
#pki_dir: /etc/salt/pki/minion

# Explicitly declare the id for this minion to use, if left commented the id
# will be the hostname as returned by the python call: socket.getfqdn()
# Since salt uses detached ids it is possible to run multiple minions on the
# same machine but with different ids, this can be useful for salt compute
# clusters.
#id:

# Append a domain to a hostname in the event that it does not exist. This is
```

```
# useful for systems where socket.getfqdn() does not actually result in a
# FQDN (for instance, Solaris).
#append_domain:

# Custom static grains for this minion can be specified here and used in SLS
# files just like all other grains. This example sets 4 custom grains, with
# the 'roles' grain having two values that can be matched against.
#grains:
#  roles:
#    - webserver
#    - memcache
#  deployment: datacenter4
#  cabinet: 13
#  cab_u: 14-15
#
# Where cache data goes.
#cachedir: /var/cache/salt/minion

# Verify and set permissions on configuration directories at startup.
#verify_env: True

# The minion can locally cache the return data from jobs sent to it, this
# can be a good way to keep track of jobs the minion has executed
# (on the minion side). By default this feature is disabled, to enable, set
# cache_jobs to True.
#cache_jobs: False

# Set the directory used to hold unix sockets.
#sock_dir: /var/run/salt/minion

# Set the default outputter used by the salt-call command. The default is
# "nested".
#output: nested
#
# By default output is colored. To disable colored output, set the color value
# to False.
#color: True

# Do not strip off the colored output from nested results and state outputs
# (true by default).
#strip_colors: False

# Backup files that are replaced by file.managed and file.recurse under
# 'cachedir'/file_backups relative to their original location and appended
# with a timestamp. The only valid setting is "minion". Disabled by default.
#
# Alternatively this can be specified for each file in state files:
# /etc/ssh/sshd_config:
#   file.managed:
#     - source: salt://ssh/sshd_config
#     - backup: minion
#
#backup_mode: minion

# When waiting for a master to accept the minion's public key, salt will
# continuously attempt to reconnect until successful. This is the time, in
# seconds, between those reconnection attempts.
#acceptance_wait_time: 10
```

```

# If this is nonzero, the time between reconnection attempts will increase by
# acceptance_wait_time seconds per iteration, up to this maximum. If this is
# set to zero, the time between reconnection attempts will stay constant.
#acceptance_wait_time_max: 0

# If the master rejects the minion's public key, retry instead of exiting.
# Rejected keys will be handled the same as waiting on acceptance.
#rejected_retry: False

# When the master key changes, the minion will try to re-auth itself to receive
# the new master key. In larger environments this can cause a SYN flood on the
# master because all minions try to re-auth immediately. To prevent this and
# have a minion wait for a random amount of time, use this optional parameter.
# The wait-time will be a random number of seconds between 0 and the defined value.
#random_reauth_delay: 60

# When waiting for a master to accept the minion's public key, salt will
# continuously attempt to reconnect until successful. This is the timeout value,
# in seconds, for each individual attempt. After this timeout expires, the minion
# will wait for acceptance_wait_time seconds before trying again. Unless your master
# is under unusually heavy load, this should be left at the default.
#auth_timeout: 60

# Number of consecutive SaltReqTimeoutError that are acceptable when trying to
# authenticate.
#auth_tries: 7

# If authentication fails due to SaltReqTimeoutError during a ping_interval,
# cause sub minion process to restart.
#auth_safemode: False

# Ping Master to ensure connection is alive (minutes).
#ping_interval: 0

# To auto recover minions if master changes IP address (DDNS)
#   auth_tries: 10
#   auth_safemode: False
#   ping_interval: 90
#
# Minions won't know master is missing until a ping fails. After the ping fail,
# the minion will attempt authentication and likely fails out and cause a restart.
# When the minion restarts it will resolve the masters IP and attempt to reconnect.

# If you don't have any problems with syn-floods, don't bother with the
# three recon_* settings described below, just leave the defaults!
#
# The ZeroMQ pull-socket that binds to the masters publishing interface tries
# to reconnect immediately, if the socket is disconnected (for example if
# the master processes are restarted). In large setups this will have all
# minions reconnect immediately which might flood the master (the ZeroMQ-default
# is usually a 100ms delay). To prevent this, these three recon_* settings
# can be used.
# recon_default: the interval in milliseconds that the socket should wait before
#                 trying to reconnect to the master (1000ms = 1 second)
#
# recon_max: the maximum time a socket should wait. each interval the time to wait
#            is calculated by doubling the previous time. if recon_max is reached,
#            it starts again at recon_default. Short example:

```

```
#
#     reconnect 1: the socket will wait 'recon_default' milliseconds
#     reconnect 2: 'recon_default' * 2
#     reconnect 3: ('recon_default' * 2) * 2
#     reconnect 4: value from previous interval * 2
#     reconnect 5: value from previous interval * 2
#     reconnect x: if value >= recon_max, it starts again with recon_default
#
# recon_randomize: generate a random wait time on minion start. The wait time will
#                 be a random value between recon_default and recon_default +
#                 recon_max. Having all minions reconnect with the same recon_default
#                 and recon_max value kind of defeats the purpose of being able to
#                 change these settings. If all minions have the same values and your
#                 setup is quite large (several thousand minions), they will still
#                 flood the master. The desired behavior is to have timeframe within
#                 all minions try to reconnect.
#
# Example on how to use these settings. The goal: have all minions reconnect within a
# 60 second timeframe on a disconnect.
# recon_default: 1000
# recon_max: 59000
# recon_randomize: True
#
# Each minion will have a randomized reconnect value between 'recon_default'
# and 'recon_default + recon_max', which in this example means between 1000ms
# 60000ms (or between 1 and 60 seconds). The generated random-value will be
# doubled after each attempt to reconnect. Lets say the generated random
# value is 11 seconds (or 11000ms).
# reconnect 1: wait 11 seconds
# reconnect 2: wait 22 seconds
# reconnect 3: wait 33 seconds
# reconnect 4: wait 44 seconds
# reconnect 5: wait 55 seconds
# reconnect 6: wait time is bigger than 60 seconds (recon_default + recon_max)
# reconnect 7: wait 11 seconds
# reconnect 8: wait 22 seconds
# reconnect 9: wait 33 seconds
# reconnect x: etc.
#
# In a setup with ~6000 thousand hosts these settings would average the reconnects
# to about 100 per second and all hosts would be reconnected within 60 seconds.
# recon_default: 100
# recon_max: 5000
# recon_randomize: False
#
# The loop_interval sets how long in seconds the minion will wait between
# evaluating the scheduler and running cleanup tasks. This defaults to a
# sane 60 seconds, but if the minion scheduler needs to be evaluated more
# often lower this value
#loop_interval: 60
#
# The grains_refresh_every setting allows for a minion to periodically check
# its grains to see if they have changed and, if so, to inform the master
# of the new grains. This operation is moderately expensive, therefore
# care should be taken not to set this value too low.
#
# Note: This value is expressed in __minutes__!
```

```

#
# A value of 10 minutes is a reasonable default.
#
# If the value is set to zero, this check is disabled.
#grains_refresh_every: 1

# Cache grains on the minion. Default is False.
#grains_cache: False

# Grains cache expiration, in seconds. If the cache file is older than this
# number of seconds then the grains cache will be dumped and fully re-populated
# with fresh data. Defaults to 5 minutes. Will have no effect if 'grains_cache'
# is not enabled.
# grains_cache_expiration: 300

# Windows platforms lack posix IPC and must rely on slower TCP based inter-
# process communications. Set ipc_mode to 'tcp' on such systems
#ipc_mode: ipc

# Overwrite the default tcp ports used by the minion when in tcp mode
#tcp_pub_port: 4510
#tcp_pull_port: 4511

# Passing very large events can cause the minion to consume large amounts of
# memory. This value tunes the maximum size of a message allowed onto the
# minion event bus. The value is expressed in bytes.
#max_event_size: 1048576

# To detect failed master(s) and fire events on connect/disconnect, set
# master_alive_interval to the number of seconds to poll the masters for
# connection events.
#
#master_alive_interval: 30

# The minion can include configuration from other files. To enable this,
# pass a list of paths to this option. The paths can be either relative or
# absolute; if relative, they are considered to be relative to the directory
# the main minion configuration file lives in (this file). Paths can make use
# of shell-style globbing. If no files are matched by a path passed to this
# option then the minion will log a warning message.
#
# Include a config file from some other path:
# include: /etc/salt/extra_config
#
# Include config from several files and directories:
#include:
# - /etc/salt/extra_config
# - /etc/roles/webserver
#
#
##### Minion module management #####
#####
# Disable specific modules. This allows the admin to limit the level of
# access the master has to the minion.
#disable_modules: [cmd,test]
#disable_returners: []
#

```

```
# Modules can be loaded from arbitrary paths. This enables the easy deployment
# of third party modules. Modules for returners and minions can be loaded.
# Specify a list of extra directories to search for minion modules and
# returners. These paths must be fully qualified!
#module_dirs: []
#returner_dirs: []
#states_dirs: []
#render_dirs: []
#utils_dirs: []
#
# A module provider can be statically overwritten or extended for the minion
# via the providers option, in this case the default module will be
# overwritten by the specified module. In this example the pkg module will
# be provided by the yumpkg5 module instead of the system default.
#providers:
# pkg: yumpkg5
#
# Enable Cython modules searching and loading. (Default: False)
#cython_enable: False
#
# Specify a max size (in bytes) for modules on import. This feature is currently
# only supported on *nix operating systems and requires psutil.
# modules_max_memory: -1

##### State Management Settings #####
#####
# The state management system executes all of the state templates on the minion
# to enable more granular control of system state management. The type of
# template and serialization used for state management needs to be configured
# on the minion, the default renderer is yamll_jinja. This is a yamll file
# rendered from a jinja template, the available options are:
# yamll_jinja
# yamll_mako
# yamll_wempy
# json_jinja
# json_mako
# json_wempy
#
#renderer: yamll_jinja
#
# The failhard option tells the minions to stop immediately after the first
# failure detected in the state execution. Defaults to False.
#failhard: False
#
# autoload_dynamic_modules turns on automatic loading of modules found in the
# environments on the master. This is turned on by default. To turn off
# autoloading modules when states run, set this value to False.
#autoload_dynamic_modules: True
#
# clean_dynamic_modules keeps the dynamic modules on the minion in sync with
# the dynamic modules on the master, this means that if a dynamic module is
# not on the master it will be deleted from the minion. By default, this is
# enabled and can be disabled by changing this value to False.
#clean_dynamic_modules: True
#
# Normally, the minion is not isolated to any single environment on the master
# when running states, but the environment can be isolated on the minion side
```

```

# by statically setting it. Remember that the recommended way to manage
# environments is to isolate via the top file.
#environment: None
#
# If using the local file directory, then the state top file name needs to be
# defined, by default this is top.sls.
#state_top: top.sls
#
# Run states when the minion daemon starts. To enable, set startup_states to:
# 'highstate' -- Execute state.highstate
# 'sls' -- Read in the sls_list option and execute the named sls files
# 'top' -- Read top_file option and execute based on that file on the Master
#startup_states: ''
#
# List of states to run when the minion starts up if startup_states is 'sls':
#sls_list:
# - edit.vim
# - hyper
#
# Top file to execute if startup_states is 'top':
#top_file: ''

# Automatically aggregate all states that have support for mod_aggregate by
# setting to True. Or pass a list of state module names to automatically
# aggregate just those types.
#
# state_aggregate:
# - pkg
#
#state_aggregate: False

#####      File Directory Settings      #####
#####
# The Salt Minion can redirect all file server operations to a local directory,
# this allows for the same state tree that is on the master to be used if
# copied completely onto the minion. This is a literal copy of the settings on
# the master but used to reference a local directory on the minion.

# Set the file client. The client defaults to looking on the master server for
# files, but can be directed to look at the local file directory setting
# defined below by setting it to "local". Setting a local file_client runs the
# minion in masterless mode.
#file_client: remote

# The file directory works on environments passed to the minion, each environment
# can have multiple root directories, the subdirectories in the multiple file
# roots cannot match, otherwise the downloaded files will not be able to be
# reliably ensured. A base environment is required to house the top file.
# Example:
# file_roots:
#   base:
#     - /srv/salt/
#   dev:
#     - /srv/salt/dev/services
#     - /srv/salt/dev/states
#   prod:
#     - /srv/salt/prod/services
#     - /srv/salt/prod/states

```

```
#
#file_roots:
#  base:
#    - /srv/salt

# Uncomment the line below if you do not want the file_server to follow
# symlinks when walking the filesystem tree. This is set to True
# by default. Currently this only applies to the default roots
# fileserver_backend.
#fileserver_followsymlinks: False
#
# Uncomment the line below if you do not want symlinks to be
# treated as the files they are pointing to. By default this is set to
# False. By uncommenting the line below, any detected symlink while listing
# files on the Master will not be returned to the Minion.
#fileserver_ignoresymlinks: True
#
# By default, the Salt fileserver recurses fully into all defined environments
# to attempt to find files. To limit this behavior so that the fileserver only
# traverses directories with SLS files and special Salt directories like _modules,
# enable the option below. This might be useful for installations where a file root
# has a very large number of files and performance is negatively impacted. Default
# is False.
#fileserver_limit_traversal: False

# The hash_type is the hash to use when discovering the hash of a file in
# the local fileserver. The default is md5, but sha1, sha224, sha256, sha384
# and sha512 are also supported.
#
# Warning: Prior to changing this value, the minion should be stopped and all
# Salt caches should be cleared.
#hash_type: md5

# The Salt pillar is searched for locally if file_client is set to local. If
# this is the case, and pillar data is defined, then the pillar_roots need to
# also be configured on the minion:
#pillar_roots:
#  base:
#    - /srv/pillar

# Set a hard-limit on the size of the files that can be pushed to the master.
# It will be interpreted as megabytes. Default: 100
#file_recv_max_size: 100
#
#
#####      Security settings      #####
#####
# Enable "open mode", this mode still maintains encryption, but turns off
# authentication, this is only intended for highly secure environments or for
# the situation where your keys end up in a bad state. If you run in open mode
# you do so at your own risk!
#open_mode: False

# Enable permissive access to the salt keys. This allows you to run the
# master or minion as root, but have a non-root group be given access to
# your pki_dir. To make the access explicit, root must belong to the group
# you've given access to. This is potentially quite insecure.
#permissive_pki_access: False
```

```

# The state_verbose and state_output settings can be used to change the way
# state system data is printed to the display. By default all data is printed.
# The state_verbose setting can be set to True or False, when set to False
# all data that has a result of True and no changes will be suppressed.
#state_verbose: True

# The state_output setting changes if the output is the full multi line
# output for each changed state if set to 'full', but if set to 'terse'
# the output will be shortened to a single line.
#state_output: full

# The state_output_diff setting changes whether or not the output from
# successful states is returned. Useful when even the terse output of these
# states is cluttering the logs. Set it to True to ignore them.
#state_output_diff: False

# The state_output_profile setting changes whether profile information
# will be shown for each state run.
#state_output_profile: True

# Fingerprint of the master public key to validate the identity of your Salt master
# before the initial key exchange. The master fingerprint can be found by running
# "salt-key -F master" on the Salt master.
#master_finger: ''

#####          Thread settings          #####
#####
# Disable multiprocessing support, by default when a minion receives a
# publication a new process is spawned and the command is executed therein.
#multiprocessing: True

#####          Logging settings          #####
#####
# The location of the minion log file
# The minion log can be sent to a regular file, local path name, or network
# location. Remote logging works best when configured to use rsyslogd(8) (e.g.:
# ``file:///dev/log``), with rsyslogd(8) configured for network logging. The URI
# format is: <file|udp|tcp>://<host|socketpath>:<port-if-required>/<log-facility>
#log_file: /var/log/salt/minion
#log_file: file:///dev/log
#log_file: udp://loghost:10514
#
#log_file: /var/log/salt/minion
#key_logfile: /var/log/salt/key

# The level of messages to send to the console.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
#
# The following log levels are considered INSECURE and may log sensitive data:
# ['garbage', 'trace', 'debug']
#
# Default: 'warning'
#log_level: warning

# The level of messages to send to the log file.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.

```

```

# If using 'log_granular_levels' this must be set to the highest desired level.
# Default: 'warning'
#log_level_logfile:

# The date and time format used in log messages. Allowed date/time formatting
# can be seen here: http://docs.python.org/library/time.html#time.strftime
#log_datefmt: '%H:%M:%S'
#log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

# The format of the console logging messages. Allowed formatting options can
# be seen here: http://docs.python.org/library/logging.html#logrecord-attributes
#log_fmt_console: '[%(levelname)-8s] %(message)s'
#log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'

# This can be used to control logging levels more specifically. This
# example sets the main salt library at the 'warning' level, but sets
# 'salt.modules' to log at the 'debug' level:
#   log_granular_levels:
#     'salt': 'warning'
#     'salt.modules': 'debug'
#
#log_granular_levels: {}

# To diagnose issues with minions disconnecting or missing returns, ZeroMQ
# supports the use of monitor sockets # to log connection events. This
# feature requires ZeroMQ 4.0 or higher.
#
# To enable ZeroMQ monitor sockets, set 'zmq_monitor' to 'True' and log at a
# debug level or higher.
#
# A sample log event is as follows:
#
# [DEBUG   ] ZeroMQ event: {'endpoint': 'tcp://127.0.0.1:4505', 'event': 512,
# 'value': 27, 'description': 'EVENT_DISCONNECTED'}
#
# All events logged will include the string 'ZeroMQ event'. A connection event
# should be logged on the as the minion starts up and initially connects to the
# master. If not, check for debug log level and that the necessary version of
# ZeroMQ is installed.
#
#zmq_monitor: False

#####      Module configuration      #####
#####
# Salt allows for modules to be passed arbitrary configuration data, any data
# passed here in valid yaml format will be passed on to the salt minion modules
# for use. It is STRONGLY recommended that a naming convention be used in which
# the module name is followed by a . and then the value. Also, all top level
# data must be applied via the yaml dict construct, some examples:
#
# You can specify that all modules should run in test mode:
#test: True
#
# A simple value for the test module:
#test.foo: foo
#
# A list for the test module:
#test.bar: [baz,quo]

```

```

#
# A dict for the test module:
#test.baz: {spam: sausage, cheese: bread}
#
#
#####      Update settings      #####
#####
# Using the features in Esky, a salt minion can both run as a frozen app and
# be updated on the fly. These options control how the update process
# (saltutil.update()) behaves.
#
# The url for finding and downloading updates. Disabled by default.
#update_url: False
#
# The list of services to restart after a successful update. Empty by default.
#update_restart_services: []

#####      Keepalive settings      #####
#####
# ZeroMQ now includes support for configuring SO_KEEPALIVE if supported by
# the OS. If connections between the minion and the master pass through
# a state tracking device such as a firewall or VPN gateway, there is
# the risk that it could tear down the connection the master and minion
# without informing either party that their connection has been taken away.
# Enabling TCP Keepalives prevents this from happening.

# Overall state of TCP Keepalives, enable (1 or True), disable (0 or False)
# or leave to the OS defaults (-1), on Linux, typically disabled. Default True, enabled.
#tcp_keepalive: True

# How long before the first keepalive should be sent in seconds. Default 300
# to send the first keepalive after 5 minutes, OS default (-1) is typically 7200 seconds
# on Linux see /proc/sys/net/ipv4/tcp_keepalive_time.
#tcp_keepalive_idle: 300

# How many lost probes are needed to consider the connection lost. Default -1
# to use OS defaults, typically 9 on Linux, see /proc/sys/net/ipv4/tcp_keepalive_probes.
#tcp_keepalive_cnt: -1

# How often, in seconds, to send keepalives after the first one. Default -1 to
# use OS defaults, typically 75 seconds on Linux, see
# /proc/sys/net/ipv4/tcp_keepalive_intvl.
#tcp_keepalive_intvl: -1

#####      Windows Software settings      #####
#####
# Location of the repository cache file on the master:
#win_repo_cache: 'salt://win/repo/winrepo.p'

#####      Returner settings      #####
#####
# Which returner(s) will be used for minion's result:
#return: mysql

```

## 30.7 Configuring Salt

Salt configuration is very simple. The default configuration for the *master* will work for most installations and the only requirement for setting up a *minion* is to set the location of the master in the minion configuration file.

The configuration files will be installed to `/etc/salt` and are named after the respective components, `/etc/salt/master`, and `/etc/salt/minion`.

### 30.7.1 Master Configuration

By default the Salt master listens on ports 4505 and 4506 on all interfaces (0.0.0.0). To bind Salt to a specific IP, redefine the `interface` directive in the master configuration file, typically `/etc/salt/master`, as follows:

```
- #interface: 0.0.0.0
+ interface: 10.0.0.1
```

After updating the configuration file, restart the Salt master. See the [master configuration reference](#) for more details about other configurable options.

### 30.7.2 Minion Configuration

Although there are many Salt Minion configuration options, configuring a Salt Minion is very simple. By default a Salt Minion will try to connect to the DNS name `salt`; if the Minion is able to resolve that name correctly, no configuration is needed.

If the DNS name `salt` does not resolve to point to the correct location of the Master, redefine the `master` directive in the minion configuration file, typically `/etc/salt/minion`, as follows:

```
- #master: salt
+ master: 10.0.0.1
```

After updating the configuration file, restart the Salt minion. See the [minion configuration reference](#) for more details about other configurable options.

### 30.7.3 Running Salt

1. Start the master in the foreground (to daemonize the process, pass the `-d flag`):

```
salt-master
```

2. Start the minion in the foreground (to daemonize the process, pass the `-d flag`):

```
salt-minion
```

---

#### Having trouble?

The simplest way to troubleshoot Salt is to run the master and minion in the foreground with `log level` set to debug:

```
salt-master --log-level=debug
```

For information on salt's logging system please see the [logging document](#).

---

Run as an unprivileged (non-root) user

---

To run Salt as another user, set the *user* parameter in the master config file.

Additionally, ownership, and permissions need to be set such that the desired user can read from and write to the following directories (and their subdirectories, where applicable):

- /etc/salt
- /var/cache/salt
- /var/log/salt
- /var/run/salt

More information about running salt as a non-privileged user can be found [here](#).

There is also a full [troubleshooting guide](#) available.

### 30.7.4 Key Identity

Salt provides commands to validate the identity of your Salt master and Salt minions before the initial key exchange. Validating key identity helps avoid inadvertently connecting to the wrong Salt master, and helps prevent a potential MiTM attack when establishing the initial connection.

#### Master Key Fingerprint

Print the master key fingerprint by running the following command on the Salt master:

```
salt-key -F master
```

Copy the master .pub fingerprint from the *Local Keys* section, and then set this value as the *master\_finger* in the minion configuration file. Save the configuration file and then restart the Salt minion.

#### Minion Key Fingerprint

Run the following command on each Salt minion to view the minion key fingerprint:

```
salt-call --local key.finger
```

Compare this value to the value that is displayed when you run the `salt-key --finger <MINION_ID>` command on the Salt master.

### 30.7.5 Key Management

Salt uses AES encryption for all communication between the Master and the Minion. This ensures that the commands sent to the Minions cannot be tampered with, and that communication between Master and Minion is authenticated through trusted, accepted keys.

Before commands can be sent to a Minion, its key must be accepted on the Master. Run the `salt-key` command to list the keys known to the Salt Master:

```
[root@master ~]# salt-key -L
Unaccepted Keys:
alpha
bravo
charlie
```

```
delta
Accepted Keys:
```

This example shows that the Salt Master is aware of four Minions, but none of the keys has been accepted. To accept the keys and allow the Minions to be controlled by the Master, again use the `salt-key` command:

```
[root@master ~]# salt-key -A
[root@master ~]# salt-key -L
Unaccepted Keys:
Accepted Keys:
alpha
bravo
charlie
delta
```

The `salt-key` command allows for signing keys individually or in bulk. The example above, using `-A` bulk-accepts all pending keys. To accept keys individually use the lowercase of the same option, `-a keyname`.

See also:

[salt-key manpage](#)

### 30.7.6 Sending Commands

Communication between the Master and a Minion may be verified by running the `test.ping` command:

```
[root@master ~]# salt alpha test.ping
alpha:
  True
```

Communication between the Master and all Minions may be tested in a similar way:

```
[root@master ~]# salt '*' test.ping
alpha:
  True
bravo:
  True
charlie:
  True
delta:
  True
```

Each of the Minions should send a `True` response as shown above.

### 30.7.7 What's Next?

Understanding [targeting](#) is important. From there, depending on the way you wish to use Salt, you should also proceed to learn about [States](#) and [Execution Modules](#).

## 30.8 Configuring the Salt Master

The Salt system is amazingly simple and easy to configure, the two components of the Salt system each have a respective configuration file. The **salt-master** is configured via the master configuration file, and the **salt-minion** is configured via the minion configuration file.

See also:

*example master configuration file*

The configuration file for the salt-master is located at `/etc/salt/master` by default. A notable exception is FreeBSD, where the configuration file is located at `/usr/local/etc/salt`. The available options are as follows:

### 30.8.1 Primary Master Configuration

#### **interface**

Default: `0.0.0.0` (all interfaces)

The local interface to bind to.

```
interface: 192.168.0.1
```

#### **ipv6**

Default: `False`

Whether the master should listen for IPv6 connections. If this is set to `True`, the `interface` option must be adjusted too (for example: `interface: ':::'`)

```
ipv6: True
```

#### **publish\_port**

Default: `4505`

The network port to set up the publication interface.

```
publish_port: 4505
```

#### **master\_id**

Default: `None`

The id to be passed in the publish job to minions. This is used for MultiSyndics to return the job to the requesting master.

---

**Note:** This must be the same string as the syndic is configured with.

---

```
master_id: MasterOfMaster
```

#### **user**

Default: `root`

The user to run the Salt processes

```
user: root
```

## max\_open\_files

Default: 100000

Each minion connecting to the master uses AT LEAST one file descriptor, the master subscription connection. If enough minions connect you might start seeing on the console (and then salt-master crashes):

```
Too many open files (tcp_listener.cpp:335)
Aborted (core dumped)
```

```
max_open_files: 100000
```

By default this value will be the one of *ulimit -Hn*, i.e., the hard limit for max open files.

To set a different value than the default one, uncomment, and configure this setting. Remember that this value CANNOT be higher than the hard limit. Raising the hard limit depends on the OS and/or distribution, a good way to find the limit is to search the internet for something like this:

```
raise_max_open_files_hard_limit_debian
```

## worker\_threads

Default: 5

The number of threads to start for receiving commands and replies from minions. If minions are stalling on replies because you have many minions, raise the `worker_threads` value.

Worker threads should not be put below 3 when using the peer system, but can drop down to 1 worker otherwise.

**Note:** When the master daemon starts, it is expected behaviour to see multiple salt-master processes, even if `worker_threads` is set to `1`. At a minimum, a controlling process will start along with a Publisher, an EventPublisher, and a number of MWorker processes will be started. The number of MWorker processes is tuneable by the `worker_threads` configuration value while the others are not.

```
worker_threads: 5
```

## ret\_port

Default: 4506

The port used by the return server, this is the server used by Salt to receive execution returns and command executions.

```
ret_port: 4506
```

## pidfile

Default: `/var/run/salt-master.pid`

Specify the location of the master pidfile.

```
pidfile: /var/run/salt-master.pid
```

## root\_dir

Default: /

The system root directory to operate from, change this to make Salt run from an alternative root.

```
root_dir: /
```

**Note:** This directory is prepended to the following options: *pki\_dir*, *cachedir*, *sock\_dir*, *log\_file*, *autosign\_file*, *autoreject\_file*, *pidfile*.

## pki\_dir

Default: /etc/salt/pki/master

The directory to store the pki authentication keys.

```
pki_dir: /etc/salt/pki/master
```

## extension\_modules

Directory for custom modules. This directory can contain subdirectories for each of Salt's module types such as ``runners``, ``output``, ``wheel``, ``modules``, ``states``, ``returners``, etc. This path is appended to *root\_dir*.

```
extension_modules: srv/modules
```

## module\_dirs

Default: []

Like *extension\_modules*, but a list of extra directories to search for Salt modules.

```
module_dirs:  
- /var/cache/salt/minion/extmods
```

## cachedir

Default: /var/cache/salt/master

The location used to store cache information, particularly the job information for executed salt commands.

```
cachedir: /var/cache/salt/master
```

## verify\_env

Default: True

Verify and set permissions on configuration directories at startup.

```
verify_env: True
```

### **keep\_jobs**

Default: 24

Set the number of hours to keep old job information.

```
keep_jobs: 24
```

### **timeout**

Default: 5

Set the default timeout for the salt command and api.

### **loop\_interval**

Default: 60

The `loop_interval` option controls the seconds for the master's maintenance process check cycle. This process updates file server backends, cleans the job cache and executes the scheduler.

### **output**

Default: nested

Set the default outputter used by the salt command.

### **color**

Default: True

By default output is colored, to disable colored output set the color value to False.

```
color: False
```

### **cli\_summary**

Default: False

When set to True, displays a summary of the number of minions targeted, the number of minions returned, and the number of minions that did not return.

```
cli_summary: False
```

### **sock\_dir**

Default: /var/run/salt/master

Set the location to use for creating Unix sockets for master process communication.

```
sock_dir: /var/run/salt/master
```

### enable\_gpu\_grains

Default: True

Enable GPU hardware data for your master. Be aware that the master can take a while to start up when lspci and/or dmidecode is used to populate the grains for the master.

### job\_cache

Default: True

The master maintains a job cache. While this is a great addition, it can be a burden on the master for larger deployments (over 5000 minions). Disabling the job cache will make previously executed jobs unavailable to the jobs system and is not generally recommended. Normally it is wise to make sure the master has access to a faster IO system or a tmpfs is mounted to the jobs dir.

### minion\_data\_cache

Default: True

The minion data cache is a cache of information about the minions stored on the master, this information is primarily the pillar and grains data. The data is cached in the Master cachedir under the name of the minion and used to predetermine what minions are expected to reply from executions.

```
minion_data_cache: True
```

### ext\_job\_cache

Default: ''

Used to specify a default returner for all minions. When this option is set, the specified returner needs to be properly configured and the minions will always default to sending returns to this returner. This will also disable the local job cache on the master.

```
ext_job_cache: redis
```

### event\_return

New in version 2015.5.0.

Default: ''

Specify the returner to use to log events. A returner may have installation and configuration requirements. Read the returner's documentation.

---

**Note:** Not all returners support event returns. Verify that a returner has an `event_return()` function before configuring this option with a returner.

---

```
event_return: cassandra_cql
```

### event\_return\_queue

New in version 2015.5.0.

Default: 0

On busy systems, enabling `event_returns` can cause a considerable load on the storage system for returners. Events can be queued on the master and stored in a batched fashion using a single transaction for multiple events. By default, events are not queued.

```
event_return_queue: 0
```

### event\_return\_whitelist

New in version 2015.5.0.

Default: []

Only return events matching tags in a whitelist.

```
event_return_whitelist:  
- salt/master/a_tag  
- salt/master/another_tag
```

### event\_return\_blacklist

New in version 2015.5.0.

Default: []

Store all event returns `_except_` the tags in a blacklist.

```
event_return_blacklist:  
- salt/master/not_this_tag  
- salt/master/or_this_one
```

### master\_job\_cache

New in version 2014.7.0.

Default: `local_cache`

Specify the returner to use for the job cache. The job cache will only be interacted with from the salt master and therefore does not need to be accessible from the minions.

```
master_job_cache: redis
```

### enforce\_mine\_cache

Default: False

By-default when disabling the `minion_data_cache` mine will stop working since it is based on cached data, by enabling this option we explicitly enabling only the cache for the mine system.

```
enforce_mine_cache: False
```

### max\_minions

Default: 0

The number of minions the master should allow to connect. Use this to accommodate the number of minions per master if you have different types of hardware serving your minions. The default of 0 means unlimited connections. Please note that this can slow down the authentication process a bit in large setups.

```
max_minions: 100
```

### con\_cache

Default: False

If `max_minions` is used in large installations, the master might experience high-load situations because of having to check the number of connected minions for every authentication. This cache provides the minion-ids of all connected minions to all MWorker-processes and greatly improves the performance of `max_minions`.

```
con_cache: True
```

### presence\_events

Default: False

Causes the master to periodically look for actively connected minions. *Presence events* are fired on the event bus on a regular interval with a list of connected minions, as well as events with lists of newly connected or disconnected minions. This is a master-only operation that does not send executions to minions. Note, this does not detect minions that connect to a master via localhost.

```
presence_events: False
```

## 30.8.2 Salt-SSH Configuration

### roster\_file

Default: ``/etc/salt/roster'`

Pass in an alternative location for the salt-ssh roster file.

```
roster_file: /root/roster
```

### ssh\_minion\_opts

Default: None

Pass in minion option overrides that will be inserted into the SHIM for salt-ssh calls. The local minion config is not used for salt-ssh. Can be overridden on a per-minion basis in the roster (`minion_opts`)

```
minion_opts:  
  gpg_keydir: /root/gpg
```

### 30.8.3 Master Security Settings

#### **open\_mode**

Default: False

Open mode is a dangerous security feature. One problem encountered with pki authentication systems is that keys can become "mixed up" and authentication begins to fail. Open mode turns off authentication and tells the master to accept all authentication. This will clean up the pki keys received from the minions. Open mode should not be turned on for general use. Open mode should only be used for a short period of time to clean up pki keys. To turn on open mode set this value to True.

```
open_mode: False
```

#### **auto\_accept**

Default: False

Enable auto\_accept. This setting will automatically accept all incoming public keys from minions.

```
auto_accept: False
```

#### **autosign\_timeout**

New in version 2014.7.0.

Default: 120

Time in minutes that a incoming public key with a matching name found in pki\_dir/minion\_autosign/keyid is automatically accepted. Expired autosign keys are removed when the master checks the minion\_autosign directory. This method to auto accept minions can be safer than an autosign\_file because the keyid record can expire and is limited to being an exact name match. This should still be considered a less than secure option, due to the fact that trust is based on just the requesting minion id.

#### **autosign\_file**

Default: not defined

If the autosign\_file is specified incoming keys specified in the autosign\_file will be automatically accepted. Matches will be searched for first by string comparison, then by globbing, then by full-string regex matching. This should still be considered a less than secure option, due to the fact that trust is based on just the requesting minion id.

#### **autoreject\_file**

New in version 2014.1.0.

Default: not defined

Works like *autosign\_file*, but instead allows you to specify minion IDs for which keys will automatically be rejected. Will override both membership in the *autosign\_file* and the *auto\_accept* setting.

## client\_acl

Default: {}

Enable user accounts on the master to execute specific modules. These modules can be expressed as regular expressions.

```
client_acl:
  fred:
    - test.ping
    - pkg.*
```

## client\_acl\_blacklist

Default: {}

Blacklist users or modules

This example would blacklist all non sudo users, including root from running any commands. It would also blacklist any use of the ``cmd" module.

This is completely disabled by default.

```
client_acl_blacklist:
  users:
    - root
    - '^(?!sudo_).*$' # all non sudo users
  modules:
    - cmd
```

## external\_auth

Default: {}

The external auth system uses the Salt auth modules to authenticate and validate users to access areas of the Salt system.

```
external_auth:
  pam:
    fred:
      - test.*
```

## token\_expire

Default: 43200

Time (in seconds) for a newly generated token to live.

Default: 12 hours

```
token_expire: 43200
```

## file\_recv

Default: False

Allow minions to push files to the master. This is disabled by default, for security purposes.

```
file_recv: False
```

### **file\_recv\_max\_size**

New in version 2014.7.0.

Default: 100

Set a hard-limit on the size of the files that can be pushed to the master. It will be interpreted as megabytes.

```
file_recv_max_size: 100
```

### **master\_sign\_pubkey**

Default: False

Sign the master auth-replies with a cryptographic signature of the master's public key. Please see the tutorial how to use these settings in the [Multimaster-PKI with Failover Tutorial](#)

```
master_sign_pubkey: True
```

### **master\_sign\_key\_name**

Default: master\_sign

The customizable name of the signing-key-pair without suffix.

```
master_sign_key_name: <filename_without_suffix>
```

### **master\_pubkey\_signature**

Default: master\_pubkey\_signature

The name of the file in the master's pki-directory that holds the pre-calculated signature of the master's public-key.

```
master_pubkey_signature: <filename>
```

### **master\_use\_pubkey\_signature**

Default: False

Instead of computing the signature for each auth-reply, use a pre-calculated signature. The *master\_pubkey\_signature* must also be set for this.

```
master_use_pubkey_signature: True
```

### rotate\_aes\_key

Default: True

Rotate the salt-masters AES-key when a minion-public is deleted with salt-key. This is a very important security-setting. Disabling it will enable deleted minions to still listen in on the messages published by the salt-master. Do not disable this unless it is absolutely clear what this does.

```
rotate_aes_key: True
```

## 30.8.4 Master Module Management

### runner\_dirs

Default: []

Set additional directories to search for runner modules.

```
runner_dirs:  
- /var/lib/salt/runners
```

### cython\_enable

Default: False

Set to true to enable Cython modules (.pyx files) to be compiled on the fly on the Salt master.

```
cython_enable: False
```

## 30.8.5 Master State System Settings

### state\_top

Default: top.sls

The state system uses a ``top" file to tell the minions what environment to use and what modules to use. The state\_top file is defined relative to the root of the base environment.

```
state_top: top.sls
```

### master\_tops

Default: {}

The master\_tops option replaces the external\_nodes option by creating a pluggable system for the generation of external top data. The external\_nodes option is deprecated by the master\_tops option. To gain the capabilities of the classic external\_nodes system, use the following configuration:

```
master_tops:  
  ext_nodes: <Shell command which returns yaml>
```

## external\_nodes

Default: None

The `external_nodes` option allows Salt to gather data that would normally be placed in a top file from an external node controller. The `external_nodes` option is the executable that will return the ENC data. Remember that Salt will look for external nodes AND top files and combine the results if both are enabled and available!

```
external_nodes: cobbler-ext-nodes
```

## renderer

Default: `yaml_jinja`

The renderer to use on the minions to render the state data.

```
renderer: yaml_jinja
```

## failhard

Default: `False`

Set the global failhard flag. This informs all states to stop running states at the moment a single state fails.

```
failhard: False
```

## state\_verbose

Default: `True`

Controls the verbosity of state runs. By default, the results of all states are returned, but setting this value to `False` will cause salt to only display output for states that failed or states that have changes.

```
state_verbose: False
```

## state\_output

Default: `full`

The `state_output` setting changes if the output is the full multi line output for each changed state if set to `'full'`, but if set to `'terse'` the output will be shortened to a single line. If set to `'mixed'`, the output will be terse unless a state failed, in which case that output will be full. If set to `'changes'`, the output will be full unless the state didn't change.

```
state_output: full
```

## state\_aggregate

Default: `False`

Automatically aggregate all states that have support for `mod_aggregate` by setting to `True`. Or pass a list of state module names to automatically aggregate just those types.

```
state_aggregate:  
  - pkg
```

```
state_aggregate: True
```

### state\_events

Default: False

Send progress events as each function in a state run completes execution by setting to True. Progress events are in the format `salt/job/<JID>/prog/<MID>/<RUN NUM>`.

```
state_events: True
```

### yaml\_utf8

Default: False

Enable extra routines for YAML renderer used states containing UTF characters.

```
yaml_utf8: False
```

### test

Default: False

Set all state calls to only test if they are going to actually make changes or just post what changes are going to be made.

```
test: False
```

## 30.8.6 Master File Server Settings

### fileserver\_backend

Default: ['roots']

Salt supports a modular fileserver backend system, this system allows the salt master to link directly to third party systems to gather and manage the files available to minions. Multiple backends can be configured and will be searched for the requested file in the order in which they are defined here. The default setting only enables the standard backend `roots`, which is configured using the `file_roots` option.

Example:

```
fileserver_backend:
  - roots
  - git
```

### fileserver\_followsymlinks

New in version 2014.1.0.

Default: True

By default, the `file_server` follows symlinks when walking the filesystem tree. Currently this only applies to the default `roots` `fileserver_backend`.

```
fileserver_followsymlinks: True
```

### **fileserver\_ignoresymlinks**

New in version 2014.1.0.

Default: False

If you do not want symlinks to be treated as the files they are pointing to, set `fileserver_ignoresymlinks` to True. By default this is set to False. When set to True, any detected symlink while listing files on the Master will not be returned to the Minion.

```
fileserver_ignoresymlinks: False
```

### **fileserver\_limit\_traversal**

New in version 2014.1.0.

Default: False

By default, the Salt fileserver recurses fully into all defined environments to attempt to find files. To limit this behavior so that the fileserver only traverses directories with SLS files and special Salt directories like `_modules`, set `fileserver_limit_traversal` to True. This might be useful for installations where a file root has a very large number of files and performance is impacted.

```
fileserver_limit_traversal: False
```

### **hash\_type**

Default: md5

The `hash_type` is the hash to use when discovering the hash of a file on the master server. The default is md5, but sha1, sha224, sha256, sha384, and sha512 are also supported.

```
hash_type: md5
```

### **file\_buffer\_size**

Default: 1048576

The buffer size in the file server in bytes.

```
file_buffer_size: 1048576
```

### **file\_ignore\_regex**

Default: ''

A regular expression (or a list of expressions) that will be matched against the file path before syncing the modules and states to the minions. This includes files affected by the `file.recurse` state. For example, if you manage your custom modules and states in subversion and don't want all the `.svn` folders and content synced to your minions, you could set this to  `/\.svn($|)/` . By default nothing is ignored.

```
file_ignore_regex:
- '/\.svn($|/)'
- '/\.git($|/)'
```

### file\_ignore\_glob

Default ''

A file glob (or list of file globs) that will be matched against the file path before syncing the modules and states to the minions. This is similar to `file_ignore_regex` above, but works on globs instead of regex. By default nothing is ignored.

```
file_ignore_glob:
- '*.pyc'
- '*/somefolder/*.bak'
- '*.swp'
```

### roots: Master's Local File Server

#### file\_roots

Default:

```
base:
- /srv/salt
```

Salt runs a lightweight file server written in ZeroMQ to deliver files to minions. This file server is built into the master daemon and does not require a dedicated port.

The file server works on environments passed to the master. Each environment can have multiple root directories. The subdirectories in the multiple file roots cannot match, otherwise the downloaded files will not be able to be reliably ensured. A base environment is required to house the top file.

Example:

```
file_roots:
  base:
    - /srv/salt
  dev:
    - /srv/salt/dev/services
    - /srv/salt/dev/states
  prod:
    - /srv/salt/prod/services
    - /srv/salt/prod/states
```

### git: Git Remote File Server Backend

#### gitfs\_remotes

Default: []

When using the `git` fileserver backend at least one git remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. Branches and tags are translated into salt environments.

```
gitfs_remotes:
- git://github.com/saltstack/salt-states.git
- file:///var/git/saltmaster
```

---

**Note:** `file://` repos will be treated as a remote and copied into the master's gitfs cache, so only the *local* refs for those repos will be exposed as fileservers environments.

---

As of 2014.7.0, it is possible to have per-repo versions of several of the gitfs configuration parameters. For more information, see the [GitFS Walkthrough](#).

### gitfs\_provider

New in version 2014.7.0.

Specify the provider to be used for gitfs. More information can be found in the [GitFS Walkthrough](#).

Specify one value among valid values: `gitpython`, `pygit2`, `dulwich`

```
gitfs_provider: dulwich
```

### gitfs\_ssl\_verify

Default: `True`

The `gitfs_ssl_verify` option specifies whether to ignore SSL certificate errors when contacting the gitfs backend. You might want to set this to `false` if you're using a git backend that uses a self-signed certificate but keep in mind that setting this flag to anything other than the default of `True` is a security concern, you may want to try using the `ssh` transport.

```
gitfs_ssl_verify: True
```

### gitfs\_mountpoint

New in version 2014.7.0.

Default: `''`

Specifies a path on the salt fileserver from which gitfs remotes are served. Can be used in conjunction with [gitfs\\_root](#). Can also be configured on a per-remote basis, see [here](#) for more info.

```
gitfs_mountpoint: salt://foo/bar
```

---

**Note:** The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent).

---

### gitfs\_root

Default: `''`

Serve files from a subdirectory within the repository, instead of the root. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with *gitfs\_mountpoint*.

```
gitfs_root: somefolder/otherfolder
```

Changed in version 2014.7.0: Ability to specify gitfs roots on a per-remote basis was added. See [here](#) for more info.

### **gitfs\_base**

Default: master

Defines which branch/tag should be used as the base environment.

```
gitfs_base: salt
```

Changed in version 2014.7.0: Ability to specify the base on a per-remote basis was added. See [here](#) for more info.

### **gitfs\_env\_whitelist**

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if the repos in *gitfs\_remotes* contain many branches/tags. More information can be found in the [GitFS Walkthrough](#).

```
gitfs_env_whitelist:
- base
- v1.*
- 'mybranch\d+'
```

### **gitfs\_env\_blacklist**

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if the repos in *gitfs\_remotes* contain many branches/tags. More information can be found in the [GitFS Walkthrough](#).

```
gitfs_env_blacklist:
- base
- v1.*
- 'mybranch\d+'
```

### **GitFS Authentication Options**

These parameters only currently apply to the pygit2 gitfs provider. Examples of how to use these can be found in the [GitFS Walkthrough](#).

**gitfs\_user** New in version 2014.7.0.

Default: ''

Along with *gitfs\_password*, is used to authenticate to HTTPS remotes.

```
gitfs_user: git
```

**gitfs\_password** New in version 2014.7.0.

Default: ''

Along with *gitfs\_user*, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

```
gitfs_password: mypassword
```

**gitfs\_insecure\_auth** New in version 2014.7.0.

Default: False

By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. **Enable this at your own risk.**

```
gitfs_insecure_auth: True
```

**gitfs\_pubkey** New in version 2014.7.0.

Default: ''

Along with *gitfs\_privkey* (and optionally *gitfs\_passphrase*), is used to authenticate to SSH remotes. This parameter (or its *per-remote counterpart*) is required for SSH remotes.

```
gitfs_pubkey: /path/to/key.pub
```

**gitfs\_privkey** New in version 2014.7.0.

Default: ''

Along with *gitfs\_pubkey* (and optionally *gitfs\_passphrase*), is used to authenticate to SSH remotes. This parameter (or its *per-remote counterpart*) is required for SSH remotes.

```
gitfs_privkey: /path/to/key
```

**gitfs\_passphrase** New in version 2014.7.0.

Default: ''

This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

```
gitfs_passphrase: mypassphrase
```

## hg: Mercurial Remote File Server Backend

### hgfs\_remotes

New in version 0.17.0.

Default: []

When using the hg fileserver backend at least one mercurial remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. Branches and/or bookmarks are translated into salt environments, as defined by the *hgfs\_branch\_method* parameter.

```
hgfs_remotes:
- https://username@bitbucket.org/username/reponame
```

**Note:** As of 2014.7.0, it is possible to have per-repo versions of the *hgfs\_root*, *hgfs\_mountpoint*, *hgfs\_base*, and *hgfs\_branch\_method* parameters. For example:

```
hgfs_remotes:
- https://username@bitbucket.org/username/repo1
  - base: saltstates
- https://username@bitbucket.org/username/repo2:
  - root: salt
  - mountpoint: salt://foo/bar/baz
- https://username@bitbucket.org/username/repo3:
  - root: salt/states
  - branch_method: mixed
```

### hgfs\_branch\_method

New in version 0.17.0.

Default: branches

Defines the objects that will be used as fileserver environments.

- **branches** - Only branches and tags will be used
- **bookmarks** - Only bookmarks and tags will be used
- **mixed** - Branches, bookmarks, and tags will be used

```
hgfs_branch_method: mixed
```

**Note:** Starting in version 2014.1.0, the value of the *hgfs\_base* parameter defines which branch is used as the base environment, allowing for a **base** environment to be used with an *hgfs\_branch\_method* of bookmarks.

Prior to this release, the default branch will be used as the base environment.

### hgfs\_mountpoint

New in version 2014.7.0.

Default: ''

Specifies a path on the salt fileserver from which hgfs remotes are served. Can be used in conjunction with [hgfs\\_root](#). Can also be configured on a per-remote basis, see [here](#) for more info.

```
hgfs_mountpoint: salt://foo/bar
```

---

**Note:** The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent).

---

### hgfs\_root

New in version 0.17.0.

Default: ''

Serve files from a subdirectory within the repository, instead of the root. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with [hgfs\\_mountpoint](#).

```
hgfs_root: somefolder/otherfolder
```

Changed in version 2014.7.0: Ability to specify hgfs roots on a per-remote basis was added. See [here](#) for more info.

### hgfs\_base

New in version 2014.1.0.

Default: default

Defines which branch should be used as the base environment. Change this if [hgfs\\_branch\\_method](#) is set to `bookmarks` to specify which bookmark should be used as the base environment.

```
hgfs_base: salt
```

### hgfs\_env\_whitelist

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if your hgfs remotes contain many branches/bookmarks/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, only branches/bookmarks/tags which match one of the specified expressions will be exposed as fileserver environments.

If used in conjunction with [hgfs\\_env\\_blacklist](#), then the subset of branches/bookmarks/tags which match the whitelist but do *not* match the blacklist will be exposed as fileserver environments.

```
hgfs_env_whitelist:
- base
- v1.*
- 'mybranch\d+'
```

## hgfs\_env\_blacklist

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if your hgfs remotes contain many branches/bookmarks/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, branches/bookmarks/tags which match one of the specified expressions will *not* be exposed as fileserver environments.

If used in conjunction with *hgfs\_env\_whitelist*, then the subset of branches/bookmarks/tags which match the whitelist but do *not* match the blacklist will be exposed as fileserver environments.

```
hgfs_env_blacklist:
- base
- v1.*
- 'mybranch\d+'
```

## svn: Subversion Remote File Server Backend

### svnfs\_remotes

New in version 0.17.0.

Default: []

When using the svn fileserver backend at least one subversion remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. The trunk, branches, and tags become environments, with the trunk being the **base** environment.

```
svnfs_remotes:
- svn://foo.com/svn/myproject
```

**Note:** As of 2014.7.0, it is possible to have per-repo versions of the following configuration parameters:

- *svnfs\_root*
- *svnfs\_mountpoint*
- *svnfs\_trunk*
- *svnfs\_branches*
- *svnfs\_tags*

For example:

```
svnfs_remotes:
- svn://foo.com/svn/project1
- svn://foo.com/svn/project2:
  - root: salt
  - mountpoint: salt://foo/bar/baz
- svn://foo.com/svn/project3:
  - root: salt/states
```

- branches: branch
- tags: tag

### svnfs\_mountpoint

New in version 2014.7.0.

Default: ''

Specifies a path on the salt fileserver from which svnfs remotes are served. Can be used in conjunction with [svnfs\\_root](#). Can also be configured on a per-remote basis, see [here](#) for more info.

```
svnfs_mountpoint: salt://foo/bar
```

**Note:** The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent).

### svnfs\_root

New in version 0.17.0.

Default: ''

Serve files from a subdirectory within the repository, instead of the root. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with [svnfs\\_mountpoint](#).

```
svnfs_root: somefolder/otherfolder
```

Changed in version 2014.7.0: Ability to specify svnfs roots on a per-remote basis was added. See [here](#) for more info.

### svnfs\_trunk

New in version 2014.7.0.

Default: trunk

Path relative to the root of the repository where the trunk is located. Can also be configured on a per-remote basis, see [here](#) for more info.

```
svnfs_trunk: trunk
```

### svnfs\_branches

New in version 2014.7.0.

Default: branches

Path relative to the root of the repository where the branches are located. Can also be configured on a per-remote basis, see [here](#) for more info.

```
svnfs_branches: branches
```

### svnfs\_tags

New in version 2014.7.0.

Default: tags

Path relative to the root of the repository where the tags are located. Can also be configured on a per-remote basis, see [here](#) for more info.

```
svnfs_tags: tags
```

### svnfs\_env\_whitelist

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if your svnfs remotes contain many branches/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, only branches/tags which match one of the specified expressions will be exposed as fileserver environments.

If used in conjunction with `svnfs_env_blacklist`, then the subset of branches/tags which match the whitelist but do *not* match the blacklist will be exposed as fileserver environments.

```
svnfs_env_whitelist:
- base
- v1.*
- 'mybranch\d+'
```

### svnfs\_env\_blacklist

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if your svnfs remotes contain many branches/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, branches/tags which match one of the specified expressions will *not* be exposed as fileserver environments.

If used in conjunction with `svnfs_env_whitelist`, then the subset of branches/tags which match the whitelist but do *not* match the blacklist will be exposed as fileserver environments.

```
svnfs_env_blacklist:
- base
- v1.*
- 'mybranch\d+'
```

## minion: MinionFS Remote File Server Backend

### minionfs\_env

New in version 2014.7.0.

Default: base

Environment from which MinionFS files are made available.

```
minionfs_env: minionfs
```

### **minionfs\_mountpoint**

New in version 2014.7.0.

Default: ''

Specifies a path on the salt fileserver from which minionfs files are served.

```
minionfs_mountpoint: salt://foo/bar
```

---

**Note:** The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent).

---

### **minionfs\_whitelist**

New in version 2014.7.0.

Default: []

Used to restrict which minions' pushed files are exposed via minionfs. If using a regular expression, the expression must match the entire minion ID.

If used, only the pushed files from minions which match one of the specified expressions will be exposed.

If used in conjunction with `minionfs_blacklist`, then the subset of hosts which match the whitelist but do *not* match the blacklist will be exposed.

```
minionfs_whitelist:  
- base  
- v1.*  
- 'mybranch\d+'
```

### **minionfs\_blacklist**

New in version 2014.7.0.

Default: []

Used to restrict which minions' pushed files are exposed via minionfs. If using a regular expression, the expression must match the entire minion ID.

If used, only the pushed files from minions which match one of the specified expressions will *not* be exposed.

If used in conjunction with `minionfs_whitelist`, then the subset of hosts which match the whitelist but do *not* match the blacklist will be exposed.

```
minionfs_blacklist:  
- base  
- v1.*  
- 'mybranch\d+'
```

### 30.8.7 Pillar Configuration

#### pillar\_roots

Default:

```
base:
  - /srv/pillar
```

Set the environments and directories used to hold pillar sls data. This configuration is the same as *file\_roots*:

```
pillar_roots:
  base:
    - /srv/pillar
  dev:
    - /srv/pillar/dev
  prod:
    - /srv/pillar/prod
```

#### ext\_pillar

The `ext_pillar` option allows for any number of external pillar interfaces to be called when populating pillar data. The configuration is based on `ext_pillar` functions. The available `ext_pillar` functions can be found herein:

<https://github.com/saltstack/salt/blob/develop/salt/pillar>

By default, the `ext_pillar` interface is not configured to run.

Default: []

```
ext_pillar:
  - hiera: /etc/hiera.yaml
  - cmd_yaml: cat /etc/salt/yaml
  - reclass:
      inventory_base_uri: /etc/reclass
```

There are additional details at *Pillars*

#### ext\_pillar\_first

New in version 2015.5.0.

The `ext_pillar_first` option allows for external pillar sources to populate before file system pillar. This allows for targeting file system pillar from `ext_pillar`.

Default: False

```
ext_pillar_first: False
```

#### pillar\_source\_merging\_strategy

New in version 2014.7.0.

Default: smart

The `pillar_source_merging_strategy` option allows you to configure merging strategy between different sources. It accepts 4 values:

- recurse:

it will merge recursively mapping of data. For example, these 2 sources:

```
foo: 42
bar:
  element1: True
```

```
bar:
  element2: True
baz: quux
```

will be merged as:

```
foo: 42
bar:
  element1: True
  element2: True
baz: quux
```

- aggregate:

instructs aggregation of elements between sources that use the `#!yamlex` renderer.

For example, these two documents:

```
#!yamlex
foo: 42
bar: !aggregate {
  element1: True
}
baz: !aggregate quux
```

```
#!yamlex
bar: !aggregate {
  element2: True
}
baz: !aggregate quux2
```

will be merged as:

```
foo: 42
bar:
  element1: True
  element2: True
baz:
  - quux
  - quux2
```

- overwrite:

Will use the behaviour of the 2014.1 branch and earlier.

Overwrites elements according the order in which they are processed.

First pillar processed:

```
A:
  first_key: blah
  second_key: blah
```

Second pillar processed:

```
A:
  third_key: blah
  fourth_key: blah
```

will be merged as:

```
A:
  third_key: blah
  fourth_key: blah
```

- smart (default):  
Guesses the best strategy based on the ``renderer'' setting.

### 30.8.8 Syndic Server Settings

A Salt syndic is a Salt master used to pass commands from a higher Salt master to minions below the syndic. Using the syndic is simple. If this is a master that will have syndic servers(s) below it, set the ``order\_masters'' setting to True.

If this is a master that will be running a syndic daemon for passthrough the ``syndic\_master'' setting needs to be set to the location of the master server.

Do not not forget that, in other words, it means that it shares with the local minion its ID and PKI\_DIR.

#### order\_masters

Default: False

Extra data needs to be sent with publications if the master is controlling a lower level master via a syndic minion. If this is the case the order\_masters value must be set to True

```
order_masters: False
```

#### syndic\_master

Default: ''

If this master will be running a salt-syndic to connect to a higher level master, specify the higher level master with this configuration value.

```
syndic_master: masterofmasters
```

You can optionally connect a syndic to multiple higher level masters by setting the `syndic\_master' value to a list:

```
syndic_master:
  - masterofmasters1
  - masterofmasters2
```

Each higher level master must be set up in a multimaster configuration.

#### syndic\_master\_port

Default: 4506

If this master will be running a salt-syndic to connect to a higher level master, specify the higher level master port with this configuration value.

```
syndic_master_port: 4506
```

### syndic\_pidfile

Default: salt-syndic.pid

If this master will be running a salt-syndic to connect to a higher level master, specify the pidfile of the syndic daemon.

```
syndic_pidfile: syndic.pid
```

### syndic\_log\_file

Default: syndic.log

If this master will be running a salt-syndic to connect to a higher level master, specify the log\_file of the syndic daemon.

```
syndic_log_file: salt-syndic.log
```

## 30.8.9 Peer Publish Settings

Salt minions can send commands to other minions, but only if the minion is allowed to. By default "Peer Publication" is disabled, and when enabled it is enabled for specific minions and specific commands. This allows secure compartmentalization of commands based on individual minions.

### peer

Default: {}

The configuration uses regular expressions to match minions and then a list of regular expressions to match functions. The following will allow the minion authenticated as foo.example.com to execute functions from the test and pkg modules.

```
peer:
  foo.example.com:
    - test.*
    - pkg.*
```

This will allow all minions to execute all commands:

```
peer:
  .*:
    - .*
```

This is not recommended, since it would allow anyone who gets root on any single minion to instantly have root on all of the minions!

By adding an additional layer you can limit the target hosts in addition to the accessible commands:

```
peer:
  foo.example.com:
    'db*':
      - test.*
      - pkg.*
```

### peer\_run

Default: {}

The `peer_run` option is used to open up runners on the master to access from the minions. The `peer_run` configuration matches the format of the peer configuration.

The following example would allow `foo.example.com` to execute the `manage.up` runner:

```
peer_run:
  foo.example.com:
    - manage.up
```

## 30.8.10 Master Logging Settings

### log\_file

Default: `/var/log/salt/master`

The master log can be sent to a regular file, local path name, or network location. See also [log\\_file](#).

Examples:

```
log_file: /var/log/salt/master
```

```
log_file: file:///dev/log
```

```
log_file: udp://loghost:10514
```

### log\_level

Default: `warning`

The level of messages to send to the console. See also [log\\_level](#).

```
log_level: warning
```

### log\_level\_logfile

Default: `warning`

The level of messages to send to the log file. See also [log\\_level\\_logfile](#).

```
log_level_logfile: warning
```

### log\_datefmt

Default: %H:%M:%S

The date and time format used in console log messages. See also *log\_datefmt*.

```
log_datefmt: '%H:%M:%S'
```

### log\_datefmt\_logfile

Default: %Y-%m-%d %H:%M:%S

The date and time format used in log file messages. See also *log\_datefmt\_logfile*.

```
log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'
```

### log\_fmt\_console

Default: [%(\levelname)-8s] %(message)s

The format of the console logging messages. See also *log\_fmt\_console*.

```
log_fmt_console: '[(\levelname)-8s] %(message)s'
```

### log\_fmt\_logfile

Default: %(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s

The format of the log file logging messages. See also *log\_fmt\_logfile*.

```
log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'
```

### log\_granular\_levels

Default: {}

This can be used to control logging levels more specifically. See also *log\_granular\_levels*.

## 30.8.11 Node Groups

Default: {}

Node groups allow for logical groupings of minion nodes. A group consists of a group name and a compound target.

```
nodegroups:  
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'  
  group2: 'G@os:Debian and foo.domain.com'  
  group3: 'G@os:Debian and N@group1'
```

More information on using nodegroups can be found *here*.

### 30.8.12 Range Cluster Settings

#### range\_server

Default: 'range:80'

The range server (and optional port) that serves your cluster information <https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec>

```
range_server: range:80
```

### 30.8.13 Include Configuration

#### default\_include

Default: master.d/\*.conf

The master can include configuration from other files. Per default the master will automatically include all config files from master.d/\*.conf where master.d is relative to the directory of the master configuration file.

#### include

Default: not defined

The master can include configuration from other files. To enable this, pass a list of paths to this option. The paths can be either relative or absolute; if relative, they are considered to be relative to the directory the main minion configuration file lives in. Paths can make use of shell-style globbing. If no files are matched by a path passed to this option then the master will log a warning message.

```
# Include files from a master.d directory in the same
# directory as the master config file
include: master.d/*

# Include a single extra file into the configuration
include: /etc/roles/webserver

# Include several files and the master.d directory
include:
  - extra_config
  - master.d/*
  - /etc/roles/webserver
```

### 30.8.14 Windows Software Repo Settings

#### win\_repo

Default: /srv/salt/win/repo

Location of the repo on the master

```
win_repo: '/srv/salt/win/repo'
```

### win\_repo\_mastercachefile

Default: /srv/salt/win/repo/winrepo.p

```
win_repo_mastercachefile: '/srv/salt/win/repo/winrepo.p'
```

### win\_gitrepos

Default: ['https://github.com/saltstack/salt-winrepo.git']

List of git repositories to include with the local repo.

```
win_gitrepos:  
- 'https://github.com/saltstack/salt-winrepo.git'
```

To specify a specific revision of the repository, preface the repository location with a commit ID:

```
win_gitrepos:  
- '<commit_id> https://github.com/saltstack/salt-winrepo.git'
```

Replacing `<commit_id>` with the ID from GitHub. Specifying a commit ID is useful if you need to revert to a previous version if an error is introduced in the latest version.

## 30.9 Configuring the Salt Minion

The Salt system is amazingly simple and easy to configure. The two components of the Salt system each have a respective configuration file. The **salt-master** is configured via the master configuration file, and the **salt-minion** is configured via the minion configuration file.

See also:

*example minion configuration file*

The Salt Minion configuration is very simple. Typically, the only value that needs to be set is the master value so the minion knows where to locate its master.

By default, the salt-minion configuration will be in `/etc/salt/minion`. A notable exception is FreeBSD, where the configuration will be in `/usr/local/etc/salt/minion`.

### 30.9.1 Minion Primary Configuration

#### master

Default: salt

The hostname or ipv4 of the master.

Default: salt

```
master: salt
```

The option can also be set to a list of masters, enabling `multi-master` mode.

```
master:  
- address1  
- address2
```

Changed in version 2014.7.0: The master can be dynamically configured. The `master` value can be set to an module function which will be executed and will assume that the returning value is the ip or hostname of the desired master. If a function is being specified, then the `master_type` option must be set to `func`, to tell the minion that the value is a function to be run and not a fully-qualified domain name.

```
master: module.function
master_type: func
```

In addition, instead of using multi-master mode, the minion can be configured to use the list of master addresses as a failover list, trying the first address, then the second, etc. until the minion successfully connects. To enable this behavior, set `master_type` to `failover`:

```
master:
- address1
- address2
master_type: failover
```

### master\_type

New in version 2014.7.0.

Default: `str`

The type of the `master` variable. Can be `str`, `failover` or `func`.

```
master_type: failover
```

If this option is set to `failover`, `master` must be a list of master addresses. The minion will then try each master in the order specified in the list until it successfully connects. `master_alive_interval` must also be set, this determines how often the minion will verify the presence of the master.

```
master_type: func
```

If the master needs to be dynamically assigned by executing a function instead of reading in the static master value, set this to `func`. This can be used to manage the minion's master setting from an execution module. By simply changing the algorithm in the module to return a new master ip/fqdn, restart the minion and it will connect to the new master.

### master\_alive\_interval

Default: `0`

Configures how often, in seconds, the minion will verify that the current master is alive and responding. The minion will try to establish a connection to the next master in the list if it finds the existing one is dead.

```
master_alive_interval: 30
```

### master\_shuffle

New in version 2014.7.0.

Default: `False`

If `master` is a list of addresses and `:conf_minion`master_type` is failover, shuffle them before trying to connect to distribute the minions over all available masters. This uses Python's random.shuffle method.`

```
master_shuffle: True
```

### random\_master

Default: False

If *master* is a list of addresses, shuffle them before trying to connect to distribute the minions over all available masters. This uses Python's `random.randint` method.

```
random_master: True
```

### retry\_dns

Default: 30

Set the number of seconds to wait before attempting to resolve the master hostname if name resolution fails. Defaults to 30 seconds. Set to zero if the minion should shutdown and not retry.

```
retry_dns: 30
```

### master\_port

Default: 4506

The port of the master ret server, this needs to coincide with the `ret_port` option on the Salt master.

```
master_port: 4506
```

### user

Default: root

The user to run the Salt processes

```
user: root
```

### sudo\_user

Default: ''

Setting `sudo_user` will cause salt to run all execution modules under a sudo to the user given in `sudo_user`. The user under which the salt minion process itself runs will still be that provided in *user* above, but all execution modules run by the minion will be rerouted through sudo.

```
sudo_user: saltadm
```

### pidfile

Default: /var/run/salt-minion.pid

The location of the daemon's process ID file

```
pidfile: /var/run/salt-minion.pid
```

### root\_dir

Default: /

This directory is prepended to the following options: *pki\_dir*, *cachedir*, *log\_file*, *sock\_dir*, and *pid-file*.

```
root_dir: /
```

### pki\_dir

Default: /etc/salt/pki/minion

The directory used to store the minion's public and private keys.

```
pki_dir: /etc/salt/pki/minion
```

### id

Default: the system's hostname

See also:

*Salt Walkthrough*

The **Setting up a Salt Minion** section contains detailed information on how the hostname is determined.

Explicitly declare the id for this minion to use. Since Salt uses detached ids it is possible to run multiple minions on the same machine but with different ids.

```
id: foo.bar.com
```

### append\_domain

Default: None

Append a domain to a hostname in the event that it does not exist. This is useful for systems where `socket.getfqdn()` does not actually result in a FQDN (for instance, Solaris).

```
append_domain: foo.org
```

### cachedir

Default: /var/cache/salt/minion

The location for minion cache data.

```
cachedir: /var/cache/salt/minion
```

## verify\_env

Default: True

Verify and set permissions on configuration directories at startup.

```
verify_env: True
```

---

**Note:** When set to `True` the `verify_env` option requires `WRITE` access to the configuration directory (`/etc/salt/`). In certain situations such as mounting `/etc/salt/` as read-only for templating this will create a stack trace when `state.apply` is called.

---

## cache\_jobs

Default: False

The minion can locally cache the return data from jobs sent to it, this can be a good way to keep track of the minion side of the jobs the minion has executed. By default this feature is disabled, to enable set `cache_jobs` to `True`.

```
cache_jobs: False
```

## grains

Default: (empty)

See also:

*Grains in the Minion Config*

Statically assigns grains to the minion.

```
grains:
  roles:
    - webserver
    - memcache
  deployment: datacenter4
  cabinet: 13
  cab_u: 14-15
```

## grains\_cache

Default: False

The minion can locally cache grain data instead of refreshing the data each time the grain is referenced. By default this feature is disabled, to enable set `grains_cache` to `True`.

```
grains_cache: False
```

## sock\_dir

Default: `/var/run/salt/minion`

The directory where Unix sockets will be kept.

```
sock_dir: /var/run/salt/minion
```

### backup\_mode

Default: ''

Backup files replaced by file.managed and file.recurse under cachedir.

```
backup_mode: minion
```

### acceptance\_wait\_time

Default: 10

The number of seconds to wait until attempting to re-authenticate with the master.

```
acceptance_wait_time: 10
```

### random\_reauth\_delay

Default: 10

When the master key changes, the minion will try to re-auth itself to receive the new master key. In larger environments this can cause a syn-flood on the master because all minions try to re-auth immediately. To prevent this and have a minion wait for a random amount of time, use this optional parameter. The wait-time will be a random number of seconds between 0 and the defined value.

```
random_reauth_delay: 60
```

### acceptance\_wait\_time\_max

Default: 0

The maximum number of seconds to wait until attempting to re-authenticate with the master. If set, the wait will increase by acceptance\_wait\_time seconds each iteration.

```
acceptance_wait_time_max: 0
```

### recon\_default

Default: 1000

The interval in milliseconds that the socket should wait before trying to reconnect to the master (1000ms = 1 second).

```
recon_default: 1000
```

### recon\_max

Default: 10000

The maximum time a socket should wait. Each interval the time to wait is calculated by doubling the previous time. If recon\_max is reached, it starts again at the recon\_default.

Short example:

- reconnect 1: the socket will wait `recon\_default` milliseconds
- reconnect 2: `recon\_default` \* 2
- reconnect 3: (`recon\_default` \* 2) \* 2
- reconnect 4: value from previous interval \* 2
- reconnect 5: value from previous interval \* 2
- reconnect x: if value >= recon\_max, it starts again with recon\_default

```
recon_max: 10000
```

### recon\_randomize

Default: True

Generate a random wait time on minion start. The wait time will be a random value between recon\_default and recon\_default + recon\_max. Having all minions reconnect with the same recon\_default and recon\_max value kind of defeats the purpose of being able to change these settings. If all minions have the same values and the setup is quite large (several thousand minions), they will still flood the master. The desired behavior is to have time-frame within all minions try to reconnect.

```
recon_randomize: True
```

### return\_retry\_timer

Default: 5

The default timeout for a minion return attempt.

```
return_retry_timer: 5
```

### return\_retry\_timer\_max

Default: 10

The maximum timeout for a minion return attempt. If non-zero the minion return retry timeout will be a random int between return\_retry\_timer and return\_retry\_timer\_max

```
return_retry_timer_max: 10
```

### cache\_sreqs

Default: True

The connection to the master ret\_port is kept open. When set to False, the minion creates a new connection for every return to the master.

```
cache_sreqs: True
```

### **ipc\_mode**

Default: `ipc`

Windows platforms lack POSIX IPC and must rely on slower TCP based inter-process communications. Set `ipc_mode` to `tcp` on such systems.

```
ipc_mode: ipc
```

### **tcp\_pub\_port**

Default: 4510

Publish port used when `ipc_mode` is set to `tcp`.

```
tcp_pub_port: 4510
```

### **tcp\_pull\_port**

Default: 4511

Pull port used when `ipc_mode` is set to `tcp`.

```
tcp_pull_port: 4511
```

## **30.9.2 Minion Module Management**

### **disable\_modules**

Default: `[]` (all modules are enabled by default)

The event may occur in which the administrator desires that a minion should not be able to execute a certain module. The `sys` module is built into the minion and cannot be disabled.

This setting can also tune the minion, as all modules are loaded into ram disabling modules will lower the minion's ram footprint.

```
disable_modules:  
- test  
- solr
```

### **disable\_returners**

Default: `[]` (all returners are enabled by default)

If certain returners should be disabled, this is the place

```
disable_returners:  
- mongo_return
```

### **module\_dirs**

Default: []

A list of extra directories to search for Salt modules

```
module_dirs:  
- /var/lib/salt/modules
```

### **returner\_dirs**

Default: []

A list of extra directories to search for Salt returners

```
returner_dirs:  
- /var/lib/salt/returners
```

### **states\_dirs**

Default: []

A list of extra directories to search for Salt states

```
states_dirs:  
- /var/lib/salt/states
```

### **grains\_dirs**

Default: []

A list of extra directories to search for Salt grains

```
grains_dirs:  
- /var/lib/salt/grains
```

### **render\_dirs**

Default: []

A list of extra directories to search for Salt renderers

```
render_dirs:  
- /var/lib/salt/renderers
```

### **cython\_enable**

Default: False

Set this value to true to enable auto-loading and compiling of .pyx modules, This setting requires that gcc and cython are installed on the minion.

```
cython_enable: False
```

## providers

Default: (empty)

A module provider can be statically overwritten or extended for the minion via the `providers` option. This can be done [on an individual basis in an SLS file](#), or globally here in the minion config, like below.

```
providers:  
  service: systemd
```

### 30.9.3 State Management Settings

#### renderer

Default: `yaml_jinja`

The default renderer used for local state executions

```
renderer: yaml_jinja
```

#### state\_verbose

Default: `True`

Controls the verbosity of state runs. By default, the results of all states are returned, but setting this value to `False` will cause salt to only display output for states that failed or states that have changes.

```
state_verbose: True
```

#### state\_output

Default: `full`

The `state_output` setting changes if the output is the full multi line output for each changed state if set to `'full'`, but if set to `'terse'` the output will be shortened to a single line.

```
state_output: full
```

#### autoload\_dynamic\_modules

Default: `True`

`autoload_dynamic_modules` turns on automatic loading of modules found in the environments on the master. This is turned on by default. To turn off auto-loading modules when states run, set this value to `False`.

```
autoload_dynamic_modules: True
```

Default: `True`

`clean_dynamic_modules` keeps the dynamic modules on the minion in sync with the dynamic modules on the master. This means that if a dynamic module is not on the master it will be deleted from the minion. By default this is enabled and can be disabled by changing this value to `False`.

```
clean_dynamic_modules: True
```

## environment

Default: None

Normally the minion is not isolated to any single environment on the master when running states, but the environment can be isolated on the minion side by statically setting it. Remember that the recommended way to manage environments is to isolate via the top file.

```
environment: None
```

## 30.9.4 File Directory Settings

### file\_client

Default: remote

The client defaults to looking on the master server for files, but can be directed to look on the minion by setting this parameter to `local`.

```
file_client: remote
```

### use\_master\_when\_local

Default: False

When using a local *file\_client*, this parameter is used to allow the client to connect to a master for remote execution.

```
use_master_when_local: False
```

### file\_roots

Default:

```
base:  
- /srv/salt
```

When using a local *file\_client*, this parameter is used to setup the fileserver's environments. This parameter operates identically to the *master config parameter* of the same name.

```
file_roots:  
  base:  
    - /srv/salt  
  dev:  
    - /srv/salt/dev/services  
    - /srv/salt/dev/states  
  prod:  
    - /srv/salt/prod/services  
    - /srv/salt/prod/states
```

### fileserver\_followsymlinks

New in version 2014.1.0.

Default: True

By default, the `file_server` follows symlinks when walking the filesystem tree. Currently this only applies to the default roots `filesERVER_backend`.

```
filesERVER_followsymlinks: True
```

### filesERVER\_ignoresymlinks

New in version 2014.1.0.

Default: False

If you do not want symlinks to be treated as the files they are pointing to, set `filesERVER_ignoresymlinks` to True. By default this is set to False. When set to True, any detected symlink while listing files on the Master will not be returned to the Minion.

```
filesERVER_ignoresymlinks: False
```

### filesERVER\_limit\_traversal

New in version 2014.1.0.

Default: False

By default, the Salt filesERVER recurses fully into all defined environments to attempt to find files. To limit this behavior so that the filesERVER only traverses directories with SLS files and special Salt directories like `_modules`, set `filesERVER_limit_traversal` to True. This might be useful for installations where a file root has a very large number of files and performance is impacted.

```
filesERVER_limit_traversal: False
```

### hash\_type

Default: md5

The `hash_type` is the hash to use when discovering the hash of a file on the local filesERVER. The default is md5, but sha1, sha224, sha256, sha384, and sha512 are also supported.

```
hash_type: md5
```

### pillar\_roots

Default:

```
base:
  - /srv/pillar
```

When using a local `file_client`, this parameter is used to setup the pillar environments.

```
pillar_roots:
  base:
    - /srv/pillar
  dev:
    - /srv/pillar/dev
```

```
prod:
  - /srv/pillar/prod
```

### **file\_recv\_max\_size**

New in version 2014.7.0.

Default: 100

Set a hard-limit on the size of the files that can be pushed to the master. It will be interpreted as megabytes.

```
file_recv_max_size: 100
```

## **30.9.5 Security Settings**

### **open\_mode**

Default: False

Open mode can be used to clean out the PKI key received from the Salt master, turn on open mode, restart the minion, then turn off open mode and restart the minion to clean the keys.

```
open_mode: False
```

### **master\_finger**

Default: ''

Fingerprint of the master public key to validate the identity of your Salt master before the initial key exchange. The master fingerprint can be found by running ``salt-key -F master`` on the Salt master.

```
master_finger: 'ba:30:65:2a:d6:9e:20:4f:d8:b2:f3:a7:d4:65:11:13'
```

### **verify\_master\_pubkey\_sign**

Default: False

Enables verification of the master-public-signature returned by the master in auth-replies. Please see the tutorial on how to configure this properly [Multimaster-PKI with Failover Tutorial](#)

New in version 2014.7.0.

```
verify_master_pubkey_sign: True
```

If this is set to True, *master\_sign\_pubkey* must be also set to True in the master configuration file.

### **master\_sign\_key\_name**

Default: master\_sign

The filename without the *.pub* suffix of the public key that should be used for verifying the signature from the master. The file must be located in the minion's pki directory.

New in version 2014.7.0.

```
master_sign_key_name: <filename_without_suffix>
```

### **always\_verify\_signature**

Default: False

If *verify\_master\_pubkey\_sign* is enabled, the signature is only verified if the public-key of the master changes. If the signature should always be verified, this can be set to True.

New in version 2014.7.0.

```
always_verify_signature: True
```

## **30.9.6 Thread Settings**

Default: True

Disable multiprocessing support by default when a minion receives a publication a new process is spawned and the command is executed therein.

```
multiprocessing: True
```

## **30.9.7 Minion Logging Settings**

### **log\_file**

Default: /var/log/salt/minion

The minion log can be sent to a regular file, local path name, or network location. See also *log\_file*.

Examples:

```
log_file: /var/log/salt/minion
```

```
log_file: file:///dev/log
```

```
log_file: udp://loghost:10514
```

### **log\_level**

Default: warning

The level of messages to send to the console. See also *log\_level*.

```
log_level: warning
```

### **log\_level\_logfile**

Default: warning

The level of messages to send to the log file. See also *log\_level\_logfile*.

```
log_level_logfile: warning
```

### **log\_datefmt**

Default: %H:%M:%S

The date and time format used in console log messages. See also *log\_datefmt*.

```
log_datefmt: '%H:%M:%S'
```

### **log\_datefmt\_logfile**

Default: %Y-%m-%d %H:%M:%S

The date and time format used in log file messages. See also *log\_datefmt\_logfile*.

```
log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'
```

### **log\_fmt\_console**

Default: [% (levelname)-8s] %(message)s

The format of the console logging messages. See also *log\_fmt\_console*.

```
log_fmt_console: '%[(levelname)-8s] %(message)s'
```

### **log\_fmt\_logfile**

Default: %(asctime)s,%(msecs)03.0f [%(name)-17s] [(levelname)-8s] %(message)s

The format of the log file logging messages. See also *log\_fmt\_logfile*.

```
log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s] [(levelname)-8s] %(message)s'
```

### **log\_granular\_levels**

Default: {}

This can be used to control logging levels more specifically. See also *log\_granular\_levels*.

### **failhard**

Default: False

Set the global failhard flag. This informs all states to stop running states at the moment a single state fails

```
failhard: False
```

### 30.9.8 Include Configuration

#### default\_include

Default: `minion.d/*.conf`

The minion can include configuration from other files. Per default the minion will automatically include all config files from `minion.d/*.conf` where `minion.d` is relative to the directory of the minion configuration file.

#### include

Default: not defined

The minion can include configuration from other files. To enable this, pass a list of paths to this option. The paths can be either relative or absolute; if relative, they are considered to be relative to the directory the main minion configuration file lives in. Paths can make use of shell-style globbing. If no files are matched by a path passed to this option then the minion will log a warning message.

```
# Include files from a minion.d directory in the same
# directory as the minion config file
include: minion.d/*.conf

# Include a single extra file into the configuration
include: /etc/roles/webserver

# Include several files and the minion.d directory
include:
- extra_config
- minion.d/*
- /etc/roles/webserver
```

### 30.9.9 Frozen Build Update Settings

These options control how `salt.modules.saltutil.update()` works with esky frozen apps. For more information look at <https://github.com/cloudmatrix/esky/>.

#### update\_url

Default: `False` (Update feature is disabled)

The url to use when looking for application updates. Esky depends on directory listings to search for new versions. A webserver running on your Master is a good starting point for most setups.

```
update_url: 'http://salt.example.com/minion-updates'
```

#### update\_restart\_services

Default: `[]` (service restarting on update is disabled)

A list of services to restart when the minion software is updated. This would typically just be a list containing the minion's service name, but you may have other services that need to go with it.

```
update_restart_services: ['salt-minion']
```

## 30.10 Running the Salt Master/Minion as an Unprivileged User

While the default setup runs the master and minion as the root user, some may consider it an extra measure of security to run the master as a non-root user. Keep in mind that doing so does not change the master's capability to access minions as the user they are running as. Due to this many feel that running the master as a non-root user does not grant any real security advantage which is why the master has remained as root by default.

---

**Note:** Some of Salt's operations cannot execute correctly when the master is not running as root, specifically the pam external auth system, as this system needs root access to check authentication.

---

As of Salt 0.9.10 it is possible to run Salt as a non-root user. This can be done by setting the `user` parameter in the master configuration file. and restarting the `salt-master` service.

The minion has it's own `user` parameter as well, but running the minion as an unprivileged user will keep it from making changes to things like users, installed packages, etc. unless access controls (sudo, etc.) are setup on the minion to permit the non-root user to make the needed changes.

In order to allow Salt to successfully run as a non-root user, ownership, and permissions need to be set such that the desired user can read from and write to the following directories (and their subdirectories, where applicable):

- `/etc/salt`
- `/var/cache/salt`
- `/var/log/salt`
- `/var/run/salt`

Ownership can be easily changed with `chown`, like so:

```
# chown -R user /etc/salt /var/cache/salt /var/log/salt /var/run/salt
```

**Warning:** Running either the master or minion with the `root_dir` parameter specified will affect these paths, as will setting options like `pki_dir`, `cachedir`, `log_file`, and other options that normally live in the above directories.

## 30.11 Logging

The salt project tries to get the logging to work for you and help us solve any issues you might find along the way.

If you want to get some more information on the nitty-gritty of salt's logging system, please head over to the [logging development document](#), if all you're after is salt's logging configurations, please continue reading.

### 30.11.1 Available Configuration Settings

#### `log_file`

The log records can be sent to a regular file, local path name, or network location. Remote logging works best when configured to use `rsyslogd(8)` (e.g.: `file:///dev/log`), with `rsyslogd(8)` configured for network logging. The format for remote addresses is: `<file|udp|tcp>://<host|socketpath>:<port-if-required>/<log-facility>`.

Default: Dependent of the binary being executed, for example, for `salt-master`, `/var/log/salt/master`.

Examples:

```
log_file: /var/log/salt/master
```

```
log_file: /var/log/salt/minion
```

```
log_file: file:///dev/log
```

```
log_file: udp://loghost:10514
```

### log\_level

Default: warning

The level of log record messages to send to the console. One of all, garbage, trace, debug, info, warning, error, critical, quiet.

```
log_level: warning
```

### log\_level\_logfile

Default: warning

The level of messages to send to the log file. One of all, garbage, trace, debug, info, warning, error, critical, quiet.

```
log_level_logfile: warning
```

### log\_datefmt

Default: %H:%M:%S

The date and time format used in console log messages. Allowed date/time formatting can be seen on `time.strftime`.

```
log_datefmt: '%H:%M:%S'
```

### log\_datefmt\_logfile

Default: %Y-%m-%d %H:%M:%S

The date and time format used in log file messages. Allowed date/time formatting can be seen on `time.strftime`.

```
log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'
```

### log\_fmt\_console

Default: [% (levelname)-8s] %(message)s

The format of the console logging messages. Allowed formatting options can be seen on the `LogRecord` attributes.

```
log_fmt_console: '%[(levelname)-8s] %(message)s'
```

### log\_fmt\_logfile

Default: `%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s`

The format of the log file logging messages. Allowed formatting options can be seen on the [LogRecord](#) attributes.

```
log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'
```

### log\_granular\_levels

Default: `{}`

This can be used to control logging levels more specifically. The example sets the main salt library at the `warning` level, but sets `salt.modules` to log at the `debug` level:

```
log_granular_levels:
  'salt': 'warning'
  'salt.modules': 'debug'
```

### External Logging Handlers

Besides the internal logging handlers used by salt, there are some external which can be used, see the [external logging handlers](#) document.

## 30.12 External Logging Handlers

<i>logstash_mod</i>	Logstash Logging Handler
<i>sentry_mod</i>	Sentry Logging Handler

### 30.12.1 Logstash Logging Handler

New in version 0.17.0.

This module provides some [Logstash](#) logging handlers.

#### UDP Logging Handler

For versions of [Logstash](#) before 1.2.0:

In the salt configuration file:

```
logstash_udp_handler:
  host: 127.0.0.1
  port: 9999
  version: 0
```

In the [Logstash](#) configuration file:

```
input {
  udp {
    type => "udp-type"
    format => "json_event"
```

```
}
}
```

For version 1.2.0 of [Logstash](#) and newer:

In the salt configuration file:

```
logstash_udp_handler:
  host: 127.0.0.1
  port: 9999
  version: 1
```

In the [Logstash](#) configuration file:

```
input {
  udp {
    port => 9999
    codec => json
  }
}
```

Please read the [UDP input](#) configuration page for additional information.

### ZeroMQ Logging Handler

For versions of [Logstash](#) before 1.2.0:

In the salt configuration file:

```
logstash_zmq_handler:
  address: tcp://127.0.0.1:2021
  version: 0
```

In the [Logstash](#) configuration file:

```
input {
  zeromq {
    type => "zeromq-type"
    mode => "server"
    topology => "pubsub"
    address => "tcp://0.0.0.0:2021"
    charset => "UTF-8"
    format => "json_event"
  }
}
```

For version 1.2.0 of [Logstash](#) and newer:

In the salt configuration file:

```
logstash_zmq_handler:
  address: tcp://127.0.0.1:2021
  version: 1
```

In the [Logstash](#) configuration file:

```
input {
  zeromq {
    topology => "pubsub"
    address => "tcp://0.0.0.0:2021"
```

```
    codec => json
  }
}
```

Please read the [ZeroMQ input](#) configuration page for additional information.

---

### Important Logstash Setting

One of the most important settings that you should not forget on your [Logstash](#) configuration file regarding these logging handlers is `format`. Both the *UDP* and *ZeroMQ* inputs need to have `format` as `json_event` which is what we send over the wire.

---

### Log Level

Both the `logstash_udp_handler` and the `logstash_zmq_handler` configuration sections accept an additional setting `log_level`. If not set, the logging level used will be the one defined for `log_level` in the global configuration file section.

### HWM

The [high water mark](#) for the ZMQ socket setting. Only applicable for the `logstash_zmq_handler`.

---

### Inspiration

This work was inspired in [pylogstash](#), [python-logstash](#), [canary](#) and the [PyZMQ logging handler](#).

---

## 30.12.2 Sentry Logging Handler

New in version 0.17.0.

This module provides a [Sentry](#) logging handler.

---

### Note

The [Raven](#) library needs to be installed on the system for this logging handler to be available.

---

Configuring the python [Sentry](#) client, [Raven](#), should be done under the `sentry_handler` configuration key. At the bare minimum, you need to define the `DSN`. As an example:

```
sentry_handler:
  dsn: https://pub-key:secret-key@app.getsentry.com/app-id
```

More complex configurations can be achieved, for example:

```
sentry_handler:
  servers:
    - https://sentry.example.com
    - http://192.168.1.1
  project: app-id
  public_key: deadbeefdeadbeefdeadbeefdeadbeef
  secret_key: beefdeadbeefdeadbeefdeadbeefdead
```

All the client configuration keys are supported, please see the [Raven client documentation](#).

The default logging level for the sentry handler is ERROR. If you wish to define a different one, define `log_level` under the `sentry_handler` configuration key:

```
sentry_handler:
  dsn: https://pub-key:secret-key@app.getsentry.com/app-id
  log_level: warning
```

The available log levels are those also available for the salt `cli` tools and configuration; `salt --help` should give you the required information.

## Threaded Transports

Raven's documents rightly suggest using its threaded transport for critical applications. However, don't forget that if you start having troubles with Salt after enabling the threaded transport, please try switching to a non-threaded transport to see if that fixes your problem.

## 30.13 Salt File Server

Salt comes with a simple file server suitable for distributing files to the Salt minions. The file server is a stateless ZeroMQ server that is built into the Salt master.

The main intent of the Salt file server is to present files for use in the Salt state system. With this said, the Salt file server can be used for any general file transfer from the master to the minions.

### 30.13.1 File Server Backends

In Salt 0.12.0, the modular fileserver was introduced. This feature added the ability for the Salt Master to integrate different file server backends. File server backends allow the Salt file server to act as a transparent bridge to external resources. A good example of this is the `git` backend, which allows Salt to serve files sourced from one or more git repositories, but there are several others as well. Click [here](#) for a full list of Salt's fileserver backends.

#### Enabling a Fileserver Backend

Fileserver backends can be enabled with the `fileserver_backend` option.

```
fileserver_backend:
  - git
```

See the [documentation](#) for each backend to find the correct value to add to `fileserver_backend` in order to enable them.

#### Using Multiple Backends

If `fileserver_backend` is not defined in the Master config file, Salt will use the `roots` backend, but the `fileserver_backend` option supports multiple backends. When more than one backend is in use, the files from the enabled backends are merged into a single virtual filesystem. When a file is requested, the backends will be searched in order for that file, and the first backend to match will be the one which returns the file.

```
fileserver_backend:  
- roots  
- git
```

With this configuration, the environments and files defined in the `file_roots` parameter will be searched first, and if the file is not found then the git repositories defined in `gitfs_remotes` will be searched.

## Environments

Just as the order of the values in `fileserver_backend` matters, so too does the order in which different sources are defined within a fileserver environment. For example, given the below `file_roots` configuration, if both `/srv/salt/dev/foo.txt` and `/srv/salt/prod/foo.txt` exist on the Master, then `salt://foo.txt` would point to `/srv/salt/dev/foo.txt` in the dev environment, but it would point to `/srv/salt/prod/foo.txt` in the base environment.

```
file_roots:  
  base:  
    - /srv/salt/prod  
  qa:  
    - /srv/salt/qa  
    - /srv/salt/prod  
  dev:  
    - /srv/salt/dev  
    - /srv/salt/qa  
    - /srv/salt/prod
```

Similarly, when using the `git` backend, if both repositories defined below have a `hotfix23` branch/tag, and both of them also contain the file `bar.txt` in the root of the repository at that branch/tag, then `salt://bar.txt` in the `hotfix23` environment would be served from the first repository.

```
gitfs_remotes:  
- https://mydomain.tld/repos/first.git  
- https://mydomain.tld/repos/second.git
```

**Note:** Environments map differently based on the fileserver backend. For instance, the mappings are explicitly defined in `roots` backend, while in the VCS backends (`git`, `hg`, `svn`) the environments are created from branches/tags/bookmarks/etc. For the `minion` backend, the files are all in a single environment, which is specified by the `minionfs_env` option.

See the documentation for each backend for a more detailed explanation of how environments are mapped.

---

### 30.13.2 Dynamic Module Distribution

New in version 0.9.5.

Custom Salt execution, state, and other modules can be distributed to Salt minions using the Salt file server.

Under the root of any environment defined via the `file_roots` option on the master server directories corresponding to the type of module can be used.

The directories are prepended with an underscore:

- `_beacons`
- `_modules`
- `_grains`

- `_renderers`
- `_returners`
- `_states`
- `_output`
- `_utils`

The contents of these directories need to be synced over to the minions after Python modules have been created in them. There are a number of ways to sync the modules.

### 30.13.3 Sync Via States

The minion configuration contains an option `autoload_dynamic_modules` which defaults to `True`. This option makes the state system refresh all dynamic modules when states are run. To disable this behavior set `autoload_dynamic_modules` to `False` in the minion config.

When dynamic modules are autoloaded via states, modules only pertinent to the environments matched in the master's top file are downloaded.

This is important to remember, because modules can be manually loaded from any specific environment that environment specific modules will be loaded when a state run is executed.

### 30.13.4 Sync Via the saltutil Module

The saltutil module has a number of functions that can be used to sync all or specific dynamic modules. The saltutil module function `saltutil.sync_all` will sync all module types over to a minion. For more information see: `salt.modules.saltutil`

### 30.13.5 File Server Configuration

The Salt file server is a high performance file server written in ZeroMQ. It manages large files quickly and with little overhead, and has been optimized to handle small files in an extremely efficient manner.

The Salt file server is an environment aware file server. This means that files can be allocated within many root directories and accessed by specifying both the file path and the environment to search. The individual environments can span across multiple directory roots to create overlays and to allow for files to be organized in many flexible ways.

#### Environments

The Salt file server defaults to the mandatory `base` environment. This environment **MUST** be defined and is used to download files when no environment is specified.

Environments allow for files and sls data to be logically separated, but environments are not isolated from each other. This allows for logical isolation of environments by the engineer using Salt, but also allows for information to be used in multiple environments.

## Directory Overlay

The `environment` setting is a list of directories to publish files from. These directories are searched in order to find the specified file and the first file found is returned.

This means that directory data is prioritized based on the order in which they are listed. In the case of this `file_roots` configuration:

```
file_roots:
  base:
    - /srv/salt/base
    - /srv/salt/failover
```

If a file's URI is `salt://httpd/httpd.conf`, it will first search for the file at `/srv/salt/base/httpd/httpd.conf`. If the file is found there it will be returned. If the file is not found there, then `/srv/salt/failover/httpd/httpd.conf` will be used for the source.

This allows for directories to be overlaid and prioritized based on the order they are defined in the configuration.

It is also possible to have `file_roots` which supports multiple environments:

```
file_roots:
  base:
    - /srv/salt/base
  dev:
    - /srv/salt/dev
    - /srv/salt/base
  prod:
    - /srv/salt/prod
    - /srv/salt/base
```

This example ensures that each environment will check the associated environment directory for files first. If a file is not found in the appropriate directory, the system will default to using the base directory.

## Local File Server

New in version 0.9.8.

The file server can be rerouted to run from the minion. This is primarily to enable running Salt states without a Salt master. To use the local file server interface, copy the file server data to the minion and set the `file_roots` option on the minion to point to the directories copied from the master. Once the minion `file_roots` option has been set, change the `file_client` option to `local` to make sure that the local file server interface is used.

### 30.13.6 The cp Module

The `cp` module is the home of minion side file server operations. The `cp` module is used by the Salt state system, `salt-cp`, and can be used to distribute files presented by the Salt file server.

## Escaping Special Characters

The `salt://` url format can potentially contain a query string, for example `salt://dir/file.txt?saltenv=base`. You can prevent the `fileclient/filesserver` from interpreting `?` as the initial token of a query string by referencing the file with `salt://|` rather than `salt://`.

```
/etc/marathon/conf/?checkpoint:
  file.managed:
    - source: salt://hw/config/?checkpoint
    - makedirs: True
```

## Environments

Since the file server is made to work with the Salt state system, it supports environments. The environments are defined in the master config file and when referencing an environment the file specified will be based on the root directory of the environment.

### get\_file

The `cp.get_file` function can be used on the minion to download a file from the master, the syntax looks like this:

```
# salt '*' cp.get_file salt://vimrc /etc/vimrc
```

This will instruct all Salt minions to download the vimrc file and copy it to `/etc/vimrc`

Template rendering can be enabled on both the source and destination file names like so:

```
# salt '*' cp.get_file "salt://{{grains.os}}/vimrc" /etc/vimrc template=jinja
```

This example would instruct all Salt minions to download the vimrc from a directory with the same name as their OS grain and copy it to `/etc/vimrc`

For larger files, the `cp.get_file` module also supports gzip compression. Because gzip is CPU-intensive, this should only be used in scenarios where the compression ratio is very high (e.g. pretty-printed JSON or YAML files).

To use compression, use the `gzip` named argument. Valid values are integers from 1 to 9, where 1 is the lightest compression and 9 the heaviest. In other words, 1 uses the least CPU on the master (and minion), while 9 uses the most.

```
# salt '*' cp.get_file salt://vimrc /etc/vimrc gzip=5
```

Finally, note that by default `cp.get_file` does *not* create new destination directories if they do not exist. To change this, use the `makedirs` argument:

```
# salt '*' cp.get_file salt://vimrc /etc/vim/vimrc makedirs=True
```

In this example, `/etc/vim/` would be created if it didn't already exist.

### get\_dir

The `cp.get_dir` function can be used on the minion to download an entire directory from the master. The syntax is very similar to `get_file`:

```
# salt '*' cp.get_dir salt://etc/apache2 /etc
```

`cp.get_dir` supports template rendering and gzip compression arguments just like `get_file`:

```
# salt '*' cp.get_dir salt://etc/{{pillar.webserver}} /etc gzip=5 template=jinja
```

### 30.13.7 File Server Client API

A client API is available which allows for modules and applications to be written which make use of the Salt file server.

The file server uses the same authentication and encryption used by the rest of the Salt system for network communication.

#### FileClient Class

The FileClient class is used to set up the communication from the minion to the master. When creating a FileClient object the minion configuration needs to be passed in. When using the FileClient from within a minion module the built in `__opts__` data can be passed:

```
import salt.minion

def get_file(path, dest, env='base'):
    """
    Used to get a single file from the Salt master

    CLI Example:
    salt '*' cp.get_file salt://vimrc /etc/vimrc
    """
    # Create the FileClient object
    client = salt.minion.FileClient(__opts__)
    # Call get_file
    return client.get_file(path, dest, False, env)
```

Using the FileClient class outside of a minion module where the `__opts__` data is not available, it needs to be generated:

```
import salt.minion
import salt.config

def get_file(path, dest, env='base'):
    """
    Used to get a single file from the Salt master
    """
    # Get the configuration data
    opts = salt.config.minion_config('/etc/salt/minion')
    # Create the FileClient object
    client = salt.minion.FileClient(opts)
    # Call get_file
    return client.get_file(path, dest, False, env)
```

## 30.14 Full list of builtin fileserver modules

<code>gitfs</code>	Git Fileserver Backend
<code>hgfs</code>	Mercurial Fileserver Backend
<code>minionfs</code>	Fileserver backend which serves files pushed to the Master
<code>roots</code>	The default file server backend
<code>s3fs</code>	Amazon S3 Fileserver Backend
<code>svnfs</code>	Subversion Fileserver Backend

### 30.14.1 salt.filesserver.gitfs

#### Git FilesServer Backend

With this backend, branches and tags in a remote git repository are exposed to salt as different environments.

To enable, add `git` to the `filesserver_backend` option in the Master config file.

```
filesserver_backend:
- git
```

As of Salt 2014.7.0, the Git filesserver backend supports `GitPython`, `pygit2`, and `dulwich` to provide the Python interface to git. If more than one of these are present, the order of preference for which one will be chosen is the same as the order in which they were listed: `pygit2`, `GitPython`, `dulwich` (keep in mind, this order is subject to change).

An optional master config parameter (`gitfs_provider`) can be used to specify which provider should be used.

More detailed information on how to use gitfs can be found in the [Gitfs Walkthrough](#).

---

#### Note: Minimum requirements

To use `GitPython` for gitfs requires a minimum `GitPython` version of 0.3.0, as well as the git CLI utility. Instructions for installing `GitPython` can be found [here](#).

To use `pygit2` for gitfs requires a minimum `pygit2` version of 0.20.3. `pygit2` 0.20.3 requires `libgit2` 0.20.0. `pygit2` and `libgit2` are developed alongside one another, so it is recommended to keep them both at the same major release to avoid unexpected behavior. For example, `pygit2` 0.21.x requires `libgit2` 0.21.x, `pygit2` 0.22.x will require `libgit2` 0.22.x, etc.

To find stale refs, `pygit2` additionally requires the git CLI utility to be installed.

---

`salt.filesserver.gitfs.clear_cache()`

Completely clear gitfs cache

`salt.filesserver.gitfs.clear_lock(remote=None)`

Clear update.lk

`remote` can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

`salt.filesserver.gitfs.dir_list(load)`

Return a list of all directories on the master

`salt.filesserver.gitfs.envs(ignore_cache=False, skip_clean=False)`

Return a list of refs that can be used as environments

`salt.filesserver.gitfs.file_hash(load, fnd)`

Return a file hash, the hash type is set in the master config file

`salt.filesserver.gitfs.file_list(load)`

Return a list of all files on the file server in a specified environment

`salt.filesserver.gitfs.file_list_emptydirs(load)`

Return a list of all empty directories on the master

`salt.filesserver.gitfs.find_file(path, tgt_env='base', **kwargs)`

Find the first file to match the path and ref, read the file out of git and send the path to the newly cached file

`salt.filesserver.gitfs.init()`

Return the git repo object for this session

`salt.fileserver.gitfs.lock(remote=None)`

Place an update.lk

`remote` can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

`salt.fileserver.gitfs.serve_file(load, fnd)`

Return a chunk from a file based on the data received

`salt.fileserver.gitfs.symlink_list(load)`

Return a dict of all symlinks based on a given path in the repo

`salt.fileserver.gitfs.update()`

Execute a git fetch on all of the repos

### 30.14.2 salt.fileserver.hgfs

Mercurial Fileserver Backend

To enable, add `hg` to the `fileserver_backend` option in the Master config file.

```
fileserver_backend:  
- hg
```

After enabling this backend, branches, bookmarks, and tags in a remote mercurial repository are exposed to salt as different environments. This feature is managed by the `fileserver_backend` option in the salt master config file.

This fileserver has an additional option `hgfs_branch_method` that will set the desired branch method. Possible values are: `branches`, `bookmarks`, or `mixed`. If using `branches` or `mixed`, the default branch will be mapped to `base`.

Changed in version 2014.1.0: The `hgfs_base` master config parameter was added, allowing for a branch other than `default` to be used for the `base` environment, and allowing for a `base` environment to be specified when using an `hgfs_branch_method` of `bookmarks`.

#### depends

- mercurial
- python bindings for mercurial (python-hglib)

`salt.fileserver.hgfs.clear_cache()`

Completely clear hgfs cache

`salt.fileserver.hgfs.clear_lock(remote=None)`

Clear update.lk

`remote` can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

`salt.fileserver.hgfs.dir_list(load)`

Return a list of all directories on the master

`salt.fileserver.hgfs.envs(ignore_cache=False)`

Return a list of refs that can be used as environments

`salt.fileserver.hgfs.file_hash(load, fnd)`

Return a file hash, the hash type is set in the master config file

`salt.fileserver.hgfs.file_list(load)`

Return a list of all files on the file server in a specified environment

`salt.fileserver.hgfs.file_list_emptydirs(load)`

Return a list of all empty directories on the master

`salt.fileserver.hgfs.find_file(path, tgt_env='base', **kwargs)`

Find the first file to match the path and ref, read the file out of hg and send the path to the newly cached file

`salt.fileserver.hgfs.init()`

Return a list of hglib objects for the various hgfs remotes

`salt.fileserver.hgfs.lock(remote=None)`

Place an update.lk

`remote` can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

`salt.fileserver.hgfs.serve_file(load, fnd)`

Return a chunk from a file based on the data received

`salt.fileserver.hgfs.update()`

Execute an hg pull on all of the repos

### 30.14.3 salt.fileserver.minionfs

Fileserver backend which serves files pushed to the Master

The `cp.push` function allows Minions to push files up to the Master. Using this backend, these pushed files are exposed to other Minions via the Salt fileserver.

To enable minionfs, `file_recv` needs to be set to `True` in the master config file (otherwise `cp.push` will not be allowed to push files to the Master), and `minion` must be added to the `fileserver_backends` list.

```
fileserver_backend:
- minion
```

Other minionfs settings include: `minionfs_whitelist`, `minionfs_blacklist`, `minionfs_mountpoint`, and `minionfs_env`.

See also:

[MinionFS Backend Walkthrough](#)

`salt.fileserver.minionfs.dir_list(load)`

Return a list of all directories on the master

CLI Example:

```
$ salt 'source-minion' cp.push /absolute/path/file # Push the file to the master
$ salt 'destination-minion' cp.list_master_dirs
destination-minion:
- source-minion/absolute
- source-minion/absolute/path
```

`salt.fileserver.minionfs.envs()`

Returns the one environment specified for minionfs in the master configuration.

`salt.fileserver.minionfs.file_hash(load, fnd)`

Return a file hash, the hash type is set in the master config file

`salt.fileserver.minionfs.file_list(load)`

Return a list of all files on the file server in a specified environment

`salt.filesserver.minionfs.find_file(path, tgt_env='base', **kwargs)`  
Search the environment for the relative path

`salt.filesserver.minionfs.serve_file(load, fnd)`  
Return a chunk from a file based on the data received

CLI Example:

```
# Push the file to the master
$ salt 'source-minion' cp.push /path/to/the/file
$ salt 'destination-minion' cp.get_file salt://source-minion/path/to/the/file /destination/file
```

`salt.filesserver.minionfs.update()`  
When we are asked to update (regular interval) lets reap the cache

### 30.14.4 salt.filesserver.roots

The default file server backend

This fileserver backend serves files from the Master's local filesystem. If `fileserver_backend` is not defined in the Master config file, then this backend is enabled by default. If it is defined then `roots` must be in the `fileserver_backend` list to enable this backend.

```
fileserver_backend:
- roots
```

Fileserver environments are defined using the `file_roots` configuration option.

`salt.filesserver.roots.dir_list(load)`  
Return a list of all directories on the master

`salt.filesserver.roots.envs()`  
Return the file server environments

`salt.filesserver.roots.file_hash(load, fnd)`  
Return a file hash, the hash type is set in the master config file

`salt.filesserver.roots.file_list(load)`  
Return a list of all files on the file server in a specified environment

`salt.filesserver.roots.file_list_emptydirs(load)`  
Return a list of all empty directories on the master

`salt.filesserver.roots.find_file(path, saltenv='base', env=None, **kwargs)`  
Search the environment for the relative path

`salt.filesserver.roots.serve_file(load, fnd)`  
Return a chunk from a file based on the data received

`salt.filesserver.roots.symlink_list(load)`  
Return a dict of all symlinks based on a given path on the Master

`salt.filesserver.roots.update()`  
When we are asked to update (regular interval) lets reap the cache

### 30.14.5 salt.filesserver.s3fs

Amazon S3 Fileserver Backend

This backend exposes directories in S3 buckets as Salt environments. To enable this backend, add `s3fs` to the `fileserver_backend` option in the Master config file.

```
fileserver_backend:
  - s3fs
```

S3 credentials must also be set in the master config file:

```
s3.keyid: GKTADJGHEIQSXMKKRBJ08H
s3.key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
```

Alternatively, if on EC2 these credentials can be automatically loaded from instance metadata.

This fileserver supports two modes of operation for the buckets:

### 1. A single bucket per environment

```
s3.buckets:
  production:
    - bucket1
    - bucket2
  staging:
    - bucket3
    - bucket4
```

### 2. Multiple environments per bucket

```
s3.buckets:
  - bucket1
  - bucket2
  - bucket3
  - bucket4
```

Note that bucket names must be all lowercase both in the AWS console and in Salt, otherwise you may encounter `SignatureDoesNotMatch` errors.

A multiple-environment bucket must adhere to the following root directory structure:

```
s3://<bucket name>/<environment>/<files>
```

**Note:** This fileserver back-end requires the use of the MD5 hashing algorithm. MD5 may not be compliant with all security policies.

`salt.fileserver.s3fs.dir_list(load)`

Return a list of all directories on the master

`salt.fileserver.s3fs.envs()`

Return a list of directories within the bucket that can be used as environments.

`salt.fileserver.s3fs.file_hash(load, fnd)`

Return an MD5 file hash

`salt.fileserver.s3fs.file_list(load)`

Return a list of all files on the file server in a specified environment

`salt.fileserver.s3fs.file_list_emptydirs(load)`

Return a list of all empty directories on the master

`salt.fileserver.s3fs.find_file(path, saltenv='base', env=None, **kwargs)`

Look through the buckets cache file for a match. If the field is found, it is retrieved from S3 only if its cached version is missing, or if the MD5 does not match.

`salt.fileserver.s3fs.serve_file(load, fnd)`  
Return a chunk from a file based on the data received

`salt.fileserver.s3fs.update()`  
Update the cache file for the bucket.

### 30.14.6 salt.fileserver.svnfs

#### Subversion Fileserver Backend

After enabling this backend, branches, and tags in a remote subversion repository are exposed to salt as different environments. To enable this backend, add `svn` to the `fileserver_backend` option in the Master config file.

```
fileserver_backend:  
- svn
```

This backend assumes a standard `svn` layout with directories for branches, tags, and trunk, at the repository root.

#### depends

- subversion
- pysvn

Changed in version 2014.7.0: The paths to the trunk, branches, and tags have been made configurable, via the config options `svnfs_trunk`, `svnfs_branches`, and `svnfs_tags`. `svnfs_mountpoint` was also added. Finally, support for per-remote configuration parameters was added. See the *documentation* for more information.

`salt.fileserver.svnfs.clear_cache()`  
Completely clear `svnfs` cache

`salt.fileserver.svnfs.clear_lock(remote=None)`  
Clear `update.lk`

`remote` can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

`salt.fileserver.svnfs.dir_list(load)`  
Return a list of all directories on the master

`salt.fileserver.svnfs.envs(ignore_cache=False)`  
Return a list of refs that can be used as environments

`salt.fileserver.svnfs.file_hash(load, fnd)`  
Return a file hash, the hash type is set in the master config file

`salt.fileserver.svnfs.file_list(load)`  
Return a list of all files on the file server in a specified environment

`salt.fileserver.svnfs.file_list_emptydirs(load)`  
Return a list of all empty directories on the master

`salt.fileserver.svnfs.find_file(path, tgt_env='base', **kwargs)`  
Find the first file to match the path and ref. This operates similarly to the roots file sever but with assumptions of the directory structure based on `svn` standard practices.

`salt.fileserver.svnfs.init()`  
Return the list of `svn` remotes and their configuration information

`salt.fileserver.svnfs.lock(remote=None)`  
Place an `update.lk`

`remote` can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

```
salt.fileserver.svnfs.serve_file(load, fnd)
```

Return a chunk from a file based on the data received

```
salt.fileserver.svnfs.update()
```

Execute an svn update on all of the repos

## 30.15 Salt code and internals

Reference documentation on Salt's internal code.

### 30.15.1 Contents

**salt.serializers**

**salt.utils.aggregation**

This library makes it possible to introspect dataset and aggregate nodes when it is instructed.

---

**Note:** The following examples will be expressed in YAML for convenience's sake:

- `!aggr-scalar` will refer to Scalar python function
  - `!aggr-map` will refer to Map python object
  - `!aggr-seq` will refer for Sequence python object
- 

**How to instructs merging** This yaml document has duplicate keys:

```
foo: !aggr-scalar first
foo: !aggr-scalar second
bar: !aggr-map {first: foo}
bar: !aggr-map {second: bar}
baz: !aggr-scalar 42
```

but tagged values instruct Salt that overlapping values they can be merged together:

```
foo: !aggr-seq [first, second]
bar: !aggr-map {first: foo, second: bar}
baz: !aggr-seq [42]
```

**Default merge strategy is keep untouched** For example, this yaml document still has duplicate keys, but does not instruct aggregation:

```
foo: first
foo: second
bar: {first: foo}
bar: {second: bar}
baz: 42
```

So the late found values prevail:

```
foo: second
bar: {second: bar}
baz: 42
```

**Limitations** Aggregation is permitted between tagged objects that share the same type. If not, the default merge strategy prevails.

For example, these examples:

```
foo: {first: value}
foo: !aggr-map {second: value}

bar: !aggr-map {first: value}
bar: 42

baz: !aggr-seq [42]
baz: [fail]

qux: 42
qux: !aggr-scalar fail
```

are interpreted like this:

```
foo: !aggr-map{second: value}

bar: 42

baz: [fail]

qux: !aggr-seq [fail]
```

**Introspection** TODO: write this part

```
salt.utils.aggregation.aggregate(obj_a, obj_b, level=False, map_class=<class
                                `salt.utils.aggregation.Map`>, sequence_class=<class
                                `salt.utils.aggregation.Sequence`>)
```

Merge obj\_b into obj\_a.

```
>>> aggregate('first', 'second', True) == ['first', 'second']
True
```

```
class salt.utils.aggregation.Aggregate
```

Aggregation base.

```
class salt.utils.aggregation.Map(*args, **kws)
```

Map aggregation.

```
salt.utils.aggregation.Scalar(obj)
```

Shortcut for Sequence creation

```
>>> Scalar('foo') == Sequence(['foo'])
True
```

```
class salt.utils.aggregation.Sequence
```

Sequence aggregation.

## Exceptions

Salt-specific exceptions should be thrown as often as possible so the various interfaces to Salt (CLI, API, etc) can handle those errors appropriately and display error messages appropriately.

---

*salt.exceptions* This module is a central location for all salt exceptions

---

### salt.exceptions

This module is a central location for all salt exceptions

**exception salt.exceptions.AuthenticationError** (*message*='')

If sha256 signature fails during decryption

**exception salt.exceptions.AuthorizationError** (*message*='')

Thrown when runner or wheel execution fails due to permissions

**exception salt.exceptions.CommandExecutionError** (*message*='')

Used when a module runs a command which returns an error and wants to show the user the output gracefully instead of dying

**exception salt.exceptions.CommandNotFoundError** (*message*='')

Used in modules or grains when a required binary is not available

**exception salt.exceptions.EauthAuthenticationError** (*message*='')

Thrown when eauth authentication fails

**exception salt.exceptions.FileserverConfigError** (*message*='')

Used when invalid fileserver settings are detected

**exception salt.exceptions.LoaderError** (*message*='')

Problems loading the right renderer

**exception salt.exceptions.MasterExit**

Rise when the master exits

**exception salt.exceptions.MinionError** (*message*='')

Minion problems reading uris such as salt:// or http://

**exception salt.exceptions.PkgParseError** (*message*='')

Used when of the pkg modules cannot correctly parse the output from the CLI tool (pacman, yum, apt, aptitude, etc)

**exception salt.exceptions.PublishError** (*message*='')

Problems encountered when trying to publish a command

**exception salt.exceptions.SaltCacheError** (*message*='')

Thrown when a problem was encountered trying to read or write from the salt cache

**exception salt.exceptions.SaltClientError** (*message*='')

Problem reading the master root key

**exception salt.exceptions.SaltClientTimeout** (*msg*, *jid=None*, *\*args*, *\*\*kwargs*)

Thrown when a job sent through one of the Client interfaces times out

Takes the *jid* as a parameter

**exception salt.exceptions.SaltCloudConfigError** (*message*='')

Raised when a configuration setting is not found and should exist.

- exception** `salt.exceptions.SaltCloudException` (*message*='')  
Generic Salt Cloud Exception
- exception** `salt.exceptions.SaltCloudExecutionFailure` (*message*='')  
Raised when too much failures have occurred while querying/waiting for data.
- exception** `salt.exceptions.SaltCloudExecutionTimeout` (*message*='')  
Raised when too much time has passed while querying/waiting for data.
- exception** `salt.exceptions.SaltCloudNotFound` (*message*='')  
Raised when some cloud provider function cannot find what's being searched.
- exception** `salt.exceptions.SaltCloudPasswordError` (*message*='')  
Raise when virtual terminal password input failed
- exception** `salt.exceptions.SaltCloudSystemExit` (*message*, *exit\_code*=1)  
This exception is raised when the execution should be stopped.
- exception** `salt.exceptions.SaltDaemonNotRunning` (*message*='')  
Throw when a running master/minion/syndic is not running but is needed to perform the requested operation (e.g., eauth).
- exception** `salt.exceptions.SaltException` (*message*='')  
Base exception class; all Salt-specific exceptions should subclass this
- pack**()  
Pack this exception into a serializable dictionary that is safe for transport via msgpack
- exception** `salt.exceptions.SaltInvocationError` (*message*='')  
Used when the wrong number of arguments are sent to modules or invalid arguments are specified on the command line
- exception** `salt.exceptions.SaltMasterError` (*message*='')  
Problem reading the master root key
- exception** `salt.exceptions.SaltRenderError` (*message*, *line\_num*=None, *buf*='', *marker*='<-----', *trace*=None)  
Used when a renderer needs to raise an explicit error. If a line number and buffer string are passed, `get_context` will be invoked to get the location of the error.
- exception** `salt.exceptions.SaltReqTimeoutError` (*message*='')  
Thrown when a salt master request call fails to return within the timeout
- exception** `salt.exceptions.SaltRunnerError` (*message*='')  
Problem in runner
- exception** `salt.exceptions.SaltSyndicMasterError` (*message*='')  
Problem while proxying a request in the syndication master
- exception** `salt.exceptions.SaltSystemExit` (*code*=0, *msg*=None)  
This exception is raised when an unsolvable problem is found. There's nothing else to do, salt should just exit.
- exception** `salt.exceptions.SaltWheelError` (*message*='')  
Problem in wheel
- exception** `salt.exceptions.TimedProcTimeoutError` (*message*='')  
Thrown when a timed subprocess does not terminate within the timeout, or if the specified timeout is not an int or a float
- exception** `salt.exceptions.TokenAuthenticationError` (*message*='')  
Thrown when token authentication fails

## salt.serializers

### salt.utils.serializers

This module implements all the serializers needed by salt. Each serializer offers the same functions and attributes:

- deserialize** function for deserializing string or stream
- serialize** function for serializing a Python object
- available** flag that tells if the serializer is available (all dependencies are met etc.)

### salt.utils.serializers.json

Implements JSON serializer.

It's just a wrapper around json (or simplejson if available).

`salt.utils.serializers.json.deserialize`(*stream\_or\_string*, *\*\*options*)  
Deserialize any string of stream like object into a Python data structure.

#### Parameters

- **stream\_or\_string** -- stream or string to deserialize.
- **options** -- options given to lower json/simplejson module.

`salt.utils.serializers.json.serialize`(*obj*, *\*\*options*)  
Serialize Python data to JSON.

#### Parameters

- **obj** -- the data structure to serialize
- **options** -- options given to lower json/simplejson module.

### salt.utils.serializers.yaml

Implements YAML serializer.

Underneath, it is based on pyyaml and use the safe dumper and loader. It also use C bindings if they are available.

`salt.utils.serializers.yaml.deserialize`(*stream\_or\_string*, *\*\*options*)  
Deserialize any string of stream like object into a Python data structure.

#### Parameters

- **stream\_or\_string** -- stream or string to deserialize.
- **options** -- options given to lower yaml module.

`salt.utils.serializers.yaml.serialize`(*obj*, *\*\*options*)  
Serialize Python data to YAML.

#### Parameters

- **obj** -- the data structure to serialize
- **options** -- options given to lower yaml module.

`salt.utils.serializers.msgpack`

Implements MsgPack serializer.

`salt.utils.serializers.msgpack.deserialize(stream_or_string, **options)`  
 Deserialize any string of stream like object into a Python data structure.

## Parameters

- **stream\_or\_string** -- stream or string to deserialize.
- **options** -- options given to lower msgpack module.

`salt.utils.serializers.msgpack.serialize(obj, **options)`  
 Serialize Python data to MsgPack.

## Parameters

- **obj** -- the data structure to serialize
- **options** -- options given to lower msgpack module.

## 30.16 Full list of builtin execution modules

### Virtual modules

#### 30.16.1 salt.modules.pkg

`pkg` is a virtual module that is fulfilled by one of the following modules:

Execution Module	Used for
<code>aptpkg</code>	Debian/Ubuntu-based distros which use <code>apt-get(8)</code> for package management
<code>brew</code>	Mac OS software management using <a href="#">Homebrew</a>
<code>ebuild</code>	Gentoo-based systems (utilizes the <code>portage</code> python module as well as <code>emerge(1)</code> )
<code>freebsdpkg</code>	FreeBSD-based OSes using <code>pkg_add(1)</code>
<code>openbsdpkg</code>	OpenBSD-based OSes using <code>pkg_add(1)</code>
<code>pacman</code>	Arch Linux-based distros using <code>pacman(8)</code>
<code>pkgin</code>	NetBSD-based OSes using <code>pkgin(1)</code>
<code>pkgng</code>	FreeBSD-based OSes using <code>pkg(8)</code>
<code>pkgutil</code>	Solaris-based OSes using <a href="#">OpenCSW's pkgutil(1)</a>
<code>solarispkg</code>	Solaris-based OSes using <code>pkgadd(1M)</code>
<code>solarisips</code>	Solaris-based OSes using <code>IPS pkg(1)</code>
<code>win_pkg</code>	Salt's Windows Package Manager <windows-package-manager
<code>yumpkg</code>	RedHat-based distros and derivatives using <code>yum(8)</code> or <code>dnf(8)</code>
<code>zypper</code>	SUSE-based distros using <code>zypper(8)</code>

<code>aliases</code>	Manage the information in the aliases file
<code>alternatives</code>	Support for Alternatives system
<code>apache</code>	Support for Apache
<code>aptpkg</code>	Support for APT (Advanced Packaging Tool)
<code>archive</code>	A module to wrap (non-Windows) archive calls
<code>artifactory</code>	Module for fetching artifacts from Artifactory
<code>at</code>	Wrapper module for <code>at(1)</code>

Table 30.6 -- continued from previous page

<i>augeas_cfg</i>	Manages configuration files via augeas
<i>aws_sqs</i>	Support for the Amazon Simple Queue Service.
<i>blockdev</i>	Module for managing block devices
<i>bluez</i>	Support for Bluetooth (using BlueZ in Linux).
<i>boto_asg</i>	Connection module for Amazon Autoscale Groups
<i>boto_cfn</i>	Connection module for Amazon Cloud Formation
<i>boto_cloudwatch</i>	Connection module for Amazon CloudWatch
<i>boto_dynamodb</i>	Connection module for Amazon DynamoDB
<i>boto_elasticache</i>	Connection module for Amazon Elasticache
<i>boto_elb</i>	Connection module for Amazon ELB
<i>boto_iam</i>	Connection module for Amazon IAM
<i>boto_route53</i>	Connection module for Amazon Route53
<i>boto_secgroup</i>	Connection module for Amazon Security Groups
<i>boto_sns</i>	Connection module for Amazon SNS
<i>boto_sqs</i>	Connection module for Amazon SQS
<i>boto_vpc</i>	Connection module for Amazon VPC
<i>brew</i>	Homebrew for Mac OS X
<i>bridge</i>	Module for gathering and managing bridging information
<i>bsd_shadow</i>	Manage the password database on BSD systems
<i>btrfs</i>	Module for managing BTRFS file systems.
<i>cassandra</i>	Cassandra NoSQL Database Module
<i>cassandra_cql</i>	Cassandra Database Module
<i>chef</i>	Execute chef in server or solo mode
<i>chocolatey</i>	A dead simple module wrapping calls to the Chocolatey package manager
<i>cloud</i>	Salt-specific interface for calling Salt Cloud directly
<i>cmdmod</i>	A module for shelling out.
<i>composer</i>	Use composer to install PHP dependencies for a directory
<i>config</i>	Return config information
<i>container_resource</i>	Common resources for LXC and systemd-nspawn containers
<i>cp</i>	Minion side functions for salt-cp
<i>cpan</i>	Manage Perl modules using CPAN
<i>cron</i>	Work with cron
<i>cyg</i>	Manage cygwin packages.
<i>cytest</i>	
<i>daemontools</i>	daemontools service module. This module will create daemontools type
<i>darwin_sysctl</i>	Module for viewing and modifying sysctl parameters
<i>data</i>	Manage a local persistent data structure that can hold any arbitrary data
<i>ddns</i>	Support for RFC 2136 dynamic DNS updates.
<i>deb_apache</i>	Support for Apache
<i>debconfmod</i>	Support for Debconf
<i>debian_ip</i>	The networking module for Debian based distros
<i>debian_service</i>	Service support for Debian systems (uses update-rc.d and /sbin/service)
<i>defaults</i>	
<i>devmap</i>	Device-Mapper module
<i>dig</i>	Compendium of generic DNS utilities.
<i>disk</i>	Module for gathering disk information
<i>djangomod</i>	Manage Django sites
<i>dnsmasq</i>	Module for managing dnsmasq
<i>dnsutil</i>	Compendium of generic DNS utilities
<i>dockerio</i>	Management of Docker Containers

<i>dpkg</i>	Support for DEB packages
<i>drac</i>	Manage Dell DRAC
<i>drbd</i>	DRBD administration module
<i>ebuild</i>	Support for Portage
<i>eix</i>	Support for Eix
<i>elasticsearch</i>	Connection module for Elasticsearch
<i>environ</i>	Support for getting and setting the environment variables of the current salt process.
<i>eselect</i>	Support for eselect, Gentoo's configuration and management tool.
<i>etcd_mod</i>	Execution module to work with etcd
<i>event</i>	Use the <a href="#">Salt Event System</a> to fire events from the master to the minion and vice-versa.
<i>extfs</i>	Module for managing ext2/3/4 file systems
<i>file</i>	Manage information about regular files, directories,
<i>firewalld</i>	Support for firewalld
<i>freebsd_sysctl</i>	Module for viewing and modifying sysctl parameters
<i>freebsdjail</i>	The jail module for FreeBSD
<i>freebsdkernel</i>	Module to manage FreeBSD kernel modules
<i>freebsdpkg</i>	Remote package support using <code>pkg_add(1)</code>
<i>freebsdports</i>	Install software from the FreeBSD <code>ports(7)</code> system
<i>freebsdservice</i>	The service module for FreeBSD
<i>fsutils</i>	Run-time utilities
<i>gem</i>	Manage ruby gems.
<i>genesis</i>	Module for managing container and VM images
<i>gentoo_service</i>	Top level package command wrapper, used to translate the os detected by grains
<i>gentoolkitmod</i>	Support for Gentoolkit
<i>git</i>	Support for the Git SCM
<i>glance</i>	Module for handling openstack glance calls.
<i>glusterfs</i>	Manage a glusterfs pool
<i>gnomedesktop</i>	GNOME implementations
<i>gpg</i>	Manage a GPG keychains, add keys, create keys, retrieve keys from key servers.
<i>grains</i>	Return/control aspects of the grains data
<b>group</b>	
<i>groupadd</i>	Manage groups on Linux, OpenBSD and NetBSD
<i>grub_legacy</i>	Support for GRUB Legacy
<i>guestfs</i>	Interact with virtual machine images via libguestfs
<i>hadoop</i>	Support for hadoop
<i>haproxyconn</i>	Support for haproxy
<i>hashutil</i>	A collection of hashing and encoding functions
<i>hg</i>	Support for the Mercurial SCM
<i>hipchat</i>	Module for sending messages to hipchat.
<i>hosts</i>	Manage the information in the hosts file
<i>htpasswd</i>	Support for htpasswd command
<i>http</i>	Module for making various web calls.
<i>ilo</i>	Manage HP ILO
<i>img</i>	Virtual machine image management tools
<i>incron</i>	Work with incron
<i>influx</i>	InfluxDB - A distributed time series database
<i>ini_manage</i>	Edit ini files
<i>introspect</i>	Functions to perform introspection on a minion, and return data in a format
<i>ipmi</i>	Support IPMI commands over LAN.
<i>ipset</i>	Support for ipset

Table 30.6 -- continued from previous page

<i>iptables</i>	Support for iptables
<i>jboss7</i>	Module for managing JBoss AS 7 through the CLI interface.
<i>jboss7_cli</i>	Module for low-level interaction with JbossAS7 through CLI.
<i>junos</i>	Module for interfacing to Junos devices
<i>key</i>	Functions to view the minion's public key information
<i>keyboard</i>	Module for managing keyboards on supported POSIX-like systems using systemd, or such as Redhat
<i>keystone</i>	Module for handling openstack keystone calls.
<i>kmod</i>	Module to manage Linux kernel modules
<i>launchctl</i>	Module for the management of MacOS systems that use launchd/launchctl
<i>layman</i>	Support for Layman
<i>ldapmod</i>	Salt interface to LDAP commands
<i>linux_acl</i>	Support for Linux File Access Control Lists
<i>linux_lvm</i>	Support for Linux LVM2
<i>linux_sysctl</i>	Module for viewing and modifying sysctl parameters
<i>localemod</i>	Module for managing locales on POSIX-like systems.
<i>locate</i>	Module for using the locate utilities
<i>logadm</i>	Module for managing Solaris logadm based log rotations.
<i>logrotate</i>	Module for managing logrotate.
<i>lvs</i>	Support for LVS (Linux Virtual Server)
<i>lxc</i>	Control Linux Containers via Salt
<i>mac_group</i>	Manage groups on Mac OS 10.7+
<i>mac_user</i>	Manage users on Mac OS 10.7+
<i>macports</i>	Support for MacPorts under Mac OSX.
<i>makeconf</i>	Support for modifying make.conf under Gentoo
<i>match</i>	The match module allows for match routines to be run and determine target specs
<i>mdadm</i>	Salt module to manage RAID arrays with mdadm
<i>memcached</i>	Module for Management of Memcached Keys
<i>mine</i>	The function cache system allows for data to be stored on the master so it can be easily read by other
<i>mod_random</i>	New in version 2014.7.0.
<i>modjk</i>	Control Modjk via the Apache Tomcat ``Status'' worker
<i>mongodb</i>	Module to provide MongoDB functionality to Salt
<i>monit</i>	Monit service module.
<i>moosefs</i>	Module for gathering and managing information about MooseFS
<i>mount</i>	Salt module to manage unix mounts and the fstab file
<i>munin</i>	Run munin plugins/checks from salt and format the output as data.
<i>mysql</i>	Module to provide MySQL compatibility to salt.
<i>nacl</i>	This module helps include encrypted passwords in pillars, grains and salt state files.
<i>nagios</i>	Run nagios plugins/checks from salt and get the return as data.
<i>netbsd_sysctl</i>	Module for viewing and modifying sysctl parameters
<i>netbsdservice</i>	The service module for NetBSD
<i>netScaler</i>	Module to provide Citrix Netscaler compatibility to Salt (compatible with netscaler 9.2+)
<i>network</i>	Module for gathering and managing network information
<i>neutron</i>	Module for handling OpenStack Neutron calls
<i>nfs3</i>	Module for managing NFS version 3.
<i>nftables</i>	Support for nftables
<i>nginx</i>	Support for nginx
<i>nova</i>	Module for handling OpenStack Nova calls
<i>npm</i>	Manage and query NPM packages.
<i>omapi</i>	This module interacts with an ISC DHCP Server via OMAPI.
<i>openbsd_sysctl</i>	Module for viewing and modifying OpenBSD sysctl parameters

<i>openbsd_pkg</i>	Package support for OpenBSD
<i>openbsdrctl</i>	The rctl service module for OpenBSD
<i>openbsd_service</i>	The service module for OpenBSD
<i>openstack_config</i>	Modify, retrieve, or delete values from OpenStack configuration files.
<i>oracle</i>	Oracle DataBase connection module
<i>osxdesktop</i>	Mac OS X implementations of various commands in the ``desktop" interface
<i>pacman</i>	A module to wrap pacman calls, since Arch is the best
<i>pagerduty</i>	Module for Firing Events via PagerDuty
<i>pam</i>	Support for pam
<i>parted</i>	Module for managing partitions on POSIX-like systems.
<i>pecl</i>	Manage PHP pecl extensions.
<i>pillar</i>	Extract the pillar data for this minion
<i>pip</i>	Install Python packages with pip to either the system or a virtualenv
<i>pkg_resource</i>	Resources needed by pkg providers
<i>pkgin</i>	Package support for pkgin based systems, inspired from freebsd_pkg module
<i>pkgng</i>	Support for pkgng, the new package manager for FreeBSD
<i>pkgutil</i>	Pkgutil support for Solaris
<i>portage_config</i>	Configure portage(5)
<i>postfix</i>	Support for Postfix
<i>postgres</i>	Module to provide Postgres compatibility to salt.
<i>poudriere</i>	Support for poudriere
<i>powerpath</i>	powerpath support.
<b>ps</b>	
<i>publish</i>	Publish a command from a minion to a target
<i>puppet</i>	Execute puppet routines
<i>pw_group</i>	Manage groups on FreeBSD
<i>pw_user</i>	Manage users with the useradd command
<i>pyenv</i>	Manage python installations with pyenv.
<i>qemu_img</i>	Qemu-img Command Wrapper
<i>qemu_nbd</i>	Qemu Command Wrapper
<i>quota</i>	Module for managing quotas on POSIX-like systems.
<i>rabbitmq</i>	Module to provide RabbitMQ compatibility to Salt.
<i>raet_publish</i>	Publish a command from a minion to a target
<i>random_org</i>	Module for retrieving random information from Random.org
<i>rbenv</i>	Manage ruby installations with rbenv.
<i>rdp</i>	Manage RDP Service on Windows servers
<i>redismod</i>	Module to provide redis functionality to Salt
<i>reg</i>	
<i>rest_package</i>	Service support for the REST example
<i>rest_sample</i>	Module for interfacing to the REST example
<i>rest_service</i>	Service support for the REST example
<i>ret</i>	Module to integrate with the returner system and retrieve data sent to a salt returner
<i>rh_ip</i>	The networking module for RHEL/Fedora based distros
<i>rh_service</i>	Service support for RHEL-based systems, including support for both upstart and sysvinit
<i>riak</i>	Riak Salt Module
<i>rpm</i>	Support for rpm
<i>rsync</i>	Wrapper for rsync
<i>runit</i>	runit service module
<i>rvm</i>	Manage ruby installations and gemsets with RVM, the Ruby Version Manager.
<i>s3</i>	Connection module for Amazon S3

Table 30.6 -- continued from previous page

<i>saltcloudmod</i>	Control a salt cloud system
<i>saltutil</i>	The Saltutil module is used to manage the state of the salt minion itself.
<i>schedule</i>	Module for managing the Salt schedule on a minion
<i>scsi</i>	SCSI administration module
<i>sdb</i>	Module for Manipulating Data via the Salt DB API
<i>seed</i>	Virtual machine image management tools
<i>selinux</i>	Execute calls on selinux
<i>sensors</i>	Read lm-sensors
<i>serverdensity_device</i>	Wrapper around Server Density API
<i>service</i>	If Salt's OS detection does not identify a different virtual service module, the minion will fall back to
<i>shadow</i>	Manage the shadow file on Linux systems
<i>slack_notify</i>	Module for sending messages to Slack
<i>smartos_imgadm</i>	Module for running imgadm command on SmartOS
<i>smartos_vmadm</i>	Module for managing VMs on SmartOS
<i>smf</i>	Service support for Solaris 10 and 11, should work with other systems that use SMF also.
<i>smtp</i>	Module for Sending Messages via SMTP
<i>softwareupdate</i>	Support for the softwareupdate command on MacOS.
<i>solaris_group</i>	Manage groups on Solaris
<i>solaris_shadow</i>	Manage the password database on Solaris systems
<i>solaris_user</i>	Manage users with the useradd command
<i>solarisips</i>	IPS pkg support for Solaris
<i>solarispkg</i>	Package support for Solaris
<i>solr</i>	Apache Solr Salt Module
<i>splunk_search</i>	Module for interop with the Splunk API
<i>sqlite3</i>	Support for SQLite3
<i>ssh</i>	Manage client ssh components
<i>state</i>	Control the state system on the minion.
<i>status</i>	Module for returning various status data about a minion.
<i>sudo</i>	Allow for the calling of execution modules via sudo.
<i>supervisord</i>	Provide the service module for system supervisord or supervisord in a
<i>svn</i>	Subversion SCM
<i>swift</i>	Module for handling OpenStack Swift calls
<i>sysbench</i>	The `sysbench` module is used to analyze the performance of the minions, right from the master! It
<i>syslog_ng</i>	Module for getting information about syslog-ng
<i>sysmod</i>	The sys module provides information about the available functions on the minion
<i>sysrc</i>	sysrc module for FreeBSD
<i>system</i>	Support for reboot, shutdown, etc
<i>system_profiler</i>	System Profiler Module
<i>systemd</i>	Provide the service module for systemd
<i>test</i>	Module for running arbitrary tests
<i>test_virtual</i>	Module for running arbitrary tests with a <code>__virtual__</code> function
<i>timezone</i>	Module for managing timezone on POSIX-like systems.
<i>tls</i>	A salt module for SSL/TLS.
<i>tomcat</i>	Support for Tomcat
<i>twilio_notify</i>	Module for notifications via Twilio
<i>upstart</i>	Module for the management of upstart systems.
<i>user</i>	Hook to allow user-specified customization code to run.
<i>useradd</i>	Manage users with the useradd command
<i>uwsgi</i>	uWSGI stats server <a href="http://uwsgi-docs.readthedocs.org/en/latest/StatsServer.html">http://uwsgi-docs.readthedocs.org/en/latest/StatsServer.html</a>
<i>varnish</i>	Support for Varnish

<code>vbox_guest</code>	VirtualBox Guest Additions installer
<code>virt</code>	Work with virtual machines managed by libvirt
<code>virtualenv_mod</code>	Create virtualenv environments.
<code>win_autoruns</code>	Module for listing programs that automatically run on startup
<code>win_disk</code>	Module for gathering disk information on Windows
<code>win_dns_client</code>	Module for configuring DNS Client on Windows systems
<code>win_file</code>	Manage information about files on the minion, set/read user, group
<code>win_firewall</code>	Module for configuring Windows Firewall
<code>win_groupadd</code>	Manage groups on Windows
<code>win_ip</code>	The networking module for Windows based systems
<code>win_network</code>	Module for gathering and managing network information
<code>win_ntp</code>	Management of NTP servers on Windows
<code>win_path</code>	Manage the Windows System PATH
<code>win_pkg</code>	A module to manage software on Windows
<code>win_repo</code>	Module to manage Windows software repo on a Standalone Minion
<code>win_servermanager</code>	Manage Windows features via the ServerManager powershell module
<code>win_service</code>	Windows Service module.
<code>win_shadow</code>	Manage the shadow file
<code>win_status</code>	Module for returning various status data about a minion.
<code>win_system</code>	Module for managing windows systems.
<code>win_timezone</code>	Module for managing timezone on Windows systems.
<code>win_update</code>	Module for running windows updates.
<code>win_useradd</code>	Module for managing Windows Users
<code>xapi</code>	This module (mostly) uses the XenAPI to manage Xen virtual machines.
<code>xfs</code>	Module for managing XFS file systems.
<code>xmpp</code>	Module for Sending Messages via XMPP (a.k.a.
<code>yumpkg</code>	Support for YUM/DNF
<code>zcbuildout</code>	Management of zc.buildout
<code>zfs</code>	Salt interface to ZFS commands
<code>zk_concurrency</code>	Concurrency controls in zookeeper
<code>znc</code>	znc - An advanced IRC bouncer
<code>zpool</code>	Module for running ZFS zpool command
<code>zypper</code>	Package support for openSUSE via the zypper package manager

### 30.16.2 salt.modules.aliases

Manage the information in the aliases file

`salt.modules.aliases.get_target(alias)`

Return the target associated with an alias

CLI Example:

```
salt '*' aliases.get_target alias
```

`salt.modules.aliases.has_target(alias, target)`

Return true if the alias/target is set

CLI Example:

```
salt '*' aliases.has_target alias target
```

`salt.modules.aliases.list_aliases()`

Return the aliases found in the aliases file in this format:

```
{'alias': 'target'}
```

CLI Example:

```
salt '*' aliases.list_aliases
```

`salt.modules.aliases.rm_alias(alias)`

Remove an entry from the aliases file

CLI Example:

```
salt '*' aliases.rm_alias alias
```

`salt.modules.aliases.set_target(alias, target)`

Set the entry in the aliases file for the given alias, this will overwrite any previous entry for the given alias or create a new one if it does not exist.

CLI Example:

```
salt '*' aliases.set_target alias target
```

### 30.16.3 salt.modules.alternatives

Support for Alternatives system

**codeauthor** Radek Rada <radek.rada@gmail.com>

`salt.modules.alternatives.auto(name)`

Trigger alternatives to set the path for <name> as specified by priority.

CLI Example:

```
salt '*' alternatives.auto name
```

`salt.modules.alternatives.check_installed(name, path)`

Check if the current highest-priority match for a given alternatives link is set to the desired path

CLI Example:

```
salt '*' alternatives.check_installed name path
```

`salt.modules.alternatives.display(name)`

Display alternatives settings for defined command name

CLI Example:

```
salt '*' alternatives.display editor
```

`salt.modules.alternatives.install(name, link, path, priority)`

Install symbolic links determining default commands

CLI Example:

```
salt '*' alternatives.install editor /usr/bin/editor /usr/bin/emacs23 50
```

`salt.modules.alternatives.remove(name, path)`

Remove symbolic links determining the default commands.

CLI Example:

```
salt '*' alternatives.remove name path
```

`salt.modules.alternatives.set_(name, path)`

Manually set the alternative <path> for <name>.

CLI Example:

```
salt '*' alternatives.set name path
```

`salt.modules.alternatives.show_current(name)`

Display the current highest-priority alternative for a given alternatives link

CLI Example:

```
salt '*' alternatives.show_current editor
```

### 30.16.4 salt.modules.apache

Support for Apache

---

**Note:** The functions in here are generic functions designed to work with all implementations of Apache. Debian-specific functions have been moved into `deb_apache.py`, but will still load under the `apache` namespace when a Debian-based system is detected.

---

`salt.modules.apache.config(name, config, edit=True)`

Create VirtualHost configuration files

**name** File for the virtual host

**config** VirtualHost configurations

---

**Note:** This function is not meant to be used from the command line. Config is meant to be an ordered dict of all of the apache configs.

---

CLI Example:

```
salt '*' apache.config /etc/httpd/conf.d/ports.conf config="{['Listen': '22']}"
```

`salt.modules.apache.directives()`

Return list of directives together with expected arguments and places where the directive is valid (`apachectl -L`)

CLI Example:

```
salt '*' apache.directives
```

`salt.modules.apache.fullversion()`

Return server version (`apachectl -V`)

CLI Example:

```
salt '*' apache.fullversion
```

`salt.modules.apache.modules()`

Return list of static and shared modules (`apachectl -M`)

CLI Example:

```
salt '*' apache.modules
```

`salt.modules.apache.server_status` (*profile='default'*)

Get Information from the Apache server-status handler

**Note:** The server-status handler is disabled by default. In order for this function to work it needs to be enabled. See [http://httpd.apache.org/docs/2.2/mod/mod\\_status.html](http://httpd.apache.org/docs/2.2/mod/mod_status.html)

The following configuration needs to exist in pillar/grains. Each entry nested in `apache.server-status` is a profile of a vhost/server. This would give support for multiple apache servers/vhosts.

```
apache.server-status:
  default:
    url: http://localhost/server-status
    user: someuser
    pass: password
    realm: 'authentication realm for digest passwords'
    timeout: 5
```

CLI Examples:

```
salt '*' apache.server_status
salt '*' apache.server_status other-profile
```

`salt.modules.apache.servermods` ()

Return list of modules compiled into the server (`apachectl -l`)

CLI Example:

```
salt '*' apache.servermods
```

`salt.modules.apache.signal` (*signal=None*)

Signals httpd to start, restart, or stop.

CLI Example:

```
salt '*' apache.signal restart
```

`salt.modules.apache.useradd` (*pwfile, user, password, opts=''*)

Add HTTP user using the `htpasswd` command. If the `htpasswd` file does not exist, it will be created. Valid options that can be passed are:

```
n Don't update file; display results on stdout.
m Force MD5 hashing of the password (default).
d Force CRYPT(3) hashing of the password.
p Do not hash the password (plaintext).
s Force SHA1 hashing of the password.
```

CLI Examples:

```
salt '*' apache.useradd /etc/httpd/htpasswd larry badpassword
salt '*' apache.useradd /etc/httpd/htpasswd larry badpass opts=ns
```

`salt.modules.apache.userdel` (*pwfile, user*)

Delete HTTP user from the specified `htpasswd` file.

CLI Example:

```
salt '*' apache.userdel /etc/httpd/htpasswd larry
```

`salt.modules.apache.version()`  
Return server version (`apachectl -v`)

CLI Example:

```
salt '*' apache.version
```

`salt.modules.apache.vhosts()`  
Show the settings as parsed from the config file (currently only shows the virtualhost settings) (`apachectl -S`). Because each additional virtual host adds to the execution time, this command may require a long timeout be specified by using `-t 10`.

CLI Example:

```
salt -t 10 '*' apache.vhosts
```

### 30.16.5 salt.modules.aptpkg

Support for APT (Advanced Packaging Tool)

---

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

---

**Note:** For virtual package support, either the `python-apt` or `dcctrl-tools` package must be installed.

For repository management, the `python-apt` package must be installed.

---

`salt.modules.aptpkg.autoremove(list_only=False)`  
New in version 2015.5.0.

Remove packages not required by another package using `apt-get autoremove`.

**list\_only** [False] Only retrieve the list of packages to be auto-removed, do not actually perform the auto-removal.

CLI Example:

```
salt '*' pkg.autoremove
salt '*' pkg.autoremove list_only=True
```

`salt.modules.aptpkg.del_repo(repo, **kwargs)`  
Delete a repo from the `sources.list` / `sources.list.d`

If the `.list` file is in the `sources.list.d` directory and the file that the repo exists in does not contain any other repo configuration, the file itself will be deleted.

The repo passed in must be a fully formed repository definition string.

CLI Examples:

```
salt '*' pkg.del_repo "myrepo definition"
```

`salt.modules.aptpkg.expand_repo_def(**kwargs)`

Take a repository definition and expand it to the full pkg repository dict that can be used for comparison. This is a helper function to make the Debian/Ubuntu apt sources sane for comparison in the `pkgrepo` states.

This is designed to be called from `pkgrepo` states and will have little use being called on the CLI.

`salt.modules.aptpkg.file_dict(*packages)`

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of `_every_file` on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.aptpkg.file_list(*packages)`

List the files that belong to a package. Not specifying any packages will return a list of `_every_file` on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.aptpkg.get_repo(repo, **kwargs)`

Display a repo from the `sources.list / sources.list.d`

The repo passed in needs to be a complete repo entry.

CLI Examples:

```
salt '*' pkg.get_repo "myrepo definition"
```

`salt.modules.aptpkg.get_selections(pattern=None, state=None)`

View package state from the `dpkg` database.

Returns a dict of dicts containing the state, and package names:

```
{ '<host>':
  { '<state>': ['pkg1',
              ...
              ]
    },
  ...
}
```

CLI Example:

```
salt '*' pkg.get_selections
salt '*' pkg.get_selections 'python-*'
salt '*' pkg.get_selections state=hold
salt '*' pkg.get_selections 'openssh*' state=hold
```

`salt.modules.aptpkg.hold(name=None, pkgs=None, sources=None, **kwargs)`

New in version 2014.7.0.

Set package in 'hold' state, meaning it will not be upgraded.

**name** The name of the package, e.g., 'tmux'

CLI Example:

```
salt '*' pkg.hold <package name>
```

**pkgs** A list of packages to hold. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.hold pkgs='["foo", "bar"]'
```

`salt.modules.aptpkg.install` (*name=None, refresh=False, fromrepo=None, skip\_verify=False, debconf=None, pkgs=None, sources=None, \*\*kwargs*)

Install the passed package, add refresh=True to update the dpkg database.

**name** The name of the package to be installed. Note that this parameter is ignored if either ``pkgs`` or ``sources`` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the ``sources`` option.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (:i386, etc.) to the end of the package name.

CLI Example:

```
salt '*' pkg.install <package name>
```

**refresh** Whether or not to refresh the package database before installing.

**fromrepo** Specify a package repository to install from (e.g., `apt-get -t unstable install somepackage`)

**skip\_verify** Skip the GPG verification check (e.g., `--allow-unauthenticated`, or `--force-bad-verify` for install from package file).

**debconf** Provide the path to a debconf answers file, processed before installation.

**version** Install a specific version of the package, e.g. `1.2.3~0ubuntu0`. Ignored if ``pkgs`` or ``sources`` is passed.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3~0ubuntu0"}]'
```

**sources** A list of DEB packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package. Dependencies are automatically resolved and marked as auto-installed.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (:i386, etc.) to the end of the package name.

Changed in version 2014.7.0.

CLI Example:

```
salt '*' pkg.install sources=[{"foo": "salt://foo.deb"}, {"bar": "salt://bar.deb"}]'
```

**force\_yes** Passes `--force-yes` to the `apt-get` command. Don't use this unless you know what you're doing.

New in version 0.17.4.

**install\_recommends** Whether to install the packages marked as recommended. Default is True.

New in version 2015.5.0.

**only\_upgrade** Only upgrade the packages, if they are already installed. Default is False.

New in version 2015.5.0.

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

`salt.modules.aptpkg.latest_version(*names, **kwargs)`

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

A specific repo can be requested using the `fromrepo` keyword argument.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> fromrepo=unstable
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

`salt.modules.aptpkg.list_pkgs(versions_as_list=False, removed=False, purge_desired=False, **kwargs)`

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

**removed** If `True`, then only packages which have been removed (but not purged) will be returned.

**purge\_desired** If `True`, then only packages which have been marked to be purged, but can't be purged due to their status as dependencies for other installed packages, will be returned. Note that these packages will appear in installed

Changed in version 2014.1.1: Packages in this state now correctly show up in the output of this function.

---

**Note:** External dependencies

Virtual package resolution requires the `dctrl-tools` package to be installed. Virtual packages will show a version of 1.

---

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

`salt.modules.aptpkg.list_repos()`

Lists all repos in the `sources.list` (and `sources.lists.d`) files

CLI Example:

```
salt '*' pkg.list_repos
salt '*' pkg.list_repos disabled=True
```

`salt.modules.aptpkg.list_upgrades(refresh=True)`

List all available package upgrades.

CLI Example:

```
salt '*' pkg.list_upgrades
```

`salt.modules.aptpkg.mod_repo(repo, saltenv='base', **kwargs)`

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the definition is

well formed. For Ubuntu the ``ppa:<project>/repo" format is acceptable. ``ppa:" format can only be used to create a new repository.

The following options are available to modify a repo definition:

```
comps (a comma separated list of components for the repo, e.g. "main")
file (a file name to be used)
keyserver (keyserver to get gpg key from)
keyid (key id to load with the keyserver argument)
key_url (URL to a gpg key to add to the apt gpg keyring)
consolidate (if true, will attempt to de-dup and consolidate sources)
```

\* Note: Due to the way keys are stored for apt, there is a known issue where the key wont be updated unless another change is made at the same time. Keys should be properly added on initial configuration.

CLI Examples:

```
salt '*' pkg.mod_repo 'myrepo definition' uri=http://new/uri
salt '*' pkg.mod_repo 'myrepo definition' comps=main,universe
```

### `salt.modules.aptpkg.owner(*paths)`

New in version 2014.7.0.

Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version`, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Example:

```
salt '*' pkg.owner /usr/bin/apachectl salt '*' pkg.owner /usr/bin/apachectl /usr/bin/basename
```

### `salt.modules.aptpkg.purge(name=None, pkgs=None, **kwargs)`

Remove packages via `apt-get purge` along with all configuration files.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>, <package2>, <package3>
salt '*' pkg.purge pkgs=['foo', 'bar']
```

### `salt.modules.aptpkg.refresh_db()`

Updates the APT database to latest packages based upon repositories

Returns a dict, with the keys being package databases and the values being the result of the update attempt. Values can be one of the following:

- True: Database updated successfully

- False: Problem updating database
- None: Database already up-to-date

CLI Example:

```
salt '*' pkg.refresh_db
```

`salt.modules.aptpkg.remove` (*name=None, pkgs=None, \*\*kwargs*)

Remove packages using `apt-get remove`.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>, <package2>, <package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

`salt.modules.aptpkg.set_selections` (*path=None, selection=None, clear=False, saltenv='base'*)

Change package state in the `dpkg` database.

The state can be any one of, documented in `dpkg(1)`:

- install
- hold
- deinstall
- purge

This command is commonly used to mark specific packages to be held from being upgraded, that is, to be kept at a certain version. When a state is changed to anything but being held, then it is typically followed by `apt-get -u dselect-upgrade`.

Note: Be careful with the `clear` argument, since it will start with setting all packages to deinstall state.

Returns a dict of dicts containing the package names, and the new and old versions:

```
{'host':
  {'package': {'new': '<new-state>',
               'old': '<old-state>'}}
  },
  ...
}
```

CLI Example:

```
salt '*' pkg.set_selections selection='{"install": ["netcat"]}'
salt '*' pkg.set_selections selection='{"hold": ["openssh-server", "openssh-client"]}'
salt '*' pkg.set_selections salt://path/to/file
salt '*' pkg.set_selections salt://path/to/file clear=True
```

`salt.modules.aptpkg.unhold`(*name=None, pkgs=None, sources=None, \*\*kwargs*)

New in version 2014.7.0.

Set package current in 'hold' state to install state, meaning it will be upgraded.

**name** The name of the package, e.g., 'tmux'

CLI Example:

```
salt '*' pkg.unhold <package name>
```

**pkgs** A list of packages to hold. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.unhold pkgs=['foo', 'bar']
```

`salt.modules.aptpkg.upgrade`(*refresh=True, dist\_upgrade=False*)

Upgrades all packages via apt-get dist-upgrade

Returns a dict containing the changes.

```
{`<package>': {'old': `<old-version>', `new': `<new-version>'}}
```

**dist\_upgrade** Whether to perform the upgrade using dist-upgrade vs upgrade. Default is to use upgrade.

New in version 2014.7.0.

CLI Example:

```
salt '*' pkg.upgrade
```

`salt.modules.aptpkg.upgrade_available`(*name*)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

`salt.modules.aptpkg.version`(*\*names, \*\*kwargs*)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

`salt.modules.aptpkg.version_cmp`(*pkg1, pkg2*)

Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

CLI Example:

```
salt '*' pkg.version_cmp '0.2.4-0ubuntu1' '0.2.4.1-0ubuntu1'
```

### 30.16.6 salt.modules.archive

A module to wrap (non-Windows) archive calls

New in version 2014.1.0.

`salt.modules.archive.cmd_unzip`(*zip\_file*, *dest*, *excludes=None*, *template=None*, *options=None*, *runas=None*)

New in version 2015.5.0: In versions 2014.7.x and earlier, this function was known as `archive.unzip`.

Uses the `unzip` command to unpack zip files. This command is part of the [Info-ZIP](#) suite of tools, and is typically packaged as simply `unzip`.

**zip\_file** Path of zip file to be unpacked

**dest** The destination directory into which the file should be unpacked

**excludes** [None] Comma-separated list of files not to unpack. Can also be passed in a Python list.

**template** [None] Can be set to ``jinja`` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.cmd_unzip template=jinja /tmp/zipfile.zip /tmp/{{grains.id}}/excludes=file
```

**options** [None] Additional command-line options to pass to the `unzip` binary.

**runas** [None] Unpack the zip file as the specified user. Defaults to the user under which the minion is running.

New in version 2015.5.0.

**options** [None] Additional command-line options to pass to the `unzip` binary.

CLI Example:

```
salt '*' archive.cmd_unzip /tmp/zipfile.zip /home/strongbad/ excludes=file_1,file_2
```

`salt.modules.archive.cmd_zip`(*zip\_file*, *sources*, *template=None*, *cwd=None*, *runas=None*)

New in version 2015.5.0: In versions 2014.7.x and earlier, this function was known as `archive.zip`.

Uses the `zip` command to create zip files. This command is part of the [Info-ZIP](#) suite of tools, and is typically packaged as simply `zip`.

**zip\_file** Path of zip file to be created

**sources** Comma-separated list of sources to include in the zip file. Sources can also be passed in a Python list.

**template** [None] Can be set to ``jinja`` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.cmd_zip template=jinja /tmp/zipfile.zip /tmp/sourcefile1,/tmp/{{grains.id}}
```

**cwd** [None] Use this argument along with relative paths in `sources` to create zip files which do not contain the leading directories. If not specified, the zip file will be created as if the `cwd` was `/`, and creating a zip file of `/foo/bar/baz.txt` will contain the parent directories `foo` and `bar`. To create a zip file containing just `baz.txt`, the following command would be used:

```
salt '*' archive.cmd_zip /tmp/baz.zip baz.txt cwd=/foo/bar
```

New in version 2014.7.1.

**runas** [None] Create the zip file as the specified user. Defaults to the user under which the minion is running.

New in version 2015.5.0.

CLI Example:

```
salt '*' archive.cmd_zip /tmp/zipfile.zip /tmp/sourcefile1,/tmp/sourcefile2
```

`salt.modules.archive.gunzip`(*gzipfile*, *template=None*, *runas=None*)

Uses the `gunzip` command to unpack gzip files

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.gunzip template=jinja /tmp/{{grains.id}}.txt.gz
```

CLI Example:

```
# Create /tmp/sourcefile.txt
salt '*' archive.gunzip /tmp/sourcefile.txt.gz
```

**salt.modules.archive.gzip** (*sourcefile*, *template=None*, *runas=None*)

Uses the `gzip` command to create `gzip` files

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.gzip template=jinja /tmp/{{grains.id}}.txt
```

CLI Example:

```
# Create /tmp/sourcefile.txt.gz
salt '*' archive.gzip /tmp/sourcefile.txt
```

**salt.modules.archive.rar** (*rarfile*, *sources*, *template=None*, *cwd=None*, *runas=None*)

Uses `rar` for Linux to create rar files

**rarfile** Path of rar file to be created

**sources** Comma-separated list of sources to include in the rar file. Sources can also be passed in a Python list.

**cwd** [None] Run the rar command from the specified directory. Use this argument along with relative file paths to create rar files which do not contain the leading directories. If not specified, this will default to the home directory of the user under which the salt minion process is running.

New in version 2014.7.1.

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.rar template=jinja /tmp/rarfile.rar '/tmp/sourcefile1,/tmp/{{grains.id}}.txt
```

CLI Example:

```
salt '*' archive.rar /tmp/rarfile.rar /tmp/sourcefile1,/tmp/sourcefile2
```

**salt.modules.archive.tar** (*options*, *tarfile*, *sources=None*, *dest=None*, *cwd=None*, *template=None*, *runas=None*)

---

**Note:** This function has changed for version 0.17.0. In prior versions, the `cwd` and `template` arguments must be specified, with the source directories/files coming as a space-separated list at the end of the command. Beginning with 0.17.0, `sources` must be a comma-separated list, and the `cwd` and `template` arguments are optional.

---

Uses the `tar` command to pack, unpack, etc. tar files

**options** Options to pass to the tar command

**tarfile** The filename of the tar archive to pack/unpack

**sources** Comma delimited list of files to pack into the tarfile. Can also be passed as a Python list.

**dest** The destination directory into which to **unpack** the tarfile

**cwd** [None] The directory in which the tar command should be executed. If not specified, will default to the home directory of the user under which the salt minion process is running.

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.tar cjvf /tmp/salt.tar.bz2 {{grains.saltpath}} template=jinja
```

CLI Examples:

```
# Create a tarfile
salt '*' archive.tar cjvf /tmp/tarfile.tar.bz2 /tmp/file_1,/tmp/file_2
# Unpack a tarfile
salt '*' archive.tar xf foo.tar dest=/target/directory
```

**salt.modules.archive.unrar** (*rarfile, dest, excludes=None, template=None, runas=None*)

Uses rar for Linux to unpack rar files

**rarfile** Name of rar file to be unpacked

**dest** The destination directory into which to **unpack** the rar file

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.unrar template=jinja /tmp/rarfile.rar /tmp/{{grains.id}}/ excludes=file_1,f
```

CLI Example:

```
salt '*' archive.unrar /tmp/rarfile.rar /home/strongbad/ excludes=file_1,file_2
```

**salt.modules.archive.unzip** (*zip\_file, dest, excludes=None, template=None, runas=None*)

Uses the zipfile Python module to unpack zip files

Changed in version 2015.5.0: This function was rewritten to use Python's native zip file support. The old functionality has been preserved in the new function *archive.cmd\_unzip*. For versions 2014.7.x and earlier, see the *archive.cmd\_zip* documentation.

**zip\_file** Path of zip file to be unpacked

**dest** The destination directory into which the file should be unpacked

**excludes** [None] Comma-separated list of files not to unpack. Can also be passed in a Python list.

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.unzip template=jinja /tmp/zipfile.zip /tmp/{{grains.id}}/ excludes=file_1,f
```

**runas** [None] Unpack the zip file as the specified user. Defaults to the user under which the minion is running.

CLI Example:

```
salt '*' archive.unzip /tmp/zipfile.zip /home/strongbad/ excludes=file_1,file_2
```

**salt.modules.archive.zip\_** (*zip\_file, sources, template=None, cwd=None, runas=None*)

Uses the zipfile Python module to create zip files

Changed in version 2015.5.0: This function was rewritten to use Python's native zip file support. The old functionality has been preserved in the new function *archive.cmd\_zip*. For versions 2014.7.x and earlier, see the *archive.cmd\_zip* documentation.

**zip\_file** Path of zip file to be created

**sources** Comma-separated list of sources to include in the zip file. Sources can also be passed in a Python list.

**template** [None] Can be set to 'jinja' or another supported template engine to render the command arguments before execution:

```
salt '*' archive.zip template=jinja /tmp/zipfile.zip /tmp/sourcefile1,/tmp/{{grains.id}}.txt
```

**cwd** [None] Use this argument along with relative paths in **sources** to create zip files which do not contain the leading directories. If not specified, the zip file will be created as if the cwd was /, and creating a zip file of /foo/bar/baz.txt will contain the parent directories foo and bar. To create a zip file containing just baz.txt, the following command would be used:

```
salt '*' archive.zip /tmp/baz.zip baz.txt cwd=/foo/bar
```

**runas** [None] Create the zip file as the specified user. Defaults to the user under which the minion is running.

CLI Example:

```
salt '*' archive.zip /tmp/zipfile.zip /tmp/sourcefile1,/tmp/sourcefile2
```

### 30.16.7 salt.modules.artifactory

Module for fetching artifacts from Artifactory

**exception** salt.modules.artifactory.**ArtifactoryError** (*value*)

salt.modules.artifactory.**get\_latest\_snapshot**(*artifactory\_url*, *repository*, *group\_id*, *artifact\_id*, *packaging*, *target\_dir*='/tmp', *target\_file*=None)

Gets latest snapshot of the given artifact

**artifactory\_url** URL of artifactory instance

**repository** Snapshot repository in artifactory to retrieve artifact from, for example: libs-snapshots

**group\_id** Group Id of the artifact

**artifact\_id** Artifact Id of the artifact

**packaging** Packaging type (jar,war,ear,etc)

**target\_dir** Target directory to download artifact to (default: /tmp)

**target\_file** Target file to download artifact to (by default it is target\_dir/artifact\_id-snapshot\_version.packaging)

salt.modules.artifactory.**get\_release**(*artifactory\_url*, *repository*, *group\_id*, *artifact\_id*, *packaging*, *version*, *target\_dir*='/tmp', *target\_file*=None)

Gets the specified release of the artifact

**artifactory\_url** URL of artifactory instance

**repository** Release repository in artifactory to retrieve artifact from, for example: libs-releases

**group\_id** Group Id of the artifact

**artifact\_id** Artifact Id of the artifact

**packaging** Packaging type (jar,war,ear,etc)

**version** Version of the artifact

**target\_dir** Target directory to download artifact to (default: /tmp)

**target\_file** Target file to download artifact to (by default it is target\_dir/artifact\_id-version.packaging)

`salt.modules.artifactory.get_snapshot`(*artifactory\_url*, *repository*, *group\_id*, *artifact\_id*, *packaging*, *version*, *snapshot\_version=None*, *target\_dir='/tmp'*, *target\_file=None*)

Gets snapshot of the desired version of the artifact

**artifactory\_url** URL of artifactory instance

**repository** Snapshot repository in artifactory to retrieve artifact from, for example: libs-snapshots

**group\_id** Group Id of the artifact

**artifact\_id** Artifact Id of the artifact

**packaging** Packaging type (jar,war,ear,etc)

**version** Version of the artifact

**target\_dir** Target directory to download artifact to (default: /tmp)

**target\_file** Target file to download artifact to (by default it is target\_dir/artifact\_id-snapshot\_version.packaging)

### 30.16.8 salt.modules.at

Wrapper module for at(1)

Also, a `tag` feature has been added to more easily tag jobs.

`salt.modules.at.at`(\*args, \*\*kwargs)

Add a job to the queue.

The `timespec` follows the format documented in the at(1) manpage.

CLI Example:

```
salt '*' at.at <timespec> <cmd> [tag=<tag>] [runas=<user>]
salt '*' at.at 12:05am '/sbin/reboot' tag=reboot
salt '*' at.at '3:05am +3 days' 'bin/myscript' tag=nightly runas=jim
```

`salt.modules.at.atc`(*jobid*)

Print the at(1) script that will run for the passed job id. This is mostly for debugging so the output will just be text.

CLI Example:

```
salt '*' at.atc <jobid>
```

`salt.modules.at.atq`(*tag=None*)

List all queued and running jobs or only those with an optional `tag`.

CLI Example:

```
salt '*' at.atq
salt '*' at.atq [tag]
salt '*' at.atq [job number]
```

`salt.modules.at.atrm`(\*args)

Remove jobs from the queue.

CLI Example:

```
salt '*' at.atrm <jobid> <jobid> .. <jobid>
salt '*' at.atrm all
salt '*' at.atrm all [tag]
```

`salt.modules.at.jobcheck` (\*\*kwargs)

Check the job from queue. The kwargs dict include `hour minute day month year tag runas` Other parameters will be ignored.

CLI Example:

```
salt '*' at.jobcheck runas=jam day=13
salt '*' at.jobcheck day=13 month=12 year=13 tag=rose
```

### 30.16.9 salt.modules.augeas\_cfg

Manages configuration files via augeas

This module requires the `augeas` Python module.

**Warning:** Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, but the functions in this execution module fail to run due to being unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing `libpython2.7` has been known to resolve the issue.

`salt.modules.augeas_cfg.execute` (context=None, lens=None, commands=())

Execute Augeas commands

New in version 2014.7.0.

CLI Example:

```
salt '*' augeas.execute /files/etc/redis/redis.conf commands='["set bind 0.0.0.0", "set maxmemory"]'
```

`salt.modules.augeas_cfg.get` (path, value='')

Get a value for a specific augeas path

CLI Example:

```
salt '*' augeas.get /files/etc/hosts/1/ ipaddr
```

`salt.modules.augeas_cfg.ls` (path)

List the direct children of a node

CLI Example:

```
salt '*' augeas.ls /files/etc/passwd
```

`salt.modules.augeas_cfg.match` (path, value='')

Get matches for path expression

CLI Example:

```
salt '*' augeas.match /files/etc/services/service-name ssh
```

**salt.modules.augeas\_cfg.remove**(*path*)

Get matches for path expression

CLI Example:

```
salt '*' augeas.remove /files/etc/sysctl.conf/net.ipv4.conf.all.log_martians
```

**salt.modules.augeas\_cfg.setvalue**(*\*args*)

Set a value for a specific augeas path

CLI Example:

```
salt '*' augeas.setvalue /files/etc/hosts/1/canonical localhost
```

This will set the first entry in /etc/hosts to localhost

CLI Example:

```
salt '*' augeas.setvalue /files/etc/hosts/01/ipaddr 192.168.1.1 \
    /files/etc/hosts/01/canonical test
```

Adds a new host to /etc/hosts the ip address 192.168.1.1 and hostname test

CLI Example:

```
salt '*' augeas.setvalue prefix=/files/etc/sudoers/ \
    "spec[user = '%wheel']/user" "%wheel" \
    "spec[user = '%wheel']/host_group/host" 'ALL' \
    "spec[user = '%wheel']/host_group/command[1]" 'ALL' \
    "spec[user = '%wheel']/host_group/command[1]/tag" 'PASSWD' \
    "spec[user = '%wheel']/host_group/command[2]" '/usr/bin/apt-get' \
    "spec[user = '%wheel']/host_group/command[2]/tag" NOPASSWD
```

Ensures that the following line is present in /etc/sudoers:

```
%wheel ALL = PASSWD : ALL , NOPASSWD : /usr/bin/apt-get , /usr/bin/aptitude
```

**salt.modules.augeas\_cfg.tree**(*path*)

Returns recursively the complete tree of a node

CLI Example:

```
salt '*' augeas.tree /files/etc/
```

### 30.16.10 salt.modules.aws\_sqs

Support for the Amazon Simple Queue Service.

**salt.modules.aws\_sqs.create\_queue**(*name, region, opts=None, user=None*)

Creates a queue with the correct name.

**name** Name of the SQS queue to create

**region** Region to create the SQS queue in

**opts** [None] Any additional options to add to the command line

**user** [None] Run hg as a user other than what the minion runs as

`salt.modules.aws_sqs.delete_message` (*queue, region, receipthandle, opts=None, user=None*)

Delete one or more messages from a queue in a region

**queue** The name of the queue to delete messages from

**region** Region where SQS queues exists

**receipthandle** The ReceiptHandle of the message to delete. The ReceiptHandle is obtained in the return from `receive_message`

**opts** [None] Any additional options to add to the command line

**user** [None] Run as a user other than what the minion runs as

CLI Example:

```
salt '*' aws_sqs.delete_message <sqs queue> <region> receipthandle='<sqs ReceiptHandle>'
```

New in version 2014.7.0.

`salt.modules.aws_sqs.delete_queue` (*name, region, opts=None, user=None*)

Deletes a queue in the region.

**name** Name of the SQS queue to deletes

**region** Name of the region to delete the queue from

**opts** [None] Any additional options to add to the command line

**user** [None] Run hg as a user other than what the minion runs as

`salt.modules.aws_sqs.list_queues` (*region, opts=None, user=None*)

List the queues in the selected region.

**region** Region to list SQS queues for

**opts** [None] Any additional options to add to the command line

**user** [None] Run hg as a user other than what the minion runs as

`salt.modules.aws_sqs.queue_exists` (*name, region, opts=None, user=None*)

Returns True or False on whether the queue exists in the region

**name** Name of the SQS queue to search for

**region** Name of the region to search for the queue in

**opts** [None] Any additional options to add to the command line

**user** [None] Run hg as a user other than what the minion runs as

`salt.modules.aws_sqs.receive_message` (*queue, region, num=1, opts=None, user=None*)

Receive one or more messages from a queue in a region

**queue** The name of the queue to receive messages from

**region** Region where SQS queues exists

**num** [1] The max number of messages to receive

**opts** [None] Any additional options to add to the command line

**user** [None] Run as a user other than what the minion runs as

CLI Example:

```
salt '*' aws_sqs.receive_message <sqs queue> <region>
salt '*' aws_sqs.receive_message <sqs queue> <region> num=10
```

New in version 2014.7.0.

### 30.16.11 salt.modules.blockdev

Module for managing block devices

New in version 2014.7.0.

**salt.modules.blockdev.dump**(*device*, *args=None*)  
Return all contents of dumpe2fs for a specified device

CLI Example: .. code-block:: bash

```
salt '*' extfs.dump /dev/sda1
```

**salt.modules.blockdev.resize2fs**(*device*)  
Resizes the filesystem.

CLI Example: .. code-block:: bash

```
salt '*' blockdev.resize2fs /dev/sda1
```

**salt.modules.blockdev.tune**(*device*, *\*\*kwargs*)  
Set attributes for the specified device

CLI Example:

```
salt '*' blockdev.tune /dev/sda1 read-ahead=1024 read-write=True
```

Valid options are: read-ahead, filesystem-read-ahead, read-only, read-write.

See the `blockdev(8)` manpage for a more complete description of these options.

**salt.modules.blockdev.wipe**(*device*)  
Remove the filesystem information

CLI Example:

```
salt '*' blockdev.wipe /dev/sda1
```

### 30.16.12 salt.modules.bluez

Support for Bluetooth (using BlueZ in Linux).

The following packages are required packages for this module:

```
bluez >= 5.7 bluez-libs >= 5.7 bluez-utils >= 5.7 pybluez >= 0.18
```

**salt.modules.bluez.address\_**()  
Get the many addresses of the Bluetooth adapter

CLI Example:

```
salt '*' bluetooth.address
```

**salt.modules.bluez.block**(*bdaddr*)  
Block a specific bluetooth device by BD Address

CLI Example:

```
salt '*' bluetooth.block DE:AD:BE:EF:CA:FE
```

`salt.modules.bluez.discoverable(dev)`  
Enable this bluetooth device to be discoverable.

CLI Example:

```
salt '*' bluetooth.discoverable hci0
```

`salt.modules.bluez.noscan(dev)`  
Turn off scanning modes on this device.

CLI Example:

```
salt '*' bluetooth.noscan hci0
```

`salt.modules.bluez.pair(address, key)`  
Pair the bluetooth adapter with a device

CLI Example:

```
salt '*' bluetooth.pair DE:AD:BE:EF:CA:FE 1234
```

Where DE:AD:BE:EF:CA:FE is the address of the device to pair with, and 1234 is the passphrase.

TODO: This function is currently broken, as the bluez-simple-agent program no longer ships with BlueZ >= 5.0. It needs to be refactored.

`salt.modules.bluez.power(dev, mode)`  
Power a bluetooth device on or off

CLI Examples:

```
salt '*' bluetooth.power hci0 on  
salt '*' bluetooth.power hci0 off
```

`salt.modules.bluez.scan()`  
Scan for bluetooth devices in the area

CLI Example:

```
salt '*' bluetooth.scan
```

`salt.modules.bluez.start()`  
Start the bluetooth service.

CLI Example:

```
salt '*' bluetooth.start
```

`salt.modules.bluez.stop()`  
Stop the bluetooth service.

CLI Example:

```
salt '*' bluetooth.stop
```

`salt.modules.bluez.unblock(bdaddr)`  
Unblock a specific bluetooth device by BD Address

CLI Example:

```
salt '*' bluetooth.unblock DE:AD:BE:EF:CA:FE
```

`salt.modules.bluez.unpair` (*address*)

Unpair the bluetooth adapter from a device

CLI Example:

```
salt '*' bluetooth.unpair DE:AD:BE:EF:CA:FE
```

Where DE:AD:BE:EF:CA:FE is the address of the device to unpair.

TODO: This function is currently broken, as the bluez-simple-agent program no longer ships with BlueZ >= 5.0. It needs to be refactored.

`salt.modules.bluez.version` ()

Return Bluez version from bluetoothd -v

CLI Example:

```
salt '*' bluetoothd.version
```

### 30.16.13 salt.modules.boto\_asg

Connection module for Amazon Autoscale Groups

New in version 2014.7.0.

**configuration** This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWupUjasdfklkdflkjlsdfjajkghs
```

A region may also be specified in the configuration:

```
asg.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkghWupUjasdfklkd-
           fkljlsdfjajkghs region: us-east-1
```

**depends** boto

`salt.modules.boto_asg.create` (*name*, *launch\_config\_name*, *availability\_zones*, *min\_size*, *max\_size*, *desired\_capacity=None*, *load\_balancers=None*, *default\_cooldown=None*, *health\_check\_type=None*, *health\_check\_period=None*, *placement\_group=None*, *vpc\_zone\_identifier=None*, *tags=None*, *termination\_policies=None*, *suspended\_processes=None*, *scaling\_policies=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Create an autoscale group.

CLI example:

```
salt myminion boto_asg.create myasg mylc ["us-east-1a", "us-east-1e"] 1 10 load_balancers=['m
```

```
salt.modules.boto_asg.create_launch_configuration(name, image_id, key_name=None,
                                                  security_groups=None,
                                                  user_data=None,           in-
                                                  stance_type='m1.small',       ker-
                                                  nel_id=None,       ramdisk_id=None,
                                                  block_device_mappings=None,
                                                  instance_monitoring=False,
                                                  spot_price=None,           in-
                                                  stance_profile_name=None,
                                                  ebs_optimized=False,       asso-
                                                  ciate_public_ip_address=None,
                                                  volume_type=None,
                                                  delete_on_termination=True,
                                                  iops=None,
                                                  use_block_device_types=False, re-
                                                  gion=None, key=None, keyid=None,
                                                  profile=None)
```

Create a launch configuration.

CLI example:

```
salt myminion boto_asg.create_launch_configuration mylc image_id=ami-0b9c9f62 key_name='mykey' s
```

```
salt.modules.boto_asg.delete(name, force=False, region=None, key=None, keyid=None, pro-
                             file=None)
```

Delete an autoscale group.

CLI example:

```
salt myminion boto_asg.delete myasg region=us-east-1
```

```
salt.modules.boto_asg.delete_launch_configuration(name, region=None, key=None,
                                                  keyid=None, profile=None)
```

Delete a launch configuration.

CLI example:

```
salt myminion boto_asg.delete_launch_configuration mylc
```

```
salt.modules.boto_asg.exists(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if an autoscale group exists.

CLI example:

```
salt myminion boto_asg.exists myasg region=us-east-1
```

```
salt.modules.boto_asg.get_cloud_init_mime(cloud_init)
```

Get a mime multipart encoded string from a cloud-init dict. Currently supports scripts and cloud-config.

CLI Example:

```
salt myminion boto.get_cloud_init_mime <cloud init>
```

```
salt.modules.boto_asg.get_config(name, region=None, key=None, keyid=None, profile=None)
```

Get the configuration for an autoscale group.

CLI example:

```
salt myminion boto_asg.get_config myasg region=us-east-1
```

`salt.modules.boto_asg.get_instances`(*name*, *lifecycle\_state*=*InService*, *health\_status*=*Healthy*, *attribute*=*private\_ip\_address*, *region*=*None*, *key*=*None*, *keyid*=*None*, *profile*=*None*)

return attribute of all instances in the named autoscale group.

CLI example:

```
salt-call boto_asg.get_instances my_autoscale_group_name
```

`salt.modules.boto_asg.get_scaling_policy_arn`(*as\_group*, *scaling\_policy\_name*, *region*=*None*, *key*=*None*, *keyid*=*None*, *profile*=*None*)

Return the arn for a scaling policy in a specific autoscale group or None if not found. Mainly used as a helper method for `boto_cloudwatch_alarm`, for linking alarms to scaling policies.

CLI Example:

```
salt '*' boto_asg.get_scaling_policy_arn mygroup mypolicy
```

`salt.modules.boto_asg.launch_configuration_exists`(*name*, *region*=*None*, *key*=*None*, *keyid*=*None*, *profile*=*None*)

Check for a launch configuration's existence.

CLI example:

```
salt myminion boto_asg.launch_configuration_exists mylc
```

`salt.modules.boto_asg.update`(*name*, *launch\_config\_name*, *availability\_zones*, *min\_size*, *max\_size*, *desired\_capacity*=*None*, *load\_balancers*=*None*, *default\_cooldown*=*None*, *health\_check\_type*=*None*, *health\_check\_period*=*None*, *placement\_group*=*None*, *vpc\_zone\_identifier*=*None*, *tags*=*None*, *termination\_policies*=*None*, *suspended\_processes*=*None*, *scaling\_policies*=*None*, *region*=*None*, *key*=*None*, *keyid*=*None*, *profile*=*None*)

Update an autoscale group.

CLI example:

```
salt myminion boto_asg.update myasg mylc '["us-east-1a", "us-east-1e"]' 1 10 load_balancers='["m
```

### 30.16.14 salt.modules.boto\_cfn

Connection module for Amazon Cloud Formation

**configuration** This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
cfn.keyid: GKTADJGHEIQSXMKKRBJ08H
cfn.key: askdjghsdfjkghWupUjasdfklkfjlsdfjajkghs
```

A region may also be specified in the configuration:

```
cfn.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkgHwupUjasdfkld-
          fklgjsdfjajkghs region: us-east-1
```

**depends** boto

```
salt.modules.boto_cfn.create(name, template_url=None, region=None, key=None, keyid=None,
                             profile=None)
```

Create a CFN stack.

CLI example to create a stack:

```
salt myminion boto_cfn.create mystack template_url='https://s3.amazonaws.com/bucket/template.cft'
```

```
salt.modules.boto_cfn.delete(name, region=None, key=None, keyid=None, profile=None)
```

Delete a CFN stack.

CLI example to delete a stack:

```
salt myminion boto_cfn.delete mystack region=us-east-1
```

```
salt.modules.boto_cfn.exists(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if a stack exists.

CLI example:

```
salt myminion boto_cfn.exists mystack region=us-east-1
```

```
salt.modules.boto_cfn.get_template(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if attributes are set on a CFN stack.

CLI example:

```
salt myminion boto_cfn.get_template mystack
```

### 30.16.15 salt.modules.boto\_cloudwatch

Connection module for Amazon CloudWatch

New in version 2014.7.0.

**configuration** This module accepts explicit credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
cloudwatch.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch.key: askdjghsdfjkgHwupUjasdfkldfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
cloudwatch.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkgHwupUjasdfldk-
          fklgjsdfjajkghs region: us-east-1
```

**depends** boto

```
salt.modules.boto_cloudwatch.convert_to_arn(arns, region=None, key=None, keyid=None,
                                             profile=None)
```

Convert a list of strings into actual arns. Converts convenience names such as `scaling\_policy:...`

CLI Example:

```
salt '*' convert_to_arn 'scaling_policy:'
```

```
salt.modules.boto_cloudwatch.create_or_update_alarm(connection=None, name=None,
                                                    metric=None, names-
                                                    pace=None, statistic=None,
                                                    comparison=None, thresh-
                                                    old=None, period=None, evalu-
                                                    ation_periods=None, unit=None,
                                                    description='', dimensions=None,
                                                    alarm_actions=None, insuf-
                                                    ficient_data_actions=None,
                                                    ok_actions=None, region=None,
                                                    key=None, keyid=None, pro-
                                                    file=None)
```

Create or update a cloudwatch alarm.

**Params are the same as:** <http://boto.readthedocs.org/en/latest/ref/cloudwatch.html#boto.ec2.cloudwatch.alarm.MetricAlarm>.

Dimensions must be a dict. If the value of Dimensions is a string, it will be json decoded to produce a dict. alarm\_actions, insufficient\_data\_actions, and ok\_actions must be lists of string. If the passed-in value is a string, it will be split on "," to produce a list. The strings themselves for alarm\_actions, insufficient\_data\_actions, and ok\_actions must be Amazon resource names (ARN's); however, this method also supports an arn lookup notation, as follows:

```
arn:aws:... ARN as per http://docs.aws.amazon.com/general/latest/gr/aws-arns-and-
namespaces.html scaling_policy:<as_name>:<scaling_policy_name> The named autoscale
group scaling policy, for the named group (e.g. scaling_policy:my-asg:ScaleDown)
```

This is convenient for setting up autoscaling as follows. First specify a boto\_asg.present state for an ASG with scaling\_policies, and then set up boto\_cloudwatch\_alarm.present states which have alarm\_actions that reference the scaling\_policy.

CLI example:

```
salt myminion boto_cloudwatch.create_alarm name=myalarm ... region=us-east-1
```

```
salt.modules.boto_cloudwatch.delete_alarm(name, region=None, key=None, keyid=None, pro-
                                             file=None)
```

Delete a cloudwatch alarm

CLI example to delete a queue:

```
salt myminion boto_cloudwatch.delete_alarm myalarm region=us-east-1
```

`salt.modules.boto_cloudwatch.get_alarm`(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Get alarm details. Also can be used to check to see if an alarm exists.

CLI example:

```
salt myminion boto_cloudwatch.get_alarm myalarm region=us-east-1
```

`salt.modules.boto_cloudwatch.get_all_alarms`(*region=None*, *prefix=None*, *key=None*, *keyid=None*, *profile=None*)

Get all alarm details. Produces results that can be used to create an sls file.

If prefix parameter is given, alarm names in the output will be prepended with the prefix; alarms that have the prefix will be skipped. This can be used to convert existing alarms to be managed by salt, as follows:

1. **Make a ``backup'' of all existing alarms** \$ salt-call boto\_cloudwatch.get\_all\_alarms --out=txt | sed ``s/local: //" > legacy\_alarms.sls
2. **Get all alarms with new prefixed names** \$ salt-call boto\_cloudwatch.get\_all\_alarms ``prefix=\*\*MANAGED BY SALT\*\*" --out=txt | sed ``s/local: //" > managed\_alarms.sls
3. **Insert the managed alarms into cloudwatch** \$ salt-call state.template managed\_alarms.sls
4. Manually verify that the new alarms look right
5. Delete the original alarms \$ sed s/present/absent/ legacy\_alarms.sls > remove\_legacy\_alarms.sls \$ salt-call state.template remove\_legacy\_alarms.sls
6. Get all alarms again, verify no changes \$ salt-call boto\_cloudwatch.get\_all\_alarms --out=txt | sed ``s/local: //" > final\_alarms.sls \$ diff final\_alarms.sls managed\_alarms.sls

CLI example:

```
salt myminion boto_cloudwatch.get_all_alarms region=us-east-1 --out=txt
```

### 30.16.16 salt.modules.boto\_dynamodb

Connection module for Amazon DynamoDB

New in version 2015.5.0.

**configuration** This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdfklkfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklkdflkgjsdfjajkghs
  region: us-east-1
```

**depends** boto

`salt.modules.boto_dynamodb.create_table`(*table\_name*, *region=None*, *key=None*, *keyid=None*, *profile=None*, *read\_capacity\_units=None*, *write\_capacity\_units=None*, *hash\_key=None*, *hash\_key\_data\_type=None*, *range\_key=None*, *range\_key\_data\_type=None*, *local\_indexes=None*, *global\_indexes=None*)

Creates a DynamoDB table.

CLI example:

```
salt myminion boto_dynamodb.create_table table_name /
region=us-east-1 /
hash_key=id /
hash_key_data_type=N /
range_key=created_at /
range_key_data_type=N /
read_capacity_units=1 /
write_capacity_units=1
```

`salt.modules.boto_dynamodb.delete`(*table\_name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Delete a DynamoDB table.

CLI example:

```
salt myminion boto_dynamodb.delete table_name region=us-east-1
```

`salt.modules.boto_dynamodb.exists`(*table\_name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Check to see if a table exists.

CLI example:

```
salt myminion boto_dynamodb.exists table_name region=us-east-1
```

### 30.16.17 salt.modules.boto\_elasticache

Connection module for Amazon Elasticache

New in version 2014.7.0.

**configuration** This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkghWupUjasdfklkfjgjsdfjajkghs
```

A region may also be specified in the configuration:

```
elasticache.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkghWupUjasdfkl-
          fklgjsdfjajkghs region: us-east-1
```

depends boto

```
salt.modules.boto_elasticache.authorize_cache_security_group_ingress(name,
                                                                    ec2_security_group_name,
                                                                    ec2_security_group_owner_id,
                                                                    re-
                                                                    gion=None,
                                                                    key=None,
                                                                    keyid=None,
                                                                    pro-
                                                                    file=None)
```

Authorize network ingress from an ec2 security group to a cache security group.

CLI example:

```
salt myminion boto_elasticache.authorize_cache_security_group_ingress myelasticachesg myec2sg 87
```

```
salt.modules.boto_elasticache.create(name, num_cache_nodes, engine, cache_node_type,
                                     replication_group_id=None, engine_version=None,
                                     cache_parameter_group_name=None,
                                     cache_subnet_group_name=None,
                                     cache_security_group_names=None, security_group_ids=None, snapshot_arns=None,
                                     preferred_availability_zone=None, preferred_maintenance_window=None,
                                     port=None, notification_topic_arn=None,
                                     auto_minor_version_upgrade=True, wait=False, re-
                                     gion=None, key=None, keyid=None, profile=None)
```

Create a cache cluster.

CLI example:

```
salt myminion boto_elasticache.create myelasticache 1 redis cache.t1.micro cache_security_group_
```

```
salt.modules.boto_elasticache.create_cache_security_group(name, description, re-
                                                         gion=None, key=None,
                                                         keyid=None, pro-
                                                         file=None)
```

Create a cache security group.

CLI example:

```
salt myminion boto_elasticache.create_cache_security_group myelasticachesg 'My Cache Security Gr
```

`salt.modules.boto_elasticache.delete`(*name*, *wait=False*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Delete a cache cluster.

CLI example:

```
salt myminion boto_elasticache.delete myelasticache
```

`salt.modules.boto_elasticache.delete_cache_security_group`(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Delete a cache security group.

CLI example:

```
salt myminion boto_elasticache.delete_cache_security_group myelasticachesg 'My Cache Security Gr
```

`salt.modules.boto_elasticache.exists`(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Check to see if a cache cluster exists.

CLI example:

```
salt myminion boto_elasticache.exists myelasticache
```

`salt.modules.boto_elasticache.get_cache_subnet_group`(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Get information about a cache subnet group.

CLI example:

```
salt myminion boto_elasticache.get_cache_subnet_group mycache_subnet_group
```

`salt.modules.boto_elasticache.get_config`(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Get the configuration for a cache cluster.

CLI example:

```
salt myminion boto_elasticache.get_config myelasticache
```

`salt.modules.boto_elasticache.revoke_cache_security_group_ingress`(*name*, *ec2\_security\_group\_name*, *ec2\_security\_group\_owner\_id*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Revoke network ingress from an ec2 security group to a cache security group.

CLI example:

```
salt myminion boto_elasticache.revoke_cache_security_group_ingress myelasticachesg myec2sg 87987
```

### 30.16.18 salt.modules.boto\_elb

Connection module for Amazon ELB

New in version 2014.7.0.

**configuration** This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdfklkfjkgjsdfjakghs
```

A region may also be specified in the configuration:

```
elb.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkghWupUjasdfkl-
          fklgjsdfjakghs region: us-east-1
```

**depends** boto

**salt.modules.boto\_elb.attach\_subnets**(*name, subnets, region=None, key=None, keyid=None, profile=None*)

Attach ELB to subnets.

CLI example:

```
salt myminion boto_elb.attach_subnets myelb '["mysubnet"]'
```

**salt.modules.boto\_elb.create**(*name, availability\_zones, listeners=None, subnets=None, security\_groups=None, scheme='internet-facing', region=None, key=None, keyid=None, profile=None*)

Create an ELB

CLI example to create an ELB:

```
salt myminion boto_elb.create myelb '["us-east-1a", "us-east-1e"]' listeners='[["HTTPS", "HTTP",
```

**salt.modules.boto\_elb.create\_listeners**(*name, listeners=None, region=None, key=None, keyid=None, profile=None*)

Create listeners on an ELB.

CLI example:

```
salt myminion boto_elb.create_listeners myelb listeners='[["HTTPS", "HTTP", 443, 80], "arn:aws:iam:
```

**salt.modules.boto\_elb.delete**(*name, region=None, key=None, keyid=None, profile=None*)

Delete an ELB.

CLI example to delete an ELB:

```
salt myminion boto_elb.delete myelb region=us-east-1
```

**salt.modules.boto\_elb.delete\_listeners**(*name, ports, region=None, key=None, keyid=None, profile=None*)

Delete listeners on an ELB.

CLI example:

```
salt myminion boto_elb.delete_listeners myelb '[80,443]'
```

**salt.modules.boto\_elb.deregister\_instances**(*name*, *instances*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Deregister instances with an ELB. Instances is either a string instance id or a list of string instance id's.

Returns:

- True: instance(s) deregistered successfully
- False: instance(s) failed to be deregistered
- None: instance(s) not valid or not registered, no action taken

CLI example:

```
salt myminion boto_elb.deregister_instances myelb instance_id
salt myminion boto_elb.deregister_instances myelb "[instance_id, instance_id]"
```

**salt.modules.boto\_elb.detach\_subnets**(*name*, *subnets*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Detach ELB from subnets.

CLI example:

```
salt myminion boto_elb.detach_subnets myelb '["mysubnet"]'
```

**salt.modules.boto\_elb.disable\_availability\_zones**(*name*, *availability\_zones*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Disable availability zones for ELB.

CLI example:

```
salt myminion boto_elb.disable_availability_zones myelb '["us-east-1a"]'
```

**salt.modules.boto\_elb.enable\_availability\_zones**(*name*, *availability\_zones*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Enable availability zones for ELB.

CLI example:

```
salt myminion boto_elb.enable_availability_zones myelb '["us-east-1a"]'
```

**salt.modules.boto\_elb.exists**(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Check to see if an ELB exists.

CLI example:

```
salt myminion boto_elb.exists myelb region=us-east-1
```

**salt.modules.boto\_elb.get\_attributes**(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Check to see if attributes are set on an ELB.

CLI example:

```
salt myminion boto_elb.get_attributes myelb
```

**salt.modules.boto\_elb.get\_elb\_config**(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Check to see if an ELB exists.

CLI example:

```
salt myminion boto_elb.exists myelb region=us-east-1
```

`salt.modules.boto_elb.get_health_check`(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Get the health check configured for this ELB.

CLI example:

```
salt myminion boto_elb.get_health_check myelb
```

`salt.modules.boto_elb.get_instance_health`(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*, *instances=None*)

Get a list of instances and their health state

CLI example:

```
salt myminion boto_elb.get_instance_health myelb
salt myminion boto_elb.get_instance_health myelb region=us-east-1 instances="[instance_id,instance_id]"
```

`salt.modules.boto_elb.register_instances`(*name*, *instances*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Register instances with an ELB. Instances is either a string instance id or a list of string instance id's.

Returns:

- True: instance(s) registered successfully
- False: instance(s) failed to be registered

CLI example:

```
salt myminion boto_elb.register_instances myelb instance_id
salt myminion boto_elb.register_instances myelb "[instance_id,instance_id]"
```

`salt.modules.boto_elb.set_attributes`(*name*, *attributes*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Set attributes on an ELB.

CLI example to set attributes on an ELB:

```
salt myminion boto_elb.set_attributes myelb '{"access_log": {"enabled": "true", "s3_bucket_name": "mybucket"}}
```

`salt.modules.boto_elb.set_health_check`(*name*, *health\_check*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Set attributes on an ELB.

CLI example to set attributes on an ELB:

```
salt myminion boto_elb.set_health_check myelb '{"target": "HTTP:80/"}'
```

### 30.16.19 salt.modules.boto\_iam

Connection module for Amazon IAM

New in version 2014.7.0.

**configuration** This module accepts explicit iam credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjkgHWupUjasdfklkdfklgjsdfjajkghs
iam.region: us-east-1
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkgHWupUjasdfklk-
              fklgjsdfjajkghs region: us-east-1
```

**depends** boto

**salt.modules.boto\_iam.associate\_profile\_to\_role**(*profile\_name*, *role\_name*, *region=None*,  
*key=None*, *keyid=None*, *profile=None*)

Associate an instance profile with an IAM role.

CLI example:

```
salt myminion boto_iam.associate_profile_to_role myirole myprofile
```

**salt.modules.boto\_iam.create\_instance\_profile**(*name*, *region=None*, *key=None*,  
*keyid=None*, *profile=None*)

Create an instance profile.

CLI example:

```
salt myminion boto_iam.create_instance_profile myprofile
```

**salt.modules.boto\_iam.create\_role**(*name*, *policy\_document=None*, *path=None*, *region=None*,  
*key=None*, *keyid=None*, *profile=None*)

Create an instance role.

CLI example:

```
salt myminion boto_iam.create_role myrole
```

**salt.modules.boto\_iam.create\_role\_policy**(*role\_name*, *policy\_name*, *policy*, *region=None*,  
*key=None*, *keyid=None*, *profile=None*)

Create or modify a role policy.

CLI example:

```
salt myminion boto_iam.create_role_policy myirole mypolicy '{"MyPolicy": "Statement": [{"Action":
```

**salt.modules.boto\_iam.delete\_instance\_profile**(*name*, *region=None*, *key=None*,  
*keyid=None*, *profile=None*)

Delete an instance profile.

CLI example:

```
salt myminion boto_iam.delete_instance_profile myprofile
```

**salt.modules.boto\_iam.delete\_role**(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Delete an IAM role.

CLI example:

```
salt myminion boto_iam.delete_role myirole
```

`salt.modules.boto_iam.delete_role_policy`(*role\_name*, *policy\_name*, *region=None*, *key=None*,  
*keyid=None*, *profile=None*)

Delete a role policy.

CLI example:

```
salt myminion boto_iam.delete_role_policy myirole mypolicy
```

`salt.modules.boto_iam.disassociate_profile_from_role`(*profile\_name*, *role\_name*,  
*region=None*, *key=None*,  
*keyid=None*, *profile=None*)

Disassociate an instance profile from an IAM role.

CLI example:

```
salt myminion boto_iam.disassociate_profile_from_role myirole myprofile
```

`salt.modules.boto_iam.get_account_id`(*region=None*, *key=None*, *keyid=None*, *profile=None*)

Get a the AWS account id associated with the used credentials.

CLI example:

```
salt myminion boto_iam.get_account_id
```

`salt.modules.boto_iam.get_role_policy`(*role\_name*, *policy\_name*, *region=None*, *key=None*,  
*keyid=None*, *profile=None*)

Get a role policy.

CLI example:

```
salt myminion boto_iam.get_role_policy myirole mypolicy
```

`salt.modules.boto_iam.instance_profile_exists`(*name*, *region=None*, *key=None*,  
*keyid=None*, *profile=None*)

Check to see if an instance profile exists.

CLI example:

```
salt myminion boto_iam.instance_profile_exists myprofile
```

`salt.modules.boto_iam.list_role_policies`(*role\_name*, *region=None*, *key=None*, *keyid=None*,  
*profile=None*)

Get a list of policy names from a role.

CLI example:

```
salt myminion boto_iam.list_role_policies myirole
```

`salt.modules.boto_iam.profile_associated`(*role\_name*, *profile\_name*, *region*, *key*, *keyid*, *profile*)

Check to see if an instance profile is associated with an IAM role.

CLI example:

```
salt myminion boto_iam.profile_associated myirole myprofile
```

`salt.modules.boto_iam.role_exists`(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Check to see if an IAM role exists.

CLI example:

```
salt myminion boto_iam.role_exists myirole
```

### 30.16.20 salt.modules.boto\_route53

Connection module for Amazon Route53

New in version 2014.7.0.

**configuration** This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdfklkfjkgjsdfjajkgghs
```

A region may also be specified in the configuration:

```
route53.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkghWupUjasdfklk-
            fklgjsdfjajkgghs region: us-east-1
```

**depends** boto

```
salt.modules.boto_route53.add_record(name, value, zone, record_type, identifier=None,
                                     ttl=None, region=None, key=None, keyid=None, profile=None, sync_wait=False)
```

Add a record to a zone.

CLI example:

```
salt myminion boto_route53.add_record test.example.org 1.1.1.1 example.org A
```

```
salt.modules.boto_route53.delete_record(name, zone, record_type, identifier=None,
                                         all_records=False, region=None, key=None,
                                         keyid=None, profile=None, sync_wait=False)
```

Modify a record in a zone.

CLI example:

```
salt myminion boto_route53.delete_record test.example.org example.org A
```

```
salt.modules.boto_route53.get_record(name, zone, record_type, fetch_all=False, region=None,
                                       key=None, keyid=None, profile=None)
```

Get a record from a zone.

CLI example:

```
salt myminion boto_route53.get_record test.example.org example.org A
```

`salt.modules.boto_route53.update_record`(*name, value, zone, record\_type, identifier=None, ttl=None, region=None, key=None, keyid=None, profile=None, sync\_wait=False*)

Modify a record in a zone.

CLI example:

```
salt myminion boto_route53.modify_record test.example.org 1.1.1.1 example.org A
```

### 30.16.21 salt.modules.boto\_secgroup

Connection module for Amazon Security Groups

New in version 2014.7.0.

**configuration** This module accepts explicit ec2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
secgroup.keyid: GKTADJGHEIQSXMKKRBJ08H
secgroup.key: askdjghsdfjkghWupUjasdfkldfkldgjsdfjajkghs
```

A region may also be specified in the configuration:

```
secgroup.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkghWupUjasdfkld-
           fklgjsdfjajkghs region: us-east-1
```

**depends** boto

`salt.modules.boto_secgroup.authorize`(*name=None, source\_group\_name=None, source\_group\_owner\_id=None, ip\_protocol=None, from\_port=None, to\_port=None, cidr\_ip=None, group\_id=None, source\_group\_group\_id=None, region=None, key=None, keyid=None, profile=None, vpc\_id=None*)

Add a new rule to an existing security group.

CLI example:

```
salt myminion boto_secgroup.authorize mysecgroup ip_protocol=tcp from_port=80 to_port=80 cidr_ip=
```

`salt.modules.boto_secgroup.convert_to_group_ids`(*groups, vpc\_id, region=None, key=None, keyid=None, profile=None*)

Given a list of security groups and a vpc\_id, `convert_to_group_ids` will convert all list items in the given list to security group ids.

CLI example:

```
salt myminion boto_secgroup.convert_to_group_ids mysecgroup vpc-89yhh7h
```

`salt.modules.boto_secgroup.create`(*name*, *description*, *vpc\_id=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Create an autoscale group.

CLI example:

```
salt myminion boto_secgroup.create mysecgroup 'My Security Group'
```

`salt.modules.boto_secgroup.delete`(*name=None*, *group\_id=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*, *vpc\_id=None*)

Delete an autoscale group.

CLI example:

```
salt myminion boto_secgroup.delete mysecgroup
```

`salt.modules.boto_secgroup.exists`(*name=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*, *vpc\_id=None*, *group\_id=None*)

Check to see if a security group exists.

CLI example:

```
salt myminion boto_secgroup.exists mysecgroup
```

`salt.modules.boto_secgroup.get_config`(*name=None*, *group\_id=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*, *vpc\_id=None*)

Get the configuration for a security group.

CLI example:

```
salt myminion boto_secgroup.get_config mysecgroup
```

`salt.modules.boto_secgroup.get_group_id`(*name*, *vpc\_id=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Get a Group ID given a Group Name or Group Name and VPC ID

CLI example:

```
salt myminion boto_secgroup.get_group_id mysecgroup
```

`salt.modules.boto_secgroup.revoke`(*name=None*, *source\_group\_name=None*, *source\_group\_owner\_id=None*, *ip\_protocol=None*, *from\_port=None*, *to\_port=None*, *cidr\_ip=None*, *group\_id=None*, *source\_group\_group\_id=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*, *vpc\_id=None*)

Remove a rule from an existing security group.

CLI example:

```
salt myminion boto_secgroup.revoke mysecgroup ip_protocol=tcp from_port=80 to_port=80 cidr_ip='1
```

### 30.16.22 salt.modules.boto\_sns

Connection module for Amazon SNS

**configuration** This module accepts explicit sns credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkghWupUjasdfklkdflkjlsdfjajkghs
```

A region may also be specified in the configuration:

```
sns.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkghWupUjasdfkl-
          fkljlsdfjajkghs region: us-east-1
```

**depends** boto

**salt.modules.boto\_sns.create**(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)  
Create an SNS topic.

CLI example to create a topic:

```
salt myminion boto_sns.create mytopic region=us-east-1
```

**salt.modules.boto\_sns.delete**(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)  
Delete an SNS topic.

CLI example to delete a topic:

```
salt myminion boto_sns.delete mytopic region=us-east-1
```

**salt.modules.boto\_sns.exists**(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)  
Check to see if an SNS topic exists.

CLI example:

```
salt myminion boto_sns.exists mytopic region=us-east-1
```

**salt.modules.boto\_sns.get\_all\_topics**(*region=None*, *key=None*, *keyid=None*, *profile=None*)  
Returns a list of the all topics..

CLI example:

```
salt myminion boto_sns.get_all_topics
```

**salt.modules.boto\_sns.get\_arn**(*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)  
Returns the full ARN for a given topic name.

CLI example:

```
salt myminion boto_sns.get_arn mytopic
```

### 30.16.23 salt.modules.boto\_sqs

Connection module for Amazon SQS

New in version 2014.7.0.

**configuration** This module accepts explicit sqs credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdfklkfjkgjsdfjajkgghs
```

A region may also be specified in the configuration:

```
sqs.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkghWupUjasdfklkdfklgjsdfjajkgghs region: us-east-1
```

**depends** boto

`salt.modules.boto_sqs.create` (*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)  
Create an SQS queue.

CLI example to create a queue:

```
salt myminion boto_sqs.create myqueue region=us-east-1
```

`salt.modules.boto_sqs.delete` (*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)  
Delete an SQS queue.

CLI example to delete a queue:

```
salt myminion boto_sqs.delete myqueue region=us-east-1
```

`salt.modules.boto_sqs.exists` (*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)  
Check to see if a queue exists.

CLI example:

```
salt myminion boto_sqs.exists myqueue region=us-east-1
```

`salt.modules.boto_sqs.get_attributes` (*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)  
Check to see if attributes are set on an SQS queue.

CLI example:

```
salt myminion boto_sqs.get_attributes myqueue
```

`salt.modules.boto_sqs.set_attributes` (*name*, *attributes*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Set attributes on an SQS queue.

CLI example to set attributes on a queue:

```
salt myminion boto_sqs.set_attributes myqueue '{ReceiveMessageWaitTimeSeconds: 20}' region=us-east-1
```

### 30.16.24 salt.modules.boto\_vpc

Connection module for Amazon VPC

New in version 2014.7.0.

**configuration** This module accepts explicit VPC credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdfklkfjgjsdfjajkgghs
```

A region may also be specified in the configuration:

```
vpc.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkghWupUjasdfklk-
              fklgjsdfjajkgghs region: us-east-1
```

**depends** boto

```
salt.modules.boto_vpc.associate_dhcp_options_to_vpc(dhcp_options_id, vpc_id,
                                                    region=None, key=None,
                                                    keyid=None, profile=None)
```

Given valid DHCP options id and a valid VPC id, associate the DHCP options record with the VPC.

Returns True if the DHCP options record were associated and returns False if the DHCP options record was not associated.

CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.associate_dhcp_options_to_vpc `dhcp-a0bl34pp` `vpc-6b1fe402`
```

```
salt.modules.boto_vpc.associate_network_acl_to_subnet(network_acl_id, subnet_id,
                                                    region=None, key=None,
                                                    keyid=None, profile=None)
```

Given a network acl ID and a subnet ID, associates a network acl to a subnet.

Returns the association ID if successful, otherwise returns False.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.associate_network_acl_to_subnet `acl-5fb85d36` `subnet-6a1fe403`
```

```
salt.modules.boto_vpc.associate_new_dhcp_options_to_vpc(vpc_id, do-
                                                    main_name=None, do-
                                                    main_name_servers=None,
                                                    ntp_servers=None, net-
                                                    bios_name_servers=None,
                                                    netbios_node_type=None,
                                                    region=None, key=None,
                                                    keyid=None, profile=None)
```

Given valid DHCP options and a valid VPC id, create and associate the DHCP options record with the VPC.

Returns True if the DHCP options record were created and associated and returns False if the DHCP options record was not created and associated.

CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.associate_new_dhcp_options_to_vpc `vpc-6b1fe402` do-
main_name='example.com' domain_name_servers='[1.2.3.4]' ntp_servers='[5.6.7.8]' net-
bios_name_servers='[10.0.0.1]' netbios_node_type=1
```

```
salt.modules.boto_vpc.associate_new_network_acl_to_subnet(vpc_id, subnet_id, net-
                                                    work_acl_name=None,
                                                    tags=None, re-
                                                    gion=None, key=None,
                                                    keyid=None, pro-
                                                    file=None)
```

Given a vpc ID and a subnet ID, associates a new network act to a subnet.

Returns a dictionary containing the network acl id and the new association id if successful. If unsuccessful, returns False.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.associate_new_network_acl_to_subnet `vpc-6b1fe402` `subnet-6a1fe403`
```

```
salt.modules.boto_vpc.associate_route_table(route_table_id, subnet_id, region=None,
                                                    key=None, keyid=None, profile=None)
```

Given a route table ID and a subnet ID, associates the route table with the subnet.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.associate_route_table `rtb-1f382e7d` `subnet-6a1fe403`
```

```
salt.modules.boto_vpc.create(cidr_block, instance_tenancy=None, vpc_name=None, tags=None, re-
                                                    gion=None, key=None, keyid=None, profile=None)
```

Given a valid CIDR block, create a VPC.

An optional `instance_tenancy` argument can be provided. If provided, the valid values are ``default`` or ``dedicated``. An optional `vpc_name` argument can be provided.

Returns True if the VPC was created and returns False if the VPC was not created.

CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.create `10.0.0.0/24`
```

```
salt.modules.boto_vpc.create_customer_gateway(vpn_connection_type, ip_address,  
                                              bgp_asn, customer_gateway_name=None,  
                                              tags=None, region=None, key=None,  
                                              keyid=None, profile=None)
```

Given a valid VPN connection type, a static IP address and a customer gateway's Border Gateway Protocol (BGP) Autonomous System Number, create a customer gateway.

Returns True if the customer gateway was created and returns False if the customer gateway was not created.

CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.create_customer_gateway `ipsec.1`, `12.1.2.3`, 65534
```

```
salt.modules.boto_vpc.create_dhcp_options(domain_name=None, do-  
                                         main_name_servers=None, ntp_servers=None,  
                                         netbios_name_servers=None,  
                                         netbios_node_type=None,  
                                         dhcp_options_name=None, tags=None, re-  
                                         gion=None, key=None, keyid=None, pro-  
                                         file=None)
```

Given valid DHCP options, create a DHCP options record.

Returns True if the DHCP options record was created and returns False if the DHCP options record was not deleted.

CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.create_dhcp_options domain_name='example.com' do-  
main_name_servers='[1.2.3.4]' ntp_servers='[5.6.7.8]' netbios_name_servers='[10.0.0.1]' net-  
bios_node_type=1
```

```
salt.modules.boto_vpc.create_network_acl(vpc_id, network_acl_name=None, tags=None, re-  
                                         gion=None, key=None, keyid=None, profile=None)
```

Given a vpc\_id, creates a network acl.

Returns the network acl id if successful, otherwise returns False.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.create_network_acl `vpc-6b1fe402`
```

```
salt.modules.boto_vpc.create_network_acl_entry(network_acl_id, rule_number, protocol,  
                                              rule_action, cidr_block, egress=None,  
                                              icmp_code=None, icmp_type=None,  
                                              port_range_from=None,  
                                              port_range_to=None, region=None,  
                                              key=None, keyid=None, profile=None)
```

Creates a network acl entry.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.create_network_acl_entry `acl-5fb85d36' `32767' `-1' `deny' `0.0.0.0/0'
```

```
salt.modules.boto_vpc.create_route(route_table_id, destination_cidr_block, gateway_id=None,
instance_id=None, interface_id=None, region=None,
key=None, keyid=None, profile=None)
```

Creates a route.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.create_route `rtb-1f382e7d' `10.0.0.0/16'
```

```
salt.modules.boto_vpc.create_route_table(vpc_id, route_table_name=None, tags=None, re-
gion=None, key=None, keyid=None, profile=None)
```

Creates a route table.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.create_route_table `vpc-6b1fe402'
```

```
salt.modules.boto_vpc.create_subnet(vpc_id, cidr_block, availability_zone=None, sub-
net_name=None, tags=None, region=None, key=None,
keyid=None, profile=None)
```

Given a valid VPC ID and a CIDR block, create a subnet for the VPC.

An optional availability zone argument can be provided.

Returns True if the VPC subnet was created and returns False if the VPC subnet was not created.

CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.create_subnet `vpc-6b1fe402' `10.0.0.0/25'
```

```
salt.modules.boto_vpc.customer_gateway_exists(customer_gateway_id, region=None,
key=None, keyid=None, profile=None)
```

Given a customer gateway ID, check if the customer gateway ID exists.

Returns True if the customer gateway ID exists; Returns False otherwise.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.customer_gateway_exists `cgw-b6a247df'
```

```
salt.modules.boto_vpc.delete(vpc_id, region=None, key=None, keyid=None, profile=None)
```

Given a VPC ID, delete the VPC.

Returns True if the VPC was deleted and returns False if the VPC was not deleted.

CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.delete `vpc-6b1fe402'
```

```
salt.modules.boto_vpc.delete_customer_gateway(customer_gateway_id, region=None,  
key=None, keyid=None, profile=None)
```

Given a customer gateway ID, delete the customer gateway.

Returns True if the customer gateway was deleted and returns False if the customer gateway was not deleted.

CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.delete_customer_gateway `cgw-b6a247df'
```

```
salt.modules.boto_vpc.delete_network_acl(network_acl_id, region=None, key=None,  
keyid=None, profile=None)
```

Deletes a network acl based on the network\_acl\_id provided.

Returns True if the network acl was deleted successfully, otherwise returns False.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.delete_network_acl `acl-5fb85d36'
```

```
salt.modules.boto_vpc.delete_network_acl_entry(network_acl_id, rule_number,  
egress=None, region=None, key=None,  
keyid=None, profile=None)
```

Deletes a network acl entry.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.delete_network_acl_entry `acl-5fb85d36' `32767'
```

```
salt.modules.boto_vpc.delete_route(route_table_id, destination_cidr_block, region=None,  
key=None, keyid=None, profile=None)
```

Deletes a route.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.delete_route `rtb-1f382e7d' `10.0.0.0/16'
```

```
salt.modules.boto_vpc.delete_route_table(route_table_id, region=None, key=None,  
keyid=None, profile=None)
```

Deletes a route table.

CLI Example:

```
.. code-example:: bash
```

```
salt myminion boto_vpc.delete_route_table `rtb-1f382e7d`
```

```
salt.modules.boto_vpc.delete_subnet(subnet_id, region=None, key=None, keyid=None, profile=None)
```

Given a subnet ID, delete the subnet.

Returns True if the subnet was deleted and returns False if the subnet was not deleted.

CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.delete_subnet `subnet-6a1fe403`
```

```
salt.modules.boto_vpc.describe(vpc_id=None, region=None, key=None, keyid=None, profile=None)
```

Given a VPC ID describe it's properties.

Returns a dictionary of interesting properties. CLI example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.describe vpc_id=vpc-123456
```

```
salt.modules.boto_vpc.dhcp_options_exists(dhcp_options_id=None, name=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Check if a dhcp option exists.

Returns True if the dhcp option exists; Returns False otherwise.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.dhcp_options_exists dhcp_options_id='dhcp-a0bl34pp'
```

```
salt.modules.boto_vpc.disassociate_network_acl(subnet_id, vpc_id=None, region=None, key=None, keyid=None, profile=None)
```

Given a subnet ID, disassociates a network acl.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.disassociate_network_acl `subnet-6a1fe403`
```

```
salt.modules.boto_vpc.disassociate_route_table(association_id, region=None, key=None, keyid=None, profile=None)
```

Dissociates a route table.

**association\_id** The Route Table Association ID to disassociate

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.disassociate_route_table `rtbassoc-d8ccddbba`
```

`salt.modules.boto_vpc.exists`(*vpc\_id=None, name=None, cidr=None, tags=None, region=None, key=None, keyid=None, profile=None*)

Given a VPC ID, check to see if the given VPC ID exists.

Returns True if the given VPC ID exists and returns False if the given VPC ID does not exist.

CLI example:

```
.. code-block:: bash
```

```
    salt myminion boto_vpc.exists myvpc
```

`salt.modules.boto_vpc.get_id`(*name=None, cidr=None, tags=None, region=None, key=None, keyid=None, profile=None*)

Given a VPC properties, return VPC ID if exist.

CLI example:

```
.. code-block:: bash
```

```
    salt myminion boto_vpc.get_id myvpc
```

`salt.modules.boto_vpc.get_subnet_association`(*subnets, region=None, key=None, keyid=None, profile=None*)

Given a subnet (aka: a vpc zone identifier) or list of subnets, returns vpc association.

Returns a VPC ID if the given subnets are associated with the same VPC ID. Returns False on an error or if the given subnets are associated with different VPC IDs.

CLI Examples:

```
.. code-block:: bash
```

```
    salt myminion boto_vpc.get_subnet_association subnet-61b47516
```

```
    salt myminion boto_vpc.get_subnet_association ['subnet-61b47516', 'subnet-2cb9785b']
```

`salt.modules.boto_vpc.network_acl_exists`(*network\_acl\_id=None, name=None, tags=None, region=None, key=None, keyid=None, profile=None*)

Checks if a network acl exists.

Returns True if the network acl exists or returns False if it doesn't exist.

CLI Example:

```
.. code-block:: bash
```

```
    salt myminion boto_vpc.network_acl_exists network_acl_id='acl-5fb85d36'
```

`salt.modules.boto_vpc.replace_network_acl_entry`(*network\_acl\_id, rule\_number, protocol, rule\_action, cidr\_block, egress=None, icmp\_code=None, icmp\_type=None, port\_range\_from=None, port\_range\_to=None, region=None, key=None, keyid=None, profile=None*)

Replaces a network acl entry.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.replace_network_acl_entry `acl-5fb85d36' `32767' `-1' `deny' `0.0.0.0/0'
```

```
salt.modules.boto_vpc.replace_route(route_table_id, destination_cidr_block, gateway_id=None,
                                     instance_id=None, interface_id=None, region=None,
                                     key=None, keyid=None, profile=None)
```

Replaces a route.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.replace_route `rtb-1f382e7d' `10.0.0.0/16'
```

```
salt.modules.boto_vpc.replace_route_table_association(association_id, route_table_id,
                                                         region=None, key=None,
                                                         keyid=None, profile=None)
```

Replaces a route table association.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.replace_route_table_association `rtbassoc-d8ccddbba' `rtb-1f382e7d'
```

```
salt.modules.boto_vpc.route_table_exists(route_table_id=None, name=None, tags=None, re-
                                           gion=None, key=None, keyid=None, profile=None)
```

Checks if a route table exists.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.route_table_exists route_table_id='rtb-1f382e7d'
```

```
salt.modules.boto_vpc.subnet_exists(subnet_id=None, name=None, tags=None, region=None,
                                       key=None, keyid=None, profile=None)
```

Check if a subnet exists.

Returns True if the subnet exists, otherwise returns False.

CLI Example:

```
.. code-block:: bash
```

```
salt myminion boto_vpc.subnet_exists subnet_id='subnet-6a1fe403'
```

### 30.16.25 salt.modules.brew

Homebrew for Mac OS X

---

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to ``pkg.install' is not available`), see [here](#).

---

`salt.modules.brew.install`(*name=None, pkgs=None, taps=None, options=None, \*\*kwargs*)

Install the passed package(s) with brew install

**name** The name of the formula to be installed. Note that this parameter is ignored if ``pkgs`` is passed.

CLI Example:

```
salt '*' pkg.install <package name>
```

**taps** Unofficial Github repos to use when updating and installing formulas.

CLI Example:

```
salt '*' pkg.install <package name> tap='<tap>'
salt '*' pkg.install zlib taps='homebrew/dupes'
salt '*' pkg.install php54 taps='["josegonzalez/php", "homebrew/dupes"]'
```

**options** Options to pass to brew. Only applies to initial install. Due to how brew works, modifying chosen options requires a full uninstall followed by a fresh install. Note that if ``pkgs`` is used, all options will be passed to all packages. Unrecognized options for a package will be silently ignored by brew.

CLI Example:

```
salt '*' pkg.install <package name> tap='<tap>'
salt '*' pkg.install php54 taps='["josegonzalez/php", "homebrew/dupes"]' options='["--with-f
```

Multiple Package Installation Options:

**pkgs** A list of formulas to install. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs='["foo","bar"]'
```

Returns a dict containing the new package names and versions:

```
{<package>: {'old': '<old-version>',
             'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.install 'package package package'
```

`salt.modules.brew.latest_version`(*\*names, \*\*kwargs*)

Return the latest version of the named package available for upgrade or installation

Note that this currently not fully implemented but needs to return something to avoid a traceback when calling pkg.latest.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

`salt.modules.brew.list_pkgs`(*versions\_as\_list=False, \*\*kwargs*)

List the packages currently installed in a dict:

```
{<package_name>: '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

`salt.modules.brew.list_upgrades` (*refresh=True*)  
Check whether or not an upgrade is available for all packages

CLI Example:

```
salt '*' pkg.list_upgrades
```

`salt.modules.brew.refresh_db`()  
Update the homebrew package repository.

CLI Example:

```
salt '*' pkg.refresh_db
```

`salt.modules.brew.remove` (*name=None, pkgs=None, \*\*kwargs*)  
Removes packages with brew uninstall.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

`salt.modules.brew.upgrade` (*refresh=True*)  
Upgrade outdated, unpinned brews.

**refresh** Fetch the newest version of Homebrew and all formulae from GitHub before installing.

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

`salt.modules.brew.upgrade_available` (*pkg*)  
Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

`salt.modules.brew.version` (*\*names, \*\*kwargs*)  
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3>
```

### 30.16.26 salt.modules.bridge

Module for gathering and managing bridging information

**salt.modules.bridge.add**(*br=None*)  
Creates a bridge

CLI Example:

```
salt '*' bridge.add br0
```

**salt.modules.bridge.addif**(*br=None, iface=None*)  
Adds an interface to a bridge

CLI Example:

```
salt '*' bridge.addif br0 eth0
```

**salt.modules.bridge.delete**(*br=None*)  
Deletes a bridge

CLI Example:

```
salt '*' bridge.delete br0
```

**salt.modules.bridge.delif**(*br=None, iface=None*)  
Removes an interface from a bridge

CLI Example:

```
salt '*' bridge.delif br0 eth0
```

**salt.modules.bridge.find\_interfaces**(*\*args*)  
Returns the bridge to which the interfaces are bond to

CLI Example:

```
salt '*' bridge.find_interfaces eth0 [eth1...]
```

**salt.modules.bridge.interfaces**(*br=None*)  
Returns interfaces attached to a bridge

CLI Example:

```
salt '*' bridge.interfaces br0
```

**salt.modules.bridge.list\_**()  
Returns the machine's bridges list

CLI Example:

```
salt '*' bridge.list
```

**salt.modules.bridge.show**(*br=None*)  
Returns bridges interfaces along with enslaved physical interfaces. If no interface is given, all bridges are shown, else only the specified bridge values are returned.

CLI Example:

```
salt '*' bridge.show
salt '*' bridge.show br0
```

`salt.modules.bridge.stp`(*br=None, state='disable', iface=None*)

Sets Spanning Tree Protocol state for a bridge

CLI Example:

```
salt '*' bridge.stp br0 enable
salt '*' bridge.stp br0 disable
```

For BSD-like operating systems, it is required to add the interface on which to enable the STP.

CLI Example:

```
salt '*' bridge.stp bridge0 enable fxp0
salt '*' bridge.stp bridge0 disable fxp0
```

### 30.16.27 salt.modules.bsd\_shadow

Manage the password database on BSD systems

**Important:** If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `'shadow.info' is not available`), see [here](#).

`salt.modules.bsd_shadow.default_hash`()

Returns the default hash used for unset passwords

CLI Example:

```
salt '*' shadow.default_hash
```

`salt.modules.bsd_shadow.info`(*name*)

Return information for the specified user

CLI Example:

```
salt '*' shadow.info someuser
```

`salt.modules.bsd_shadow.set_change`(*name, change*)

Sets the time at which the password expires (in seconds since the EPOCH). See man usermod on NetBSD and OpenBSD or man pw on FreeBSD. ``0" means the password never expires.

CLI Example:

```
salt '*' shadow.set_change username 1419980400
```

`salt.modules.bsd_shadow.set_expire`(*name, expire*)

Sets the time at which the account expires (in seconds since the EPOCH). See man usermod on NetBSD and OpenBSD or man pw on FreeBSD. ``0" means the account never expires.

CLI Example:

```
salt '*' shadow.set_expire username 1419980400
```

`salt.modules.bsd_shadow.set_password`(*name, password*)

Set the password for a named user. The password must be a properly defined hash. The password hash can be generated with this command:

```
python -c "import crypt; print crypt.crypt('password', ciphersalt)"
```

NOTE: When constructing the `ciphersalt` string, you must escape any dollar signs, to avoid them being interpolated by the shell.

'password' is, of course, the password for which you want to generate a hash.

`ciphersalt` is a combination of a cipher identifier, an optional number of rounds, and the cryptographic salt. The arrangement and format of these fields depends on the cipher and which flavor of BSD you are using. For more information on this, see the manpage for `crypt(3)`. On NetBSD, additional information is available in `passwd.conf(5)`.

It is important to make sure that a supported cipher is used.

CLI Example:

```
salt '*' shadow.set_password someuser '$1$UYCIxa628.9qXjpQCjM4a..'
```

### 30.16.28 salt.modules.btrfs

Module for managing BTRFS file systems.

`salt.modules.btrfs.add`(*mountpoint*, *\*devices*, *\*\*kwargs*)

Add a devices to a BTRFS filesystem.

General options:

- nodiscard**: Do not perform whole device TRIM
- force**: Force overwrite existing filesystem on the disk

CLI Example:

```
salt '*' btrfs.add /mountpoint /dev/sda1 /dev/sda2
```

`salt.modules.btrfs.convert`(*device*, *permanent=False*, *keeplf=False*)

Convert ext2/3/4 to BTRFS. Device should be mounted.

Filesystem can be converted temporarily so the further processing and rollback is possible, or permanently, where previous extended filesystem image gets deleted. Please note, permanent conversion takes a while as BTRFS filesystem needs to be properly rebalanced afterwards.

General options:

- permanent**: Specify if the migration should be permanent (false by default)
- keeplf**: Keep **lost+found** of the partition (removed by default, but still in the image, if not permanent migration)

CLI Example:

```
salt '*' btrfs.convert /dev/sda1
salt '*' btrfs.convert /dev/sda1 permanent=True
```

`salt.modules.btrfs.defragment`(*path*)

Defragment mounted BTRFS filesystem. In order to defragment a filesystem, device should be properly mounted and writable.

If passed a device name, then defragmented whole filesystem, mounted on in. If passed a mount point of the filesystem, then only this mount point is defragmented.

CLI Example:

```
salt '*' btrfs.defragment /dev/sda1
salt '*' btrfs.defragment /path/on/filesystem
```

**salt.modules.btrfs.delete**(*mountpoint*, *\*devices*, *\*\*kwargs*)  
Remove devices from a BTRFS filesystem.

CLI Example:

```
salt '*' btrfs.delete /mountpoint /dev/sda1 /dev/sda2
```

**salt.modules.btrfs.devices**()  
Get known BTRFS formatted devices on the system.

CLI Example:

```
salt '*' btrfs.devices
```

**salt.modules.btrfs.features**()  
List currently available BTRFS features.

CLI Example:

```
salt '*' btrfs.mkfs_features
```

**salt.modules.btrfs.info**(*device*)  
Get BTRFS filesystem information.

CLI Example:

```
salt '*' btrfs.info /dev/sda1
```

**salt.modules.btrfs.mkfs**(*\*devices*, *\*\*kwargs*)  
Create a file system on the specified device. By default wipes out with force.

General options:

- allocsize**: Specify the BTRFS offset from the start of the device.
- bytecount**: Specify the size of the resultant filesystem.
- nodesize**: Node size.
- leafsize**: Specify the nodesize, the tree block size in which btrfs stores data.
- noforce**: Prevent force overwrite when an existing filesystem is detected on the device.
- sectorsize**: Specify the sectorsize, the minimum data block allocation unit.
- nodiscard**: Do not perform whole device TRIM operation by default.
- uuid**: Pass UUID or pass True to generate one.

Options:

- dto**: (**raid0|raid1|raid5|raid6|raid10|single|dup**) Specify how the data must be spanned across the devices specified.
- mtto**: (**raid0|raid1|raid5|raid6|raid10|single|dup**) Specify how metadata must be spanned across the devices specified.
- fts**: Features (call `salt <host> btrfs.features` for full list of available features)

See the `mkfs.btrfs(8)` manpage for a more complete description of corresponding options description.

CLI Example:

```
salt '*' btrfs.mkfs /dev/sda1
salt '*' btrfs.mkfs /dev/sda1 noforce=True
```

**salt.modules.btrfs.properties** (*obj*, *type=None*, *set=None*)

List properties for given btrfs object. The object can be path of BTRFS device, mount point, or any directories/files inside the BTRFS filesystem.

General options:

- type**: Possible types are s[ubvol], f[ilesystem], i[node] and d[evice].
- force**: Force overwrite existing filesystem on the disk
- set**: <key=value,key1=value1...> Options for a filesystem properties.

CLI Example:

```
salt '*' btrfs.properties /mountpoint
salt '*' btrfs.properties /dev/sda1 type=subvol set='ro=false,label="My Storage"'
```

**salt.modules.btrfs.resize** (*mountpoint*, *size*)

Resize filesystem.

General options:

- mountpoint**: Specify the BTRFS mountpoint to resize.
- size**: ([+/-]<newsize>[kKmMgGtTpPeE]|max) Specify the new size of the target.

CLI Example:

```
salt '*' btrfs.resize /mountpoint size=+1g
salt '*' btrfs.resize /dev/sda1 size=max
```

**salt.modules.btrfs.usage** (*path*)

Show in which disk the chunks are allocated.

CLI Example:

```
salt '*' btrfs.usage /your/mountpoint
```

**salt.modules.btrfs.version** ()

Return BTRFS version.

CLI Example:

```
salt '*' btrfs.version
```

### 30.16.29 salt.modules.cassandra

Cassandra NoSQL Database Module

**depends**

- pycassa Cassandra Python adapter

**configuration** The location of the `nodetool` command, host, and thrift port needs to be specified via pillar:

```
cassandra.nodetool: /usr/local/bin/nodetool
cassandra.host: localhost
cassandra.thrift_port: 9160
```

`salt.modules.cassandra.column_families` (*keyspace=None*)  
Return existing column families for all keyspaces or just the provided one.

CLI Example:

```
salt '*' cassandra.column_families
salt '*' cassandra.column_families <keyspace>
```

`salt.modules.cassandra.column_family_definition` (*keyspace=None, column\_family=None*)  
Return a dictionary of column family definitions for the given keyspace/column\_family

CLI Example:

```
salt '*' cassandra.column_family_definition <keyspace> <column_family>
```

`salt.modules.cassandra.compactionstats` ()  
Return compactionstats info

CLI Example:

```
salt '*' cassandra.compactionstats
```

`salt.modules.cassandra.info` ()  
Return cassandra node info

CLI Example:

```
salt '*' cassandra.info
```

`salt.modules.cassandra.keyspaces` ()  
Return existing keyspaces

CLI Example:

```
salt '*' cassandra.keyspaces
```

`salt.modules.cassandra.netstats` ()  
Return netstats info

CLI Example:

```
salt '*' cassandra.netstats
```

`salt.modules.cassandra.ring` ()  
Return cassandra ring info

CLI Example:

```
salt '*' cassandra.ring
```

`salt.modules.cassandra.tpstats` ()  
Return tpstats info

CLI Example:

```
salt '*' cassandra.tpstats
```

`salt.modules.cassandra.version` ()  
Return the cassandra version

CLI Example:

```
salt '*' cassandra.version
```

### 30.16.30 salt.modules.cassandra\_cql

Cassandra Database Module

New in version 2015.5.0.

**depends** DataStax Python Driver for Apache Cassandra <https://github.com/datastax/python-driver> pip  
install cassandra-driver

**referenced by** Salt's `cassandra_cql` returner

**configuration** The Cassandra cluster members and connection port can either be specified in the master or minion config, the minion's pillar or be passed to the module.

Example configuration in the config for a single node:

```
cassandra:
  cluster: 192.168.50.10
  port: 9000
```

Example configuration in the config for a cluster:

```
cassandra:
  cluster:
    - 192.168.50.10
    - 192.168.50.11
    - 192.168.50.12
  port: 9000
  username: cas_admin
```

`salt.modules.cassandra_cql.cql_query` (*query*, *contact\_points=None*, *port=None*, *cql\_user=None*,  
*cql\_pass=None*)

Run a query on a Cassandra cluster and return a dictionary.

#### Parameters

- **query** (*str*) -- The query to execute.
- **contact\_points** (*str* | *list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.
- **params** (*str*) -- The parameters for the query, optional.

**Returns** A dictionary from the return values of the query

**Return type** `list[dict]`

`salt.modules.cassandra_cql.create_keyspace` (*keyspace*, *replica-  
tion\_strategy='SimpleStrategy'*, *replica-  
tion\_factor=1*, *replication\_datacenters=None*,  
*contact\_points=None*, *port=None*,  
*cql\_user=None*, *cql\_pass=None*)

Create a new keyspace in Cassandra.

**Parameters**

- **keyspace** (*str*) -- The keyspace name
- **replication\_strategy** (*str*) -- either *SimpleStrategy* or *NetworkTopologyStrategy*
- **replication\_factor** (*int*) -- number of replicas of data on multiple nodes. not used if using *NetworkTopologyStrategy*
- **replication\_datacenters** (*str* | *dict[str, int]*) -- string or dict of data-center names to replication factors, required if using *NetworkTopologyStrategy* (will be a dict if coming from state file).
- **contact\_points** (*str* | *list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

**Returns** The info for the keyspace or False if it does not exist.

**Return type** dict

```
salt 'minion1' cassandra_cql.create_keyspace keyspace=newkeyspace
```

```
salt 'minion1' cassandra_cql.create_keyspace keyspace=newkeyspace replication_strategy=NetworkTo
```

```
salt.modules.cassandra_cql.create_user(username, password, superuser=False, contact_points=None, port=None, cql_user=None, cql_pass=None)
```

Create a new cassandra user with credentials and superuser status.

**Parameters**

- **username** (*str*) -- The name of the new user.
- **password** (*str*) -- The password of the new user.
- **superuser** (*bool*) -- Is the new user going to be a superuser? default: False
- **contact\_points** (*str* | *list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

**Returns**

**Return type**

```
salt 'minion1' cassandra_cql.create_user username=joe password=secret
```

```
salt 'minion1' cassandra_cql.create_user username=joe password=secret superuser=True
```

```
salt 'minion1' cassandra_cql.create_user username=joe password=secret superuser=True contact_po
```

```
salt.modules.cassandra_cql.drop_keyspace(keyspace, contact_points=None, port=None, cql_user=None, cql_pass=None)
```

Drop a keyspace if it exists in a Cassandra cluster.

**Parameters**

- **keyspace** (*str*) -- The keyspace to drop.
- **contact\_points** (*str* | *list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

**Returns** The info for the keyspace or False if it does not exist.

**Return type** `dict`

CLI Example:

```
salt 'minion1' cassandra_cql.drop_keyspace keyspace=test
salt 'minion1' cassandra_cql.drop_keyspace keyspace=test contact_points=minion1
```

```
salt.modules.cassandra_cql.grant_permission(username, resource=None, re-
                                         source_type='keyspace', permission=None,
                                         contact_points=None, port=None,
                                         cql_user=None, cql_pass=None)
```

Grant permissions to a user.

**Parameters**

- **username** (*str*) -- The name of the user to grant permissions to.
- **resource** (*str*) -- The resource (keyspace or table), if None, permissions for all resources are granted.
- **resource\_type** (*str*) -- The resource\_type (keyspace or table), defaults to `keyspace`.
- **permission** (*str*) -- A permission name (e.g. select), if None, all permissions are granted.
- **contact\_points** (*str* | *list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

**Returns**

**Return type**

```
salt 'minion1' cassandra_cql.grant_permission
salt 'minion1' cassandra_cql.grant_permission username=joe resource=test_keyspace permission=sel
salt 'minion1' cassandra_cql.grant_permission username=joe resource=test_table resource_type=tab
```

```
salt.modules.cassandra_cql.info(contact_points=None, port=None, cql_user=None,
                                cql_pass=None)
```

Show the Cassandra information for this cluster.

**Parameters**

- **contact\_points** (*str* | *list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

**Returns** The information for this Cassandra cluster.

**Return type** `dict`

CLI Example:

```
salt 'minion1' cassandra_cql.info
salt 'minion1' cassandra_cql.info contact_points=minion1
```

`salt.modules.cassandra_cql.keyspace_exists` (*keyspace*, *contact\_points=None*, *port=None*, *cql\_user=None*, *cql\_pass=None*)

Check if a keyspace exists in a Cassandra cluster.

:param keyspace The keyspace name to check for. :type keyspace: str :param contact\_points: The Cassandra cluster addresses, can either be a string or a list of IPs. :type contact\_points: str | list[str] :param cql\_user: The Cassandra user if authentication is turned on. :type cql\_user: str :param cql\_pass: The Cassandra user password if authentication is turned on. :type cql\_pass: str :param port: The Cassandra cluster port, defaults to None. :type port: int :return: The info for the keyspace or False if it does not exist. :rtype: dict

CLI Example:

```
salt 'minion1' cassandra_cql.keyspace_exists keyspace=system
salt 'minion1' cassandra_cql.list_keyspaces keyspace=system contact_points=minion1
```

`salt.modules.cassandra_cql.list_column_families` (*keyspace=None*, *contact\_points=None*, *port=None*, *cql\_user=None*, *cql\_pass=None*)

List column families in a Cassandra cluster for all keyspaces or just the provided one.

**Parameters**

- **keyspace** (*str*) -- The keyspace to provide the column families for, optional.
- **contact\_points** (*str* | *list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

**Returns** The column families in this Cassandra cluster.

**Return type** `list[dict]`

CLI Example:

```
salt 'minion1' cassandra_cql.list_column_families
salt 'minion1' cassandra_cql.list_column_families contact_points=minion1
salt 'minion1' cassandra_cql.list_column_families keyspace=system
```

`salt.modules.cassandra_cql.list_keyspaces` (*contact\_points=None, port=None, cql\_user=None, cql\_pass=None*)

List keyspaces in a Cassandra cluster.

#### Parameters

- **contact\_points** (*str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

**Returns** The keyspaces in this Cassandra cluster.

**Return type** `list[dict]`

CLI Example:

```
salt 'minion1' cassandra_cql.list_keyspaces
salt 'minion1' cassandra_cql.list_keyspaces contact_points=minion1 port=9000
```

`salt.modules.cassandra_cql.list_permissions` (*username=None, resource=None, resource\_type='keyspace', permission=None, contact\_points=None, port=None, cql\_user=None, cql\_pass=None*)

List permissions.

#### Parameters

- **username** (*str*) -- The name of the user to list permissions for.
- **resource** (*str*) -- The resource (keyspace or table), if None, permissions for all resources are listed.
- **resource\_type** (*str*) -- The resource\_type (keyspace or table), defaults to 'keyspace'.
- **permission** (*str*) -- A permission name (e.g. select), if None, all permissions are listed.
- **contact\_points** (*str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

**Returns** Dictionary of permissions.

**Return type** `dict`

```
salt 'minion1' cassandra_cql.list_permissions
salt 'minion1' cassandra_cql.list_permissions username=joe resource=test_keyspace permission=select
salt 'minion1' cassandra_cql.list_permissions username=joe resource=test_table resource_type=table
```

`salt.modules.cassandra_cql.list_users` (*contact\_points=None, port=None, cql\_user=None, cql\_pass=None*)

List existing users in this Cassandra cluster.

#### Parameters

- **contact\_points** (*str* | *list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.

**Returns** The list of existing users.

**Return type** `dict`

```
salt 'minion1' cassandra_cql.list_users
salt 'minion1' cassandra_cql.list_users contact_points=minion1
```

```
salt.modules.cassandra_cql.version(contact_points=None, port=None, cql_user=None,
                                   cql_pass=None)
```

Show the Cassandra version.

**Parameters**

- **contact\_points** (*str* | *list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql\_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql\_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

**Returns** The version for this Cassandra cluster.

**Return type** `str`

CLI Example:

```
salt 'minion1' cassandra_cql.version
salt 'minion1' cassandra_cql.version contact_points=minion1
```

### 30.16.31 salt.modules.chef

Execute chef in server or solo mode

```
salt.modules.chef.client(whyrun=False, localmode=False, logfile=None, **kwargs)
Execute a chef client run and return a dict with the stderr, stdout, return code, and pid.
```

CLI Example:

```
salt '*' chef.client server=https://localhost
```

**server** The chef server URL

**client\_key** Set the client key file location

**config** The configuration file to use

**config-file-jail** Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside this path will be loaded).

**environment** Set the Chef Environment on the node

**group** Group to set privilege to

**json-attributes** Load attributes from a JSON file or URL

**localmode** Point chef-client at local repository if True

**log\_level** Set the log level (debug, info, warn, error, fatal)

**logfile** Set the log file location

**node-name** The node name for this client

**override-runlist** Replace current run list with specified items for a single run

**pid** Set the PID file location, defaults to /tmp/chef-client.pid

**run-lock-timeout** Set maximum duration to wait for another client run to finish, default is indefinitely.

**runlist** Permanently replace current run list with specified items

**user** User to set privilege to

**validation\_key** Set the validation key file location, used for registering new clients

**whyrun** Enable whyrun mode when set to True

`salt.modules.chef.solo` (*whyrun=False, logfile=None, \*\*kwargs*)  
Execute a chef solo run and return a dict with the stderr, stdout, return code, and pid.

CLI Example:

```
salt '*' chef.solo override-runlist=test
```

**config** The configuration file to use

**environment** Set the Chef Environment on the node

**group** Group to set privilege to

**json-attributes** Load attributes from a JSON file or URL

**log\_level** Set the log level (debug, info, warn, error, fatal)

**logfile** Set the log file location

**node-name** The node name for this client

**override-runlist** Replace current run list with specified items for a single run

**recipe-url** Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache

**run-lock-timeout** Set maximum duration to wait for another client run to finish, default is indefinitely.

**user** User to set privilege to

**whyrun** Enable whyrun mode when set to True

### 30.16.32 salt.modules.chocolatey

A dead simple module wrapping calls to the Chocolatey package manager (<http://chocolatey.org>)

New in version 2014.1.0.

`salt.modules.chocolatey.bootstrap` (*force=False*)

Download and install the latest version of the Chocolatey package manager via the official bootstrap.

Chocolatey requires Windows PowerShell and the .NET v4.0 runtime. Depending on the host's version of Windows, `chocolatey.bootstrap` will attempt to ensure these prerequisites are met by downloading and executing the appropriate installers from Microsoft.

Note that if PowerShell is installed, you may have to restart the host machine for Chocolatey to work.

**force** Run the bootstrap process even if Chocolatey is found in the path.

CLI Example:

```
salt '*' chocolatey.bootstrap
salt '*' chocolatey.bootstrap force=True
```

`salt.modules.chocolatey.chocolatey_version` ()

New in version 2014.7.0.

Returns the version of Chocolatey installed on the minion.

CLI Example:

```
salt '*' chocolatey.chocolatey_version
```

`salt.modules.chocolatey.install` (*name, version=None, source=None, force=False*)

Instructs Chocolatey to install a package.

**name** The name of the package to be installed. Only accepts a single argument.

**version** Install a specific version of the package. Defaults to latest version.

**source** Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

**force** Reinstall the current version of an existing package.

CLI Example:

```
salt '*' chocolatey.install <package name>
salt '*' chocolatey.install <package name> version=<package version>
```

`salt.modules.chocolatey.install_cygwin` (*name*)

Instructs Chocolatey to install a package via Cygwin.

**name** The name of the package to be installed. Only accepts a single argument.

CLI Example:

```
salt '*' chocolatey.install_cygwin <package name>
```

`salt.modules.chocolatey.install_gem` (*name, version=None*)

Instructs Chocolatey to install a package via Ruby's Gems.

**name** The name of the package to be installed. Only accepts a single argument.

**version** Install a specific version of the package. Defaults to latest version available.

CLI Example:

```
salt '*' chocolatey.install_gem <package name>
salt '*' chocolatey.install_gem <package name> version=<package version>
```

`salt.modules.chocolatey.install_missing`(*name*, *version=None*, *source=None*)

Instructs Chocolatey to install a package if it doesn't already exist.

Changed in version 2014.7.0: If the minion has Chocolatey >= 0.9.8.24 installed, this function calls `chocolatey.install` instead, as `installmissing` is deprecated as of that version and will be removed in Chocolatey 1.0.

**name** The name of the package to be installed. Only accepts a single argument.

**version** Install a specific version of the package. Defaults to latest version available.

**source** Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

CLI Example:

```
salt '*' chocolatey.install_missing <package name>
salt '*' chocolatey.install_missing <package name> version=<package version>
```

`salt.modules.chocolatey.install_python`(*name*, *version=None*)

Instructs Chocolatey to install a package via Python's `easy_install`.

**name** The name of the package to be installed. Only accepts a single argument.

**version** Install a specific version of the package. Defaults to latest version available.

CLI Example:

```
salt '*' chocolatey.install_python <package name>
salt '*' chocolatey.install_python <package name> version=<package version>
```

`salt.modules.chocolatey.install_webpi`(*name*)

Instructs Chocolatey to install a package via the Microsoft Web PI service.

**name** The name of the package to be installed. Only accepts a single argument.

CLI Example:

```
salt '*' chocolatey.install_webpi <package name>
```

`salt.modules.chocolatey.install_windowsfeatures`(*name*)

Instructs Chocolatey to install a Windows Feature via the Deployment Image Servicing and Management tool.

**name** The name of the feature to be installed. Only accepts a single argument.

CLI Example:

```
salt '*' chocolatey.install_windowsfeatures <package name>
```

`salt.modules.chocolatey.list_`(*narrow*, *all\_versions=False*, *pre\_versions=False*, *source=None*)

Instructs Chocolatey to pull a vague package list from the repository.

**narrow** Term used to narrow down results. Searches against name/description/tag.

**all\_versions** Display all available package versions in results. Defaults to False.

**pre\_versions** Display pre-release packages in results. Defaults to False.

**source** Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

CLI Example:

```
salt '*' chocolatey.list <narrow>
salt '*' chocolatey.list <narrow> all_versions=True
```

`salt.modules.chocolatey.list_webpi()`

Instructs Chocolatey to pull a full package list from the Microsoft Web PI repository.

CLI Example:

```
salt '*' chocolatey.list_webpi
```

`salt.modules.chocolatey.list_windowsfeatures()`

Instructs Chocolatey to pull a full package list from the Windows Features list, via the Deployment Image Servicing and Management tool.

CLI Example:

```
salt '*' chocolatey.list_windowsfeatures
```

`salt.modules.chocolatey.uninstall(name, version=None)`

Instructs Chocolatey to uninstall a package.

**name** The name of the package to be uninstalled. Only accepts a single argument.

**version** Uninstalls a specific version of the package. Defaults to latest version installed.

CLI Example:

```
salt '*' chocolatey.uninstall <package name>
salt '*' chocolatey.uninstall <package name> version=<package version>
```

`salt.modules.chocolatey.update(name, source=None, pre_versions=False)`

Instructs Chocolatey to update packages on the system.

**name** The name of the package to update, or ``all`` to update everything installed on the system.

**source** Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

**pre\_versions** Include pre-release packages in comparison. Defaults to False.

CLI Example:

```
salt "*" chocolatey.update all
salt "*" chocolatey.update <package name> pre_versions=True
```

`salt.modules.chocolatey.version(name, check_remote=False, source=None, pre_versions=False)`

Instructs Chocolatey to check an installed package version, and optionally compare it to one available from a remote feed.

**name** The name of the package to check.

**check\_remote** Get the version number of the latest package from the remote feed. Defaults to False.

**source** Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

**pre\_versions** Include pre-release packages in comparison. Defaults to False.

CLI Example:

```
salt "*" chocolatey.version <package name>
salt "*" chocolatey.version <package name> check_remote=True
```

### 30.16.33 salt.modules.cloud

Salt-specific interface for calling Salt Cloud directly

**salt.modules.cloud.action**(*fun=None, cloudmap=None, names=None, provider=None, instance=None, \*\*kwargs*)

Execute a single action on the given provider/instance

CLI Example:

```
salt '*' cloud.action start instance=myinstance
salt '*' cloud.action stop instance=myinstance
salt '*' cloud.action show_image provider=my-ec2-config image=ami-1624987f
```

**salt.modules.cloud.create**(*provider, names, \*\*kwargs*)

Create an instance using Salt Cloud

CLI Example:

```
salt minionname cloud.create my-ec2-config myinstance image=ami-1624987f size='t1.micro' ssh_use
```

**salt.modules.cloud.destroy**(*names*)

Destroy the named VM(s)

CLI Example:

```
salt '*' cloud.destroy myinstance
```

**salt.modules.cloud.full\_query**(*query\_type='list\_nodes\_full'*)

List all available cloud provider data

CLI Example:

```
salt '*' cloud.full_query
```

**salt.modules.cloud.get\_instance**(*name, provider=None*)

Return details on an instance.

Similar to the cloud action show\_instance but returns only the instance details.

CLI Example:

```
salt '*' cloud.get_instance myinstance
```

SLS Example:

```
{{ salt['cloud.get_instance']('myinstance')['mac_address'] }}
```

**salt.modules.cloud.has\_instance**(*name, provider=None*)

Return true if the instance is found on a provider

CLI Example:

```
salt '*' cloud.has_instance myinstance
```

**salt.modules.cloud.list\_images**(*provider='all'*)

List cloud provider images for the given providers

CLI Example:

```
salt '*' cloud.list_images my-gce-config
```

`salt.modules.cloud.list_locations` (*provider='all'*)  
List cloud provider locations for the given providers

CLI Example:

```
salt '*' cloud.list_locations my-gce-config
```

`salt.modules.cloud.list_sizes` (*provider='all'*)  
List cloud provider sizes for the given providers

CLI Example:

```
salt '*' cloud.list_sizes my-gce-config
```

`salt.modules.cloud.network_create` (*provider, names, \*\*kwargs*)  
Create private network

CLI Example:

```
salt minionname cloud.network_create my-nova names=['salt'] cidr='192.168.100.0/24'
```

`salt.modules.cloud.network_list` (*provider*)  
List private networks

CLI Example:

```
salt minionname cloud.network_list my-nova
```

`salt.modules.cloud.profile_` (*profile, names, vm\_overrides=None, \*\*kwargs*)  
Spin up an instance using Salt Cloud

CLI Example:

```
salt '*' cloud.profile my-gce-config myinstance
```

`salt.modules.cloud.query` (*query\_type='list\_nodes'*)  
List cloud provider data for all providers

CLI Examples:

```
salt '*' cloud.query
salt '*' cloud.query list_nodes_full
salt '*' cloud.query list_nodes_select
```

`salt.modules.cloud.select_query` (*query\_type='list\_nodes\_select'*)  
List selected nodes

CLI Example:

```
salt '*' cloud.select_query
```

`salt.modules.cloud.virtual_interface_create` (*provider, names, \*\*kwargs*)  
Attach private interfaces to a server

CLI Example:

```
salt minionname cloud.virtual_interface_create my-nova names=['salt-master'] net_name='salt'
```

`salt.modules.cloud.virtual_interface_list` (*provider, names, \*\*kwargs*)  
List virtual interfaces on a server

CLI Example:

```
salt minionname cloud.virtual_interface_list my-nova names=['salt-master']
```

`salt.modules.cloud.volume_attach(provider, names, **kwargs)`

Attach volume to a server

CLI Example:

```
salt minionname cloud.volume_attach my-nova myblock server_name=myserver device='/dev/xvdf'
```

`salt.modules.cloud.volume_create(provider, names, **kwargs)`

Create volume

CLI Example:

```
salt minionname cloud.volume_create my-nova myblock size=100 voltype=SSD
```

`salt.modules.cloud.volume_delete(provider, names, **kwargs)`

Delete volume

CLI Example:

```
salt minionname cloud.volume_delete my-nova myblock
```

`salt.modules.cloud.volume_detach(provider, names, **kwargs)`

Detach volume from a server

CLI Example:

```
salt minionname cloud.volume_detach my-nova myblock server_name=myserver
```

`salt.modules.cloud.volume_list(provider)`

List block storage volumes

CLI Example:

```
salt minionname cloud.volume_list my-nova
```

### 30.16.34 salt.modules.cmdmod

A module for shelling out.

Keep in mind that this module is insecure, in that it can give whomever has access to the master root execution access to all salt minions.

`salt.modules.cmdmod.exec_code(lang, code, cwd=None)`

Pass in two strings, the first naming the executable language, aka - python2, python3, ruby, perl, lua, etc. the second string containing the code you wish to execute. The stdout will be returned.

CLI Example:

```
salt '*' cmd.exec_code ruby 'puts "cheese"'
```

`salt.modules.cmdmod.exec_code_all(lang, code, cwd=None)`

Pass in two strings, the first naming the executable language, aka - python2, python3, ruby, perl, lua, etc. the second string containing the code you wish to execute. All cmd artifacts (stdout, stderr, retcode, pid) will be returned.

CLI Example:

```
salt '*' cmd.exec_code_all ruby 'puts "cheese"'
```

`salt.modules.cmdmod.has_exec(cmd)`

Returns true if the executable is available on the minion, false otherwise

CLI Example:

```
salt '*' cmd.has_exec cat
```

`salt.modules.cmdmod.retcode(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', python_shell=None, env=None, clean_env=False, template=None, umask=None, output_loglevel='debug', log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)`

Execute a shell command and return the command's return code.

Note that `env` represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

**Return type** `int`

**Return type** `None`

**Returns** Return Code as an int or None if there was an exception.

CLI Example:

```
salt '*' cmd.retcode "file /bin/bash"
```

The `template` arg can be set to `'jinja'` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.retcode template=jinja "file {{grains.pythonpath[0]}}/python"
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.:

```
salt '*' cmd.retcode "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

`salt.modules.cmdmod.run(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', python_shell=None, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)`

Execute the passed command and return the output as a string

Note that `env` represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

**Warning:** This function does not process commands through a shell unless the `python_shell` flag is set to `True`. This means that any shell-specific functionality such as `'echo'` or the use of pipes, redirection or `&&`, should either be migrated to `cmd.shell` or have the `python_shell=True` flag set here.

The use of `python_shell=True` means that the shell will accept `_any_` input including potentially malicious commands such as `'good_command;rm -rf/'`. Be absolutely certain that you have sanitized your input prior to using `python_shell=True`

CLI Example:

```
salt '*' cmd.run "ls -l | awk '/foo/{print \$2}'"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}'"
```

Specify an alternate shell with the shell parameter:

```
salt '*' cmd.run "Get-ChildItem C:\ " shell='powershell'
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.:

```
salt '*' cmd.run "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format `key=val`. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' cmd.run cmd='sed -e s/=/:/g'
```

```
salt.modules.cmdmod.run_all(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh',
                             python_shell=None, env=None, clean_env=False, template=None,
                             rstrip=True, umask=None, output_loglevel='debug',
                             log_callback=None, timeout=None, reset_system_locale=True,
                             ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)
```

Execute the passed command and return a dict of return data

Note that `env` represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

```
salt '*' cmd.run_all "ls -l | awk '/foo/{print \$2}'"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run_all template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}'"
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.:

```
salt '*' cmd.run_all "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

```
salt.modules.cmdmod.run_chroot(root, cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh',
                               python_shell=True, env=None, clean_env=False, template=None,
                               rstrip=True, umask=None, output_loglevel='quiet',
                               log_callback=None, quiet=False, timeout=None,
                               reset_system_locale=True, ignore_retcode=False, saltenv='base',
                               use_vt=False, **kwargs)
```

New in version 2014.7.0.

This function runs `cmd.run_all` wrapped within a chroot, with `dev` and `proc` mounted in the chroot

**stdin** [None] Standard input to be used for the command

New in version 2014.7.1.

**output\_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

New in version 2014.7.1.

CLI Example:

```
salt '*' cmd.run_chroot /var/lib/lxc/container_name/rootfs 'sh /tmp/bootstrap.sh'
```

```
salt.modules.cmdmod.run_stderr(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh',
                               python_shell=None, env=None, clean_env=False, template=None,
                               rstrip=True, umask=None, output_loglevel='debug',
                               log_callback=None, timeout=None, reset_system_locale=True,
                               ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)
```

Execute a command and only return the standard error

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

```
salt '*' cmd.run_stderr "ls -l | awk '/foo/{print \$2}'"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run_stderr template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}'"
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.:

```
salt '*' cmd.run_stderr "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

```
salt.modules.cmdmod.run_stdout(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh',
                               python_shell=None, env=None, clean_env=False, template=None,
                               rstrip=True, umask=None, output_loglevel='debug',
                               log_callback=None, timeout=None, reset_system_locale=True,
                               ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)
```

Execute a command, and only return the standard out

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

```
salt '*' cmd.run_stdout "ls -l | awk '/foo/{print \$2}'"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run_stdout template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}'"
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.:

```
salt '*' cmd.run_stdout "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

```
salt.modules.cmdmod.script(source, args=None, cwd=None, stdin=None, runas=None, shell='/bin/sh',
                             python_shell=None, env=None, template=None, umask=None, out-
                             put_loglevel='debug', log_callback=None, quiet=False, timeout=None,
                             reset_system_locale=True, __env__=None, saltenv='base', use_vt=False,
                             **kwargs)
```

Download a script from a remote location and execute the script locally. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

The script can also be formatted as a template, the default is jinja. Arguments for the script can be specified as well.

CLI Example:

```
salt '*' cmd.script salt://scripts/runme.sh
salt '*' cmd.script salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' cmd.script salt://scripts/windows_task.ps1 args=' -Input c:\tmp\infile.txt' shell='powershell'
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.:

```
salt '*' cmd.script salt://scripts/runme.sh stdin='one\ntwo\nthree\nfour\nfive\n'
```

```
salt.modules.cmdmod.script_retcode(source, args=None, cwd=None, stdin=None, runas=None,
                                       shell='/bin/sh', python_shell=None, env=None, tem-
                                       plate='jinja', umask=None, timeout=None, re-
                                       set_system_locale=True, __env__=None, saltenv='base',
                                       output_loglevel='debug', log_callback=None, use_vt=False,
                                       **kwargs)
```

Download a script from a remote location and execute the script locally. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

The script can also be formatted as a template, the default is jinja.

Only evaluate the script return code and do not block for terminal output

CLI Example:

```
salt '*' cmd.script_retcode salt://scripts/runme.sh
salt '*' cmd.script_retcode salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' cmd.script_retcode salt://scripts/windows_task.ps1 args=' -Input c:\tmp\infile.txt' shell='powershell'
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.:

```
salt '*' cmd.script_retcode salt://scripts/runme.sh stdin='one\ntwo\nthree\nfour\nfive\n'
```

```
salt.modules.cmdmod.shell(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', env=None,
                             clean_env=False, template=None, rstrip=True, umask=None, out-
                             put_loglevel='debug', log_callback=None, quiet=False, timeout=None,
                             reset_system_locale=True, ignore_retcode=False, saltenv='base',
                             use_vt=False, **kwargs)
```

Execute the passed command and return the output as a string.

New in version 2015.5.0.

**Warning:** This passes the `cmd` argument directly to the shell without any further processing! Be absolutely sure that you have properly santized the command passed to this function and do not use untrusted inputs.

Note that `env` represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

```
salt '*' cmd.shell "ls -l | awk '/foo/{print \$2}'"
```

The template arg can be set to `'jinja'` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.shell template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}'"
```

Specify an alternate shell with the `shell` parameter:

```
salt '*' cmd.shell "Get-ChildItem C:\ " shell='powershell'
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.:

```
salt '*' cmd.shell "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format `key=val`. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the `kwarg`:

```
salt '*' cmd.shell cmd='sed -e s/=/:/g'
```

`salt.modules.cmdmod.shells()`

Lists the valid shells on this system via the `/etc/shells` file

New in version 2015.5.0.

CLI Example:

```
salt '*' cmd.shells
```

`salt.modules.cmdmod.tty(device, echo=None)`

Echo a string to a specific tty

CLI Example:

```
salt '*' cmd.tty tty0 'This is a test'
salt '*' cmd.tty pts3 'This is a test'
```

`salt.modules.cmdmod.which(cmd)`

Returns the path of an executable available on the minion, None otherwise

CLI Example:

```
salt '*' cmd.which cat
```

`salt.modules.cmdmod.which_bin(cmds)`

Returns the first command found in a list of commands

CLI Example:

```
salt '*' cmd.which_bin '[pip2, pip, pip-python]'
```

### 30.16.35 salt.modules.composer

Use composer to install PHP dependencies for a directory

`salt.modules.composer.did_composer_install(dir)`

Test to see if the vendor directory exists in this directory

**dir** Directory location of the composer.json file

CLI Example:

```
salt '*' composer.did_composer_install /var/www/application
```

`salt.modules.composer.install(dir, composer=None, php=None, runas=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root')`

Install composer dependencies for a directory.

If composer has not been installed globally making it available in the system PATH & making it executable, the `composer` and `php` parameters will need to be set to the location of the executables.

**dir** Directory location of the composer.json file.

**composer** Location of the composer.phar file. If not set composer will just execute ``composer" as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**runas** Which system user to run composer as.

**prefer\_source** --prefer-source option of composer.

**prefer\_dist** --prefer-dist option of composer.

**no\_scripts** --no-scripts option of composer.

**no\_plugins** --no-plugins option of composer.

**optimize** --optimize-autoloader option of composer. Recommended for production.

**no\_dev** --no-dev option for composer. Recommended for production.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer\_home** \$COMPOSER\_HOME environment variable

CLI Example:

```
salt '*' composer.install /var/www/application
```

```
salt '*' composer.install /var/www/application no_dev=True optimize=True
```

`salt.modules.composer.selfupdate(composer=None, php=None, runas=None, quiet=False, composer_home='/root')`

Update composer itself.

If composer has not been installed globally making it available in the system PATH & making it executable, the `composer` and `php` parameters will need to be set to the location of the executables.

**composer** Location of the composer.phar file. If not set composer will just execute ``composer" as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**runas** Which system user to run composer as.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer\_home** \$COMPOSER\_HOME environment variable

CLI Example:

```
salt '*' composer.selfupdate
```

```
salt.modules.composer.update(dir, composer=None, php=None, runas=None, prefer_source=None,
                             prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root')
```

Update composer dependencies for a directory.

If *composer install* has not yet been run, this runs *composer install* instead.

If composer has not been installed globally making it available in the system PATH & making it executable, the *composer* and *php* parameters will need to be set to the location of the executables.

**dir** Directory location of the composer.json file.

**composer** Location of the composer.phar file. If not set composer will just execute ``composer" as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**runas** Which system user to run composer as.

**prefer\_source** --prefer-source option of composer.

**prefer\_dist** --prefer-dist option of composer.

**no\_scripts** --no-scripts option of composer.

**no\_plugins** --no-plugins option of composer.

**optimize** --optimize-autoloader option of composer. Recommended for production.

**no\_dev** --no-dev option for composer. Recommended for production.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer\_home** \$COMPOSER\_HOME environment variable

CLI Example:

```
salt '*' composer.update /var/www/application
```

```
salt '*' composer.update /var/www/application no_dev=True optimize=True
```

### 30.16.36 salt.modules.config

Return config information

```
salt.modules.config.backup_mode(backup='')
```

Return the backup mode

CLI Example:

```
salt '*' config.backup_mode
```

```
salt.modules.config.dot_vals(value)
```

Pass in a configuration value that should be preceded by the module name and a dot, this will return a list of all read key/value pairs

CLI Example:

```
salt '*' config.dot_vals host
```

`salt.modules.config.gather_bootstrap_script` (*bootstrap=None*)

Download the salt-bootstrap script, and return its location

**bootstrap** URL of alternate bootstrap script

CLI Example:

```
salt '*' config.gather_bootstrap_script
```

`salt.modules.config.get` (*key*, *default=''*, *delimiter=':'*, *merge=None*)

Attempt to retrieve the named value from the minion config file, pillar, grains or the master config. If the named value is not available, return the value specified by default. If not specified, the default is an empty string.

Values can also be retrieved from nested dictionaries. Assume the below data structure:

```
{'pkg': {'apache': 'httpd'}}
```

To retrieve the value associated with the `apache` key, in the sub-dictionary corresponding to the `pkg` key, the following command can be used:

```
salt myminion config.get pkg:apache
```

The `:` (colon) is used to represent a nested dictionary level.

Changed in version 2015.5.0: The `delimiter` argument was added, to allow delimiters other than `:` to be used.

This function traverses these data stores in this order:

- Minion config file
- Minion's grains
- Minion's pillar data
- Master config file

**delimiter** New in version 2015.5.0.

Override the delimiter used to separate nested levels of a data structure.

**merge** New in version 2015.5.0.

If passed, this parameter will change the behavior of the function so that, instead of traversing each data store above in order and returning the first match, the data stores are first merged together and then searched. The pillar data is merged into the master config data, then the grains are merged, followed by the Minion config data. The resulting data structure is then searched for a match. This allows for configurations to be more flexible.

---

**Note:** The merging described above does not mean that grain data will end up in the Minion's pillar data, or pillar data will end up in the master config data, etc. The data is just combined for the purposes of searching an amalgam of the different data stores.

---

The supported merge strategies are as follows:

- **recurse** - If a key exists in both dictionaries, and the new value is not a dictionary, it is replaced. Otherwise, the sub-dictionaries are merged together into a single dictionary, recursively on down, following the same criteria. For example:

```
>>> dict1 = {'foo': {'bar': 1, 'qux': True},
             'hosts': ['a', 'b', 'c'],
             'only_x': None}
>>> dict2 = {'foo': {'baz': 2, 'qux': False},
             'hosts': ['d', 'e', 'f'],
             'only_y': None}
>>> merged
{'foo': {'bar': 1, 'baz': 2, 'qux': False},
 'hosts': ['d', 'e', 'f'],
 'only_dict1': None,
 'only_dict2': None}
```

- **overwrite** - If a key exists in the top level of both dictionaries, the new value completely overwrites the old. For example:

```
>>> dict1 = {'foo': {'bar': 1, 'qux': True},
             'hosts': ['a', 'b', 'c'],
             'only_x': None}
>>> dict2 = {'foo': {'baz': 2, 'qux': False},
             'hosts': ['d', 'e', 'f'],
             'only_y': None}
>>> merged
{'foo': {'baz': 2, 'qux': False},
 'hosts': ['d', 'e', 'f'],
 'only_dict1': None,
 'only_dict2': None}
```

CLI Example:

```
salt '*' config.get pkg:apache
salt '*' config.get lxc.container_profile:centos merge=recurse
```

`salt.modules.config.manage_mode(mode)`

Return a mode value, normalized to a string

CLI Example:

```
salt '*' config.manage_mode
```

`salt.modules.config.merge(value, default='', omit_opts=False, omit_master=False, omit_pillar=False)`

Retrieves an option based on key, merging all matches.

Same as `option()` except that it merges all matches, rather than taking the first match.

CLI Example:

```
salt '*' config.merge schedule
```

`salt.modules.config.option(value, default='', omit_opts=False, omit_master=False, omit_pillar=False)`

Pass in a generic option and receive the value that will be assigned

CLI Example:

```
salt '*' config.option redis.host
```

`salt.modules.config.valid_fileproto(uri)`

Returns a boolean value based on whether or not the URI passed has a valid remote file protocol designation

CLI Example:

```
salt '*' config.valid_fileproto salt://path/to/file
```

### 30.16.37 salt.modules.container\_resource

Common resources for LXC and systemd-nspawn containers

These functions are not designed to be called directly, but instead from the `lxc` and the (future) `nspawn` execution modules.

`salt.modules.container_resource.run(name, cmd, output=None, no_start=False, stdin=None, python_shell=True, output_loglevel='debug', ignore_retcode=False, use_vt=False)`

Common logic for running shell commands in containers

Requires the full command to be passed to `cmd.run/cmd.run_all`

### 30.16.38 salt.modules.cp

Minion side functions for salt-cp

`salt.modules.cp.cache_dir(path, saltenv='base', include_empty=False, include_pat=None, exclude_pat=None, env=None)`

Download and cache everything under a directory from the master

**include\_pat** [None] Glob or regex to narrow down the files cached from the given path. If matching with a regex, the regex must be prefixed with `E@`, otherwise the expression will be interpreted as a glob.

New in version 2014.7.0.

**exclude\_pat** [None] Glob or regex to exclude certain files from being cached from the given path. If matching with a regex, the regex must be prefixed with `E@`, otherwise the expression will be interpreted as a glob.

---

**Note:** If used with `include_pat`, files matching this pattern will be excluded from the subset of files defined by `include_pat`.

---

New in version 2014.7.0.

CLI Examples:

```
salt '*' cp.cache_dir salt://path/to/dir
salt '*' cp.cache_dir salt://path/to/dir include_pat='E@*.py$'
```

`salt.modules.cp.cache_file(path, saltenv='base', env=None)`

Used to cache a single file on the salt-minion Returns the location of the new cached file on the minion

CLI Example:

```
salt '*' cp.cache_file salt://path/to/file
```

`salt.modules.cp.cache_files` (*paths*, *saltenv='base'*, *env=None*)

Used to gather many files from the master, the gathered files will be saved in the minion cachedir reflective to the paths retrieved from the master.

CLI Example:

```
salt '*' cp.cache_files salt://pathto/file1,salt://pathto/file1
```

`salt.modules.cp.cache_local_file` (*path*)

Cache a local file on the minion in the localfiles cache

CLI Example:

```
salt '*' cp.cache_local_file /etc/hosts
```

`salt.modules.cp.cache_master` (*saltenv='base'*, *env=None*)

Retrieve all of the files on the master and cache them locally

CLI Example:

```
salt '*' cp.cache_master
```

`salt.modules.cp.get_dir` (*path*, *dest*, *saltenv='base'*, *template=None*, *gzip=None*, *env=None*, *\*\*kwargs*)

Used to recursively copy a directory from the salt master

CLI Example:

```
salt '*' cp.get_dir salt://path/to/dir/ /minion/dest
```

`get_dir` supports the same `template` and `gzip` arguments as `get_file`.

`salt.modules.cp.get_file` (*path*, *dest*, *saltenv='base'*, *makedirs=False*, *template=None*, *gzip=None*, *env=None*, *\*\*kwargs*)

Used to get a single file from the salt master

CLI Example:

```
salt '*' cp.get_file salt://path/to/file /minion/dest
```

Template rendering can be enabled on both the source and destination file names like so:

```
salt '*' cp.get_file "salt://{{grains.os}}/vimrc" /etc/vimrc template=jinja
```

This example would instruct all Salt minions to download the vimrc from a directory with the same name as their os grain and copy it to /etc/vimrc

For larger files, the `cp.get_file` module also supports gzip compression. Because gzip is CPU-intensive, this should only be used in scenarios where the compression ratio is very high (e.g. pretty-printed JSON or YAML files).

Use the `gzip` named argument to enable it. Valid values are 1..9, where 1 is the lightest compression and 9 the heaviest. 1 uses the least CPU on the master (and minion), 9 uses the most.

`salt.modules.cp.get_file_str` (*path*, *saltenv='base'*, *env=None*)

Return the contents of a file from a URL

CLI Example:

```
salt '*' cp.get_file_str salt://my/file
```

`salt.modules.cp.get_template`(*path*, *dest*, *template='jinja'*, *saltenv='base'*, *env=None*, *makedirs=False*, *\*\*kwargs*)

Render a file as a template before setting it down. Warning, order is not the same as in `fileclient.cp` for non breaking old API.

CLI Example:

```
salt '*' cp.get_template salt://path/to/template /minion/dest
```

`salt.modules.cp.get_url`(*path*, *dest*, *saltenv='base'*, *env=None*)

Used to get a single file from a URL.

The default behaviour is to write the fetched file to the given destination path. To simply return the text contents instead, set destination to `None`.

CLI Example:

```
salt '*' cp.get_url salt://my/file /tmp/mine
salt '*' cp.get_url http://www.slashdot.org /tmp/index.html
```

`salt.modules.cp.hash_file`(*path*, *saltenv='base'*, *env=None*)

Return the hash of a file, to get the hash of a file on the salt master file server prepend the path with `salt://<file on server>` otherwise, prepend the file with `/` for a local file.

CLI Example:

```
salt '*' cp.hash_file salt://path/to/file
```

`salt.modules.cp.is_cached`(*path*, *saltenv='base'*, *env=None*)

Return a boolean if the given path on the master has been cached on the minion

CLI Example:

```
salt '*' cp.is_cached salt://path/to/file
```

`salt.modules.cp.list_master`(*saltenv='base'*, *prefix=''*, *env=None*)

List all of the files stored on the master

CLI Example:

```
salt '*' cp.list_master
```

`salt.modules.cp.list_master_dirs`(*saltenv='base'*, *prefix=''*, *env=None*)

List all of the directories stored on the master

CLI Example:

```
salt '*' cp.list_master_dirs
```

`salt.modules.cp.list_master_symlinks`(*saltenv='base'*, *prefix=''*, *env=None*)

List all of the symlinks stored on the master

CLI Example:

```
salt '*' cp.list_master_symlinks
```

`salt.modules.cp.list_minion`(*saltenv='base'*, *env=None*)

List all of the files cached on the minion

CLI Example:

```
salt '*' cp.list_minion
```

`salt.modules.cp.list_states` (*saltenv='base', env=None*)

List all of the available state modules in an environment

CLI Example:

```
salt '*' cp.list_states
```

`salt.modules.cp.push` (*path, keep\_symlinks=False*)

Push a file from the minion up to the master, the file will be saved to the salt master in the master's minion files cachedir (defaults to `/var/cache/salt/master/minions/minion-id/files`)

Since this feature allows a minion to push a file up to the master server it is disabled by default for security purposes. To enable, set `file_recv` to `True` in the master configuration file, and restart the master.

**keep\_symlinks** Keep the path value without resolving its canonical form

CLI Example:

```
salt '*' cp.push /etc/fstab
salt '*' cp.push /etc/system-release keep_symlinks=True
```

`salt.modules.cp.push_dir` (*path, glob=None*)

Push a directory from the minion up to the master, the files will be saved to the salt master in the master's minion files cachedir (defaults to `/var/cache/salt/master/minions/minion-id/files`). It also has a `glob` for matching specific files using globbing.

New in version 2014.7.0.

Since this feature allows a minion to push files up to the master server it is disabled by default for security purposes. To enable, set `file_recv` to `True` in the master configuration file, and restart the master.

CLI Example:

```
salt '*' cp.push /usr/lib/mysql
salt '*' cp.push_dir /etc/modprobe.d/ glob='*.conf'
```

`salt.modules.cp.recv` (*files, dest*)

Used with `salt-cp`, pass the files dict, and the destination.

This function receives small fast copy files from the master via `salt-cp`. It does not work via the CLI.

### 30.16.39 salt.modules.cpan

Manage Perl modules using CPAN

New in version 2015.5.0.

`salt.modules.cpan.install` (*module*)

Install a Perl module from CPAN

CLI Example:

```
salt '*' cpan.install Template::Alloy
```

`salt.modules.cpan.list_` ()

List installed Perl modules, and the version installed

CLI Example:

```
salt '*' cpan.list
```

`salt.modules.cpan.remove`(*module*, *details=False*)

Attempt to remove a Perl module that was installed from CPAN. Because the `cpan` command doesn't actually support ``uninstall"-like functionality, this function will attempt to do what it can, with what it has from CPAN.

Until this function is declared stable, USE AT YOUR OWN RISK!

CLI Example:

```
salt '*' cpan.remove Old::Package
```

`salt.modules.cpan.show`(*module*)

Show information about a specific Perl module

CLI Example:

```
salt '*' cpan.show Template::Alloy
```

`salt.modules.cpan.show_config`()

Return a dict of CPAN configuration values

CLI Example:

```
salt '*' cpan.show_config
```

### 30.16.40 salt.modules.cron

Work with cron

`salt.modules.cron.list_tab`(*user*)

Return the contents of the specified user's crontab

CLI Example:

```
salt '*' cron.list_tab root
```

`salt.modules.cron.ls`(*user*)

Return the contents of the specified user's crontab

CLI Example:

```
salt '*' cron.list_tab root
```

`salt.modules.cron.raw_cron`(*user*)

Return the contents of the user's crontab

CLI Example:

```
salt '*' cron.raw_cron root
```

`salt.modules.cron.rm`(*user*, *cmd*, *minute=None*, *hour=None*, *daymonth=None*, *month=None*, *day-week=None*, *identifier=None*)

Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.

CLI Example:

```
salt '*' cron.rm_job root /usr/local/weekly
salt '*' cron.rm_job root /usr/bin/foo dayweek=1
```

**salt.modules.cron.rm\_env**(*user, name*)

Remove cron environment variable for a specified user.

CLI Example:

```
salt '*' cron.rm_env root MAILTO
```

**salt.modules.cron.rm\_job**(*user, cmd, minute=None, hour=None, daymonth=None, month=None, dayweek=None, identifier=None*)

Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.

CLI Example:

```
salt '*' cron.rm_job root /usr/local/weekly
salt '*' cron.rm_job root /usr/bin/foo dayweek=1
```

**salt.modules.cron.set\_env**(*user, name, value=None*)

Set up an environment variable in the crontab.

CLI Example:

```
salt '*' cron.set_env root MAILTO user@example.com
```

**salt.modules.cron.set\_job**(*user, minute, hour, daymonth, month, dayweek, cmd, comment=None, identifier=None*)

Sets a cron job up for a specified user.

CLI Example:

```
salt '*' cron.set_job root '*' '*' '*' '*' 1 /usr/local/weekly
```

**salt.modules.cron.set\_special**(*user, special, cmd*)

Set up a special command in the crontab.

CLI Example:

```
salt '*' cron.set_special root @hourly 'echo foobar'
```

**salt.modules.cron.write\_cron\_file**(*user, path*)

Writes the contents of a file to a user's crontab

CLI Example:

```
salt '*' cron.write_cron_file root /tmp/new_cron
```

**salt.modules.cron.write\_cron\_file\_verbose**(*user, path*)

Writes the contents of a file to a user's crontab and return error message on error

CLI Example:

```
salt '*' cron.write_cron_file_verbose root /tmp/new_cron
```

### 30.16.41 salt.modules.cyg

Manage cygwin packages.

Module file to accompany the cyg state.

`salt.modules.cyg.check_valid_package`(*package*, *cyg\_arch*='x86\_64', *mirrors*=None)

Check if the package is valid on the given mirrors.

`salt.modules.cyg.install`(*packages*=None, *cyg\_arch*='x86\_64', *mirrors*=None)

Install one or several packages.

**packages** [None] The packages to install

**cyg\_arch** [x86\_64] Specify the architecture to install the package under Current options are x86 and x86\_64

CLI Example:

```
salt '*' cyg.install dos2unix
salt '*' cyg.install dos2unix mirrors=[{'http://mirror': 'http://url/to/public/key'}]
```

`salt.modules.cyg.list_`(*package*='', *cyg\_arch*='x86\_64')

List locally installed packages.

**package** [''] package name to check. else all

**cyg\_arch** : Cygwin architecture to use Options are x86 and x86\_64

CLI Example:

```
salt '*' cyg.list
```

`salt.modules.cyg.uninstall`(*packages*, *cyg\_arch*='x86\_64', *mirrors*=None)

Uninstall one or several packages.

**packages** The packages to uninstall.

**cyg\_arch** [x86\_64] Specify the architecture to remove the package from Current options are x86 and x86\_64

CLI Example:

```
salt '*' cyg.uninstall dos2unix
salt '*' cyg.uninstall dos2unix mirrors=[{'http://mirror': 'http://url/to/public/key'}]
```

`salt.modules.cyg.update`(*cyg\_arch*='x86\_64', *mirrors*=None)

Update all packages.

**cyg\_arch** [x86\_64] Specify the cygwin architecture update Current options are x86 and x86\_64

CLI Example:

```
salt '*' cyg.update
salt '*' cyg.update dos2unix mirrors=[{'http://mirror': 'http://url/to/public/key'}]
```

### 30.16.42 salt.modules.daemontools

daemontools service module. This module will create daemontools type service watcher.

This module is compatible with the [service](#) states, so it can be used to maintain services using the provider argument:

```
myservice:
  service.running:
    - provider: daemontools
```

`salt.modules.daemontools.available`(*name*)

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' daemontools.available foo
```

`salt.modules.daemontools.disabled(name)`  
Return True if the named service is enabled, false otherwise

New in version 2015.5.6.

CLI Example:

```
salt '*' daemontools.disabled <service name>
```

`salt.modules.daemontools.enabled(name, **kwargs)`  
Return True if the named service is enabled, false otherwise A service is considered enabled if in your service directory: - an executable `./run` file exist - a file named `down` does not exist

New in version 2015.5.7.

**name** Service name

CLI Example:

```
salt '*' daemontools.enabled <service name>
```

`salt.modules.daemontools.full_restart(name)`  
Calls `daemontools.restart()` function

CLI Example:

```
salt '*' daemontools.full_restart <service name>
```

`salt.modules.daemontools.get_all()`  
Return a list of all available services

CLI Example:

```
salt '*' daemontools.get_all
```

`salt.modules.daemontools.missing(name)`  
The inverse of `daemontools.available`. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' daemontools.missing foo
```

`salt.modules.daemontools.reload_(name)`  
Wrapper for `term()`

CLI Example:

```
salt '*' daemontools.reload <service name>
```

`salt.modules.daemontools.restart(name)`  
Restart service via `daemontools`. This will stop/start service

CLI Example:

```
salt '*' daemontools.restart <service name>
```

`salt.modules.daemontools.start(name)`  
Starts service via `daemontools`

CLI Example:

```
salt '*' daemontools.start <service name>
```

`salt.modules.daemontools.status`(*name*, *sig=None*)  
Return the status for a service via daemontools, return pid if running

CLI Example:

```
salt '*' daemontools.status <service name>
```

`salt.modules.daemontools.stop`(*name*)  
Stops service via daemontools

CLI Example:

```
salt '*' daemontools.stop <service name>
```

`salt.modules.daemontools.term`(*name*)  
Send a TERM to service via daemontools

CLI Example:

```
salt '*' daemontools.term <service name>
```

### 30.16.43 salt.modules.darwin\_sysctl

Module for viewing and modifying sysctl parameters

`salt.modules.darwin_sysctl.assign`(*name*, *value*)  
Assign a single sysctl parameter for this minion

**name** The name of the sysctl value to edit.

**value** The sysctl value to apply.

CLI Example:

```
salt '*' sysctl.assign net.inet.icmp.icmplim 50
```

`salt.modules.darwin_sysctl.get`(*name*)  
Return a single sysctl parameter for this minion

**name** The name of the sysctl value to display.

CLI Example:

```
salt '*' sysctl.get hw.physmem
```

`salt.modules.darwin_sysctl.persist`(*name*, *value*, *config='/etc/sysctl.conf'*, *apply\_change=False*)  
Assign and persist a simple sysctl parameter for this minion

**name** The name of the sysctl value to edit.

**value** The sysctl value to apply.

**config** The location of the sysctl configuration file.

**apply\_change** Default is False; Default behavior only creates or edits the sysctl.conf file. If apply is set to True, the changes are applied to the system.

CLI Example:

```
salt '*' sysctl.persist net.inet.icmp.icmplim 50
salt '*' sysctl.persist coretemp_load NO config=/etc/sysctl.conf
```

`salt.modules.darwin_sysctl.show`(*config\_file=False*)

Return a list of sysctl parameters for this minion

CLI Example:

```
salt '*' sysctl.show
```

### 30.16.44 salt.modules.data

Manage a local persistent data structure that can hold any arbitrary data specific to the minion

`salt.modules.data.cas`(*key, value, old\_value*)

Check and set a value in the minion datastore

CLI Example:

```
salt '*' data.cas <key> <value> <old_value>
```

`salt.modules.data.clear`()

Clear out all of the data in the minion datastore, this function is destructive!

CLI Example:

```
salt '*' data.clear
```

`salt.modules.data.dump`(*new\_data*)

Replace the entire datastore with a passed data structure

CLI Example:

```
salt '*' data.dump '{"eggs': 'spam'}'
```

`salt.modules.data.getval`(*key*)

Get a value from the minion datastore

CLI Example:

```
salt '*' data.getval <key>
```

`salt.modules.data.getvals`(*\*keys*)

Get values from the minion datastore

CLI Example:

```
salt '*' data.getvals <key> [<key> ...]
```

`salt.modules.data.load`()

Return all of the data in the minion datastore

CLI Example:

```
salt '*' data.load
```

`salt.modules.data.pop`(*key, default=None*)

Pop (return & delete) a value from the minion datastore

New in version 2015.5.2.

CLI Example:

```
salt '*' data.pop <key> "there was no val"
```

`salt.modules.data.update`(*key*, *value*)

Update a key with a value in the minion datastore

CLI Example:

```
salt '*' data.update <key> <value>
```

### 30.16.45 salt.modules.ddns

Support for RFC 2136 dynamic DNS updates.

**depends**

- dnspython Python module

**configuration** If you want to use TSIG authentication for the server, there are a couple of optional configuration parameters made available to support this (the keyname is only needed if the keyring contains more than one key):

```
keyring: keyring file (default=None)
keyname: key name in file (default=None)
```

The keyring file needs to be in json format and the key name needs to end with an extra period in the file, similar to this:

```
{"keyname.": "keycontent"}
```

`salt.modules.ddns.add_host`(*zone*, *name*, *ttl*, *ip*, *nameserver*=`127.0.0.1`, *replace*=*True*, *\*\*kwargs*)

Add, replace, or update the A and PTR (reverse) records for a host.

CLI Example:

```
salt ns1 ddns.add_host example.com host1 60 10.1.1.1
```

`salt.modules.ddns.delete`(*zone*, *name*, *rdtype*=*None*, *data*=*None*, *nameserver*=`127.0.0.1`, *\*\*kwargs*)

Delete a DNS record.

CLI Example:

```
salt ns1 ddns.delete example.com host1 A
```

`salt.modules.ddns.delete_host`(*zone*, *name*, *nameserver*=`127.0.0.1`, *\*\*kwargs*)

Delete the forward and reverse records for a host.

Returns true if any records are deleted.

CLI Example:

```
salt ns1 ddns.delete_host example.com host1
```

`salt.modules.ddns.update`(*zone*, *name*, *ttl*, *rdtype*, *data*, *nameserver*=`127.0.0.1`, *replace*=*False*, *\*\*kwargs*)

Add, replace, or update a DNS record. *nameserver* must be an IP address and the minion running this module must have update privileges on that server. If *replace* is true, first deletes all records for this name and type.

CLI Example:

```
salt ns1 ddns.update example.com host1 60 A 10.0.0.1
```

### 30.16.46 salt.modules.deb\_apache

Support for Apache

Please note: The functions in here are Debian-specific. Placing them in this separate file will allow them to load only on Debian-based systems, while still loading under the `apache` namespace.

`salt.modules.deb_apache.a2dismod(mod)`

Runs `a2dismod` for the given `mod`.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```
salt '*' apache.a2dismod vhost_alias
```

`salt.modules.deb_apache.a2dissite(site)`

Runs `a2dissite` for the given `site`.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```
salt '*' apache.a2dissite example.com
```

`salt.modules.deb_apache.a2enmod(mod)`

Runs `a2enmod` for the given `mod`.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```
salt '*' apache.a2enmod vhost_alias
```

`salt.modules.deb_apache.a2ensite(site)`

Runs `a2ensite` for the given `site`.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```
salt '*' apache.a2ensite example.com
```

`salt.modules.deb_apache.check_mod_enabled(mod)`

Checks to see if the specific `mod` symlink is in `/etc/apache2/mods-enabled`.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```
salt '*' apache.check_mod_enabled status.conf
salt '*' apache.check_mod_enabled status.load
```

`salt.modules.deb_apache.check_site_enabled(site)`

Checks to see if the specific `Site` symlink is in `/etc/apache2/sites-enabled`.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```
salt '*' apache.check_site_enabled example.com
```

### 30.16.47 salt.modules.debconfmod

Support for Debconf

**salt.modules.debconfmod.get\_selections** (*fetchempty=True*)

Answers to debconf questions for all packages in the following format:

```
{'package': [['question', 'type', 'value'], ...]}
```

CLI Example:

```
salt '*' debconf.get_selections
```

**salt.modules.debconfmod.set\_** (*package, question, type, value, \*extra*)

Set answers to debconf questions for a package.

CLI Example:

```
salt '*' debconf.set <package> <question> <type> <value> [<value> ...]
```

**salt.modules.debconfmod.set\_file** (*path, saltenv='base', \*\*kwargs*)

Set answers to debconf questions from a file.

CLI Example:

```
salt '*' debconf.set_file salt://pathto/pkg.selections
```

**salt.modules.debconfmod.set\_template** (*path, template, context, defaults, saltenv='base', \*\*kwargs*)

Set answers to debconf questions from a template.

**path** location of the file containing the package selections

**template** template format

**context** variables to add to the template environment

**default** default values for the template environment

CLI Example:

```
salt '*' debconf.set_template salt://pathto/pkg.selections.jinja jinja None None
```

**salt.modules.debconfmod.show** (*name*)

Answers to debconf questions for a package in the following format:

```
[['question', 'type', 'value'], ...]
```

If debconf doesn't know about a package, we return None.

CLI Example:

```
salt '*' debconf.show <package name>
```

### 30.16.48 salt.modules.debian\_ip

The networking module for Debian based distros

References:

- <http://www.debian.org/doc/manuals/debian-reference/ch05.en.html>

`salt.modules.debian_ip.apply_network_settings(**settings)`

Apply global network configuration.

CLI Example:

```
salt '*' ip.apply_network_settings
```

`salt.modules.debian_ip.build_bond(iface, **settings)`

Create a bond script in /etc/modprobe.d with the passed settings and load the bonding kernel module.

CLI Example:

```
salt '*' ip.build_bond bond0 mode=balance-alb
```

`salt.modules.debian_ip.build_interface(iface, iface_type, enabled, **settings)`

Build an interface script for a network interface.

CLI Example:

```
salt '*' ip.build_interface eth0 eth <settings>
```

`salt.modules.debian_ip.build_network_settings(**settings)`

Build the global network script.

CLI Example:

```
salt '*' ip.build_network_settings <settings>
```

`salt.modules.debian_ip.build_routes(iface, **settings)`

Add route scripts for a network interface using up commands.

CLI Example:

```
salt '*' ip.build_routes eth0 <settings>
```

`salt.modules.debian_ip.down(iface, iface_type)`

Shutdown a network interface

CLI Example:

```
salt '*' ip.down eth0
```

`salt.modules.debian_ip.get_bond(iface)`

Return the content of a bond script

CLI Example:

```
salt '*' ip.get_bond bond0
```

`salt.modules.debian_ip.get_interface(iface)`

Return the contents of an interface script

CLI Example:

```
salt '*' ip.get_interface eth0
```

`salt.modules.debian_ip.get_network_settings()`  
Return the contents of the global network script.

CLI Example:

```
salt '*' ip.get_network_settings
```

`salt.modules.debian_ip.get_routes(iface)`  
Return the routes for the interface

CLI Example:

```
salt '*' ip.get_routes eth0
```

`salt.modules.debian_ip.up(iface, iface_type)`  
Start up a network interface

CLI Example:

```
salt '*' ip.up eth0
```

### 30.16.49 salt.modules.debian\_service

Service support for Debian systems (uses update-rc.d and /sbin/service)

---

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `'service.start' is not available`), see [here](#).

---

`salt.modules.debian_service.available(name)`  
Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available sshd
```

`salt.modules.debian_service.disable(name, **kwargs)`  
Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

`salt.modules.debian_service.disabled(name)`  
Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.disabled <service name>
```

`salt.modules.debian_service.enable(name, **kwargs)`  
Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

`salt.modules.debian_service.enabled(name, **kwargs)`  
Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.enabled <service name>
```

`salt.modules.debian_service.force_reload(name)`  
Force-reload the named service

CLI Example:

```
salt '*' service.force_reload <service name>
```

`salt.modules.debian_service.get_all()`  
Return all available boot services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.debian_service.get_disabled()`  
Return a set of services that are installed but disabled

CLI Example:

```
salt '*' service.get_disabled
```

`salt.modules.debian_service.get_enabled()`  
Return a list of service that are enabled on boot

CLI Example:

```
salt '*' service.get_enabled
```

`salt.modules.debian_service.missing(name)`  
The inverse of `service.available`. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing sshd
```

`salt.modules.debian_service.reload_(name)`  
Reload the named service

CLI Example:

```
salt '*' service.reload <service name>
```

`salt.modules.debian_service.restart(name)`  
Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.debian_service.start(name)`  
Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.debian_service.status`(*name*, *sig=None*)

Return the status for a service, pass a signature to use to find the service via ps

CLI Example:

```
salt '*' service.status <service name>
```

`salt.modules.debian_service.stop`(*name*)

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.50 salt.modules.defaults

`salt.modules.defaults.get`(*key*, *default=''*)

`defaults.get` is used much like `pillar.get` except that it will read a default value for a pillar from `defaults.json` or `defaults.yaml` files that are stored in the root of a salt formula.

CLI Example:

```
salt '*' defaults.get core:users:root
```

The defaults is computed from pillar key. The first entry is considered as the formula namespace.

For example, querying `core:users:root` will try to load `salt://core/defaults.yaml` and `salt://core/defaults.json`.

### 30.16.51 salt.modules.devmap

Device-Mapper module

`salt.modules.devmap.multipath_flush`(*device*)

Device-Mapper Multipath flush

CLI Example:

```
salt '*' devmap.multipath_flush mpath1
```

`salt.modules.devmap.multipath_list`()

Device-Mapper Multipath list

CLI Example:

```
salt '*' devmap.multipath_list
```

### 30.16.52 salt.modules.dig

Compendium of generic DNS utilities. The `dig` command line tool must be installed in order to use this module.

`salt.modules.dig.A`(*host*, *nameserver=None*)

Return the A record for *host*.

Always returns a list.

CLI Example:

```
salt ns1 dig.A www.google.com
```

`salt.modules.dig.AAAA` (*host, nameserver=None*)

Return the AAAA record for `host`.

Always returns a list.

CLI Example:

```
salt ns1 dig.AAAA www.google.com
```

`salt.modules.dig.MX` (*domain, resolve=False, nameserver=None*)

Return a list of lists for the MX of `domain`.

If the `resolve` argument is `True`, resolve IPs for the servers.

It's limited to one IP, because although in practice it's very rarely a round robin, it is an acceptable configuration and pulling just one IP lets the data be similar to the non-resolved version. If you think an MX has multiple IPs, don't use the resolver here, resolve them in a separate step.

CLI Example:

```
salt ns1 dig.MX google.com
```

`salt.modules.dig.NS` (*domain, resolve=True, nameserver=None*)

Return a list of IPs of the nameservers for `domain`

If `resolve` is `False`, don't resolve names.

CLI Example:

```
salt ns1 dig.NS google.com
```

`salt.modules.dig.SPF` (*domain, record='SPF', nameserver=None*)

Return the allowed IPv4 ranges in the SPF record for `domain`.

If `record` is `SPF` and the SPF record is empty, the TXT record will be searched automatically. If you know the domain uses TXT and not SPF, specifying that will save a lookup.

CLI Example:

```
salt ns1 dig.SPF google.com
```

`salt.modules.dig.TXT` (*host, nameserver=None*)

Return the TXT record for `host`.

Always returns a list.

CLI Example:

```
salt ns1 dig.TXT google.com
```

`salt.modules.dig.check_ip` (*addr*)

Check if address is a valid IP. returns `True` if valid, otherwise `False`.

CLI Example:

```
salt ns1 dig.check_ip 127.0.0.1
salt ns1 dig.check_ip 1111:2222:3333:4444:5555:6666:7777:8888
```

### 30.16.53 salt.modules.disk

Module for gathering disk information

`salt.modules.disk.blkid` (*device=None*)

Return block device attributes: UUID, LABEL, etc. This function only works on systems where blkid is available.

CLI Example:

```
salt '*' disk.blkid
salt '*' disk.blkid /dev/sda
```

`salt.modules.disk.inodeusage` (*args=None*)

Return inode usage information for volumes mounted on this minion

CLI Example:

```
salt '*' disk.inodeusage
```

`salt.modules.disk.percent` (*args=None*)

Return partition information for volumes mounted on this minion

CLI Example:

```
salt '*' disk.percent /var
```

`salt.modules.disk.usage` (*args=None*)

Return usage information for volumes mounted on this minion

CLI Example:

```
salt '*' disk.usage
```

### 30.16.54 salt.modules.djangomod

Manage Django sites

`salt.modules.djangomod.collectstatic` (*settings\_module, bin\_env=None, no\_post\_process=False, ignore=None, dry\_run=False, clear=False, link=False, no\_default\_ignore=False, pythonpath=None, env=None*)

Collect static files from each of your applications into a single location that can easily be served in production.

CLI Example:

```
salt '*' django.collectstatic <settings_module>
```

`salt.modules.djangomod.command` (*settings\_module, command, bin\_env=None, pythonpath=None, env=None, \*args, \*\*kwargs*)

Run arbitrary django management command

CLI Example:

```
salt '*' django.command <settings_module> <command>
```

`salt.modules.djangomod.createsuperuser` (*settings\_module, username, email, bin\_env=None, database=None, pythonpath=None, env=None*)

Create a super user for the database. This function defaults to use the `--noinput` flag which prevents the creation of a password for the superuser.

CLI Example:

```
salt '*' django.createsuperuser <settings_module> user user@example.com
```

`salt.modules.djangomod.loaddata`(*settings\_module*, *fixtures*, *bin\_env=None*, *database=None*, *pythonpath=None*, *env=None*)

Load fixture data

**Fixtures:** comma separated list of fixtures to load

CLI Example:

```
salt '*' django.loaddata <settings_module> <comma delimited list of fixtures>
```

`salt.modules.djangomod.syncdb`(*settings\_module*, *bin\_env=None*, *migrate=False*, *database=None*, *pythonpath=None*, *env=None*, *noinput=True*)

Run syncdb

Execute the Django-Admin syncdb command, if South is available on the minion the `migrate` option can be passed as `True` calling the migrations to run after the syncdb completes

CLI Example:

```
salt '*' django.syncdb <settings_module>
```

### 30.16.55 salt.modules.dnsmasq

Module for managing dnsmasq

`salt.modules.dnsmasq.fullversion`()

Shows installed version of dnsmasq and compile options.

CLI Example:

```
salt '*' dnsmasq.version
```

`salt.modules.dnsmasq.get_config`(*config\_file=/etc/dnsmasq.conf*)

Dumps all options from the config file.

CLI Examples:

```
salt '*' dnsmasq.get_config
salt '*' dnsmasq.get_config file=/etc/dnsmasq.conf
```

`salt.modules.dnsmasq.set_config`(*config\_file=/etc/dnsmasq.conf*, *follow=True*, *\*\*kwargs*)

Sets a value or a set of values in the specified file. By default, if `conf-dir` is configured in this file, salt will attempt to set the option in any file inside the `conf-dir` where it has already been enabled. If it does not find it inside any files, it will append it to the main config file. Setting `follow` to `False` will turn off this behavior.

If a config option currently appears multiple times (such as `dhcp-host`, which is specified at least once per host), the new option will be added to the end of the main config file (and not to any includes). If you need an option added to a specific include file, specify it as the `config_file`.

CLI Examples:

```
salt '*' dnsmasq.set_config domain=mydomain.com
salt '*' dnsmasq.set_config follow=False domain=mydomain.com
salt '*' dnsmasq.set_config file=/etc/dnsmasq.conf domain=mydomain.com
```

`salt.modules.dnsmasq.version`()

Shows installed version of dnsmasq.

CLI Example:

```
salt '*' dnsmasq.version
```

### 30.16.56 salt.modules.dnsutil

Compendium of generic DNS utilities

**salt.modules.dnsutil.A**(*host, nameserver=None*)

Return the A record(s) for *host*.

Always returns a list.

CLI Example:

```
salt ns1 dnsutil.A www.google.com
```

**salt.modules.dnsutil.AAAA**(*host, nameserver=None*)

Return the AAAA record(s) for *host*.

Always returns a list.

New in version 2014.7.5.

CLI Example:

```
salt ns1 dnsutil.AAAA www.google.com
```

**salt.modules.dnsutil.MX**(*domain, resolve=False, nameserver=None*)

Return a list of lists for the MX of *domain*.

If the `'resolve'` argument is True, resolve IPs for the servers.

It's limited to one IP, because although in practice it's very rarely a round robin, it is an acceptable configuration and pulling just one IP lets the data be similar to the non-resolved version. If you think an MX has multiple IPs, don't use the resolver here, resolve them in a separate step.

CLI Example:

```
salt ns1 dig.MX google.com
```

**salt.modules.dnsutil.NS**(*domain, resolve=True, nameserver=None*)

Return a list of IPs of the nameservers for *domain*

If `'resolve'` is False, don't resolve names.

CLI Example:

```
salt ns1 dig.NS google.com
```

**salt.modules.dnsutil.SPF**(*domain, record='SPF', nameserver=None*)

Return the allowed IPv4 ranges in the SPF record for *domain*.

If `record` is SPF and the SPF record is empty, the TXT record will be searched automatically. If you know the domain uses TXT and not SPF, specifying that will save a lookup.

CLI Example:

```
salt ns1 dig.SPF google.com
```

`salt.modules.dnsutil.check_ip(ip_addr)`  
 Check that string `ip_addr` is a valid IP

CLI Example:

```
salt ns1 dig.check_ip 127.0.0.1
```

`salt.modules.dnsutil.hosts_append(hostsfile='/etc/hosts', ip_addr=None, entries=None)`  
 Append a single line to the `/etc/hosts` file.

CLI Example:

```
salt '*' dnsutil.hosts_append /etc/hosts 127.0.0.1 ad1.yuk.co,ad2.yuk.co
```

`salt.modules.dnsutil.hosts_remove(hostsfile='/etc/hosts', entries=None)`  
 Remove a host from the `/etc/hosts` file. If doing so will leave a line containing only an IP address, then the line will be deleted. This function will leave comments and blank lines intact.

CLI Examples:

```
salt '*' dnsutil.hosts_remove /etc/hosts ad1.yuk.co
salt '*' dnsutil.hosts_remove /etc/hosts ad2.yuk.co,ad1.yuk.co
```

`salt.modules.dnsutil.parse_hosts(hostsfile='/etc/hosts', hosts=None)`  
 Parse `/etc/hosts` file.

CLI Example:

```
salt '*' dnsutil.parse_hosts
```

`salt.modules.dnsutil.parse_zone(zonefile=None, zone=None)`  
 Parses a zone file. Can be passed raw zone data on the API level.

CLI Example:

```
salt ns1 dnsutil.parse_zone /var/lib/named/example.com.zone
```

`salt.modules.dnsutil.serial(zone='', update=False)`  
 Return, store and update a dns serial for your zone files.

zone: a keyword for a specific zone

update: store an updated version of the serial in a grain

If `update` is `False`, the function will retrieve an existing serial or return the current date if no serial is stored. Nothing will be stored

If `update` is `True`, the function will set the serial to the current date if none exist or if the existing serial is for a previous date. If a serial for greater than the current date is already stored, the function will increment it.

This module stores the serial in a grain, you can explicitly set the stored value as a grain named `dnsserial_<zone_name>`.

CLI Example:

```
salt ns1 dnsutil.serial example.com
```

### 30.16.57 salt.modules.dockerio

Management of Docker Containers

New in version 2014.1.0.

---

**Note:** The DockerIO integration is still in beta; the API is subject to change

---

## General Notes

As we use states, we don't want to be continuously popping dockers, so we will map each container id (or image) with a grain whenever it is relevant.

As a corollary, we will resolve a container id either directly by the id or try to find a container id matching something stocked in grain.

## Installation Prerequisites

- You will need the `docker-py` python package in your python installation path that is running salt. Its version should support [Docker Remote API v1.12](#).

Currently, `docker-py 0.6.0` is known to support [Docker Remote API v1.12](#)

```
pip install docker-py==0.6.0
```

## Prerequisite Pillar Configuration for Authentication

- To push or pull you will need to be authenticated as the `docker-py` bindings require it
- For this to happen, you will need to configure a mapping in the pillar representing your per URL authentication bits:

```
docker-registries:
  registry_url:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

- You need at least an entry to the default docker index:

```
docker-registries:
  https://index.docker.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

- You can define multiple registry blocks for them to be aggregated. The only thing to keep in mind is that their ID must finish with `-docker-registries`:

```
ac-docker-registries:
  https://index.bar.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo

ab-docker-registries:
  https://index.foo.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

This could be also written as:

```
docker-registries:
  https://index.bar.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
  https://index.foo.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

## Methods

- **Registry Dialog**
  - *login*
  - *push*
  - *pull*
- **Docker Management**
  - *version*
  - *info*
- **Image Management**
  - *search*
  - *inspect\_image*
  - *get\_images*
  - *remove\_image*
  - *import\_image*
  - *build*
  - *tag*
  - *save*
  - *load*
- **Container Management**
  - *start*
  - *stop*
  - *restart*
  - *kill*
  - *wait*
  - *get\_containers*
  - *inspect\_container*
  - *remove\_container*
  - *is\_running*

- *top*
- *port*
- *logs*
- *diff*
- *commit*
- *create\_container*
- *export*
- *get\_container\_root*

### Runtime Execution within a specific, already existing/running container

Idea is to use `lxc-attach` to execute inside the container context. We do not want to use `docker run` but want to execute something inside a running container.

These are the available methods:

- *retcode*
- *run*
- *run\_all*
- *run\_stderr*
- *run\_stdout*
- *script*
- *script\_retcode*

`salt.modules.dockerio.build`(*path=None, tag=None, quiet=False, fileobj=None, nocache=False, rm=True, timeout=None*)

Build a docker image from a dockerfile or an URL

**path** url/branch/docker\_dir or path on the filesystem to the dockerfile

**tag** tag of the image

**quiet** quiet mode, Default is `False`

**nocache** do not use docker image cache, Default is `False`

**rm** remove intermediate commits, Default is `True`

**timeout** timeout value before aborting (in seconds)

CLI Example:

```
salt '*' docker.build vieux/apache
salt '*' docker.build github.com/creack/docker-firefox
```

`salt.modules.dockerio.commit`(*container, repository=None, tag=None, message=None, author=None, conf=None*)

Commit a container (promotes it to an image)

**container** container id

**repository** repository/image to commit to

**tag** tag of the image (Optional)

**message** commit message (Optional)

**author** author name (Optional)

**conf** conf (Optional)

CLI Example:

```
salt '*' docker.commit <container id>
```

```
salt.modules.dockerio.create_container(image, command=None, hostname=None, user=None,
                                         detach=True, stdin_open=False, tty=False,
                                         mem_limit=0, ports=None, environment=None,
                                         dns=None, volumes=None, volumes_from=None,
                                         name=None, cpu_shares=None, cpuset=None,
                                         binds=None)
```

Create a new container

**image** image to create the container from

**command** command to execute while starting

**hostname** hostname of the container

**user** user to run docker as

**detach** daemon mode, Default is True

**environment** environment variable mapping ({'foo': 'BAR'})

**ports** port redirections ({'222': {}})

**volumes** list of volume mappings in either local volume, bound volume, or read-only bound volume form:

```
(['/var/lib/mysql/', '/usr/local/etc/ssl:/etc/ssl', '/etc/passwd:/etc/passwd:ro'])
```

**binds** complete dictionary of bound volume mappings:

```
{ '/usr/local/etc/ssl/certs/internal.crt': {
  'bind': '/etc/ssl/certs/com.example.internal.crt',
  'ro': True
},
  '/var/lib/mysql': {
  'bind': '/var/lib/mysql/',
  'ro': False
}
}
```

This dictionary is suitable for feeding directly into the Docker API, and all keys are required. (see <http://docker-py.readthedocs.org/en/latest/volumes/>)

**tty** attach ttys, Default is False

**stdin\_open** let stdin open, Default is False

**name** name given to container

**cpu\_shares** CPU shares (relative weight)

**cpuset** CPUs in which to allow execution ('0-3' or '0,1')

CLI Example:

```
salt '*' docker.create_container o/ubuntu volumes="['/s', '/m:/f']"
```

`salt.modules.dockerio.diff(container)`

Get container diffs

**container** container id

CLI Example:

```
salt '*' docker.diff <container id>
```

`salt.modules.dockerio.exists(container)`

Check if a given container exists

**container** container id

Returns True if container exists otherwise returns False

CLI Example:

```
salt '*' docker.exists <container id>
```

`salt.modules.dockerio.export(container, path)`

Export a container to a file

**container** container id

**path** path to which file is to be exported

CLI Example:

```
salt '*' docker.export <container id>
```

`salt.modules.dockerio.get_container_root(container)`

Get the container rootfs path

**container** container id or grain

CLI Example:

```
salt '*' docker.get_container_root <container id>
```

`salt.modules.dockerio.get_containers(all=True, trunc=False, since=None, before=None, limit=-1, host=False, inspect=False)`

Get a list of mappings representing all containers

**all** return all containers, Default is True

**trunc** set it to True to have the short ID, Default is False

**host** include the Docker host's ipv4 and ipv6 address in return, Default is False

**inspect** Get more granular information about each container by running a docker inspect

CLI Example:

```
salt '*' docker.get_containers
salt '*' docker.get_containers host=True
salt '*' docker.get_containers host=True inspect=True
```

`salt.modules.dockerio.get_images(name=None, quiet=False, all=True)`

List docker images

**name** repository name

**quiet** only show image id, Default is False

**all** show all images, Default is True

CLI Example:

```
salt '*' docker.get_images <name> [quiet=True|False] [all=True|False]
```

`salt.modules.dockerio.import_image(src, repo, tag=None)`

Import content from a local tarball or a URL to a docker image

**src** content to import (URL or absolute path to a tarball)

**repo** repository to import to

**tag** set tag of the image (Optional)

CLI Example:

```
salt '*' docker.import_image <src> <repo> [tag]
```

`salt.modules.dockerio.info()`

Get the version information about docker. This is similar to `docker info` command

CLI Example:

```
salt '*' docker.info
```

`salt.modules.dockerio.inspect_container(container)`

Get container information. This is similar to `docker inspect` command but only for containers

**container** container id

CLI Example:

```
salt '*' docker.inspect_container <container id>
```

`salt.modules.dockerio.inspect_image(image)`

Inspect the status of an image and return relative data. This is similar to `docker inspect` command but only for images

**image** name of the image

CLI Example:

```
salt '*' docker.inspect_image <image>
```

`salt.modules.dockerio.is_running(container)`

Check if the specified container is running

**container** container id

Returns True if container is running otherwise returns False

CLI Example:

```
salt '*' docker.is_running <container id>
```

`salt.modules.dockerio.kill(container)`

Kill a running container

**container** container id

CLI Example:

```
salt '*' docker.kill <container id>
```

`salt.modules.dockerio.load(imagepath)`

Load the specified file at `imagepath` into docker that was generated from a docker save command e.g. `docker load < imagepath`

**imagepath** imagepath to docker tar file

CLI Example:

```
salt '*' docker.load /path/to/image
```

`salt.modules.dockerio.login(url=None, username=None, password=None, email=None)`

Wrapper to the `docker.py` login method (does not do much yet)

**url** registry url to authenticate to

**username** username to authenticate

**password** password to authenticate

**email** email to authenticate

CLI Example:

```
salt '*' docker.login <url> <username> <password> <email>
```

`salt.modules.dockerio.logs(container)`

Return logs for a specified container

**container** container id

CLI Example:

```
salt '*' docker.logs <container id>
```

`salt.modules.dockerio.port(container, private_port)`

Private port mapping allocation information. This method is broken on docker-py side. Just use the result of `inspect` to mangle port allocation

**container** container id

**private\_port** private port on the container to query for

CLI Example:

```
salt '*' docker.port <container id> <private port>
```

`salt.modules.dockerio.pull(repo, tag=None, insecure_registry=False)`

Pulls an image from any registry. See documentation at top of this page to configure authenticated access

**repo** name of repository

**tag** specific tag to pull (Optional)

**insecure\_registry** set as `True` to use insecure (non HTTPS) registry. Default is `False` (only available if using `docker-py >= 0.5.0`)

CLI Example:

```
salt '*' docker.pull <repository> [tag]
```

`salt.modules.dockerio.push(repo, tag=None, quiet=False, insecure_registry=False)`

Pushes an image to any registry. See documentation at top of this page to configure authenticated access

**repo** name of repository

**tag** specific tag to push (Optional)

**quiet** set as True to quiet output, Default is False

**insecure\_registry** set as True to use insecure (non HTTPS) registry. Default is False (only available if using docker-py >= 0.5.0)

CLI Example:

```
salt '*' docker.push <repository> [tag] [quiet=True|False]
```

**salt.modules.dockerio.remove\_container**(*container*, *force=False*, *v=False*)

Remove a container from a docker installation

**container** container id

**force** remove a running container, Default is False

**v** remove the volumes associated to the container, Default is False

CLI Example:

```
salt '*' docker.remove_container <container id> [force=True|False] [v=True|False]
```

**salt.modules.dockerio.remove\_image**(*image*)

Remove an image from a system.

**image** name of image

CLI Example:

```
salt '*' docker.remove_image <image>
```

**salt.modules.dockerio.restart**(*container*, *timeout=10*)

Restart a running container

**container** container id

**timeout** timeout for container to exit gracefully before killing it, Default is 10 seconds

CLI Example:

```
salt '*' docker.restart <container id> [timeout=20]
```

**salt.modules.dockerio.retcode**(*container*, *cmd*)

Wrapper for *cmdmod.retcode* inside a container context

**container** container id (or grain)

**cmd** command to execute

**Note:** The return is True or False depending on the commands success.

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:

```
salt '*' docker.retcode <container id> 'ls -l /etc'
```

**salt.modules.dockerio.run**(*container*, *cmd*)

Wrapper for *cmdmod.run* inside a container context

**container** container id (or grain)

**cmd** command to execute

---

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always True.

---

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

---

CLI Example:

```
salt '*' docker.run <container id> 'ls -l /etc'
```

---

`salt.modules.dockerio.run_all`(*container*, *cmd*)

Wrapper for `cmdmod.run_all` inside a container context

**container** container id (or grain)

**cmd** command to execute

---

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is False if command failed to execute.

---

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

---

CLI Example:

```
salt '*' docker.run_all <container id> 'ls -l /etc'
```

---

`salt.modules.dockerio.run_stderr`(*container*, *cmd*)

Wrapper for `cmdmod.run_stderr` inside a container context

**container** container id (or grain)

**cmd** command to execute

---

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always True.

---

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

---

CLI Example:

```
salt '*' docker.run_stderr <container id> 'ls -l /etc'
```

---

`salt.modules.dockerio.run_stdout`(*container*, *cmd*)

Wrapper for `cmdmod.run_stdout` inside a container context

**container** container id (or grain)

**cmd** command to execute

---

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always True.

---

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:

```
salt '*' docker.run_stdout <container id> 'ls -l /etc'
```

`salt.modules.dockerio.save`(*image*, *filename*)

New in version 2015.5.0.

Save the specified image to filename from docker e.g. *docker save image > filename*

**image** name of image

**filename** The filename of the saved docker image

CLI Example:

```
salt '*' docker.save arch_image /path/to/save/image
```

`salt.modules.dockerio.script`(*container*, *source*, *args=None*, *cwd=None*, *stdin=None*, *runas=None*, *shell='/bin/sh'*, *env=None*, *template='jinja'*, *umask=None*, *timeout=None*, *reset\_system\_locale=True*, *no\_clean=False*, *saltenv='base'*)

Wrapper for `cmdmod.script` inside a container context

**container** container id (or grain)

**additional parameters** See `cmd.script`

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

Download a script from a remote location and execute the script in the container. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

The script can also be formatted as a template, the default is jinja. Arguments for the script can be specified as well.

CLI Example:

```
salt '*' docker.script <container id> salt://docker_script.py
salt '*' docker.script <container id> salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' docker.script <container id> salt://scripts/windows_task.ps1 args=' -Input c:\tmp\infil
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

CLI Example:

```
salt '*' docker.script <container id> salt://scripts/runme.sh stdin='one\ntwo\nthree\nfour\nfive
```

`salt.modules.dockerio.script_retcode`(*container*, *source*, *cwd=None*, *stdin=None*, *runas=None*, *shell='/bin/sh'*, *env=None*, *template='jinja'*, *umask=None*, *timeout=None*, *reset\_system\_locale=True*, *no\_clean=False*, *saltenv='base'*)

Wrapper for `cmdmod.script_retcode` inside a container context

**container** container id (or grain)

**additional parameters** See `cmd.script_retcode`

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:

```
salt '*' docker.script_retcode <container id> salt://docker_script.py
```

`salt.modules.dockerio.search(term)`

Search for an image on the registry

**term** search keyword

CLI Example:

```
salt '*' docker.search <term>
```

`salt.modules.dockerio.start(container, binds=None, port_bindings=None, lxc_conf=None, publish_all_ports=None, links=None, privileged=False, dns=None, volumes_from=None, network_mode=None, restart_policy=None, cap_add=None, cap_drop=None)`

Start the specified container

**container** container id

CLI Example:

```
salt '*' docker.start <container id>
```

`salt.modules.dockerio.stop(container, timeout=10)`

Stop a running container

**container** container id

**timeout** timeout for container to exit gracefully before killing it, Default is 10 seconds

CLI Example:

```
salt '*' docker.stop <container id> [timeout=20]
```

`salt.modules.dockerio.tag(image, repository, tag=None, force=False)`

Tag an image into a repository

**image** name of image

**repository** name of repository

**tag** tag to apply (Optional)

**force** force apply tag, Default is False

CLI Example:

```
salt '*' docker.tag <image> <repository> [tag] [force=True|False]
```

`salt.modules.dockerio.top(container)`

Run the docker top command on a specific container

**container** container id

CLI Example:

```
salt '*' docker.top <container id>
```

**salt.modules.dockerio.version()**

Get docker version

CLI Example:

```
salt '*' docker.version
```

**salt.modules.dockerio.wait(*container*)**

Wait for a container to exit gracefully

**container** container id

CLI Example:

```
salt '*' docker.wait <container id>
```

### 30.16.58 salt.modules.dpkg

Support for DEB packages

**salt.modules.dpkg.file\_dict(*\*packages*)**

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of `_every_file` on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

**salt.modules.dpkg.file\_list(*\*packages*)**

List the files that belong to a package. Not specifying any packages will return a list of `_every_file` on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

**salt.modules.dpkg.list\_pkgs(*\*packages*)**

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

External dependencies:

Virtual package resolution requires aptitude. Because this function uses dpkg, virtual packages will be reported as not installed.

CLI Example:

```
salt '*' lowpkg.list_pkgs
salt '*' lowpkg.list_pkgs httpd
```

**salt.modules.dpkg.unpurge(*\*packages*)**

Change package selection for each package specified to `'install'`

CLI Example:

```
salt '*' lowpkg.unpurge curl
```

### 30.16.59 salt.modules.drac

Manage Dell DRAC

**salt.modules.drac.change\_password**(*username, password, uid=None*)

Change users password

CLI Example:

```
salt dell drac.change_password [USERNAME] [PASSWORD] [UID - optional]
salt dell drac.change_password diana secret
```

**salt.modules.drac.create\_user**(*username, password, permissions, users=None*)

Create user accounts

CLI Example:

```
salt dell drac.create_user [USERNAME] [PASSWORD] [PRIVELEGES]
salt dell drac.create_user diana secret login,test_alerts,clear_logs
```

#### DRAC Privileges

- login : Login to iDRAC
- drac : Configure iDRAC
- user\_management : Configure Users
- clear\_logs : Clear Logs
- server\_control\_commands : Execute Server Control Commands
- console\_redirection : Access Console Redirection
- virtual\_media : Access Virtual Media
- test\_alerts : Test Alerts
- debug\_commands : Execute Debug Commands

**salt.modules.drac.delete\_user**(*username, uid=None*)

Delete a user

CLI Example:

```
salt dell drac.delete_user [USERNAME] [UID - optional]
salt dell drac.delete_user diana 4
```

**salt.modules.drac.email\_alerts**(*action*)

Enable/Disable email alerts

CLI Example:

```
salt dell drac.email_alerts True
salt dell drac.email_alerts False
```

**salt.modules.drac.list\_users()**

List all DRAC users

CLI Example:

```
salt dell drac.list_users
```

**salt.modules.drac.nameservers(\*ns)**

Configure the nameservers on the DRAC

CLI Example:

```
salt dell drac.nameservers [NAMESERVERS]
salt dell drac.nameservers ns1.example.com ns2.example.com
```

**salt.modules.drac.network\_info()**

Return Network Configuration

CLI Example:

```
salt dell drac.network_info
```

**salt.modules.drac.server\_hardreset()**

Performs a reset (reboot) operation on the managed server.

CLI Example:

```
salt dell drac.server_hardreset
```

**salt.modules.drac.server\_poweroff()**

Powers down the managed server.

CLI Example:

```
salt dell drac.server_poweroff
```

**salt.modules.drac.server\_poweron()**

Powers up the managed server.

CLI Example:

```
salt dell drac.server_poweron
```

**salt.modules.drac.server\_pxe()**

Configure server to PXE perform a one off PXE boot

CLI Example:

```
salt dell drac.server_pxe
```

**salt.modules.drac.server\_reboot()**

Issues a power-cycle operation on the managed server. This action is similar to pressing the power button on the system's front panel to power down and then power up the system.

CLI Example:

```
salt dell drac.server_reboot
```

**salt.modules.drac.set\_network(ip, netmask, gateway)**

Configure Network

CLI Example:

```
salt dell drac.set_network [DRAC IP] [NETMASK] [GATEWAY]
salt dell drac.set_network 192.168.0.2 255.255.255.0 192.168.0.1
```

`salt.modules.drac.set_permissions` (*username, permissions, uid=None*)

Configure users permissions

CLI Example:

```
salt dell drac.set_permissions [USERNAME] [PRIVELEGES] [USER INDEX - optional]
salt dell drac.set_permissions diana login,test_alerts,clear_logs 4
```

### DRAC Privileges

- login : Login to iDRAC
- drac : Configure iDRAC
- user\_management : Configure Users
- clear\_logs : Clear Logs
- server\_control\_commands : Execute Server Control Commands
- console\_redirection : Access Console Redirection
- virtual\_media : Access Virtual Media
- test\_alerts : Test Alerts
- debug\_commands : Execute Debug Commands

`salt.modules.drac.set_snmp` (*community*)

Configure SNMP community string

CLI Example:

```
salt dell drac.set_snmp [COMMUNITY]
salt dell drac.set_snmp public
```

`salt.modules.drac.syslog` (*server, enable=True*)

Configure syslog remote logging, by default syslog will automatically be enabled if a server is specified. However, if you want to disable syslog you will need to specify a server followed by False

CLI Example:

```
salt dell drac.syslog [SYSLOG IP] [ENABLE/DISABLE]
salt dell drac.syslog 0.0.0.0 False
```

`salt.modules.drac.system_info` ()

Return System information

CLI Example:

```
salt dell drac.system_info
```

## 30.16.60 salt.modules.drbd

DRBD administration module

`salt.modules.drbd.overview()`

Show status of the DRBD devices

CLI Example:

```
salt '*' drbd.overview
```

### 30.16.61 salt.modules.ebuild

Support for Portage

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

#### optdepends

- portage Python adapter

For now all package names *MUST* include the package category, i.e. 'vim' will not work, 'app-editors/vim' will.

`salt.modules.ebuild.check_db(*names, **kwargs)`

New in version 0.17.0.

Returns a dict containing the following information for each specified package:

- 1.A key `found`, which will be a boolean value denoting if a match was found in the package database.
- 2.If `found` is `False`, then a second key called `suggestions` will be present, which will contain a list of possible matches. This list will be empty if the package name was specified in `category/pkgname` format, since the suggestions are only intended to disambiguate ambiguous package names (ones submitted without a category).

CLI Examples:

```
salt '*' pkg.check_db <package1> <package2> <package3>
```

`salt.modules.ebuild.check_extra_requirements(pkgname, pkgver)`

Check if the installed package already has the given requirements.

CLI Example:

```
salt '*' pkg.check_extra_requirements 'sys-devel/gcc' '~>4.1.2:4.1::gentoo[nls,fortran]'
```

`salt.modules.ebuild.depclean(name=None, slot=None, fromrepo=None, pkgs=None)`

Portage has a function to remove unused dependencies. If a package is provided, it will only removed the package if no other package depends on it.

**name** The name of the package to be cleaned.

**slot** Restrict the remove to a specific slot. Ignored if `name` is `None`.

**fromrepo** Restrict the remove to a specific slot. Ignored if `name` is `None`.

**pkgs** Clean multiple packages. `slot` and `fromrepo` arguments are ignored if this argument is present. Must be passed as a python list.

Return a list containing the removed packages:

CLI Example:

```
salt '*' pkg.depclean <package name>
```

#### `salt.modules.ebuild.ex_mod_init`(*low*)

If the config option `ebuild.enforce_nice_config` is set to `True`, this module will enforce a nice tree structure for `/etc/portage/package.*` configuration files.

New in version 0.17.0: Initial automatic enforcement added when `pkg` is used on a Gentoo system.

Changed in version 2014.1.0-Hydrogen: Configure option added to make this behaviour optional, defaulting to off.

See also:

`ebuild.ex_mod_init` is called automatically when a state invokes a `pkg` state on a Gentoo system.  
`salt.states.pkg.mod_init()`

`ebuild.ex_mod_init` uses `portage_config.enforce_nice_config` to do the lifting.  
[salt.modules.portage\\_config.enforce\\_nice\\_config\(\)](#)

CLI Example:

```
salt '*' pkg.ex_mod_init
```

#### `salt.modules.ebuild.install`(*name=None, refresh=False, pkgs=None, sources=None, slot=None, fromrepo=None, uses=None, binhost=None, \*\*kwargs*)

Install the passed package(s), add `refresh=True` to sync the portage tree before package is installed.

**name** The name of the package to be installed. Note that this parameter is ignored if either `pkgs` or `sources` is passed. Additionally, please note that this option can only be used to emerge a package from the portage tree. To install a `tbz2` package manually, use the `sources` option described below.

CLI Example:

```
salt '*' pkg.install <package name>
```

**refresh** Whether or not to sync the portage tree before installing.

**version** Install a specific version of the package, e.g. `1.0.9-r1`. Ignored if `pkgs` or `sources` is passed.

**slot** Similar to `version`, but specifies a valid slot to be installed. It will install the latest available version in the specified slot. Ignored if `pkgs` or `sources` or `version` is passed.

CLI Example:

```
salt '*' pkg.install sys-devel/gcc slot='4.4'
```

**fromrepo** Similar to `slot`, but specifies the repository from the package will be installed. It will install the latest available version in the specified repository. Ignored if `pkgs` or `sources` or `version` is passed.

CLI Example:

```
salt '*' pkg.install salt fromrepo='gentoo'
```

**uses** Similar to `slot`, but specifies a list of use flag. Ignored if `pkgs` or `sources` or `version` is passed.

CLI Example:

```
salt '*' pkg.install sys-devel/gcc uses='["nptl","-nossp"]'
```

Multiple Package Installation Options:

**pkgs** A list of packages to install from the portage tree. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs='["foo","bar","~category/package:slot::repository[use]"']'
```

**sources** A list of tbz2 packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources='[{"foo": "salt://foo.tbz2"}, {"bar": "salt://bar.tbz2"}]'
```

**binhost** has two options `try` and `force`. `try` - tells emerge to try and install the package from a configured binhost. `force` - forces emerge to install the package from a binhost otherwise it fails out.

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

**salt.modules.ebuild.latest\_version**(*\*names, \*\*kwargs*)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

**salt.modules.ebuild.list\_pkgs**(*versions\_as\_list=False, \*\*kwargs*)

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

**salt.modules.ebuild.list\_upgrades**(*refresh=True*)

List all available package upgrades.

CLI Example:

```
salt '*' pkg.list_upgrades
```

**salt.modules.ebuild.porttree\_matches**(*name*)

Returns a list containing the matches for a given package name from the portage tree. Note that the specific version of the package will not be provided for packages that have several versions in the portage tree, but rather the name of the package (i.e. `dev-python/paramiko`).

**salt.modules.ebuild.purge**(*name=None, slot=None, fromrepo=None, pkgs=None, \*\*kwargs*)

Portage does not have a purge, this function calls `remove` followed by `depclean` to emulate a purge process

**name** The name of the package to be deleted.

**slot** Restrict the remove to a specific slot. Ignored if `name` is `None`.

**fromrepo** Restrict the remove to a specific slot. Ignored if `name` is `None`.

Multiple Package Options:

**pkgs** Uninstall multiple packages. `slot` and `fromrepo` arguments are ignored if this argument is present. Must be passed as a python list.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package name> slot=4.4
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

**salt.modules.ebuild.refresh\_db()**

Updates the portage tree (emerge --sync). Uses eix-sync if available.

CLI Example:

```
salt '*' pkg.refresh_db
```

**salt.modules.ebuild.remove**(*name=None, slot=None, fromrepo=None, pkgs=None, \*\*kwargs*)

Remove packages via emerge --unmerge.

**name** The name of the package to be deleted.

**slot** Restrict the remove to a specific slot. Ignored if name is None.

**fromrepo** Restrict the remove to a specific slot. Ignored if name is None.

Multiple Package Options:

**pkgs** Uninstall multiple packages. **slot** and **fromrepo** arguments are ignored if this argument is present. Must be passed as a python list.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package name> slot=4.4 fromrepo=gentoo
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

**salt.modules.ebuild.update**(*pkg, slot=None, fromrepo=None, refresh=False, binhost=None*)

Updates the passed package (emerge --update package)

**slot** Restrict the update to a particular slot. It will update to the latest version within the slot.

**fromrepo** Restrict the update to a particular repository. It will update to the latest version within the repository.

**binhost** has two options try and force. try - tells emerge to try and install the package from a configured binhost. force - forces emerge to install the package from a binhost otherwise it fails out.

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.update <package name>
```

**salt.modules.ebuild.upgrade**(*refresh=True, binhost=None*)

Run a full system upgrade (emerge --update world)

**binhost** has two options `try` and `force`. `try` - tells emerge to try and install the package from a configured binhost. `force` - forces emerge to install the package from a binhost otherwise it fails out.

Return a dict containing the new package names and versions:

```
{'package': {'old': '<old-version>',
              'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

`salt.modules.ebuild.upgrade_available(name)`

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

`salt.modules.ebuild.version(*names, **kwargs)`

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

`salt.modules.ebuild.version_clean(version)`

Clean the version string removing extra data.

CLI Example:

```
salt '*' pkg.version_clean <version_string>
```

`salt.modules.ebuild.version_cmp(pkg1, pkg2)`

Do a cmp-style comparison on two packages. Return -1 if `pkg1 < pkg2`, 0 if `pkg1 == pkg2`, and 1 if `pkg1 > pkg2`. Return None if there was a problem making the comparison.

CLI Example:

```
salt '*' pkg.version_cmp '0.2.4-0' '0.2.4.1-0'
```

### 30.16.62 salt.modules.eix

Support for Eix

`salt.modules.eix.sync()`

Sync portage/overlay trees and update the eix database

CLI Example:

```
salt '*' eix.sync
```

`salt.modules.eix.update()`

Update the eix database

CLI Example:

```
salt '*' eix.update
```

### 30.16.63 salt.modules.elasticsearch

Connection module for Elasticsearch

**depends** elasticsearch

**salt.modules.elasticsearch.delete**(*index, doc\_type, id, hosts=None, profile='elasticsearch'*)

Delete the document specified by the id in the index.

CLI example:

```
salt myminion elasticsearch.delete grafana-dash dashboard mydash profile='grafana'
```

**salt.modules.elasticsearch.exists**(*index, id, doc\_type='\_all', hosts=None, profile='elasticsearch'*)

Check for the existence of an elasticsearch document specified by id in the index.

CLI example:

```
salt myminion elasticsearch.exists grafana-dash mydash profile='grafana'
```

**salt.modules.elasticsearch.get**(*index, id, doc\_type='\_all', hosts=None, profile='elasticsearch'*)

Get the contents of the specified id from the index.

CLI example:

```
salt myminion elasticsearch.get grafana-dash mydash profile='grafana'
```

**salt.modules.elasticsearch.index**(*index, doc\_type, body, id=None, hosts=None, profile='elasticsearch'*)

Create or update an index with the specified body for the specified id.

CLI example:

```
salt myminion elasticsearch.index grafana-dash dashboard '{"user":"guest","group":"guest","body":
```

### 30.16.64 salt.modules.environ

Support for getting and setting the environment variables of the current salt process.

**salt.modules.environ.get**(*key, default=''*)

Get a single salt process environment variable.

**key** String used as the key for environment lookup.

**default** If the key is not found in the environment, return this value. Default: ``

CLI Example:

```
salt '*' environ.get foo
salt '*' environ.get baz default=False
```

**salt.modules.environ.has\_value**(*key, value=None*)

Determine whether the key exists in the current salt process environment dictionary. Optionally compare the current value of the environment against the supplied value string.

**key** Must be a string. Used as key for environment lookup.

**value:** Optional. If key exists in the environment, compare the current value with this value. Return True if they are equal.

CLI Example:

```
salt '*' environ.has_value foo
```

`salt.modules.environ.item(keys, default='')`

Get one or more salt process environment variables. Returns a dict.

**keys** Either a string or a list of strings that will be used as the keys for environment lookup.

**default** If the key is not found in the environment, return this value. Default: ''

CLI Example:

```
salt '*' environ.item foo
salt '*' environ.item '[foo, baz]' default=None
```

`salt.modules.environ.items()`

Return a dict of the entire environment set for the salt process

CLI Example:

```
salt '*' environ.items
```

`salt.modules.environ.setenv(envIRON, false_unsets=False, clear_all=False, update_minion=False)`

Set multiple salt process environment variables from a dict. Returns a dict.

**envIRON** Must be a dict. The top-level keys of the dict are the names of the environment variables to set. Each key's value must be a string or False. Refer to the 'false\_unsets' parameter for behavior when a value set to False.

**false\_unsets** If a key's value is False and false\_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key's value is False and false\_unsets is not True, then the key's value will be set to an empty string. Default: False

**clear\_all** USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear\_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False

**update\_minion** If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False

CLI Example:

```
salt '*' environ.setenv '{"foo": "bar", "baz": "quux"}'
salt '*' environ.setenv '{"a": "b", "c": False}' false_unsets=True
```

`salt.modules.environ.setval(key, val, false_unsets=False)`

Set a single salt process environment variable. Returns True on success.

**key** The environment key to set. Must be a string.

**val** The value to set. Must be a string or False. Refer to the 'false\_unsets' parameter for behavior when set to False.

**false\_unsets** If val is False and false\_unsets is True, then the key will be removed from the salt processes environment dict entirely. If val is False and false\_unsets is not True, then the key's value will be set to an empty string. Default: False.

CLI Example:

```
salt '*' environ.setval foo bar
salt '*' environ.setval baz val=False false_unsets=True
```

### 30.16.65 salt.modules.eselect

Support for eselect, Gentoo's configuration and management tool.

**salt.modules.eselect.exec\_action**(*module*, *action*, *module\_parameter=None*, *action\_parameter=None*, *state\_only=False*)

Execute an arbitrary action on a module.

**module** name of the module to be executed

**action** name of the module's action to be run

**module\_parameter** additional params passed to the defined module

**action\_parameter** additional params passed to the defined action

**state\_only** don't return any output but only the success/failure of the operation

CLI Example (updating the php implementation used for apache2):

```
salt '*' eselect.exec_action php update action_parameter='apache2'
```

**salt.modules.eselect.get\_current\_target**(*module*, *module\_parameter=None*, *action\_parameter=None*)

Get the currently selected target for the given module.

**module** name of the module to be queried for its current target

**module\_parameter** additional params passed to the defined module

**action\_parameter** additional params passed to the `show' action

CLI Example (current target of system-wide java-vm):

```
salt '*' eselect.get_current_target java-vm action_parameter='system'
```

CLI Example (current target of kernel symlink):

```
salt '*' eselect.get_current_target kernel
```

**salt.modules.eselect.get\_modules**()

List available eselect modules.

CLI Example:

```
salt '*' eselect.get_modules
```

**salt.modules.eselect.get\_target\_list**(*module*)

List available targets for the given module.

**module** name of the module to be queried for its targets

CLI Example:

```
salt '*' eselect.get_target_list kernel
```

**salt.modules.eselect.set\_target**(*module*, *target*, *module\_parameter=None*, *action\_parameter=None*)

Set the target for the given module. Target can be specified by index or name.

**module** name of the module for which a target should be set

**target** name of the target to be set for this module

**module\_parameter** additional params passed to the defined module

**action\_parameter** additional params passed to the defined action

CLI Example (setting target of system-wide java-vm):

```
salt '*' eselect.set_target java-vm icedtea-bin-7 action_parameter='system'
```

CLI Example (setting target of kernel symlink):

```
salt '*' eselect.set_target kernel linux-3.17.5-gentoo
```

### 30.16.66 salt.modules.etcmod

Execution module to work with etcd

#### depends

- python-etcd

In order to use an etcd server, a profile should be created in the master configuration file:

```
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```
etcd.host: 127.0.0.1
etcd.port: 4001
```

**salt.modules.etcmod.get\_**(*key*, *recurse=False*, *profile=None*)

New in version 2014.7.0.

Get a value from etcd, by direct path

CLI Examples:

```
salt myminion etcd.get /path/to/key
salt myminion etcd.get /path/to/key profile=my_etcd_config
salt myminion etcd.get /path/to/key recurse=True profile=my_etcd_config
```

**salt.modules.etcmod.ls\_**(*path='/'*, *profile=None*)

New in version 2014.7.0.

Return all keys and dirs inside a specific path

CLI Example:

```
salt myminion etcd.ls /path/to/dir/
salt myminion etcd.ls /path/to/dir/ profile=my_etcd_config
```

**salt.modules.etcmod.rm\_**(*key*, *recurse=False*, *profile=None*)

New in version 2014.7.0.

Delete a key from etcd

CLI Example:

```
salt myminion etcd.rm /path/to/key
salt myminion etcd.rm /path/to/key profile=my_etcd_config
salt myminion etcd.rm /path/to/dir recurse=True profile=my_etcd_config
```

`salt.modules.etcd_mod.set_`(*key, value, profile=None*)

New in version 2014.7.0.

Set a value in etcd, by direct path

CLI Example:

```
salt myminion etcd.set /path/to/key value
salt myminion etcd.set /path/to/key value profile=my_etcd_config
```

`salt.modules.etcd_mod.tree`(*path='/', profile=None*)

New in version 2014.7.0.

Recurse through etcd and return all values

CLI Example:

```
salt myminion etcd.tree
salt myminion etcd.tree profile=my_etcd_config
salt myminion etcd.tree /path/to/keys profile=my_etcd_config
```

### 30.16.67 salt.modules.event

Use the [Salt Event System](#) to fire events from the master to the minion and vice-versa.

`salt.modules.event.fire`(*data, tag*)

Fire an event on the local minion event bus. Data must be formed as a dict.

CLI Example:

```
salt '*' event.fire '{"data":"my event data"}' 'tag'
```

`salt.modules.event.fire_master`(*data, tag, preload=None*)

Fire an event off up to the master server

CLI Example:

```
salt '*' event.fire_master '{"data":"my event data"}' 'tag'
```

`salt.modules.event.send`(*tag, data=None, preload=None, with\_env=False, with\_grains=False, with\_pillar=False, \*\*kwargs*)

Send an event to the Salt Master

New in version 2014.7.0.

#### Parameters

- **tag** -- A tag to give the event. Use slashes to create a namespace for related events. E.g., `myco/build/buildserver1/start`, `myco/build/buildserver1/success`, `myco/build/buildserver1/failure`.
- **data** -- A dictionary of data to send in the event. This is free-form. Send any data points that are needed for whoever is consuming the event. Arguments on the CLI are interpreted as YAML so complex data structures are possible.

- **with\_env** (Specify `True` to include all environment variables, or specify a list of strings of variable names to include.) -- Include environment variables from the current shell environment in the event data as `environ..` This is a short-hand for working with systems that seed the environment with relevant data such as Jenkins.
- **with\_grains** (Specify `True` to include all grains, or specify a list of strings of grain names to include.) -- Include grains from the current minion in the event data as `grains`.
- **with\_pillar** (Specify `True` to include all Pillar values, or specify a list of strings of Pillar keys to include. It is a best-practice to only specify a relevant subset of Pillar data.) -- Include Pillar values from the current minion in the event data as `pillar`. Remember Pillar data is often sensitive data so be careful. This is useful for passing ephemeral Pillar values through an event. Such as passing the `pillar={}` kwarg in `state.sls` from the Master, through an event on the Minion, then back to the Master.
- **kwargs** -- Any additional keyword arguments passed to this function will be interpreted as key-value pairs and included in the event data. This provides a convenient alternative to YAML for simple values.

CLI Example:

```
salt-call event.send myco/mytag foo=Foo bar=Bar
salt-call event.send 'myco/mytag' '{foo: Foo, bar: Bar}'
```

A convenient way to allow Jenkins to execute `salt-call` is via `sudo`. The following rule in `sudoers` will allow the `jenkins` user to run only the following command.

`/etc/sudoers` (allow preserving the environment):

```
jenkins ALL=(ALL) NOPASSWD:SETENV: /usr/bin/salt-call event.send*
```

Call Jenkins via `sudo` (preserve the environment):

```
sudo -E salt-call event.send myco/jenkins/build/success with_env=[BUILD_ID, BUILD_URL, GIT_BRANCH]
```

### 30.16.68 salt.modules.extfs

Module for managing ext2/3/4 file systems

`salt.modules.extfs.attributes` (*device, args=None*)

Return attributes from `dumpe2fs` for a specified device

CLI Example:

```
salt '*' extfs.attributes /dev/sda1
```

`salt.modules.extfs.blocks` (*device, args=None*)

Return block and inode info from `dumpe2fs` for a specified device

CLI Example:

```
salt '*' extfs.blocks /dev/sda1
```

`salt.modules.extfs.dump` (*device, args=None*)

Return all contents of `dumpe2fs` for a specified device

CLI Example:

```
salt '*' extfs.dump /dev/sda1
```

`salt.modules.extfs.mkfs` (*device*, *fs\_type*, *\*\*kwargs*)

Create a file system on the specified device

CLI Example:

```
salt '*' extfs.mkfs /dev/sda1 fs_type=ext4 opts='acl,noexec'
```

Valid options are:

- block\_size**: 1024, 2048 or 4096
- check**: check for bad blocks
- direct**: use direct IO
- ext\_opts**: extended file system options (comma-separated)
- fragment\_size**: size of fragments
- force**: setting force to True will cause mke2fs to specify the -F option twice (it is already set once); this is truly dangerous
- blocks\_per\_group**: number of blocks in a block group
- number\_of\_groups**: ext4 option for a virtual block group
- bytes\_per\_inode**: set the bytes/inode ratio
- inode\_size**: size of the inode
- journal**: set to True to create a journal (default on ext3/4)
- journal\_opts**: options for the fs journal (comma separated)
- blocks\_file**: read bad blocks from file
- label**: label to apply to the file system
- reserved**: percentage of blocks reserved for super-user
- last\_dir**: last mounted directory
- test**: set to True to not actually create the file system (mke2fs -n)
- number\_of\_inodes**: override default number of inodes
- creator\_os**: override ``creator operating system" field
- opts**: mount options (comma separated)
- revision**: set the filesystem revision (default 1)
- super**: write superblock and group descriptors only
- fs\_type**: set the filesystem type (REQUIRED)
- usage\_type**: how the filesystem is going to be used
- uuid**: set the UUID for the file system

See the `mke2fs(8)` manpage for a more complete description of these options.

`salt.modules.extfs.tune` (*device*, *\*\*kwargs*)

Set attributes for the specified device (using `tune2fs`)

CLI Example:

```
salt '*' extfs.tune /dev/sda1 force=True label=wildstallyns opts='acl,noexec'
```

Valid options are:

- max**: max mount count
- count**: mount count
- error**: error behavior
- extended\_opts**: extended options (comma separated)
- force**: force, even if there are errors (set to True)
- group**: group name or gid that can use the reserved blocks
- interval**: interval between checks
- journal**: set to True to create a journal (default on ext3/4)
- journal\_opts**: options for the fs journal (comma separated)
- label**: label to apply to the file system
- reserved**: percentage of blocks reserved for super-user
- last\_dir**: last mounted directory
- opts**: mount options (comma separated)
- feature**: set or clear a feature (comma separated)
- mmp\_check**: mmp check interval
- reserved**: reserved blocks count
- quota\_opts**: quota options (comma separated)
- time**: time last checked
- user**: user or uid who can use the reserved blocks
- uuid**: set the UUID for the file system

See the `mke2fs(8)` manpage for a more complete description of these options.

### 30.16.69 salt.modules.file

Manage information about regular files, directories, and special files on the minion, set/read user, group, mode, and data

`salt.modules.file.access`(*path, mode*)

New in version 2014.1.0.

Test whether the Salt process has the specified access to the file. One of the following modes must be specified:

CLI Example:

```
salt '*' file.access /path/to/file f
salt '*' file.access /path/to/file x
```

`salt.modules.file.append`(*path, \*args, \*\*kwargs*)

New in version 0.9.5.

Append text to the end of a file

**path** path to file

**\*args** strings to append to file

CLI Example:

```
salt '*' file.append /etc/motd \  
    "With all thine offerings thou shalt offer salt." \  
    "Salt is what makes things taste bad when it isn't in them."
```

---

#### Attention

If you need to pass a string to append and that string contains an equal sign, you **must** include the argument name, `args`. For example:

```
salt '*' file.append /etc/motd args='cheese=spam'  
  
salt '*' file.append /etc/motd args="['cheese=spam','spam=cheese']"
```

---

`salt.modules.file.basename`(*path*)

Returns the final component of a pathname

New in version 2015.5.0.

This can be useful at the CLI but is frequently useful when scripting.

```
{%- set filename = salt['file.basename'](source_file) %}
```

CLI Example:

```
salt '*' file.basename 'test/test.config'
```

`salt.modules.file.blockreplace`(*path*, *marker\_start*='#-- start managed zone --', *marker\_end*='#-- end managed zone --', *content*='', *append\_if\_not\_found*=False, *prepend\_if\_not\_found*=False, *backup*='.bak', *dry\_run*=False, *show\_changes*=True)

New in version 2014.1.0.

Replace content of a text block in a file, delimited by line markers

A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal.

---

**Note:** This function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

---

**path** Filesystem path to the file to be edited

**marker\_start** The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

**marker\_end** The line content identifying a line as the end of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

**content** The content to be used between the two lines identified by `marker_start` and `marker_stop`.

**append\_if\_not\_found** [False] If markers are not found and set to `True` then, the markers and content will be appended to the file.

**prepend\_if\_not\_found** [False] If markers are not found and set to `True` then, the markers and content will be prepended to the file.

**backup** The file extension to use for a backup of the file if any edit is made. Set to `False` to skip making a backup.

**dry\_run** Don't make any edits to the file.

**show\_changes** Output a unified diff of the old file and the new file. If `False`, return a boolean if any changes were made.

CLI Example:

```
salt '*' file.blockreplace /etc/hosts '#-- start managed zone foobar : DO NOT EDIT --' \
'#-- end managed zone foobar --' '$'10.0.1.1 foo.foobar\n10.0.1.2 bar.foobar' True
```

`salt.modules.file.check_file_meta`(*name, sfn, source, source\_sum, user, group, mode, saltenv, contents=None*)

Check for the changes in the file metadata.

CLI Example:

```
salt '*' file.check_file_meta /etc/httpd/conf.d/httpd.conf salt://http/httpd.conf '{hash_type: '}
```

**Note:** Supported hash types include sha512, sha384, sha256, sha224, sha1, and md5.

**name** Path to file destination

**sfn** Template-processed source file contents

**source** URL to file source

**source\_sum** File checksum information as a dictionary

```
{hash_type: md5, hsum: <md5sum>}
```

**user** Destination file user owner

**group** Destination file group owner

**mode** Destination file permissions mode

**saltenv** Salt environment used to resolve source files

**contents** File contents

`salt.modules.file.check_hash`(*path, file\_hash*)

Check if a file matches the given hash string

Returns true if the hash matched, otherwise false. Raises `ValueError` if the hash was not formatted correctly.

**path** A file path

**hash** A string in the form `<hash_type>:<hash_value>`. For example:  
md5:e138491e9d5b97023cea823fe17bac22

CLI Example:

```
salt '*' file.check_hash /etc/fstab md5:<md5sum>
```

`salt.modules.file.check_managed`(*name, source, source\_hash, user, group, mode, template, context, defaults, saltenv, contents=None, \*\*kwargs*)

Check to see what changes need to be made for a file

CLI Example:

```
salt '*' file.check_managed /etc/httpd/conf.d/httpd.conf salt://http/httpd.conf '{hash_type: 'md
```

`salt.modules.file.check_managed_changes`(*name, source, source\_hash, user, group, mode, template, context, defaults, saltenv, contents=None, \*\*kwargs*)

Return a dictionary of what changes need to be made for a file

CLI Example:

```
salt '*' file.check_managed_changes /etc/httpd/conf.d/httpd.conf salt://http/httpd.conf '{hash_t
```

`salt.modules.file.check_perms`(*name, ret, user, group, mode, follow\_symlinks=False*)

Check the permissions on files and chown if needed

CLI Example:

```
salt '*' file.check_perms /etc/sudoers '{}' root root 400
```

Changed in version 2014.1.3: `follow_symlinks` option added

`salt.modules.file.chgrp`(*path, group*)

Change the group of a file

**path** path to the file or directory

**group** group owner

CLI Example:

```
salt '*' file.chgrp /etc/passwd root
```

`salt.modules.file.chown`(*path, user, group*)

Chown a file, pass the file the desired user and group

**path** path to the file or directory

**user** user owner

**group** group owner

CLI Example:

```
salt '*' file.chown /etc/passwd root root
```

`salt.modules.file.comment`(*path, regex, char='#', backup='.bak'*)

Deprecated since version 0.17.0: Use `replace()` instead.

Comment out specified lines in a file

**path** The full path to the file to be edited

**regex** A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing `^` or `$` characters outside the parenthesis (e.g., the pattern `^foo$` will be rewritten as `^(foo)$`)

**char** [#] The character to be inserted at the beginning of a line in order to comment it out

**backup** [.bak] The file will be backed up before edit with this file extension

**Warning:** This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

CLI Example:

```
salt '*' file.comment /etc/modules pcspr
```

**salt.modules.file.comment\_line**(*path, regex, char='#, cmnt=True, backup='.bak'*)  
Comment or Uncomment a line in a text file.

**Parameters path** -- string

The full path to the text file.

**Parameters regex** -- string

A regex expression that begins with ^ that will find the line you wish to comment. Can be as simple as ^color =

**Parameters char** -- string

The character used to comment a line in the type of file you're referencing. Default is #

**Parameters cmnt** -- boolean

True to comment the line. False to uncomment the line. Default is True.

**Parameters backup** -- string

The file extension to give the backup file. Default is .bak

**Returns** boolean

Returns True if successful, False if not

CLI Example:

The following example will comment out the pcspr line in the /etc/modules file using the default # character and create a backup file named modules.bak

```
salt '*' file.comment_line '/etc/modules' '^pcspr'
```

CLI Example:

The following example will uncomment the log\_level setting in minion config file if it is set to either warning, info, or debug using the # character and create a backup file named minion.bk

```
salt '*' file.comment_line `C:saltconfminion` `^log_level: (warning|info|debug) `#` False `bk`
```

**salt.modules.file.contains**(*path, text*)  
Deprecated since version 0.17.0: Use [search\(\)](#) instead.

Return True if the file at path contains text

CLI Example:

```
salt '*' file.contains /etc/crontab 'mymaintenance.sh'
```

**salt.modules.file.contains\_glob**(*path, glob\_expr*)  
Deprecated since version 0.17.0: Use [search\(\)](#) instead.

Return True if the given glob matches a string in the named file

CLI Example:

```
salt '*' file.contains_glob /etc/foobar '*cheese*'
```

`salt.modules.file.contains_regex(path, regex, lchar='')`

Deprecated since version 0.17.0: Use `search()` instead.

Return True if the given regular expression matches on any line in the text of a given file.

If the `lchar` argument (leading char) is specified, it will strip `lchar` from the left side of each line before trying to match

CLI Example:

```
salt '*' file.contains_regex /etc/crontab
```

`salt.modules.file.contains_regex_multiline(path, regex)`

Deprecated since version 0.17.0: Use `search()` instead.

Return True if the given regular expression matches anything in the text of a given file

Traverses multiple lines at a time, via the salt BufferedReader (reads in chunks)

CLI Example:

```
salt '*' file.contains_regex_multiline /etc/crontab '^maint'
```

`salt.modules.file.copy(src, dst, recurse=False, remove_existing=False)`

Copy a file or directory from source to dst

In order to copy a directory, the `recurse` flag is required, and will by default overwrite files in the destination with the same path, and retain all other existing files. (similar to `cp -r` on unix)

`remove_existing` will remove all files in the target directory, and then copy files from the source.

CLI Example:

```
salt '*' file.copy /path/to/src /path/to/dst
salt '*' file.copy /path/to/src_dir /path/to/dst_dir recurse=True
salt '*' file.copy /path/to/src_dir /path/to/dst_dir recurse=True remove_existing=True
```

`salt.modules.file.delete_backup(path, backup_id)`

New in version 0.17.0.

Delete a previous version of a file that was backed up using Salt's `file state backup` system.

**path** The path on the minion to check for backups

**backup\_id** The numeric id for the backup you wish to delete, as found using `file.list_backups`

CLI Example:

```
salt '*' file.restore_backup /foo/bar/baz.txt 0
```

`salt.modules.file.directory_exists(path)`

Tests to see if path is a valid directory. Returns True/False.

CLI Example:

```
salt '*' file.directory_exists /etc
```

`salt.modules.file.dirname(path)`

Returns the directory component of a pathname

New in version 2015.5.0.

This can be useful at the CLI but is frequently useful when scripting.

```
{%- from salt['file.dirname'](tpldir) + '/vars.jinja' import parent_vars %}
```

CLI Example:

```
salt '*' file.dirname 'test/path/filename.config'
```

`salt.modules.file.diskusage`(*path*)

Recursively calculate disk usage of path and return it in bytes

CLI Example:

```
salt '*' file.diskusage /path/to/check
```

`salt.modules.file.extract_hash`(*hash\_fn*, *hash\_type='sha256'*, *file\_name=''*)

This routine is called from the *file.managed* state to pull a hash from a remote file. Regular expressions are used line by line on the *source\_hash* file, to find a potential candidate of the indicated hash type. This avoids many problems of arbitrary file lay out rules. It specifically permits pulling hash codes from debian *\*.dsc* files.

For example:

```
openerp_7.0-latest-1.tar.gz:
  file.managed:
    - name: /tmp/openerp_7.0-20121227-075624-1_all.deb
    - source: http://nightly.openerp.com/7.0/nightly/deb/openerp_7.0-20121227-075624-1.tar.gz
    - source_hash: http://nightly.openerp.com/7.0/nightly/deb/openerp_7.0-20121227-075624-1.dsc
```

CLI Example:

```
salt '*' file.extract_hash /etc/foo sha512 /path/to/hash/file
```

`salt.modules.file.file_exists`(*path*)

Tests to see if path is a valid file. Returns True/False.

CLI Example:

```
salt '*' file.file_exists /etc/passwd
```

`salt.modules.file.find`(*path*, *\*args*, *\*\*kwargs*)

Approximate the Unix `find(1)` command and return a list of paths that meet the specified criteria.

The options include match criteria:

```
name      = path-glob          # case sensitive
iname     = path-glob          # case insensitive
regex     = path-regex         # case sensitive
iregex    = path-regex         # case insensitive
type      = file-types         # match any listed type
user      = users              # match any listed user
group     = groups             # match any listed group
size      = [+]-number[size-unit] # default unit = byte
mtime     = interval           # modified since date
grep      = regex              # search file contents
```

and/or actions:

```
delete [= file-types]          # default type = 'f'
exec   = command [arg ...]     # where {} is replaced by pathname
print  [= print-opts]
```

and/or depth criteria:

```
maxdepth = maximum depth to transverse in path
mindepth = minimum depth to transverse before checking files or directories
```

The default action is `print=path`

`path-glob`:

```
*           = match zero or more chars
?           = match any char
[abc]       = match a, b, or c
[!abc] or [^abc] = match anything except a, b, and c
[x-y]       = match chars x through y
[!x-y] or [^x-y] = match anything except chars x through y
{a,b,c}     = match a or b or c
```

`path-regex`: a Python Regex (regular expression) pattern to match pathnames

`file-types`: a string of one or more of the following:

```
a: all file types
b: block device
c: character device
d: directory
p: FIFO (named pipe)
f: plain file
l: symlink
s: socket
```

`users`: a space and/or comma separated list of user names and/or uids

`groups`: a space and/or comma separated list of group names and/or gids

`size-unit`:

```
b: bytes
k: kilobytes
m: megabytes
g: gigabytes
t: terabytes
```

`interval`:

```
[<num>w] [<num>d] [<num>h] [<num>m] [<num>s]
```

where:

```
w: week
d: day
h: hour
m: minute
s: second
```

`print-opts`: a comma and/or space separated list of one or more of the following:

```
group: group name
md5: MD5 digest of file contents
mode: file permissions (as integer)
mtime: last modification time (as time_t)
name: file basename
path: file absolute path
size: file size in bytes
```

```
type: file type
user: user name
```

CLI Examples:

```
salt '*' file.find / type=f name=\*.bak size=+10m
salt '*' file.find /var mtime=+30d size=+10m print=path,size,mtime
salt '*' file.find /var/log name=\*.[0-9] mtime=+30d size=+10m delete
```

`salt.modules.file.get_devmm(name)`

Get major/minor info from a device

CLI Example:

```
salt '*' file.get_devmm /dev/chr
```

`salt.modules.file.get_diff(minionfile, masterfile, env=None, saltenv='base')`

Return unified diff of file compared to file on master

CLI Example:

```
salt '*' file.get_diff /home/fred/.vimrc salt://users/fred/.vimrc
```

`salt.modules.file.get_gid(path, follow_symlinks=True)`

Return the id of the group that owns a given file

**path** file or directory of which to get the gid

**follow\_symlinks** indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_gid /etc/passwd
```

Changed in version 0.16.4: `follow_symlinks` option added

`salt.modules.file.get_group(path, follow_symlinks=True)`

Return the group that owns a given file

**path** file or directory of which to get the group

**follow\_symlinks** indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_group /etc/passwd
```

Changed in version 0.16.4: `follow_symlinks` option added

`salt.modules.file.get_hash(path, form='sha256', chunk_size=65536)`

Get the hash sum of a file

This is better than `get_sum` for the following reasons:

- It does not read the entire file into memory.
- It does not return a string on error. The returned value of `get_sum` cannot really be trusted since it is vulnerable to collisions: `get_sum(..., 'xyz') == 'Hash xyz not supported'`

**path** path to the file or directory

**form** desired sum format

**chunk\_size** amount to sum at once

CLI Example:

```
salt '*' file.get_hash /etc/shadow
```

`salt.modules.file.get_managed`(*name*, *template*, *source*, *source\_hash*, *user*, *group*, *mode*, *saltenv*, *context*, *defaults*, *\*\*kwargs*)

Return the managed file data for file.managed

**name** location where the file lives on the server

**template** template format

**source** managed source file

**source\_hash** hash of the source file

**user** user owner

**group** group owner

**mode** file mode

**context** variables to add to the environment

**default** default values of for context\_dict

CLI Example:

```
salt '*' file.get_managed /etc/httpd/conf.d/httpd.conf jinja salt://http/httpd.conf '{hash_type:
```

`salt.modules.file.get_mode`(*path*, *follow\_symlinks=True*)

Return the mode of a file

**path** file or directory of which to get the mode

**follow\_symlinks** indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_mode /etc/passwd
```

Changed in version 2014.1.0: `follow_symlinks` option added

`salt.modules.file.get_selinux_context`(*path*)

Get an SELinux context from a given path

CLI Example:

```
salt '*' file.get_selinux_context /etc/hosts
```

`salt.modules.file.get_sum`(*path*, *form='sha256'*)

Return the checksum for the given file. The following checksum algorithms are supported:

- md5
- sha1
- sha224
- sha256 (default)
- sha384
- sha512

**path** path to the file or directory

**form** desired sum format

CLI Example:

```
salt '*' file.get_sum /etc/passwd sha512
```

`salt.modules.file.get_uid(path, follow_symlinks=True)`

Return the id of the user that owns a given file

**path** file or directory of which to get the uid

**follow\_symlinks** indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_uid /etc/passwd
```

Changed in version 0.16.4: `follow_symlinks` option added

`salt.modules.file.get_user(path, follow_symlinks=True)`

Return the user that owns a given file

**path** file or directory of which to get the user

**follow\_symlinks** indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_user /etc/passwd
```

Changed in version 0.16.4: `follow_symlinks` option added

`salt.modules.file.gid_to_group(gid)`

Convert the group id to the group name on this system

**gid** gid to convert to a group name

CLI Example:

```
salt '*' file.gid_to_group 0
```

`salt.modules.file.grep(path, pattern, *args)`

Grep for a string in the specified file

---

**Note:** This function's return value is slated for refinement in future versions of Salt

---

**path** A file path

**pattern** A string. For example: `test a[0-5]`

**args** grep options. For example: `" -v" " -i -B2"`

CLI Example:

```
salt '*' file.grep /etc/passwd nobody
salt '*' file.grep /etc/sysconfig/network-scripts/ifcfg-eth0 ipaddr " -i"
salt '*' file.grep /etc/sysconfig/network-scripts/ifcfg-eth0 ipaddr " -i -B2"
salt '*' file.grep "/etc/sysconfig/network-scripts/*" ipaddr " -i -l"
```

`salt.modules.file.group_to_gid(group)`

Convert the group to the gid on this system

**group** group to convert to its gid

CLI Example:

```
salt '*' file.group_to_gid root
```

**salt.modules.file.is\_blkdev**(*name*)

Check if a file exists and is a block device.

CLI Example:

```
salt '*' file.is_blkdev /dev/blk
```

**salt.modules.file.is\_chrdev**(*name*)

Check if a file exists and is a character device.

CLI Example:

```
salt '*' file.is_chrdev /dev/chr
```

**salt.modules.file.is\_fifo**(*name*)

Check if a file exists and is a FIFO.

CLI Example:

```
salt '*' file.is_fifo /dev/fifo
```

**salt.modules.file.is\_link**(*path*)

Check if the path is a symlink

CLI Example:

```
salt '*' file.is_link /path/to/link
```

**salt.modules.file.join**(\**args*)

Return a normalized file system path for the underlying OS

New in version 2014.7.0.

This can be useful at the CLI but is frequently useful when scripting combining path variables:

```
{% set www_root = '/var' %}
{% set app_dir = 'myapp' %}

myapp_config:
  file:
    - managed
    - name: {{ salt['file.join'](www_root, app_dir, 'config.yaml') }}
```

CLI Example:

```
salt '*' file.join '/' 'usr' 'local' 'bin'
```

**salt.modules.file.lchown**(*path*, *user*, *group*)

Chown a file, pass the file the desired user and group without following symlinks.

**path** path to the file or directory

**user** user owner

**group** group owner

CLI Example:

```
salt '*' file.chown /etc/passwd root root
```

**salt.modules.file.link**(*src, path*)

New in version 2014.1.0.

Create a hard link to a file

CLI Example:

```
salt '*' file.link /path/to/file /path/to/link
```

**salt.modules.file.list\_backups**(*path, limit=None*)

New in version 0.17.0.

Lists the previous versions of a file backed up using Salt's [file state backup](#) system.

**path** The path on the minion to check for backups

**limit** Limit the number of results to the most recent N backups

CLI Example:

```
salt '*' file.list_backups /foo/bar/baz.txt
```

**salt.modules.file.list\_backups\_dir**(*path, limit=None*)

Lists the previous versions of a directory backed up using Salt's [file state backup](#) system.

**path** The directory on the minion to check for backups

**limit** Limit the number of results to the most recent N backups

CLI Example:

```
salt '*' file.list_backups_dir /foo/bar/baz/
```

**salt.modules.file.lstat**(*path*)

New in version 2014.1.0.

Returns the lstat attributes for the given file or dir. Does not support symbolic links.

CLI Example:

```
salt '*' file.lstat /path/to/file
```

**salt.modules.file.makedirs\_**(*path, user=None, group=None, mode=None*)

Ensure that the directory containing this path is available.

---

**Note:** The path must end with a trailing slash otherwise the directory/directories will be created up to the parent directory. For example if path is `/opt/code`, then it would be treated as `/opt/` but if the path ends with a trailing slash like `/opt/code/`, then it would be treated as `/opt/code/`.

---

CLI Example:

```
salt '*' file.makedirs /opt/code/
```

**salt.modules.file.makedirs\_perms**(*name, user=None, group=None, mode='0755'*)

Taken and modified from `os.makedirs` to set user, group and mode for each directory created.

CLI Example:

```
salt '*' file.makedirs_perms /opt/code
```

`salt.modules.file.manage_file`(*name, sfn, ret, source, source\_sum, user, group, mode, saltenv, backup, makedirs=False, template=None, show\_diff=True, contents=None, dir\_mode=None, follow\_symlinks=True*)

Checks the destination against what was retrieved with `get_managed` and makes the appropriate modifications (if necessary).

**name** location to place the file

**sfn** location of cached file on the minion

This is the path to the file stored on the minion. This file is placed on the minion using `cp.cache_file`. If the hash sum of that file matches the `source_sum`, we do not transfer the file to the minion again.

This file is then grabbed and if it has `template` set, it renders the file to be placed into the correct place on the system using `salt.files.utils.copyfile()`

**ret** The initial state return data structure. Pass in `NONE` to use the default structure.

**source** file reference on the master

**source\_hash** sum hash for source

**user** user owner

**group** group owner

**backup** backup\_mode

**makedirs** make directories if they do not exist

**template** format of templating

**show\_diff** Include diff in state return

**contents:** contents to be placed in the file

**dir\_mode** mode for directories created with `makedirs`

CLI Example:

```
salt '*' file.manage_file /etc/httpd/conf.d/httpd.conf '' '{}' salt://http/httpd.conf '{hash_type}
```

Changed in version 2014.7.0: `follow_symlinks` option added

`salt.modules.file.mkdir`(*dir\_path, user=None, group=None, mode=None*)

Ensure that a directory is available.

CLI Example:

```
salt '*' file.mkdir /opt/jetty/context
```

`salt.modules.file.mknod`(*name, ntype, major=0, minor=0, user=None, group=None, mode='0660'*)

New in version 0.17.0.

Create a block device, character device, or fifo pipe. Identical to the `gnu mknod`.

CLI Examples:

```
salt '*' file.mknod /dev/chr c 180 31
salt '*' file.mknod /dev/blk b 8 999
salt '*' file.nknod /dev/fifo p
```

`salt.modules.file.mknod_blkdev`(*name, major, minor, user=None, group=None, mode='0660'*)

New in version 0.17.0.

Create a block device.

CLI Example:

```
salt '*' file.mknod_blkdev /dev/blk 8 999
```

`salt.modules.file.mknod_chrdev`(*name*, *major*, *minor*, *user=None*, *group=None*, *mode='0660'*)  
New in version 0.17.0.

Create a character device.

CLI Example:

```
salt '*' file.mknod_chrdev /dev/chr 180 31
```

`salt.modules.file.mknod_fifo`(*name*, *user=None*, *group=None*, *mode='0660'*)  
New in version 0.17.0.

Create a FIFO pipe.

CLI Example:

```
salt '*' file.mknod_fifo /dev/fifo
```

`salt.modules.file.move`(*src*, *dst*)  
Move a file or directory

CLI Example:

```
salt '*' file.move /path/to/src /path/to/dst
```

`salt.modules.file.normpath`(*path*)  
Returns Normalize path, eliminating double slashes, etc.  
New in version 2015.5.0.

This can be useful at the CLI but is frequently useful when scripting.

```
{%- from salt['file.normpath'](tpldir + '/../vars.jinja') import parent_vars %}
```

CLI Example:

```
salt '*' file.normpath 'a/b/c/..'
```

`salt.modules.file.open_files`(*by\_pid=False*)  
Return a list of all physical open files on the system.

CLI Examples:

```
salt '*' file.open_files
salt '*' file.open_files by_pid=True
```

`salt.modules.file.pardir`()  
Return the relative parent directory path symbol for underlying OS  
New in version 2014.7.0.

This can be useful when constructing Salt Formulas.

```
{% set pardir = salt['file.pardir']() %}
{% set final_path = salt['file.join']('subdir', pardir, 'confdir') %}
```

CLI Example:

```
salt '*' file.pardir
```

`salt.modules.file.patch`(*originalfile*, *patchfile*, *options*='', *dry\_run*=False)

New in version 0.10.4.

Apply a patch to a file

Equivalent to:

```
patch <options> <originalfile> <patchfile>
```

**originalfile** The full path to the file or directory to be patched

**patchfile** A patch file to apply to *originalfile*

**options** Options to pass to patch.

CLI Example:

```
salt '*' file.patch /opt/file.txt /tmp/file.txt.patch
```

`salt.modules.file.path_exists_glob`(*path*)

Tests to see if path after expansion is a valid path (file or directory). Expansion allows usage of ? \* and character ranges []. Tilde expansion is not supported. Returns True/False.

New in version Hellium.

CLI Example:

```
salt '*' file.path_exists_glob /etc/pam*/pass*
```

`salt.modules.file.prepend`(*path*, *\*args*, *\*\*kwargs*)

New in version 2014.7.0.

Prepend text to the beginning of a file

**path** path to file

**\*args** strings to prepend to the file

CLI Example:

```
salt '*' file.prepend /etc/motd \  
    "With all thine offerings thou shalt offer salt." \  
    "Salt is what makes things taste bad when it isn't in them."
```

---

### Attention

If you need to pass a string to append and that string contains an equal sign, you **must** include the argument name, *args*. For example:

```
salt '*' file.prepend /etc/motd args='cheese=spam'
```

```
salt '*' file.prepend /etc/motd args="['cheese=spam', 'spam=cheese']"
```

`salt.modules.file.psed`(*path*, *before*, *after*, *limit*='', *backup*='.bak', *flags*='gMS', *escape\_all*=False, *multi*=False)

Deprecated since version 0.17.0: Use `replace()` instead.

Make a simple edit to a file (pure Python version)

Equivalent to:

```
sed <backup> <options> "/<limit>/ s/<before>/<after>/<flags> <file>"
```

**path** The full path to the file to be edited

**before** A pattern to find in order to replace with **after**

**after** Text that will replace **before**

**limit** [' '] An initial pattern to search for before searching for **before**

**backup** [.bak] The file will be backed up before edit with this file extension; **WARNING**: each time `sed/comment/uncomment` is called will overwrite this backup

**flags** [gMS]

**Flags to modify the search. Valid values are:**

- **g**: Replace all occurrences of the pattern, not just the first.
- **I**: Ignore case.
- **L**: Make `\w`, `\W`, `\b`, `\B`, `\s` and `\S` dependent on the locale.
- **M**: Treat multiple lines as a single line.
- **S**: Make `.` match all characters, including newlines.
- **U**: Make `\w`, `\W`, `\b`, `\B`, `\d`, `\D`, `\s` and `\S` dependent on Unicode.
- **X**: Verbose (whitespace is ignored).

**multi**: **False** If True, treat the entire file as a single line

Forward slashes and single quotes will be escaped automatically in the **before** and **after** patterns.

CLI Example:

```
salt '*' file.sed /etc/httpd/httpd.conf 'LogLevel warn' 'LogLevel info'
```

`salt.modules.file.readdir`(*path*)

New in version 2014.1.0.

Return a list containing the contents of a directory

CLI Example:

```
salt '*' file.readdir /path/to/dir/
```

`salt.modules.file.readlink`(*path*)

New in version 2014.1.0.

Return the path that a symlink points to

CLI Example:

```
salt '*' file.readlink /path/to/link
```

`salt.modules.file.remove`(*path*)

Remove the named file

CLI Example:

```
salt '*' file.remove /tmp/foo
```

`salt.modules.file.rename(src, dst)`

Rename a file or directory

CLI Example:

```
salt '*' file.rename /path/to/src /path/to/dst
```

`salt.modules.file.replace(path, pattern, repl, count=0, flags=8, bufsize=1, append_if_not_found=False, prepend_if_not_found=False, not_found_content=None, backup='.bak', dry_run=False, search_only=False, show_changes=True)`

New in version 0.17.0.

Replace occurrences of a pattern in a file

This is a pure Python implementation that wraps Python's `sub()`.

**path** Filesystem path to the file to be edited

**pattern** Python's regular expression search <https://docs.python.org/2/library/re.html>

**repl** The replacement text

**count** Maximum number of pattern occurrences to be replaced. Defaults to 0. If count is a positive integer n, only n occurrences will be replaced, otherwise all occurrences will be replaced.

**flags (list or int)** A list of flags defined in the [re module documentation](#). Each list item should be a string that will correlate to the human-friendly flag name. E.g., [ 'IGNORECASE', 'MULTILINE' ]. Optionally, `flags` may be an int, with a value corresponding to the XOR (|) of all the desired flags. Defaults to 8 (which supports 'MULTILINE').

**bufsize (int or str)** How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value `file` may be specified which will read the entire file into memory before processing.

**append\_if\_not\_found** New in version 2014.7.0.

If pattern is not found and set to `True` then, the content will be appended to the file. Default is `False`

**prepend\_if\_not\_found** New in version 2014.7.0.

If pattern is not found and set to `True` then, the content will be appended to the file. Default is `False`

**not\_found\_content** New in version 2014.7.0.

Content to use for append/prepend if not found. If `None` (default), uses `repl`. Useful when `repl` uses references to group in pattern.

**backup** The file extension to use for a backup of the file before editing. Set to `False` to skip making a backup. Default is `.bak`

**dry\_run** Don't make any edits to the file, Default is `False`

**search\_only** Just search for the pattern; ignore the replacement; stop on the first match. Default is `False`

**show\_changes** Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made. Default is `True`

---

**Note:** Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

---

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format `key=val`. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' file.replace /path/to/file pattern='=' repl=':'
salt '*' file.replace /path/to/file pattern="bind-address\s*" repl='bind-address:'
```

CLI Examples:

```
salt '*' file.replace /etc/httpd/httpd.conf pattern='LogLevel warn' repl='LogLevel info'
salt '*' file.replace /some/file pattern='before' repl='after' flags=[MULTILINE, IGNORECASE]
```

`salt.modules.file.restore_backup(path, backup_id)`

New in version 0.17.0.

Restore a previous version of a file that was backed up using Salt's file state backup system.

**path** The path on the minion to check for backups

**backup\_id** The numeric id for the backup you wish to restore, as found using `file.list_backups`

CLI Example:

```
salt '*' file.restore_backup /foo/bar/baz.txt 0
```

`salt.modules.file.restorecon(path, recursive=False)`

Reset the SELinux context on a given path

CLI Example:

```
salt '*' file.restorecon /home/user/.ssh/authorized_keys
```

`salt.modules.file.rmdir(path)`

New in version 2014.1.0.

Remove the specified directory. Fails if a directory is not empty.

CLI Example:

```
salt '*' file.rmdir /tmp/foo/
```

`salt.modules.file.search(path, pattern, flags=8, bufsize=1)`

New in version 0.17.0.

Search for occurrences of a pattern in a file

Params are identical to `replace()`.

CLI Example:

```
salt '*' file.search /etc/crontab 'mymaintenance.sh'
```

`salt.modules.file.sed(path, before, after, limit=' ', backup='.bak', options='-r -e', flags='g', escape_all=False, negate_match=False)`

Deprecated since version 0.17.0: Use `replace()` instead.

Make a simple edit to a file

Equivalent to:

```
sed <backup> <options> "/<limit>/ s/<before>/<after>/<flags> <file>"
```

**path** The full path to the file to be edited

**before** A pattern to find in order to replace with `after`

**after** Text that will replace `before`

**limit** [' '] An initial pattern to search for before searching for **before**

**backup** [.bak] The file will be backed up before edit with this file extension; **WARNING**: each time **sed/comment/uncomment** is called will overwrite this backup

**options** [-r -e] Options to pass to **sed**

**flags** [g] Flags to modify the **sed** search; e.g., **i** for case-insensitive pattern matching

**negate\_match** [False] Negate the search command (!)

New in version 0.17.0.

Forward slashes and single quotes will be escaped automatically in the **before** and **after** patterns.

CLI Example:

```
salt '*' file.sed /etc/httpd/httpd.conf 'LogLevel warn' 'LogLevel info'
```

**salt.modules.file.sed\_contains**(*path, text, limit='', flags='g'*)

Deprecated since version 0.17.0: Use [search\(\)](#) instead.

Return True if the file at **path** contains **text**. Utilizes **sed** to perform the search (line-wise search).

Note: the **p** flag will be added to any flags you pass in.

CLI Example:

```
salt '*' file.contains /etc/crontab 'mymaintenance.sh'
```

**salt.modules.file.seek\_read**(*path, size, offset*)

New in version 2014.1.0.

Seek to a position on a file and read it

**path** path to file

**seek** amount to read at once

**offset** offset to start into the file

CLI Example:

```
salt '*' file.seek_read /path/to/file 4096 0
```

**salt.modules.file.seek\_write**(*path, data, offset*)

New in version 2014.1.0.

Seek to a position on a file and write to it

**path** path to file

**data** data to write to file

**offset** position in file to start writing

CLI Example:

```
salt '*' file.seek_write /path/to/file 'some data' 4096
```

**salt.modules.file.set\_mode**(*path, mode*)

Set the mode of a file

**path** file or directory of which to set the mode

**mode** mode to set the path to

CLI Example:

```
salt '*' file.set_mode /etc/passwd 0644
```

`salt.modules.file.set_selinux_context`(*path*, *user=None*, *role=None*, *type=None*, *range=None*)  
Set a specific SELinux label on a given path

CLI Example:

```
salt '*' file.set_selinux_context path <role> <type> <range>
```

`salt.modules.file.source_list`(*source*, *source\_hash*, *saltenv*)  
Check the source list and return the source to use

CLI Example:

```
salt '*' file.source_list salt://http/httpd.conf '{hash_type: 'md5', 'hsum': <md5sum>}' base
```

`salt.modules.file.stats`(*path*, *hash\_type=None*, *follow\_symlinks=True*)  
Return a dict containing the stats for a given file

CLI Example:

```
salt '*' file.stats /etc/passwd
```

`salt.modules.file.statvfs`(*path*)  
New in version 2014.1.0.

Perform a statvfs call against the filesystem that the file resides on

CLI Example:

```
salt '*' file.statvfs /path/to/file
```

`salt.modules.file.symlink`(*src*, *path*)  
Create a symbolic link to a file

CLI Example:

```
salt '*' file.symlink /path/to/file /path/to/link
```

`salt.modules.file.touch`(*name*, *atime=None*, *mtime=None*)  
New in version 0.9.5.

Just like the `touch` command, create a file if it doesn't exist or simply update the `atime` and `mtime` if it already does.

**atime**: Access time in Unix epoch time

**mtime**: Last modification in Unix epoch time

CLI Example:

```
salt '*' file.touch /var/log/emptyfile
```

`salt.modules.file.truncate`(*path*, *length*)  
New in version 2014.1.0.

Seek to a position on a file and delete everything after that point

**path** path to file

**length** offset into file to truncate

CLI Example:

```
salt '*' file.truncate /path/to/file 512
```

`salt.modules.file.uid_to_user`(*uid*)

Convert a uid to a user name

**uid** uid to convert to a username

CLI Example:

```
salt '*' file.uid_to_user 0
```

`salt.modules.file.uncomment`(*path*, *regex*, *char*='#', *backup*='bak')

Deprecated since version 0.17.0: Use `replace()` instead.

Uncomment specified commented lines in a file

**path** The full path to the file to be edited

**regex** A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading `^` character will be stripped for convenience (for easily switching between `comment()` and `uncomment()`).

**char** [#] The character to remove in order to uncomment a line

**backup** [.bak] The file will be backed up before edit with this file extension; **WARNING**: each time `sed/comment/uncomment` is called will overwrite this backup

CLI Example:

```
salt '*' file.uncomment /etc/hosts.deny 'ALL: PARANOID'
```

`salt.modules.file.user_to_uid`(*user*)

Convert user name to a uid

**user** user name to convert to its uid

CLI Example:

```
salt '*' file.user_to_uid root
```

`salt.modules.file.write`(*path*, *\*args*, *\*\*kwargs*)

New in version 2014.7.0.

Write text to a file, overwriting any existing contents.

**path** path to file

**\*args** strings to write to the file

CLI Example:

```
salt '*' file.write /etc/motd \  
    "With all thine offerings thou shalt offer salt."
```

---

### Attention

If you need to pass a string to append and that string contains an equal sign, you **must** include the argument name, `args`. For example:

```
salt '*' file.write /etc/motd args='cheese=spam'
```

```
salt '*' file.write /etc/motd args="['cheese=spam','spam=cheese']"
```

### 30.16.70 salt.modules.firewalld

Support for firewalld

**salt.modules.firewalld.add\_service**(*name, zone=None, permanent=True*)  
Add a service for zone. If zone is omitted, default zone will be used.

CLI Example:

```
salt '*' firewalld.add_service ssh
```

To assign a service to a specific zone

```
salt '*' firewalld.add_service ssh my_zone
```

**salt.modules.firewalld.default\_zone**()  
Print default zone for connections and interfaces

CLI Example:

```
salt '*' firewalld.default_zone
```

**salt.modules.firewalld.delete\_service**(*name, restart=True*)  
Delete an existing service

CLI Example:

```
salt '*' firewalld.delete_service my_service
```

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False

```
salt '*' firewalld.delete_service my_service False
```

**salt.modules.firewalld.delete\_zone**(*zone, restart=True*)  
Delete an existing zone

CLI Example:

```
salt '*' firewalld.delete_zone my_zone
```

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False

```
salt '*' firewalld.delete_zone my_zone False
```

**salt.modules.firewalld.get\_icmp\_types**()  
Print predefined icmp types

CLI Example:

```
salt '*' firewalld.get_icmp_types
```

**salt.modules.firewalld.get\_services**()  
Print predefined services

CLI Example:

```
salt '*' firewalld.get_services
```

`salt.modules.firewalld.get_zones()`

Print predefined zones

CLI Example:

```
salt '*' firewalld.get_zones
```

`salt.modules.firewalld.list_all(zone=None)`

List everything added for or enabled in a zone

CLI Example:

```
salt '*' firewalld.list_all
```

List a specific zone

```
salt '*' firewalld.list_all my_zone
```

`salt.modules.firewalld.list_services(zone=None)`

List services added for zone as a space separated list. If zone is omitted, default zone will be used.

CLI Example:

```
salt '*' firewalld.list_services
```

List a specific zone

```
salt '*' firewalld.list_services my_zone
```

`salt.modules.firewalld.list_zones()`

List everything added for or enabled in all zones

CLI Example:

```
salt '*' firewalld.list_zones
```

`salt.modules.firewalld.new_service(name, restart=True)`

Add a new service

CLI Example:

```
salt '*' firewalld.new_service my_service
```

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False

```
salt '*' firewalld.new_service my_service False
```

`salt.modules.firewalld.new_zone(zone, restart=True)`

Add a new zone

CLI Example:

```
salt '*' firewalld.new_zone my_zone
```

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False

```
salt '*' firewalld.new_zone my_zone False
```

`salt.modules.firewalld.remove_service(name, zone=None, permanent=True)`

Remove a service from zone. This option can be specified multiple times. If zone is omitted, default zone will be used.

CLI Example:

```
salt '*' firewallld.remove_service ssh
```

To remove a service from a specific zone

```
salt '*' firewallld.remove_service ssh dmz
```

**salt.modules.firewalld.set\_default\_zone**(*zone*)

Set default zone

CLI Example:

```
salt '*' firewallld.set_default_zone damian
```

**salt.modules.firewalld.version**()

Return version from firewall-cmd

CLI Example:

```
salt '*' firewallld.version
```

### 30.16.71 salt.modules.freebsd\_sysctl

Module for viewing and modifying sysctl parameters

**salt.modules.freebsd\_sysctl.assign**(*name*, *value*)

Assign a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.assign net.inet.icmp.icmplim 50
```

**salt.modules.freebsd\_sysctl.get**(*name*)

Return a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.get hw.physmem
```

**salt.modules.freebsd\_sysctl.persist**(*name*, *value*, *config*='/etc/sysctl.conf')

Assign and persist a simple sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.persist net.inet.icmp.icmplim 50
salt '*' sysctl.persist coretemp_load NO config=/boot/loader.conf
```

**salt.modules.freebsd\_sysctl.show**(*config\_file*=False)

Return a list of sysctl parameters for this minion

CLI Example:

```
salt '*' sysctl.show
```

### 30.16.72 salt.modules.freebsdjail

The jail module for FreeBSD

`salt.modules.freebsdjail.fstab(jail)`

Display contents of a `fstab(5)` file defined in specified jail's configuration. If no file is defined, return False.

CLI Example:

```
salt '*' jail.fstab <jail name>
```

`salt.modules.freebsdjail.get_enabled()`

Return which jails are set to be run

CLI Example:

```
salt '*' jail.get_enabled
```

`salt.modules.freebsdjail.is_enabled()`

See if jail service is actually enabled on boot

CLI Example:

```
salt '*' jail.is_enabled <jail name>
```

`salt.modules.freebsdjail.restart(jail='')`

Restart the specified jail or all, if none specified

CLI Example:

```
salt '*' jail.restart [<jail name>]
```

`salt.modules.freebsdjail.show_config(jail)`

Display specified jail's configuration

CLI Example:

```
salt '*' jail.show_config <jail name>
```

`salt.modules.freebsdjail.start(jail='')`

Start the specified jail or all, if none specified

CLI Example:

```
salt '*' jail.start [<jail name>]
```

`salt.modules.freebsdjail.status(jail)`

See if specified jail is currently running

CLI Example:

```
salt '*' jail.status <jail name>
```

`salt.modules.freebsdjail.stop(jail='')`

Stop the specified jail or all, if none specified

CLI Example:

```
salt '*' jail.stop [<jail name>]
```

`salt.modules.freebsdjail.sysctl()`

Dump all jail related kernel states (`sysctl`)

CLI Example:

```
salt '*' jail.sysctl
```

### 30.16.73 salt.modules.freebsdmod

Module to manage FreeBSD kernel modules

**salt.modules.freebsdmod.available()**

Return a list of all available kernel modules

CLI Example:

```
salt '*' kmod.available
```

**salt.modules.freebsdmod.check\_available(mod)**

Check to see if the specified kernel module is available

CLI Example:

```
salt '*' kmod.check_available vmm
```

**salt.modules.freebsdmod.is\_loaded(mod)**

Check to see if the specified kernel module is loaded

CLI Example:

```
salt '*' kmod.is_loaded vmm
```

**salt.modules.freebsdmod.load(mod, persist=False)**

Load the specified kernel module

**mod** Name of the module to add

**persist** Write the module to sysrc kld\_modules to make it load on system reboot

CLI Example:

```
salt '*' kmod.load bhyve
```

**salt.modules.freebsdmod.lsmod()**

Return a dict containing information about currently loaded modules

CLI Example:

```
salt '*' kmod.lsmod
```

**salt.modules.freebsdmod.mod\_list(only\_persist=False)**

Return a list of the loaded module names

CLI Example:

```
salt '*' kmod.mod_list
```

**salt.modules.freebsdmod.remove(mod, persist=False)**

Remove the specified kernel module

CLI Example:

```
salt '*' kmod.remove vmm
```

### 30.16.74 salt.modules.freebsdpkg

Remote package support using pkg\_add(1)

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available`), see [here](#).

**Warning:** This module has been completely rewritten. Up to and including version 0.17.0, it supported `pkg_add(1)`, but checked for the existence of a `pkgng` local database and, if found, would provide some of `pkgng`'s functionality. The rewrite of this module has removed all `pkgng` support, and moved it to the `pkgng` execution module. For versions `<= 0.17.0`, the documentation here should not be considered accurate. If your Minion is running one of these versions, then the documentation for this module can be viewed using the `sys.doc` function:

```
salt bsdminion sys.doc pkg
```

This module acts as the default package provider for FreeBSD 9 and older. If you need to use `pkgng` on a FreeBSD 9 system, you will need to override the `pkg` provider by setting the `providers` parameter in your Minion config file, in order to use `pkgng`.

```
providers:
  pkg: pkgng
```

More information on `pkgng` support can be found in the documentation for the `pkgng` module.

This module will respect the `PACKAGEROOT` and `PACKAGESITE` environment variables, if set, but these values can also be overridden in several ways:

1. **Salt configuration parameters.** The configuration parameters `freebsdpkg.PACKAGEROOT` and `freebsdpkg.PACKAGESITE` are recognized. These config parameters are looked up using `config.get` and can thus be specified in the Master config file, Grains, Pillar, or in the Minion config file. Example:

```
freebsdpkg.PACKAGEROOT: ftp://ftp.freebsd.org/
freebsdpkg.PACKAGESITE: ftp://ftp.freebsd.org/pub/FreeBSD/ports/ia64/packages-9-stable/Latest/
```

2. **CLI arguments.** Both the `packageroot` (used interchangeably with `fromrepo` for API compatibility) and `packagesite` CLI arguments are recognized, and override their config counterparts from section 1 above.

```
salt -G 'os:FreeBSD' pkg.install zsh fromrepo=ftp://ftp2.freebsd.org/
salt -G 'os:FreeBSD' pkg.install zsh packageroot=ftp://ftp2.freebsd.org/
salt -G 'os:FreeBSD' pkg.install zsh packagesite=ftp://ftp2.freebsd.org/pub/FreeBSD/ports/ia64/packages-9-stable/Latest/

.. note::

  These arguments can also be passed through in states:

.. code-block:: yaml

  zsh:
    pkg.installed:
      - fromrepo: ftp://ftp2.freebsd.org/
```

`salt.modules.freebsdpkg.file_dict(*packages)`

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of `_every_file` on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.freebsdpkg.file_list(*packages)`

List the files that belong to a package. Not specifying any packages will return a list of `_every_` file on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.freebsdpkg.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, **kwargs)`

Install package(s) using `pkg_add(1)`

**name** The name of the package to be installed.

**refresh** Whether or not to refresh the package database before installing.

**fromrepo or packageroot** Specify a package repository from which to install. Overrides the system default, as well as the `PACKAGEROOT` environment variable.

**packagesite** Specify the exact directory from which to install the remote package. Overrides the `PACKAGE-SITE` environment variable, if present.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs=['foo', 'bar']
```

**sources** A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources=[{"foo": "salt://foo.deb"}, {"bar": "salt://bar.deb"}]
```

Return a dict containing the new package names and versions:

```
{'package': {'old': 'old-version',
              'new': 'new-version'}}
```

CLI Example:

```
salt '*' pkg.install <package name>
```

`salt.modules.freebsdpkg.latest_version(*names, **kwargs)`

`pkg_add(1)` is not capable of querying for remote packages, so this function will always return results as if there is no package available for install or upgrade.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

`salt.modules.freebsdpkg.list_pkgs` (*versions\_as\_list=False, with\_origin=False, \*\*kwargs*)

List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

**with\_origin** [False] Return a nested dictionary containing both the origin name and version for each installed package.

New in version 2014.1.0.

CLI Example:

```
salt '*' pkg.list_pkgs
```

`salt.modules.freebsdpkg.refresh_db`()

`pkg_add(1)` does not use a local database of available packages, so this function simply returns True. it exists merely for API compatibility.

CLI Example:

```
salt '*' pkg.refresh_db
```

`salt.modules.freebsdpkg.remove` (*name=None, pkgs=None, \*\*kwargs*)

Remove packages using `pkg_delete(1)`

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>, <package2>, <package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

`salt.modules.freebsdpkg.upgrade`()

Upgrades are not supported with `pkg_add(1)`. This function is included for API compatibility only and always returns an empty dict.

CLI Example:

```
salt '*' pkg.upgrade
```

`salt.modules.freebsdpkg.version` (*\*names, \*\*kwargs*)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

**with\_origin** [False] Return a nested dictionary containing both the origin name and version for each specified package.

New in version 2014.1.0.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

### 30.16.75 salt.modules.freebsdports

Install software from the FreeBSD ports (7) system

New in version 2014.1.0.

This module allows you to install ports using BATCH=yes to bypass configuration prompts. It is recommended to use the ports state to install ports, but it is also possible to use this module exclusively from the command line.

```
salt minion-id ports.config security/nmap IPV6=off
salt minion-id ports.install security/nmap
```

**salt.modules.freebsdports.config**(name, reset=False, \*\*kwargs)

Modify configuration options for a given port. Multiple options can be specified. To see the available options for a port, use [ports.showconfig](#).

**name** The port name, in category/name format

**reset** [False] If True, runs a make rmconfig for the port, clearing its configuration before setting the desired options

CLI Examples:

```
salt '*' ports.config security/nmap IPV6=off
```

**salt.modules.freebsdports.deinstall**(name)

De-install a port.

CLI Example:

```
salt '*' ports.deinstall security/nmap
```

**salt.modules.freebsdports.install**(name, clean=True)

Install a port from the ports tree. Installs using BATCH=yes for non-interactive building. To set config options for a given port, use [ports.config](#).

**clean** [True] If True, cleans after installation. Equivalent to running make install clean BATCH=yes.

**Note:** It may be helpful to run this function using the -t option to set a higher timeout, since compiling a port may cause the Salt command to exceed the default timeout.

CLI Example:

```
salt -t 1200 '*' ports.install security/nmap
```

**salt.modules.freebsdports.list\_all**()

Lists all ports available.

CLI Example:

```
salt '*' ports.list_all
```

**Warning:** Takes a while to run, and returns a LOT of output

`salt.modules.freebsdports.rmconfig(name)`

Clear the cached options for the specified port; run a `make rmconfig`

**name** The name of the port to clear

CLI Example:

```
salt '*' ports.rmconfig security/nmap
```

`salt.modules.freebsdports.search(name)`

Search for matches in the ports tree. Globs are supported, and the category is optional

CLI Examples:

```
salt '*' ports.search 'security/*'  
salt '*' ports.search 'security/n*'  
salt '*' ports.search nmap
```

**Warning:** Takes a while to run

`salt.modules.freebsdports.showconfig(name, default=False, dict_return=False)`

Show the configuration options for a given port.

**default** [False] Show the default options for a port (not necessarily the same as the current configuration)

**dict\_return** [False] Instead of returning the output of `make showconfig`, return the data in a dictionary

CLI Example:

```
salt '*' ports.showconfig security/nmap  
salt '*' ports.showconfig security/nmap default=True
```

`salt.modules.freebsdports.update(extract=False)`

Update the ports tree

**extract** [False] If True, runs a `portsnap extract` after fetching, should be used for first-time installation of the ports tree.

CLI Example:

```
salt '*' ports.update
```

### 30.16.76 salt.modules.freebsdservice

The service module for FreeBSD

---

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `'service.start' is not available`), see [here](#).

---

`salt.modules.freebsdservice.available(name)`

Check that the given service is available.

CLI Example:

```
salt '*' service.available sshd
```

`salt.modules.freebsdservice.disable(name, **kwargs)`

Disable the named service to start at boot

Arguments the same as for `enable()`

CLI Example:

```
salt '*' service.disable <service name>
```

`salt.modules.freebsdservice.disabled(name)`

Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.disabled <service name>
```

`salt.modules.freebsdservice.enable(name, **kwargs)`

Enable the named service to start at boot

**name** service name

**config** [/etc/rc.conf] Config file for managing service. If config value is empty string, then /etc/rc.conf.d/<service> used. See man rc.conf(5) for details.

Also service.config variable can be used to change default.

CLI Example:

```
salt '*' service.enable <service name>
```

`salt.modules.freebsdservice.enabled(name, **kwargs)`

Return True if the named service is enabled, false otherwise

**name** Service name

CLI Example:

```
salt '*' service.enabled <service name>
```

`salt.modules.freebsdservice.get_all()`

Return a list of all available services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.freebsdservice.get_disabled()`

Return what services are available but not enabled to start at boot

CLI Example:

```
salt '*' service.get_disabled
```

`salt.modules.freebsdservice.get_enabled()`

Return what services are set to run on boot

CLI Example:

```
salt '*' service.get_enabled
```

`salt.modules.freebsdservice.missing(name)`

The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing sshd
```

`salt.modules.freebsdservice.reload_(name)`

Restart the named service

CLI Example:

```
salt '*' service.reload <service name>
```

`salt.modules.freebsdservice.restart(name)`

Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.freebsdservice.start(name)`

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.freebsdservice.status(name, sig=None)`

Return the status for a service (True or False).

**name** Name of service

CLI Example:

```
salt '*' service.status <service name>
```

`salt.modules.freebsdservice.stop(name)`

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.77 salt.modules.fsutils

Run-time utilities

### 30.16.78 salt.modules.gem

Manage ruby gems.

`salt.modules.gem.install(gems, ruby=None, gem_bin=None, runas=None, version=None, rdoc=False, ri=False, pre_releases=False, proxy=None)`

Installs one or several gems.

#### Parameters

- **gems** -- string The gems to install
- **gem\_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.
- **runas** -- string : None The user to run gem as.
- **version** -- string : None Specify the version to install for the gem. Doesn't play nice with multiple gems at once

- **rdoc** -- boolean : False Generate RDoc documentation for the gem(s).
- **ri** -- boolean : False Generate RI documentation for the gem(s).
- **pre\_releases** -- boolean : False Include pre-releases in the available versions
- **proxy** -- string : None Use the specified HTTP proxy server for all outgoing traffic. Format: [http://hostname\[:port\]](http://hostname[:port])

CLI Example:

```
salt '*' gem.install vagrant
salt '*' gem.install redphone gem_bin=/opt/sensu/embedded/bin/gem
```

`salt.modules.gem.list_` (*prefix='', ruby=None, runas=None, gem\_bin=None*)  
List locally installed gems.

#### Parameters

- **prefix** -- string : Only list gems when the name matches this prefix.
- **gem\_bin** -- string : None Full path to `gem` binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:

```
salt '*' gem.list
```

`salt.modules.gem.sources_add` (*source\_uri, ruby=None, runas=None, gem\_bin=None*)  
Add a gem source.

#### Parameters

- **source\_uri** -- string The source URI to add.
- **gem\_bin** -- string : None Full path to `gem` binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:

```
salt '*' gem.sources_add http://rubygems.org/
```

`salt.modules.gem.sources_list` (*ruby=None, runas=None, gem\_bin=None*)  
List the configured gem sources.

#### Parameters

- **gem\_bin** -- string : None Full path to `gem` binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:

```
salt '*' gem.sources_list
```

`salt.modules.gem.sources_remove`(*source\_uri*, *ruby=None*, *runas=None*, *gem\_bin=None*)  
Remove a gem source.

#### Parameters

- **source\_uri** -- string The source URI to remove.
- **gem\_bin** -- string : None Full path to `gem` binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:

```
salt '*' gem.sources_remove http://rubygems.org/
```

`salt.modules.gem.uninstall`(*gems*, *ruby=None*, *runas=None*, *gem\_bin=None*)  
Uninstall one or several gems.

#### Parameters

- **gems** -- string The gems to uninstall.
- **gem\_bin** -- string : None Full path to `gem` binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:

```
salt '*' gem.uninstall vagrant
```

`salt.modules.gem.update`(*gems*, *ruby=None*, *runas=None*, *gem\_bin=None*)  
Update one or several gems.

#### Parameters

- **gems** -- string The gems to update.
- **gem\_bin** -- string : None Full path to `gem` binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:

```
salt '*' gem.update vagrant
```

`salt.modules.gem.update_system`(*version=''*, *ruby=None*, *runas=None*, *gem\_bin=None*)  
Update rubygems.

#### Parameters

- **version** -- string : (newest) The version of rubygems to install.
- **gem\_bin** -- string : None Full path to `gem` binary to use.

- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:

```
salt '*' gem.update_system
```

### 30.16.79 salt.modules.genesis

Module for managing container and VM images

New in version 2014.7.0.

`salt.modules.genesis.avail_platforms()`

Return which platforms are available

CLI Example:

```
salt myminion genesis.avail_platforms
```

`salt.modules.genesis.bootstrap(platform, root, img_format='dir', fs_format='ext2', arch=None, flavor=None, repo_url=None, static_qemu=None)`

Create an image for a specific platform.

Please note that this function *MUST* be run as root, as images that are created make files belonging to root.

**platform** Which platform to use to create the image. Currently supported platforms are rpm, deb and pacman.

**root** Local path to create the root of the image filesystem.

**img\_format** Which format to create the image in. By default, just copies files into a directory on the local filesystem (`dir`). Future support will exist for `sparse`.

**fs\_format** When using a non-`dir` `img_format`, which filesystem to format the image to. By default, `ext2`.

**arch** Architecture to install packages for, if supported by the underlying bootstrap tool. Currently only used for deb.

**flavor** Which flavor of operating system to install. This correlates to a specific directory on the distribution repositories. For instance, `wheezy` on Debian.

**repo\_url** Mainly important for Debian-based repos. Base URL for the mirror to install from. (e.x.: <http://ftp.debian.org/debian/>)

**static\_qemu** Local path to the static qemu binary required for this arch. (e.x.: `/usr/bin/qemu-amd64-static`)

**pkg\_confs** The location of the conf files to copy into the image, to point the installer to the right repos and configuration.

CLI Examples:

```
salt myminion genesis.bootstrap pacman /root/arch
salt myminion genesis.bootstrap rpm /root/redhat
salt myminion genesis.bootstrap deb /root/wheezy arch=amd64 flavor=wheezy static_qemu
```

`salt.modules.genesis.pack(name, root, path=None, pack_format='tar', compress='bzip2')`

Pack up a directory structure, into a specific format

CLI Examples:

```
salt myminion genesis.pack centos /root/centos
salt myminion genesis.pack centos /root/centos pack_format='tar'
```

`salt.modules.genesis.unpack`(*name*, *dest=None*, *path=None*, *pack\_format='tar'*, *compress='bz2'*)

Unpack an image into a directory structure

CLI Example:

```
salt myminion genesis.unpack centos /root/centos
```

### 30.16.80 salt.modules.gentoo\_service

Top level package command wrapper, used to translate the os detected by grains to the correct service manager

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `'service.start' is not available`), see [here](#).

---

`salt.modules.gentoo_service.available`(*name*)

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available sshd
```

`salt.modules.gentoo_service.disable`(*name*, *\*\*kwargs*)

Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

`salt.modules.gentoo_service.disabled`(*name*)

Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.disabled <service name>
```

`salt.modules.gentoo_service.enable`(*name*, *\*\*kwargs*)

Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

`salt.modules.gentoo_service.enabled`(*name*, *\*\*kwargs*)

Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.enabled <service name>
```

`salt.modules.gentoo_service.get_all`()

Return all available boot services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.gentoo_service.get_disabled()`

Return a set of services that are installed but disabled

CLI Example:

```
salt '*' service.get_disabled
```

`salt.modules.gentoo_service.get_enabled()`

Return a list of service that are enabled on boot

CLI Example:

```
salt '*' service.get_enabled
```

`salt.modules.gentoo_service.missing(name)`

The inverse of `service.available`. Returns `True` if the specified service is not available, otherwise returns `False`.

CLI Example:

```
salt '*' service.missing sshd
```

`salt.modules.gentoo_service.restart(name)`

Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.gentoo_service.start(name)`

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.gentoo_service.status(name, sig=None)`

Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via `ps`

CLI Example:

```
salt '*' service.status <service name> [service signature]
```

`salt.modules.gentoo_service.stop(name)`

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.81 salt.modules.gentoolkitmod

Support for Gentoolkit

`salt.modules.gentoolkitmod.eclean_dist` (*destructive=False*, *package\_names=False*, *size\_limit=0*, *time\_limit=0*, *fetch\_restricted=False*, *exclude\_file='/etc/eclean/distfiles.exclude'*)

Clean obsolete portage sources

**destructive** Only keep minimum for reinstallation

**package\_names** Protect all versions of installed packages. Only meaningful if used with `destructive=True`

**size\_limit** <size> Don't delete distfiles bigger than <size>. <size> is a size specification: ``10M" is ``ten megabytes", ``200K" is ``two hundreds kilobytes", etc. Units are: G, M, K and B.

**time\_limit** <time> Don't delete distfiles files modified since <time> <time> is an amount of time: ``1y" is ``one year", ``2w" is ``two weeks", etc. Units are: y (years), m (months), w (weeks), d (days) and h (hours).

**fetch\_restricted** Protect fetch-restricted files. Only meaningful if used with `destructive=True`

**exclude\_file** Path to exclusion file. Default is `/etc/eclean/distfiles.exclude` This is the same default `eclean-dist` uses. Use `None` if this file exists and you want to ignore.

Returns a dict containing the cleaned, saved, and deprecated dists:

```
{'cleaned': {<dist file>: <size>},
 'deprecated': {<package>: <dist file>},
 'saved': {<package>: <dist file>},
 'total_cleaned': <size>}
```

CLI Example:

```
salt '*' gentoolkit.eclean_dist destructive=True
```

`salt.modules.gentoolkitmod.eclean_pkg`(*destructive=False, package\_names=False, time\_limit=0, exclude\_file='/etc/eclean/packages.exclude'*)

Clean obsolete binary packages

**destructive** Only keep minimum for reinstallation

**package\_names** Protect all versions of installed packages. Only meaningful if used with `destructive=True`

**time\_limit** <time> Don't delete distfiles files modified since <time> <time> is an amount of time: ``1y" is ``one year", ``2w" is ``two weeks", etc. Units are: y (years), m (months), w (weeks), d (days) and h (hours).

**exclude\_file** Path to exclusion file. Default is `/etc/eclean/packages.exclude` This is the same default `eclean-pkg` uses. Use `None` if this file exists and you want to ignore.

Returns a dict containing the cleaned binary packages:

```
{'cleaned': {<dist file>: <size>},
 'total_cleaned': <size>}
```

CLI Example:

```
salt '*' gentoolkit.eclean_pkg destructive=True
```

`salt.modules.gentoolkitmod.glsa_check_list`(*glsa\_list*)

List the status of Gentoo Linux Security Advisories

**glsa\_list** can contain an arbitrary number of GLSA ids, filenames containing GLSAs or the special identifiers ``all" and ``affected"

Returns a dict containing glsa ids with a description, status, and CVEs:

```
{<glsa_id>: {'description': <glsa_description>,
 'status': <glsa status>,
 'CVEs': [<list of CVEs>]}}
```

CLI Example:

```
salt '*' gentoolkit.glsa_check_list 'affected'
```

`salt.modules.gentoolkitmod.revdep_rebuild` (*lib=None*)

Fix up broken reverse dependencies

**lib** Search for reverse dependencies for a particular library rather than every library on the system. It can be a full path to a library or basic regular expression.

CLI Example:

```
salt '*' gentoolkit.revdep_rebuild
```

### 30.16.82 salt.modules.git

Support for the Git SCM

`salt.modules.git.add` (*cwd, file\_name, user=None, opts=None*)

add a file to git

**cwd** The path to the Git repository

**file\_name** Path to the file in the cwd

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.add /path/to/git/repo /path/to/file
```

`salt.modules.git.archive` (*cwd, output, rev='HEAD', fmt=None, prefix=None, user=None*)

Export a tarball from the repository

**cwd** The path to the Git repository

**output** The path to the archive tarball

**rev: HEAD** The revision to create an archive from

**fmt: None** Format of the resulting archive, zip and tar are commonly used

**prefix** [None] Prepend <prefix>/ to every filename in the archive

**user** [None] Run git as a user other than what the minion runs as

If `prefix` is not specified it defaults to the basename of the repo directory.

CLI Example:

```
salt '*' git.archive /path/to/repo /path/to/archive.tar.gz
```

`salt.modules.git.branch` (*cwd, rev, opts=None, user=None*)

Interacts with branches.

**cwd** The path to the Git repository

**rev** The branch/revision to be used in the command.

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.branch mybranch --set-upstream-to=origin/mybranch
```

**salt.modules.git.checkout**(*cwd, rev, force=False, opts=None, user=None*)

Checkout a given revision

**cwd** The path to the Git repository

**rev** The remote branch or revision to checkout

**force** [False] Force a checkout even if there might be overwritten changes

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

CLI Examples:

```
salt '*' git.checkout /path/to/repo somebranch user=jeff
```

```
salt '*' git.checkout /path/to/repo opts='testbranch -- conf/file1 file2'
```

```
salt '*' git.checkout /path/to/repo rev=origin/mybranch opts=--track
```

**salt.modules.git.clone**(*cwd, repository, opts=None, user=None, identity=None, https\_user=None, https\_pass=None*)

Clone a new repository

**cwd** The path to the Git repository

**repository** The git URI of the repository

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

**identity** [None] A path to a private key to use over SSH

**https\_user** [None] HTTP Basic Auth username for HTTPS (only) clones

New in version 2015.5.0.

**https\_pass** [None] HTTP Basic Auth password for HTTPS (only) clones

New in version 2015.5.0.

CLI Example:

```
salt '*' git.clone /path/to/repo git://github.com/saltstack/salt.git
```

```
salt '*' git.clone /path/to/repo.git\  
git://github.com/saltstack/salt.git '--bare --origin github'
```

**salt.modules.git.commit**(*cwd, message, user=None, opts=None*)

create a commit

**cwd** The path to the Git repository

**message** The commit message

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.commit /path/to/git/repo 'The commit message'
```

**salt.modules.git.config\_get**(*cwd=None, setting\_name=None, user=None*)

Get a key or keys from the git configuration file (.git/config).

**cwd** [None] Optional path to a Git repository

Changed in version 2014.7.0: Made *cwd* optional

**setting\_name** [None] The name of the configuration key to get. Required.

**user** [None] Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.config_get setting_name=user.email
salt '*' git.config_get /path/to/repo user.name arthur
```

**salt.modules.git.config\_set**(*cwd=None, setting\_name=None, setting\_value=None, user=None, is\_global=False*)

Set a key in the git configuration file (.git/config) of the repository or globally.

**cwd** [None] Options path to the Git repository

Changed in version 2014.7.0: Made *cwd* optional

**setting\_name** [None] The name of the configuration key to set. Required.

**setting\_value** [None] The (new) value to set. Required.

**user** [None] Run git as a user other than what the minion runs as

**is\_global** [False] Set to True to use the '--global' flag with 'git config'

CLI Example:

```
salt '*' git.config_set /path/to/repo user.email me@example.com
```

**salt.modules.git.current\_branch**(*cwd, user=None*)

Returns the current branch name, if on a branch.

CLI Example:

```
salt '*' git.current_branch /path/to/repo
```

**salt.modules.git.describe**(*cwd, rev='HEAD', user=None*)

Returns the git describe string (or the SHA hash if there are no tags) for the given revision

**cwd** The path to the Git repository

**rev: HEAD** The revision to describe

**user** [None] Run git as a user other than what the minion runs as

CLI Examples:

```
salt '*' git.describe /path/to/repo
salt '*' git.describe /path/to/repo develop
```

**salt.modules.git.fetch**(*cwd, opts=None, user=None, identity=None*)

Perform a fetch on the given repository

**cwd** The path to the Git repository

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

**identity** [None] A path to a private key to use over SSH

CLI Example:

```
salt '*' git.fetch /path/to/repo '--all'

salt '*' git.fetch cwd=/path/to/repo opts='--all' user=johnny
```

**salt.modules.git.init**(*cwd, opts=None, user=None*)

Initialize a new git repository

**cwd** The path to the Git repository

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.init /path/to/repo.git opts='--bare'
```

**salt.modules.git.ls\_remote**(*cwd, repository='origin', branch='master', user=None, identity=None, https\_user=None, https\_pass=None*)

Returns the upstream hash for any given URL and branch.

**cwd** The path to the Git repository

**repository: origin** The name of the repository to get the revision from. Can be the name of a remote, an URL, etc.

**branch: master** The name of the branch to get the revision from.

**user** [none] run git as a user other than what the minion runs as

**identity** [none] a path to a private key to use over ssh

**https\_user** [None] HTTP Basic Auth username for HTTPS (only) clones

New in version 2015.5.0.

**https\_pass** [None] HTTP Basic Auth password for HTTPS (only) clones

New in version 2015.5.0.

CLI Example:

```
salt '*' git.ls_remote /pat/to/repo origin master
```

**salt.modules.git.merge**(*cwd, branch='@{upstream}', opts=None, user=None*)

Merge a given branch

**cwd** The path to the Git repository

**branch** [{upstream}] The remote branch or revision to merge into the current branch

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.fetch /path/to/repo
salt '*' git.merge /path/to/repo @{upstream}
```

`salt.modules.git.pull(cwd, opts=None, user=None, identity=None)`

Perform a pull on the given repository

**cwd** The path to the Git repository

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

**identity** [None] A path to a private key to use over SSH

CLI Example:

```
salt '*' git.pull /path/to/repo opts='--rebase origin master'
```

`salt.modules.git.push(cwd, remote_name, branch='master', user=None, opts=None, identity=None)`

Push to remote

**cwd** The path to the Git repository

**remote\_name** Name of the remote to push to

**branch** [master] Name of the branch to push

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

**identity** [None] A path to a private key to use over SSH

CLI Example:

```
salt '*' git.push /path/to/git/repo remote-name
```

`salt.modules.git.rebase(cwd, rev='master', opts=None, user=None)`

Rebase the current branch

**cwd** The path to the Git repository

**rev** [master] The revision to rebase onto the current branch

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.rebase /path/to/repo master
salt '*' git.rebase /path/to/repo 'origin master'
```

That is the same as:

```
git rebase master
git rebase origin master
```

`salt.modules.git.remote_get(cwd, remote='origin', user=None, redact_auth=True)`

get the fetch and push URL for a specified remote name

**remote** [origin] the remote name used to define the fetch and push URL

**user** [None] Run git as a user other than what the minion runs as

**redact\_auth** [True] Set to `False` to include the username/password if the remote uses HTTPS Basic Auth. Otherwise, this information will be redacted.

**Warning:** Setting this to `False` will not only reveal any HTTPS Basic Auth that is configured, but the return data will also be written to the job cache. When possible, it is recommended to use SSH for authentication.

New in version 2015.5.6.

CLI Example:

```
salt '*' git.remote_get /path/to/repo
salt '*' git.remote_get /path/to/repo upstream
```

`salt.modules.git.remote_set(cwd, name='origin', url=None, user=None, https_user=None, https_pass=None)`

sets a remote with name and URL like `git remote add <remote_name> <remote_url>`

**remote\_name** [origin] defines the remote name

**remote\_url** [None] defines the remote URL; should not be None!

**user** [None] Run git as a user other than what the minion runs as

**https\_user** [None] HTTP Basic Auth username for HTTPS (only) clones

New in version 2015.5.0.

**https\_pass** [None] HTTP Basic Auth password for HTTPS (only) clones

New in version 2015.5.0.

CLI Example:

```
salt '*' git.remote_set /path/to/repo remote_url=git@github.com:saltstack/salt.git
salt '*' git.remote_set /path/to/repo origin git@github.com:saltstack/salt.git
```

`salt.modules.git.remotes(cwd, user=None, redact_auth=True)`

Get remotes like `git remote -v`

**cwd** The path to the Git repository

**user** [None] Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.remotes /path/to/repo
```

`salt.modules.git.reset(cwd, opts=None, user=None)`

Reset the repository checkout

**cwd** The path to the Git repository

**opts** [None] Any additional options to add to the command line

**user** [None] Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.reset /path/to/repo master
```

`salt.modules.git.revision(cwd, rev='HEAD', short=False, user=None)`

Returns the long hash of a given identifier (hash, branch, tag, HEAD, etc)

**cwd** The path to the Git repository

**rev:** HEAD The revision

**short:** `False` Return an abbreviated SHA1 git hash

**user** `[None]` Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.revision /path/to/repo mybranch
```

`salt.modules.git.rm(cwd, file_name, user=None, opts=None)`

Remove a file from git

**cwd** The path to the Git repository

**file\_name** Path to the file in the cwd

**opts** `[None]` Any additional options to add to the command line

**user** `[None]` Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.rm /path/to/git/repo /path/to/file
```

`salt.modules.git.stash(cwd, opts=None, user=None)`

Stash changes in the repository checkout

**cwd** The path to the Git repository

**opts** `[None]` Any additional options to add to the command line

**user** `[None]` Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.stash /path/to/repo master
```

`salt.modules.git.status(cwd, user=None)`

Return the status of the repository. The returned format uses the status codes of git's `porcelain` output mode

**cwd** The path to the Git repository

**user** `[None]` Run git as a user other than what the minion runs as

CLI Example:

```
salt '*' git.status /path/to/git/repo
```

`salt.modules.git.submodule(cwd, init=True, opts=None, user=None, identity=None)`

Initialize git submodules

**cwd** The path to the Git repository

**init** `[True]` Ensure that new submodules are initialized

**opts** `[None]` Any additional options to add to the command line

**user** `[None]` Run git as a user other than what the minion runs as

**identity** `[None]` A path to a private key to use over SSH

CLI Example:

```
salt '*' git.submodule /path/to/repo.git/sub/repo
```

### 30.16.83 salt.modules.glance

Module for handling openstack glance calls.

#### optdepends

- glanceclient Python adapter

**configuration** This module is not usable until the following are specified either in a pillar or in the minion's config file:

```
glance.user: admin
glance.password: verybadpass
glance.tenant: admin
glance.insecure: False #(optional)
glance.auth_url: 'http://127.0.0.1:5000/v2.0/'
```

If configuration for multiple openstack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
  glance.user: admin
  glance.password: verybadpass
  glance.tenant: admin
  glance.auth_url: 'http://127.0.0.1:5000/v2.0/'

openstack2:
  glance.user: admin
  glance.password: verybadpass
  glance.tenant: admin
  glance.auth_url: 'http://127.0.0.2:5000/v2.0/'
```

With this configuration in place, any of the keystone functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' glance.image_list profile=openstack1
```

**salt.modules.glance.image\_create**(*name*, *location*, *profile=None*, *visibility='public'*, *container\_format='bare'*, *disk\_format='raw'*)

Create an image (glance image-create)

CLI Example:

```
salt '*' glance.image_create name=f16-jeos visibility=public \
  disk_format=qcow2 container_format=ovf \
  copy_from=http://berrange.fedorapeople.org/
images/2012-02-29/f16-x86_64-jeos-1.0.qcow2
```

For all possible values, run `glance help image-create` on the minion.

**salt.modules.glance.image\_delete**(*id=None*, *name=None*, *profile=None*)

Delete an image (glance image-delete)

CLI Examples:

```
salt '*' glance.image_delete c2eb2eb0-53e1-4a80-b990-8ec887eae7df
salt '*' glance.image_delete id=c2eb2eb0-53e1-4a80-b990-8ec887eae7df
salt '*' glance.image_delete name=f16-jeos
```

**salt.modules.glance.image\_list**(*id=None*, *profile=None*)

Return a list of available images (glance image-list)

CLI Example:

```
salt '*' glance.image_list
```

**salt.modules.glance.image\_schema**(*profile=None*)  
Returns names and descriptions of the schema ``image``'s properties for this profile's instance of glance

**salt.modules.glance.image\_show**(*id=None, name=None, profile=None*)  
Return details about a specific image (glance image-show)

CLI Example:

```
salt '*' glance.image_show
```

**salt.modules.glance.schema\_get**(*name, profile=None*)

Known valid names of schemas are:

- image
- images
- member
- members

### 30.16.84 salt.modules.glusterfs

Manage a glusterfs pool

**salt.modules.glusterfs.add\_volume\_bricks**(*name, bricks*)  
Add brick(s) to an existing volume

**name** Volume name

**bricks** List of bricks to add to the volume

**salt.modules.glusterfs.create**(*name, bricks, stripe=False, replica=False, device\_vg=False, transport='tcp', start=False*)

Create a glusterfs volume.

**name** Name of the gluster volume

**bricks** Bricks to create volume from, in <peer>:<brick path> format. For multiple bricks use list format:  
`["<peer1>:<brick1>", "<peer2>:<brick2>"]`

**stripe** Stripe count, the number of bricks should be a multiple of the stripe count for a distributed striped volume

**replica** Replica count, the number of bricks should be a multiple of the replica count for a distributed replicated volume

**device\_vg** If true, specifies volume should use block backend instead of regular posix backend. Block device backend volume does not support multiple bricks

**transport** Transport protocol to use, can be `tcp`, `rdma` or `tcp,rdma`

**start** Start the volume after creation

CLI Example:

```
salt host1 glusterfs.create newvolume host1:/brick
```

```
salt gluster1 glusterfs.create vol2 '["gluster1:/export/vol2/brick", "gluster2:/export/v
```

`salt.modules.glusterfs.delete(target, stop=True)`

Deletes a gluster volume

**target** Volume to delete

**stop** Stop volume before delete if it is started, True by default

`salt.modules.glusterfs.list_peers()`

Return a list of gluster peers

CLI Example:

```
salt '*' glusterfs.list_peers
```

GLUSTER direct CLI example (to show what salt is sending to gluster):

```
$ gluster peer status
```

GLUSTER CLI 3.4.4 return example (so we know what we are parsing):

```
Number of Peers: 2
```

```
Hostname: ftp2 Port: 24007 Uuid: cbc256b-e66e-4ec7-a718-21082d396c24 State: Peer in Cluster (Connected)
```

```
Hostname: ftp3 Uuid: 5ea10457-6cb2-427b-a770-7897509625e9 State: Peer in Cluster (Connected)
```

`salt.modules.glusterfs.list_volumes()`

List configured volumes

CLI Example:

```
salt '*' glusterfs.list_volumes
```

`salt.modules.glusterfs.peer(name)`

Add another node into the peer list.

**name** The remote host to probe.

CLI Example:

```
salt 'one.gluster.*' glusterfs.peer two
```

GLUSTER direct CLI example (to show what salt is sending to gluster):

```
$ gluster peer probe ftp2
```

GLUSTER CLI 3.4.4 return example (so we know what we are parsing): #if the ``peer" is the local host:  
peer probe: success: on localhost not needed

```
#if the peer was just added: peer probe: success
```

```
#if the peer was already part of the cluster: peer probe: success: host ftp2 port 24007 already in peer list
```

`salt.modules.glusterfs.start_volume(name)`

Start a gluster volume.

**name** Volume name

CLI Example:

```
salt '*' glusterfs.start mycluster
```

`salt.modules.glusterfs.status(name)`

Check the status of a gluster volume.

**name** Volume name

CLI Example:

```
salt '*' glusterfs.status myvolume
```

**salt.modules.glusterfs.stop\_volume**(*name*)

Stop a gluster volume.

**name** Volume name

CLI Example:

```
salt '*' glusterfs.stop_volume mycluster
```

### 30.16.85 salt.modules.gnomedesktop

GNOME implementations

**salt.modules.gnomedesktop.get**(*schema=None, key=None, user=None, \*\*kwargs*)

Get key in a particular GNOME schema

CLI Example:

```
salt '*' gnome.get user=<username> schema=org.gnome.desktop.screensaver key=idle-activation-enab
```

**salt.modules.gnomedesktop.getClockFormat**(*\*\*kwargs*)

Return the current clock format, either 12h or 24h format.

CLI Example:

```
salt '*' gnome.getClockFormat user=<username>
```

**salt.modules.gnomedesktop.getClockShowDate**(*\*\*kwargs*)

Return the current setting, if the date is shown in the clock

CLI Example:

```
salt '*' gnome.getClockShowDate user=<username>
```

**salt.modules.gnomedesktop.getIdleActivation**(*\*\*kwargs*)

Get whether the idle activation is enabled

CLI Example:

```
salt '*' gnome.getIdleActivation user=<username>
```

**salt.modules.gnomedesktop.getIdleDelay**(*\*\*kwargs*)

Return the current idle delay setting in seconds

CLI Example:

```
salt '*' gnome.getIdleDelay user=<username>
```

**salt.modules.gnomedesktop.ping**(*\*\*kwargs*)

A test to ensure the GNOME module is loaded

CLI Example:

```
salt '*' gnome.ping user=<username>
```

`salt.modules.gnomedesktop.setClockFormat`(*clockFormat*, *\*\*kwargs*)

Set the clock format, either 12h or 24h format.

CLI Example:

```
salt '*' gnome.setClockFormat <12h|24h> user=<username>
```

`salt.modules.gnomedesktop.setClockShowDate`(*kvalue*, *\*\*kwargs*)

Set whether the date is visible in the clock

CLI Example:

```
salt '*' gnome.setClockShowDate <True|False> user=<username>
```

`salt.modules.gnomedesktop.setIdleActivation`(*kvalue*, *\*\*kwargs*)

Set whether the idle activation is enabled

CLI Example:

```
salt '*' gnome.setIdleActivation <True|False> user=<username>
```

`salt.modules.gnomedesktop.setIdleDelay`(*delaySeconds*, *\*\*kwargs*)

Set the current idle delay setting in seconds

CLI Example:

```
salt '*' gnome.setIdleDelay <seconds> user=<username>
```

`salt.modules.gnomedesktop.set_`(*schema=None*, *key=None*, *user=None*, *value=None*, *\*\*kwargs*)

Set key in a particular GNOME schema

CLI Example:

```
salt '*' gnome.set user=<username> schema=org.gnome.desktop.screensaver key=idle-activation-enab
```

### 30.16.86 salt.modules.gpg

Manage a GPG keychains, add keys, create keys, retrieve keys from key servers. Sign, encrypt and sign & encrypt text and files.

New in version 2015.5.0.

---

**Note:** The `python-gnupg` library and `gpg` binary are required to be installed.

---

`salt.modules.gpg.create_key`(*key\_type='RSA'*, *key\_length=1024*, *name\_real='Autogenerated Key'*, *name\_comment='Generated by SaltStack'*, *name\_email=None*, *subkey\_type=None*, *subkey\_length=None*, *expire\_date=None*, *use\_passphrase=False*, *user=None*)

Create a key in the GPG keychain

---

**Note:** GPG key generation requires *a lot* of entropy and randomness. Difficult to do over a remote connection, consider having another process available which is generating randomness for the machine. Also especially difficult on virtual machines, consider the `rpg-tools` package.

The `create_key` process takes awhile so increasing the timeout may be necessary, e.g. `-t 15`.

---

**key\_type** The type of the primary key to generate. It must be capable of signing. `'RSA'` or `'DSA'`.

**key\_length** The length of the primary key in bits.

**name\_real** The real name of the user identity which is represented by the key.

**name\_comment** A comment to attach to the user id.

**name\_email** An email address for the user.

**subkey\_type** The type of the secondary key to generate.

**subkey\_length** The length of the secondary key in bits.

**expire\_date** The expiration date for the primary and any secondary key. You can specify an ISO date, A number of days/weeks/months/years, an epoch value, or 0 for a non-expiring key.

**use\_passphrase** Whether to use a passphrase with the signing key. Passphrase is received from pillar.

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpgkeys`.

CLI Example:

```
salt -t 15 '*' gpg.create_key
```

`salt.modules.gpg.decrypt` (*user=None, text=None, filename=None, output=None, use\_passphrase=False*)

Decrypt a message or file

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpg`.

**text** The encrypted text to decrypt.

**filename** The encrypted filename to decrypt.

**output** The filename where the decrypted data will be written, default is standard out.

**use\_passphrase** Whether to use a passphrase with the signing key. Passphrase is received from pillar.

CLI Example:

```
salt '*' gpg.decrypt filename='/path/to/important.file.gpg'
```

```
salt '*' gpg.decrypt filename='/path/to/important.file.gpg' use_pasphrase=True
```

`salt.modules.gpg.delete_key` (*keyid=None, fingerprint=None, delete\_secret=False, user=None*)

Get a key from the GPG keychain

**keyid** The keyid of the key to be deleted.

**fingerprint** The fingerprint of the key to be deleted.

**delete\_secret** Whether to delete a corresponding secret key prior to deleting the public key. Secret keys must be deleted before deleting any corresponding public keys.

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpgkeys`.

CLI Example:

```
salt '*' gpg.delete_key keyid=3FAD9F1E
```

```
salt '*' gpg.delete_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
```

```
salt '*' gpg.delete_key keyid=3FAD9F1E user=username
```

```
salt '*' gpg.delete_key keyid=3FAD9F1E user=username delete_secret=True
```

**salt.modules.gpg.encrypt**(*user=None, recipients=None, text=None, filename=None, output=None, sign=None, use\_passphrase=False*)

Encrypt a message or file

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpg`.

**recipients** The fingerprints for those recipient whom the data is being encrypted for.

**text** The text to encrypt.

**filename** The filename to encrypt.

**output** The filename where the signed file will be written, default is standard out.

**sign** Whether to sign, in addition to encrypt, the data. True to use default key or fingerprint to specify a different key to sign with.

**use\_passphrase** Whether to use a passphrase with the signing key. Passphrase is received from pillar.

CLI Example:

```
salt '*' gpg.encrypt text='Hello there. How are you?'
salt '*' gpg.encrypt filename='/path/to/important.file'
salt '*' gpg.encrypt filename='/path/to/important.file' use_pasphrase=True
```

**salt.modules.gpg.export\_key**(*keyids=None, secret=False, user=None*)

Export a key from the GPG keychain

**keyids** The keyid(s) of the key(s) to be exported. Can be specified as a comma separated string or a list. Anything which GnuPG itself accepts to identify a key - for example, the keyid or the fingerprint could be used.

**secret** Export the secret key identified by the keyid information passed.

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpg`.

CLI Example:

```
salt '*' gpg.export_key keyids=3FAD9F1E
salt '*' gpg.export_key keyids=3FAD9F1E secret=True
salt '*' gpg.export_key keyid="['3FAD9F1E','3FBD8F1E']" user=username
```

**salt.modules.gpg.get\_key**(*keyid=None, fingerprint=None, user=None*)

Get a key from the GPG keychain

**keyid** The keyid of the key to be retrieved.

**fingerprint** The fingerprint of the key to be retrieved.

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpg`.

CLI Example:

```

salt '*' gpg.get_key keyid=3FAD9F1E

salt '*' gpg.get_key fingerprint=53C96788253E58416D20BCD352952C84C3252192

salt '*' gpg.get_key keyid=3FAD9F1E user=username

```

`salt.modules.gpg.get_secret_key` (*keyid=None, fingerprint=None, user=None*)

Get a key from the GPG keychain

**keyid** The keyid of the key to be retrieved.

**fingerprint** The fingerprint of the key to be retrieved.

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpg`.

CLI Example:

```

salt '*' gpg.get_secret_key keyid=3FAD9F1E

salt '*' gpg.get_secret_key fingerprint=53C96788253E58416D20BCD352952C84C3252192

salt '*' gpg.get_secret_key keyid=3FAD9F1E user=username

```

`salt.modules.gpg.import_key` (*user=None, text=None, filename=None*)

Import a key from text or file

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpg`.

**text** The text containing to import.

**filename** The filename containing the key to import.

CLI Example:

```

salt '*' gpg.import_key text='-----BEGIN PGP PUBLIC KEY BLOCK-----

```

```

... -----END PGP PUBLIC KEY BLOCK-----` salt `*` gpg.import_key filename='/path/to/public-key-file'

```

`salt.modules.gpg.list_keys` (*user=None*)

List keys in GPG keychain

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpgkeys`.

CLI Example:

```

salt '*' gpg.list_keys

```

`salt.modules.gpg.list_secret_keys` (*user=None*)

List secret keys in GPG keychain

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpgkeys`.

CLI Example:

```

salt '*' gpg.list_secret_keys

```

`salt.modules.gpg.receive_keys` (*keyserver=None, keys=None, user=None*)

Receive key(s) from keyserver and add them to keychain

**keyserver** Keyserver to use for searching for GPG keys, defaults to `pgp.mit.edu`

**keys** The keyID(s) to retrieve from the keyserver. Can be specified as a comma separated string or a list.

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `'salt'` will set the GPG home directory to `/etc/salt/gpg`.

CLI Example:

```
salt '*' gpg.receive_key keys='3FAD9F1E'
salt '*' gpg.receive_key keys="['3FAD9F1E', '3FBD9F2E']"
salt '*' gpg.receive_key keys=3FAD9F1E user=username
```

`salt.modules.gpg.search_keys` (*text, keyserver=None, user=None*)

Search keys from keyserver

**text** Text to search the keyserver for, e.g. email address, keyID or fingerprint.

**keyserver** Keyserver to use for searching for GPG keys, defaults to `pgp.mit.edu`

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `'salt'` will set the GPG home directory to `/etc/salt/gpgkeys`.

CLI Example:

```
salt '*' gpg.search_keys user@example.com
salt '*' gpg.search_keys user@example.com keyserver=keyserver.ubuntu.com
salt '*' gpg.search_keys user@example.com keyserver=keyserver.ubuntu.com user=username
```

`salt.modules.gpg.sign` (*user=None, keyid=None, text=None, filename=None, output=None, use\_passphrase=False*)

Sign message or file

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `'salt'` will set the GPG home directory to `/etc/salt/gpg`.

**keyid** The keyid of the key to set the trust level for, defaults to first key in the secret keyring.

**text** The text to sign.

**filename** The filename to sign.

**output** The filename where the signed file will be written, default is standard out.

**use\_passphrase** Whether to use a passphrase with the signing key. Passphrase is received from pillar.

CLI Example:

```
salt '*' gpg.sign text='Hello there. How are you?'
salt '*' gpg.sign filename='/path/to/important.file'
salt '*' gpg.sign filename='/path/to/important.file' use_pasphrase=True
```

`salt.modules.gpg.trust_key` (*keyid=None, fingerprint=None, trust\_level=None, user=None*)

Set the trust level for a key in GPG keychain

**keyid** The keyid of the key to set the trust level for.

**fingerprint** The fingerprint of the key to set the trust level for.

**trust\_level** The trust level to set for the specified key, must be one of the following:

expired, unknown, not\_trusted, marginally, fully, ultimately

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpg`.

CLI Example:

```
salt '*' gpg.trust_key keyid='3FAD9F1E' trust_level='marginally'
salt '*' gpg.trust_key fingerprint='53C96788253E58416D20BCD352952C84C3252192' trust_level='not_t
salt '*' gpg.trust_key keys=3FAD9F1E trust_level='ultimately' user='username'
```

**salt.modules.gpg.verify**(*text=None, user=None, filename=None*)

Verify a message or file

**text** The text to verify.

**filename** The filename to verify.

**user** Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpg`.

CLI Example:

```
salt '*' gpg.verify text='Hello there. How are you?'
salt '*' gpg.verify filename='/path/to/important.file'
salt '*' gpg.verify filename='/path/to/important.file' use_pasphrase=True
```

### 30.16.87 salt.modules.grains

Return/control aspects of the grains data

**salt.modules.grains.append**(*key, val, convert=False, delimiter=':'*)

New in version 0.17.0.

Append a value to a list in the grains config file. If the grain doesn't exist, the grain key is added and the value is appended to the new grain as a list item.

**key** The grain key to be appended to

**val** The value to append to the grain key

#### Parameters

- **convert** -- If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.
- **delimiter** -- The key can be a nested dict key. Use this parameter to specify the delimiter you use. You can now append values to a list in nested dictionary grains. If the list doesn't exist at this level, it will be created. .. versionadded:: 2014.7.6

CLI Example:

```
salt '*' grains.append key val
```

`salt.modules.grains.delval`(*key*, *destructive=False*)

New in version 0.17.0.

Delete a grain from the grains config file

**Parameters** **destructive** -- Delete the key, too. Defaults to False.

CLI Example:

```
salt '*' grains.delval key
```

`salt.modules.grains.filter_by`(*lookup\_dict*, *grain='os\_family'*, *merge=None*, *default='default'*, *base=None*)

New in version 0.17.0.

Look up the given grain in a given dictionary for the current OS and return the result

Although this may occasionally be useful at the CLI, the primary intent of this function is for use in Jinja to make short work of creating lookup tables for OS-specific data. For example:

```
{% set apache = salt['grains.filter_by']({
    'Debian': {'pkg': 'apache2', 'srv': 'apache2'},
    'RedHat': {'pkg': 'httpd', 'srv': 'httpd'},
}, default='Debian') %}
```

```
myapache:
  pkg.installed:
    - name: {{ apache.pkg }}
  service.running:
    - name: {{ apache.srv }}
```

Values in the lookup table may be overridden by values in Pillar. An example Pillar to override values in the example above could be as follows:

```
apache:
  lookup:
    pkg: apache_13
    srv: apache
```

The call to `filter_by()` would be modified as follows to reference those Pillar values:

```
{% set apache = salt['grains.filter_by']({
    ...
}, merge=salt['pillar.get']('apache:lookup')) %}
```

### Parameters

- **lookup\_dict** -- A dictionary, keyed by a grain, containing a value or values relevant to systems matching that grain. For example, a key could be the grain for an OS and the value could be the name of a package on that particular OS.
- **grain** -- The name of a grain to match with the current system's grains. For example, the value of the `os_family` grain for the current system could be used to pull values from the `lookup_dict` dictionary.
- **merge** -- A dictionary to merge with the results of the grain selection from `lookup_dict`. This allows Pillar to override the values in the `lookup_dict`. This could be useful, for example, to override the values for non-standard package names such

as when using a different Python version from the default Python version provided by the OS (e.g., `python26-mysql` instead of `python-mysql`).

- **default** -- default `lookup_dict`'s key used if the grain does not exist or if the grain value has no match on `lookup_dict`. If unspecified the value is `default`.

New in version 2014.1.0.

- **base** -- A `lookup_dict` key to use for a base dictionary. The grain-selected `lookup_dict` is merged over this and then finally the `merge` dictionary is merged. This allows common values for each case to be collected in the base and overridden by the grain selection dictionary and the merge dictionary. Default is unset.

New in version 2015.5.0.

CLI Example:

```
salt '*' grains.filter_by '{Debian: Debheads rule, RedHat: I love my hat}'
# this one will render {D: {E: I, G: H}, J: K}
salt '*' grains.filter_by '{A: B, C: {D: {E: F,G: H}}}' 'xxx' '{D: {E: I},J: K}' 'C'
# next one renders {A: {B: G}, D: J}
salt '*' grains.filter_by '{default: {A: {B: C}, D: E}, F: {A: {B: G}}, H: {D: I}}' 'xxx' '{D: J}'
# next same as above when default='H' instead of 'F' renders {A: {B: C}, D: J}
```

`salt.modules.grains.get(key, default='', delimiter=':')`

Attempt to retrieve the named value from grains, if the named value is not available return the passed default. The default return is an empty string.

The value can also represent a value in a nested dict using a ":" delimiter for the dict. This means that if a dict in grains looks like this:

```
{'pkg': {'apache': 'httpd'}}
```

To retrieve the value associated with the `apache` key in the `pkg` dict this key can be passed:

```
pkg:apache
```

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

CLI Example:

```
salt '*' grains.get pkg:apache
```

`salt.modules.grains.get_or_set_hash(name, length=8, chars='abcdefghijklmnopqrstuvwxyz0123456789!@#%&^*(_+=)')`

Perform a one-time generation of a hash and write it to the local grains. If that grain has already been set return the value instead.

This is useful for generating passwords or keys that are specific to a single minion that don't need to be stored somewhere centrally.

State Example:

```
some_mysql_user:
  mysql_user:
    - present
    - host: localhost
    - password: {{ salt['grains.get_or_set_hash']('mysql:some_mysql_user') }}
```

CLI Example:

```
salt '*' grains.get_or_set_hash 'django:SECRET_KEY' 50
```

**Warning:** This function could return strings which may contain characters which are reserved as directives by the YAML parser, such as strings beginning with `%`. To avoid issues when using the output of this function in an SLS file containing YAML+Jinja, surround the call with single quotes.

**salt.modules.grains.has\_value**(*key*)

Determine whether a named value exists in the grains dictionary.

Given a grains dictionary that contains the following structure:

```
{'pkg': {'apache': 'httpd'}}
```

One would determine if the apache key in the pkg dict exists by:

```
pkg:apache
```

CLI Example:

```
salt '*' grains.has_value pkg:apache
```

**salt.modules.grains.item**(*\*args, \*\*kwargs*)

Return one or more grains

CLI Example:

```
salt '*' grains.item os
salt '*' grains.item os osrelease oscodename
```

Sanitized CLI Example:

```
salt '*' grains.item host sanitize=True
```

**salt.modules.grains.items**(*sanitize=False*)

Return all of the minion's grains

CLI Example:

```
salt '*' grains.items
```

Sanitized CLI Example:

```
salt '*' grains.items sanitize=True
```

**salt.modules.grains.ls**()

Return a list of all available grains

CLI Example:

```
salt '*' grains.ls
```

**salt.modules.grains.remove**(*key, val*)

New in version 0.17.0.

Remove a value from a list in the grains config file

CLI Example:

```
salt '*' grains.remove key val
```

`salt.modules.grains.setval`(*key*, *val*, *destructive=False*)

Set a grains value in the grains config file

**Parameters** **Destructive** -- If an operation results in a key being removed, delete the key, too.  
Defaults to False.

CLI Example:

```
salt '*' grains.setval key val
salt '*' grains.setval key '{"sub-key': 'val', 'sub-key2': 'val2'}"
```

`salt.modules.grains.setvals`(*grains*, *destructive=False*)

Set new grains values in the grains config file

**Parameters** **Destructive** -- If an operation results in a key being removed, delete the key, too.  
Defaults to False.

CLI Example:

```
salt '*' grains.setvals '{"key1': 'val1', 'key2': 'val2'}"
```

### 30.16.88 salt.modules.groupadd

Manage groups on Linux, OpenBSD and NetBSD

**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `group.info is not available`), see [here](#).

`salt.modules.groupadd.add`(*name*, *gid=None*, *system=False*)

Add the specified group

CLI Example:

```
salt '*' group.add foo 3456
```

`salt.modules.groupadd.adduser`(*name*, *username*)

Add a user in the group.

CLI Example:

```
salt '*' group.adduser foo bar
```

Verifies if a valid username `bar` as a member of an existing group `foo`, if not then adds it.

`salt.modules.groupadd.chgid`(*name*, *gid*)

Change the gid for a named group

CLI Example:

```
salt '*' group.chgid foo 4376
```

`salt.modules.groupadd.delete`(*name*)

Remove the named group

CLI Example:

```
salt '*' group.delete foo
```

`salt.modules.groupadd.deluser`(*name*, *username*)

Remove a user from the group.

CLI Example:

```
salt '*' group.deluser foo bar
```

Removes a member user `bar` from a group `foo`. If group is not present then returns True.

`salt.modules.groupadd.getent`(*refresh=False*)

Return info on all groups

CLI Example:

```
salt '*' group.getent
```

`salt.modules.groupadd.info`(*name*)

Return information about a group

CLI Example:

```
salt '*' group.info foo
```

`salt.modules.groupadd.members`(*name*, *members\_list*)

Replaces members of the group with a provided list.

CLI Example:

```
salt '*' group.members foo `user1,user2,user3,...`
```

Replaces a membership list for a local group `foo`. foo:x:1234:user1,user2,user3,...

### 30.16.89 salt.modules.grub\_legacy

Support for GRUB Legacy

`salt.modules.grub_legacy.conf`()

Parse GRUB conf file

CLI Example:

```
salt '*' grub.conf
```

`salt.modules.grub_legacy.version`()

Return server version from grub --version

CLI Example:

```
salt '*' grub.version
```

### 30.16.90 salt.modules.guestfs

Interact with virtual machine images via libguestfs

**depends**

- libguestfs

`salt.modules.guestfs.mount(location, access='rw')`

Mount an image

CLI Example:

```
salt '*' guest.mount /srv/images/fedora.qcow
```

### 30.16.91 salt.modules.hadoop

Support for hadoop

**maintainer** Yann Jouanin <yann.jouanin@intelunix.fr>

**maturity** new

**depends**

**platform** linux

`salt.modules.hadoop.dfs(command=None, *args)`

Execute a command on DFS

CLI Example:

```
salt '*' hadoop.dfs ls /
```

`salt.modules.hadoop.dfs_absent(path)`

Check if a file or directory is absent on the distributed FS.

CLI Example:

```
salt '*' hadoop.dfs_absent /some_random_file
```

Returns True if the file is absent

`salt.modules.hadoop.dfs_present(path)`

Check if a file or directory is present on the distributed FS.

CLI Example:

```
salt '*' hadoop.dfs_present /some_random_file
```

Returns True if the file is present

`salt.modules.hadoop.namenode_format(force=None)`

Format a name node

```
salt '*' hadoop.namenode_format force=True
```

`salt.modules.hadoop.version()`

Return version from hadoop version

CLI Example:

```
salt '*' hadoop.version
```

### 30.16.92 salt.modules.haproxyconn

Support for haproxy

New in version 2014.7.0.

`salt.modules.haproxyconn.disable_server` (*name*, *backend*, *socket*='/var/run/haproxy.sock')

Disable server in haproxy.

**name** Server to disable

**backend** haproxy backend

**socket** haproxy stats socket

```
salt '*' haproxy.disable_server db1.example.com mysql
```

`salt.modules.haproxyconn.enable_server` (*name*, *backend*, *socket*='/var/run/haproxy.sock')

Enable Server in haproxy

**name** Server to enable

**backend** haproxy backend

**socket** haproxy stats socket

```
salt '*' haproxy.enable_server web1.example.com www
```

`salt.modules.haproxyconn.get_weight` (*name*, *backend*, *socket*='/var/run/haproxy.sock')

Get server weight

**name** Server name

**backend** haproxy backend

**socket** haproxy stats socket

```
salt '*' haproxy.get_weight web1.example.com www
```

`salt.modules.haproxyconn.list_servers` (*backend*, *socket*='/var/run/haproxy.sock')

List servers in haproxy backend.

**backend** haproxy backend

**socket** haproxy stats socket

```
salt '*' haproxy.list_servers mysql
```

`salt.modules.haproxyconn.set_weight` (*name*, *backend*, *weight*=0, *socket*='/var/run/haproxy.sock')

Set server weight

**name** Server name

**backend** haproxy backend

**weight** Server Weight

**socket** haproxy stats socket

```
salt '*' haproxy.set_weight web1.example.com www 13
```

`salt.modules.haproxyconn.show_backends` (*socket*='/var/run/haproxy.sock')

Show HaProxy Backends

**socket** haproxy stats socket

```
salt '*' haproxy.show_backends
```

`salt.modules.haproxyconn.show_frontends` (*socket*='/var/run/haproxy.sock')

Show HaProxy frontends

```
socket haproxy stats socket
```

```
salt '*' haproxy.show_frontends
```

### 30.16.93 salt.modules.hashutil

A collection of hashing and encoding functions

**salt.modules.hashutil.base64\_decodestring**(*instr*)

Decode a base64-encoded string

New in version 2014.7.0.

CLI Example:

```
salt '*' hashutil.base64_decodestring 'Z2V0IHNhbHRLZA==\n'
```

**salt.modules.hashutil.base64\_encodestring**(*instr*)

Encode a string as base64

New in version 2014.7.0.

CLI Example:

```
salt '*' hashutil.base64_encodestring 'get salted'
```

**salt.modules.hashutil.hmac\_signature**(*string*, *shared\_secret*, *challenge\_hmac*)

Verify a challenging hmac signature against a string / shared-secret

New in version 2014.7.0.

Returns a boolean if the verification succeeded or failed.

CLI Example:

```
salt '*' hashutil.hmac_signature 'get salted' 'shared secret' 'NS2BvKxFRk+rndAlFbCYIFNVkPtI/3KiI'
```

**salt.modules.hashutil.md5\_digest**(*instr*)

Generate an md5 hash of a given string

New in version 2014.7.0.

CLI Example:

```
salt '*' hashutil.md5_digest 'get salted'
```

**salt.modules.hashutil.sha256\_digest**(*instr*)

Generate an sha256 hash of a given string

New in version 2014.7.0.

CLI Example:

```
salt '*' hashutil.sha256_digest 'get salted'
```

**salt.modules.hashutil.sha512\_digest**(*instr*)

Generate an sha512 hash of a given string

New in version 2014.7.0.

CLI Example:

```
salt '*' hashutil.sha512_digest 'get salted'
```

### 30.16.94 salt.modules.hg

Support for the Mercurial SCM

**salt.modules.hg.archive** (*cwd, output, rev='tip', fmt=None, prefix=None, user=None*)

Export a tarball from the repository

**cwd** The path to the Mercurial repository

**output** The path to the archive tarball

**rev: tip** The revision to create an archive from

**fmt: None** Format of the resulting archive. Mercurial supports: tar, tbz2, tgz, zip, uzip, and files formats.

**prefix** [None] Prepend <prefix>/ to every filename in the archive

**user** [None] Run hg as a user other than what the minion runs as

If **prefix** is not specified it defaults to the basename of the repo directory.

CLI Example:

```
salt '*' hg.archive /path/to/repo output=/tmp/archive.tgz fmt=tgz
```

**salt.modules.hg.clone** (*cwd, repository, opts=None, user=None, identity=None*)

Clone a new repository

**cwd** The path to the Mercurial repository

**repository** The hg URI of the repository

**opts** [None] Any additional options to add to the command line

**user** [None] Run hg as a user other than what the minion runs as

**identity** [None] Private SSH key on the minion server for authentication (ssh://)

New in version 2015.5.0.

CLI Example:

```
salt '*' hg.clone /path/to/repo https://bitbucket.org/birkenfeld/sphinx
```

**salt.modules.hg.describe** (*cwd, rev='tip', user=None*)

Mimic git describe and return an identifier for the given revision

**cwd** The path to the Mercurial repository

**rev: tip** The path to the archive tarball

**user** [None] Run hg as a user other than what the minion runs as

CLI Example:

```
salt '*' hg.describe /path/to/repo
```

**salt.modules.hg.pull** (*cwd, opts=None, user=None, identity=None, repository=None*)

Perform a pull on the given repository

**cwd** The path to the Mercurial repository

**repository** [None] Perform pull from the repository different from .hg/hgrc:[paths]:default

**opts** [None] Any additional options to add to the command line  
**user** [None] Run hg as a user other than what the minion runs as  
**identity** [None] Private SSH key on the minion server for authentication (ssh://)

New in version 2015.5.0.

CLI Example:

```
salt '*' hg.pull /path/to/repo opts=-u
```

**salt.modules.hg.revision**(*cwd*, *rev='tip'*, *short=False*, *user=None*)  
 Returns the long hash of a given identifier (hash, branch, tag, HEAD, etc)

**cwd** The path to the Mercurial repository

**rev: tip** The revision

**short: False** Return an abbreviated commit hash

**user** [None] Run hg as a user other than what the minion runs as

CLI Example:

```
salt '*' hg.revision /path/to/repo mybranch
```

**salt.modules.hg.update**(*cwd*, *rev*, *force=False*, *user=None*)

Update to a given revision

**cwd** The path to the Mercurial repository

**rev** The revision to update to

**force** [False] Force an update

**user** [None] Run hg as a user other than what the minion runs as

CLI Example:

```
salt devserver1 hg.update /path/to/repo somebranch
```

### 30.16.95 salt.modules.hipchat

Module for sending messages to hipchat.

New in version 2015.5.0.

**configuration** This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
hipchat:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
  api_version: v1
```

**salt.modules.hipchat.find\_room**(*name*, *api\_key=None*, *api\_version=None*)

Find a room by name and return it. :param name: The room name. :param api\_key: The HipChat admin api key. :param api\_version: The HipChat api version, if not specified in the configuration. :return: The room object.

CLI Example:

```
salt '*' hipchat.find_room name="Development Room"
```

```
salt '*' hipchat.find_room name="Development Room" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_
```

`salt.modules.hipchat.find_user` (*name*, *api\_key=None*, *api\_version=None*)

Find a user by name and return it. :param name: The user name. :param api\_key: The HipChat admin api key.

:param api\_version: The HipChat api version, if not specified in the configuration. :return: The user object.

CLI Example:

```
salt '*' hipchat.find_user name="Thomas Hatch"
```

```
salt '*' hipchat.find_user name="Thomas Hatch" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_verse
```

`salt.modules.hipchat.list_rooms` (*api\_key=None*, *api\_version=None*)

List all HipChat rooms.

#### Parameters

- **api\_key** -- The HipChat admin api key.
- **api\_version** -- The HipChat api version, if not specified in the configuration.

**Returns** The room list.

CLI Example:

```
salt '*' hipchat.list_rooms
```

```
salt '*' hipchat.list_rooms api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

`salt.modules.hipchat.list_users` (*api\_key=None*, *api\_version=None*)

List all HipChat users. :param api\_key: The HipChat admin api key. :param api\_version: The HipChat api

version, if not specified in the configuration. :return: The user list.

CLI Example:

```
salt '*' hipchat.list_users
```

```
salt '*' hipchat.list_users api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

`salt.modules.hipchat.send_message` (*room\_id*, *message*, *from\_name*, *api\_key=None*,  
*api\_version=None*, *color='yellow'*, *notify=False*)

Send a message to a HipChat room. :param room\_id: The room id or room name, either will work. :param

message: The message to send to the HipChat room. :param from\_name: Specify who the message is from.

:param api\_key: The HipChat api key, if not specified in the configuration. :param api\_version: The HipChat

api version, if not specified in the configuration. :param color: The color for the message, default: yellow.

:param notify: Whether to notify the room, default: False. :return: Boolean if message was sent successfully.

CLI Example:

```
salt '*' hipchat.send_message room_id="Development Room" message="Build is done" from_name="Build
```

```
salt '*' hipchat.send_message room_id="Development Room" message="Build failed" from_name="Build
```

### 30.16.96 salt.modules.hosts

Manage the information in the hosts file

`salt.modules.hosts.add_host(ip, alias)`

Add a host to an existing entry, if the entry is not in place then create it with the given host

CLI Example:

```
salt '*' hosts.add_host <ip> <alias>
```

`salt.modules.hosts.get_alias(ip)`

Return the list of aliases associated with an ip

CLI Example:

```
salt '*' hosts.get_alias <ip addr>
```

`salt.modules.hosts.get_ip(host)`

Return the ip associated with the named host

CLI Example:

```
salt '*' hosts.get_ip <hostname>
```

`salt.modules.hosts.has_pair(ip, alias)`

Return true if the alias is set

CLI Example:

```
salt '*' hosts.has_pair <ip> <alias>
```

`salt.modules.hosts.list_hosts()`

Return the hosts found in the hosts file in this format:

```
{'<ip addr>': ['alias1', 'alias2', ...]}
```

CLI Example:

```
salt '*' hosts.list_hosts
```

`salt.modules.hosts.rm_host(ip, alias)`

Remove a host entry from the hosts file

CLI Example:

```
salt '*' hosts.rm_host <ip> <alias>
```

`salt.modules.hosts.set_host(ip, alias)`

Set the host entry in the hosts file for the given ip, this will overwrite any previous entry for the given ip

CLI Example:

```
salt '*' hosts.set_host <ip> <alias>
```

### 30.16.97 salt.modules.htpasswd

Support for htpasswd command

New in version 2014.1.0.

The functions here will load inside the webutil module. This allows other functions that don't use htpasswd to use the webutil module name.

`salt.modules.htpasswd.useradd`(*pwfile, user, password, opts=''*)

Add an HTTP user using the `htpasswd` command. If the `htpasswd` file does not exist, it will be created. Valid options that can be passed are:

n Don't update file; display results on stdout. m Force MD5 encryption of the password (default). d Force CRYPT encryption of the password. p Do not encrypt the password (plaintext). s Force SHA encryption of the password.

CLI Examples:

```
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpassword
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpass opts=ns
```

`salt.modules.htpasswd.useradd_all`(*pwfile, user, password, opts=''*)

Add an HTTP user using the `htpasswd` command. If the `htpasswd` file does not exist, it will be created. Valid options that can be passed are:

n Don't update file; display results on stdout. m Force MD5 encryption of the password (default). d Force CRYPT encryption of the password. p Do not encrypt the password (plaintext). s Force SHA encryption of the password.

CLI Examples:

```
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpassword
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpass opts=ns
```

`salt.modules.htpasswd.userdel`(*pwfile, user*)

Delete an HTTP user from the specified `htpasswd` file.

CLI Examples:

```
salt '*' webutil.userdel /etc/httpd/htpasswd larry
```

### 30.16.98 salt.modules.http

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

`salt.modules.http.query`(*url, \*\*kwargs*)

Query a resource, and decode the return data

New in version 2015.5.0.

CLI Example:

```
salt '*' http.query http://somelink.com/
salt '*' http.query http://somelink.com/ method=POST params='key1=val1&key2=val2'
salt '*' http.query http://somelink.com/ method=POST data='<xml>somecontent</xml>'
```

`salt.modules.http.update_ca_bundle`(*target=None, source=None, merge\_files=None*)

Update the local CA bundle file from a URL

New in version 2015.5.0.

CLI Example:

```
salt '*' http.update_ca_bundle
salt '*' http.update_ca_bundle target=/path/to/cacerts.pem
salt '*' http.update_ca_bundle source=https://example.com/cacerts.pem
```

If the `target` is not specified, it will be pulled from the `ca_cert` configuration variable available to the minion. If it cannot be found there, it will be placed at `<<FILE_ROOTS>>/cacerts.pem`.

If the `source` is not specified, it will be pulled from the `ca_cert_url` configuration variable available to the minion. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

`merge_files` may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:

```
salt '*' http.update_ca_bundle merge_files=/path/to/mycert.pem
```

### 30.16.99 salt.modules.ilo

Manage HP ILO

**depends** hponcfg (SmartStart Scripting Toolkit Linux Edition)

**salt.modules.ilo.change\_password**(*username, password*)

Reset a users password

CLI Example:

```
salt '*' ilo.change_password damianMyerscough
```

**salt.modules.ilo.change\_username**(*old\_username, new\_username*)

Change a username

CLI Example:

```
salt '*' ilo.change_username damian diana
```

**salt.modules.ilo.configure\_network**(*ip, netmask, gateway*)

Configure Network Interface

CLI Example:

```
salt '*' ilo.configure_network [IP ADDRESS] [NETMASK] [GATEWAY]
```

**salt.modules.ilo.configure\_snmp**(*community, snmp\_port=161, snmp\_trapport=161*)

Configure SNMP

CLI Example:

```
salt '*' ilo.configure_snmp [COMMUNITY STRING] [SNMP PORT] [SNMP TRAP PORT]
```

**salt.modules.ilo.create\_user**(*name, password, \*privileges*)

Create user

CLI Example:

```
salt '*' ilo.create_user damian secretagent VIRTUAL_MEDIA_PRIV
```

If no permissions are specify the user will only have a read-only account.

Supported privileges:

- ADMIN\_PRIV Enables the user to administer user accounts.
- REMOTE\_CONS\_PRIV Enables the user to access the Remote Console functionality.

- RESET\_SERVER\_PRIV Enables the user to remotely manipulate the server power setting.
- VIRTUAL\_MEDIA\_PRIV Enables the user permission to access the virtual media functionality.
- CONFIG\_ILO\_PRIV Enables the user to configure iLO settings.

`salt.modules.ilo.delete_ssh_key`(*username*)

Delete a users SSH key from the ILO

CLI Example:

```
salt '*' ilo.delete_user_sshkey damian
```

`salt.modules.ilo.delete_user`(*username*)

Delete a user

CLI Example:

```
salt '*' ilo.delete_user damian
```

`salt.modules.ilo.disable_dhcp`()

Disable DHCP

CLI Example:

```
salt '*' ilo.disable_dhcp
```

`salt.modules.ilo.disable_ssh`()

Disable the SSH daemon

CLI Example:

```
salt '*' ilo.disable_ssh
```

`salt.modules.ilo.enable_dhcp`()

Enable DHCP

CLI Example:

```
salt '*' ilo.enable_dhcp
```

`salt.modules.ilo.enable_ssh`()

Enable the SSH daemon

CLI Example:

```
salt '*' ilo.enable_ssh
```

`salt.modules.ilo.get_user`(*username*)

Returns local user information, excluding the password

CLI Example:

```
salt '*' ilo.get_user damian
```

`salt.modules.ilo.global_settings`()

Show global settings

CLI Example:

```
salt '*' ilo.global_settings
```

`salt.modules.ilo.list_users()`

List all users

CLI Example:

```
salt '*' ilo.list_users
```

`salt.modules.ilo.list_users_info()`

List all users in detail

CLI Example:

```
salt '*' ilo.list_users_info
```

`salt.modules.ilo.network()`

Grab the current network settings

CLI Example:

```
salt '*' ilo.network
```

`salt.modules.ilo.set_http_port(port=80)`

Configure the port HTTP should listen on

CLI Example:

```
salt '*' ilo.set_http_port 8080
```

`salt.modules.ilo.set_https_port(port=443)`

Configure the port HTTPS should listen on

CLI Example:

```
salt '*' ilo.set_https_port 4334
```

`salt.modules.ilo.set_ssh_key(public_key)`

Configure SSH public keys for specific users

CLI Example:

```
salt '*' ilo.set_ssh_key "ssh-dss AAAAB3NzaC1kc3MAAACBA... damian"
```

The SSH public key needs to be DSA and the last argument in the key needs to be the username (case-sensitive) of the ILO username.

`salt.modules.ilo.set_ssh_port(port=22)`

Enable SSH on a user defined port

CLI Example:

```
salt '*' ilo.set_ssh_port 2222
```

### 30.16.100 salt.modules.img

Virtual machine image management tools

`salt.modules.img.bootstrap(location, size, fmt)`

HIGHLY EXPERIMENTAL Bootstrap a virtual machine image

**location:** The location to create the image

**size:** The size of the image to create in megabytes

**fmt:** The image format, raw or qcow2

CLI Example:

```
salt '*' img.bootstrap /srv/salt-images/host.qcow 4096 qcow2
```

**salt.modules.img.mount\_image**(*location*)

Mount the named image and return the mount point

CLI Example:

```
salt '*' img.mount_image /tmp/foo
```

**salt.modules.img.umount\_image**(*mnt*)

Unmount an image mountpoint

CLI Example:

```
salt '*' img.umount_image /mnt/foo
```

### 30.16.101 salt.modules.incron

Work with incron

**salt.modules.incron.list\_tab**(*user*)

Return the contents of the specified user's incrontab

CLI Example:

```
salt '*' incron.list_tab root
```

**salt.modules.incron.ls**(*user*)

Return the contents of the specified user's incrontab

CLI Example:

```
salt '*' incron.list_tab root
```

**salt.modules.incron.raw\_incron**(*user*)

Return the contents of the user's incrontab

CLI Example:

```
salt '*' incron.raw_cron root
```

**salt.modules.incron.raw\_system\_incron**()

Return the contents of the system wide incrontab

CLI Example:

```
salt '*' incron.raw_system_cron
```

**salt.modules.incron.rm**(*user, path, mask, cmd*)

Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.

CLI Example:

```
salt '*' incron.rm_job root /path
```

`salt.modules.incron.rm_job`(*user, path, mask, cmd*)

Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.

CLI Example:

```
salt '*' incron.rm_job root /path
```

`salt.modules.incron.set_job`(*user, path, mask, cmd*)

Sets a cron job up for a specified user.

CLI Example:

```
salt '*' incron.set_job root '/root' 'IN_MODIFY' 'echo "$$ $@ $# $% $&"'
```

`salt.modules.incron.write_cron_file_verbose`(*user, path*)

Writes the contents of a file to a user's crontab and return error message on error

CLI Example:

```
salt '*' incron.write_incron_file_verbose root /tmp/new_cron
```

`salt.modules.incron.write_incron_file`(*user, path*)

Writes the contents of a file to a user's crontab

CLI Example:

```
salt '*' incron.write_cron_file root /tmp/new_cron
```

### 30.16.102 salt.modules.influx

InfluxDB - A distributed time series database

Module to provide InfluxDB compatibility to Salt (compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

#### depends

- influxdb Python module

**configuration** This module accepts connection configuration details either as parameters or as configuration settings in `/etc/salt/minion` on the relevant minions:

```
influxdb.host: 'localhost'
influxdb.port: 8086
influxdb.user: 'root'
influxdb.password: 'root'
```

This data can also be passed into pillar. Options passed into `opts` will overwrite options passed into `pillar`.

`salt.modules.influx.db_create`(*name, user=None, password=None, host=None, port=None*)

Create a database

**name** Database name to create

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.db_create <name>
salt '*' influxdb.db_create <name> <user> <password> <host> <port>
```

**salt.modules.influx.db\_exists** (*name, user=None, password=None, host=None, port=None*)

Checks if a database exists in InfluxDB

**name** Database name to create

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.db_exists <name>
salt '*' influxdb.db_exists <name> <user> <password> <host> <port>
```

**salt.modules.influx.db\_list** (*user=None, password=None, host=None, port=None*)

List all InfluxDB databases

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.db_list
salt '*' influxdb.db_list <user> <password> <host> <port>
```

**salt.modules.influx.db\_remove** (*name, user=None, password=None, host=None, port=None*)

Remove a database

**name** Database name to remove

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.db_remove <name>
salt '*' influxdb.db_remove <name> <user> <password> <host> <port>
```

**salt.modules.influx.query** (*database, query, time\_precision='s', chunked=False, user=None, password=None, host=None, port=None*)

Querying data

**database** The database to query

**query** Query to be executed

**time\_precision** Time precision to use (`s`, `m`, or `u`)

**chunked** Whether is chunked or not

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.query <database> <query>
salt '*' influxdb.query <database> <query> <time_precision> <chunked> <user> <password> <host> <port>
```

**salt.modules.influx.user\_chpass**(*name, passwd, database=None, user=None, password=None, host=None, port=None*)

Change password for a cluster admin or a database user.

If a database is specified: it will update database user password. If a database is not specified: it will update cluster admin password.

**name** User name for whom to change the password

**passwd** New password

**database** The database on which to operate

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.user_chpass <name> <passwd>
salt '*' influxdb.user_chpass <name> <passwd> <database>
salt '*' influxdb.user_chpass <name> <passwd> <database> <user> <password> <host> <port>
```

**salt.modules.influx.user\_create**(*name, passwd, database=None, user=None, password=None, host=None, port=None*)

Create a cluster admin or a database user.

If a database is specified: it will create database user. If a database is not specified: it will create a cluster admin.

**name** User name for the new user to create

**passwd** Password for the new user to create

**database** The database to create the user in

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.user_create <name> <passwd>
salt '*' influxdb.user_create <name> <passwd> <database>
salt '*' influxdb.user_create <name> <passwd> <database> <user> <password> <host> <port>
```

`salt.modules.influx.user_exists`(*name*, *database=None*, *user=None*, *password=None*, *host=None*, *port=None*)

Checks if a cluster admin or database user exists.

If a database is specified: it will check for database user existence. If a database is not specified: it will check for cluster admin existence.

**name** User name

**database** The database to check for the user to exist

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.user_exists <name>
salt '*' influxdb.user_exists <name> <database>
salt '*' influxdb.user_exists <name> <database> <user> <password> <host> <port>
```

`salt.modules.influx.user_list`(*database=None*, *user=None*, *password=None*, *host=None*, *port=None*)

List cluster admins or database users.

If a database is specified: it will return database users list. If a database is not specified: it will return cluster admins list.

**database** The database to list the users from

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.user_list
salt '*' influxdb.user_list <database>
salt '*' influxdb.user_list <database> <user> <password> <host> <port>
```

`salt.modules.influx.user_remove`(*name*, *database=None*, *user=None*, *password=None*, *host=None*, *port=None*)

Remove a cluster admin or a database user.

If a database is specified: it will remove the database user. If a database is not specified: it will remove the cluster admin.

**name** User name to remove

**database** The database to remove the user from

**user** User name for the new user to delete

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.user_remove <name>
salt '*' influxdb.user_remove <name> <database>
salt '*' influxdb.user_remove <name> <database> <user> <password> <host> <port>
```

### 30.16.103 salt.modules.ini\_manage

Edit ini files

**maintainer** <akilesh1597@gmail.com>

**maturity** new

**depends** re

**platform** all

Use section as DEFAULT\_IMPLICIT if your ini file does not have any section (for example /etc/sysctl.conf)

**salt.modules.ini\_manage.get\_option**(*file\_name, section, option*)

Get value of a key from a section in an ini file. Returns None if no matching key was found.

API Example:

```
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.get_option',
      [path_to_ini_file, section_name, option])
```

CLI Example:

```
salt '*' ini.get_option /path/to/ini section_name option_name
```

**salt.modules.ini\_manage.get\_section**(*file\_name, section*)

Retrieve a section from an ini file. Returns the section as dictionary. If the section is not found, an empty dictionary is returned.

API Example:

```
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.get_section',
      [path_to_ini_file, section_name])
```

CLI Example:

```
salt '*' ini.get_section /path/to/ini section_name
```

**salt.modules.ini\_manage.remove\_option**(*file\_name, section, option*)

Remove a key/value pair from a section in an ini file. Returns the value of the removed key, or None if nothing was removed.

API Example:

```
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.remove_option',
      [path_to_ini_file, section_name, option])
```

CLI Example:

```
salt '*' ini.remove_option /path/to/ini section_name option_name
```

`salt.modules.ini_manage.remove_section`(*file\_name*, *section*)

Remove a section in an ini file. Returns the removed section as dictionary, or None if nothing was removed.

API Example:

```
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.remove_section',
      [path_to_ini_file, section_name])
```

CLI Example:

```
salt '*' ini.remove_section /path/to/ini section_name
```

`salt.modules.ini_manage.set_option`(*file\_name*, *sections=None*, *summary=True*)

Edit an ini file, replacing one or more sections. Returns a dictionary containing the changes made.

**file\_name** path of ini file

**sections** [None] A dictionary representing the sections to be edited ini file

Set `summary=False` if return data need not have previous option value

API Example:

```
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.set_option',
      ['path_to_ini_file', '{"section_to_change": {"key": "value"}}'])
```

CLI Example:

```
salt '*' ini.set_option /path/to/ini '{section_foo: {key: value}}'
```

### 30.16.104 salt.modules.introspect

Functions to perform introspection on a minion, and return data in a format usable by Salt States

`salt.modules.introspect.enabled_service_owners`()

Return which packages own each of the services that are currently enabled.

CLI Example:

```
salt myminion introspect.enabled_service_owners
```

`salt.modules.introspect.running_service_owners`(*exclude=(/dev', /home', /media', /proc', /run', /sys', /tmp', /var')*)

Determine which packages own the currently running services. By default, excludes files whose full path starts with /dev, /home, /media, /proc, /run, /sys, /tmp and /var. This can be overridden by passing in a new list to exclude.

CLI Example:

```
salt myminion introspect.running_service_owners
```

`salt.modules.introspect.service_highstate` (*requires=True*)

Return running and enabled services in a highstate structure. By default also returns package dependencies for those services, which means that package definitions must be created outside this function. To drop the package dependencies, set `requires` to `False`.

CLI Example:

```
salt myminion introspect.service_highstate salt myminion introspect.service_highstate requires=False
```

### 30.16.105 salt.modules.ipmi

Support IPMI commands over LAN. This module does not talk to the local systems hardware through IPMI drivers. It uses a python module `pyghmi`.

**depends** Python module `pyghmi`. You can install `pyghmi` using `pip`:

```
pip install pyghmi
```

**configuration** The following configuration defaults can be define (pillar or config files):

```
ipmi.config:
  api_host: 127.0.0.1
  api_user: admin
  api_pass: apassword
  api_port: 623
  api_kg: None
```

Usage can override the config defaults:

```
salt-call ipmi.get_user api_host=myipmienabled.system
                    api_user=admin api_pass=pass
                    uid=1
```

`salt.modules.ipmi.create_user` (*uid, name, password, channel=14, callback=False, link\_auth=True, ipmi\_msg=True, privilege\_level='administrator', \*\*kwargs*)  
create/ensure a user is created with provided settings.

**Parameters**

- **privilege\_level** -- User Privilege Limit. (Determines the maximum privilege level that the user is allowed to switch to on the specified channel.) \* `callback` \* `user` \* `operator` \* `administrator` \* `proprietary` \* `no_access`
- **kwargs** --
  - `api_host=127.0.0.1`
  - `api_user=admin`
  - `api_pass=example`
  - `api_port=623`
  - `api_kg=None`

CLI Examples:

```
salt-call ipmi.create_user uid=2 name=steverweber api_host=172.168.0.7 api_pass=nevertell
```

`salt.modules.ipmi.fast_connect_test(**kwargs)`

Returns True if connection success. This uses an aggressive timeout value!

**Parameters** `kwargs` --

- `api_host=127.0.0.1`
- `api_user=admin`
- `api_pass=example`
- `api_port=623`
- `api_kg=None`

CLI Examples:

```
salt-call ipmi.fast_connect_test api_host=172.168.0.9
```

`salt.modules.ipmi.get_bootdev(**kwargs)`

Get current boot device override information.

Provides the current requested boot device. Be aware that not all IPMI devices support this. Even in BMCs that claim to, occasionally the BIOS or UEFI fail to honor it. This is usually only applicable to the next reboot.

**Parameters** `kwargs` --

- `api_host=127.0.0.1`
- `api_user=admin`
- `api_pass=example`
- `api_port=623`
- `api_kg=None`

CLI Example:

```
salt-call ipmi.get_bootdev api_host=127.0.0.1 api_user=admin api_pass=pass
```

`salt.modules.ipmi.get_channel_access(channel=14, read_mode='non_volatile', **kwargs)`

:param kwargs:api\_host='127.0.0.1' api\_user='admin' api\_pass='example' api\_port=623

**Parameters**

- **channel** -- number [1:7]
- **read\_mode** --
  - `non_volatile` = get non-volatile Channel Access
  - `volatile` = get present volatile (active) setting of Channel Access
- **kwargs** --
  - `api_host=127.0.0.1`
  - `api_user=admin`
  - `api_pass=example`
  - `api_port=623`
  - `api_kg=None`

**return** A Python dict with the following keys/values:

```

{
  alerting:
  per_msg_auth:
  user_level_auth:
  access_mode:{ (ONE OF)
    0: 'disabled',
    1: 'pre_boot',
    2: 'always',
    3: 'shared'
  }
  privilege_level: { (ONE OF)
    1: 'callback',
    2: 'user',
    3: 'operator',
    4: 'administrator',
    5: 'proprietary',
  }
}

```

CLI Examples:

```
salt-call ipmi.get_channel_access channel=1
```

`salt.modules.ipmi.get_channel_info(channel=14, **kwargs)`

Get channel info

Parameters

- **channel** -- number [1:7]
- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

**return** channel session supports:

```

- no_session: channel is session-less
- single: channel is single-session
- multi: channel is multi-session
- auto: channel is session-based (channel could alternate between
      single- and multi-session operation, as can occur with a
      serial/modem channel that supports connection mode auto-detect)

```

CLI Examples:

```
salt-call ipmi.get_channel_info
```

`salt.modules.ipmi.get_channel_max_user_count(channel=14, **kwargs)`

Get max users in channel

Parameters

- **channel** -- number [1:7]

- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

**Returns** int -- often 16

CLI Examples:

```
salt-call ipmi.get_channel_max_user_count
```

`salt.modules.ipmi.get_health(**kwargs)`

Get Summarize health

This provides a summary of the health of the managed system. It additionally provides an iterable list of reasons for warning, critical, or failed assessments.

good health: {'badreadings': [], 'health': 0}

**Parameters** **kwargs** --

- api\_host=127.0.0.1
- api\_user=admin
- api\_pass=example
- api\_port=623
- api\_kg=None

CLI Example:

```
salt-call ipmi.get_health api_host=127.0.0.1 api_user=admin api_pass=pass
```

`salt.modules.ipmi.get_power(**kwargs)`

Get current power state

The response, if successful, should contain 'powerstate' key and either 'on' or 'off' to indicate current state.

**Parameters** **kwargs** --

- api\_host=127.0.0.1
- api\_user=admin
- api\_pass=example
- api\_port=623
- api\_kg=None

CLI Example:

```
salt-call ipmi.get_power api_host=127.0.0.1 api_user=admin api_pass=pass
```

`salt.modules.ipmi.get_sensor_data(**kwargs)`

Get sensor readings

Iterates sensor reading objects

**Parameters `kwargs` --**

- `api_host=127.0.0.1`
- `api_user=admin`
- `api_pass=example`
- `api_port=623`
- `api_kg=None`

CLI Example:

```
salt-call ipmi.get_sensor_data api_host=127.0.0.1 api_user=admin api_pass=pass
```

`salt.modules.ipmi.get_user`(*uid*, *channel=14*, *\*\*kwargs*)

Get user from uid and access on channel

**Parameters**

- **uid** -- user number [1:16]
- **channel** -- number [1:7]
- **kwargs** --
  - `api_host=127.0.0.1`
  - `api_user=admin`
  - `api_pass=example`
  - `api_port=623`
  - `api_kg=None`

return

```
name: (str)
uid: (int)
channel: (int)
access:
  - callback (bool)
  - link_auth (bool)
  - ipmi_msg (bool)
  - privilege_level: (str)[callback, user, operator, administrator,
    proprietary, no_access]
```

CLI Examples:

```
salt-call ipmi.get_user uid=2
```

`salt.modules.ipmi.get_user_access`(*uid*, *channel=14*, *\*\*kwargs*)

Get user access

**Parameters**

- **uid** -- user number [1:16]
- **channel** -- number [1:7]
- **kwargs** --
  - `api_host=127.0.0.1`
  - `api_user=admin`

- api\_pass=example
- api\_port=623
- api\_kg=None

return

```
channel_info:
  - max_user_count = maximum number of user IDs on this channel
  - enabled_users = count of User ID slots presently in use
  - users_with_fixed_names = count of user IDs with fixed names
access:
  - callback
  - link_auth
  - ipmi_msg
  - privilege_level: [reserved, callback, user, operator
                    administrator, proprietary, no_access]
```

CLI Examples:

```
salt-call ipmi.get_user_access uid=2
```

`salt.modules.ipmi.get_user_name`(*uid*, *return\_none\_on\_error=True*, *\*\*kwargs*)

Get user name

Parameters

- **uid** -- user number [1:16]
- **return\_none\_on\_error** -- return None on error
- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

CLI Examples:

```
salt-call ipmi.get_user_name uid=2
```

`salt.modules.ipmi.get_users`(*channel=14*, *\*\*kwargs*)

get list of users and access information

Parameters

- **channel** -- number [1:7]
- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

**Returns**

name: (str) uid: (int) channel: (int) access:

- callback (bool)
- link\_auth (bool)
- ipmi\_msg (bool)
- **privilege\_level**: (str)[callback, user, operator, administrator, proprietary, no\_access]

CLI Examples:

```
salt-call ipmi.get_users api_host=172.168.0.7
```

`salt.modules.ipmi.raw_command`(*netfn*, *command*, *bridge\_request*=None, *data*=(), *retry*=True, *delay\_xmit*=None, *\*\*kwargs*)

Send raw ipmi command

This allows arbitrary IPMI bytes to be issued. This is commonly used for certain vendor specific commands.

**Parameters**

- **netfn** -- Net function number
- **command** -- Command value
- **bridge\_request** -- The target slave address and channel number for the bridge request.
- **data** -- Command data as a tuple or list
- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

**Returns** dict -- The response from IPMI device

CLI Examples:

```
salt-call ipmi.raw_command netfn=0x06 command=0x46 data=[0x02]
# this will return the name of the user with id 2 in bytes
```

`salt.modules.ipmi.set_bootdev`(*bootdev*='default', *persist*=False, *uefiboot*=False, *\*\*kwargs*)

Set boot device to use on next reboot

**Parameters**

- **bootdev** -- *\*network* -- Request network boot *\*hd* -- Boot from hard drive *\*safe* -- Boot from hard drive, requesting 'safe mode' *\*optical* -- boot from CD/DVD/BD drive *\*setup* -- Boot into setup utility *\*default* -- remove any IPMI directed boot device request
- **persist** -- If true, ask that system firmware use this device beyond next boot. Be aware many systems do not honor this
- **uefiboot** -- If true, request UEFI boot explicitly. Strictly speaking, the spec suggests that if not set, the system should BIOS boot and offers no ``don't care" option. In practice, this flag not being set does not preclude UEFI boot on any system I've encountered.

- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

**Returns** dict or True -- If callback is not provided, the response

CLI Examples:

```
salt-call ipmi.set_bootdev bootdev=network persist=True
```

```
salt.modules.ipmi.set_channel_access(channel=14, access_update_mode='non_volatile',
                                     alerting=False, per_msg_auth=False,
                                     user_level_auth=False, access_mode='always',
                                     privilege_update_mode='non_volatile', privilege_level='administrator', **kwargs)
```

Set channel access

#### Parameters

- **channel** -- number [1:7]
- **access\_update\_mode** -- one of - `dont\_change` = don't set or change Channel Access - `non\_volatile` = set non-volatile Channel Access - `volatile` = set volatile (active) setting of Channel Access
- **alerting** -- PEF Alerting Enable/Disable - True = enable PEF Alerting - False = disable PEF Alerting on this channel
  - (Alert Immediate command can still be used to generate alerts)
- **per\_msg\_auth** -- Per-message Authentication - True = enable - False = disable Per-message Authentication. [Authentication required to activate any session on this channel, but authentication not used on subsequent packets for the session.]
- **user\_level\_auth** -- User Level Authentication Enable/Disable. - True = enable User Level Authentication. All User Level commands are to be authenticated per the Authentication Type that was negotiated when the session was activated.
  - **False = disable User Level Authentication. Allow User Level commands to be executed without being authenticated.** If the option to disable User Level Command authentication is accepted, the BMC will accept packets with Authentication Type set to None if they contain user level commands. For outgoing packets, the BMC returns responses with the same Authentication Type that was used for the request.
- **access\_mode** -- Access Mode for IPMI messaging (PEF Alerting is enabled/disabled separately from IPMI messaging) \* disabled = disabled for IPMI messaging \* pre\_boot = pre-boot only channel only available when system is in a powered down state or in BIOS prior to start of boot.

- **always** = channel always available regardless of system mode. BIOS typically dedicates the serial connection to the BMC.
- **shared** = same as always available, but BIOS typically leaves the serial port available for software use.
- **privilege\_update\_mode** -- Channel Privilege Level Limit. This value sets the maximum privilege level that can be accepted on the specified channel. \* dont\_change = don't set or change channel Privilege Level Limit \* non\_volatile = non-volatile Privilege Level Limit according \* volatile = volatile setting of Privilege Level Limit
- **privilege\_level** -- Channel Privilege Level Limit \* reserved = unused \* callback \* user \* operator \* administrator \* proprietary = used by OEM
- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

CLI Examples:

```
salt-call ipmi.set_channel_access privilege_level='administrator'
```

`salt.modules.ipmi.set_identify` (*on=True, duration=600, \*\*kwargs*)

Request identify light

Request the identify light to turn off, on for a duration, or on indefinitely. Other than error exceptions,

#### Parameters

- **on** -- Set to True to force on or False to force off
- **duration** -- Set if wanting to request turn on for a duration in seconds, None = indefinitely.
- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

CLI Examples:

```
salt-call ipmi.set_identify
```

`salt.modules.ipmi.set_power` (*state='power\_on', wait=True, \*\*kwargs*)

Request power state change

#### Parameters

- **name** --
  - power\_on -- system turn on

- power\_off -- system turn off (without waiting for OS)
- shutdown -- request OS proper shutdown
- reset -- reset (without waiting for OS)
- boot -- If system is off, then `on`, else `reset`
- **ensure** -- If (bool True), do not return until system actually completes requested state change for 300 seconds. If a non-zero (int), adjust the wait time to the requested number of seconds
- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

**Returns** dict -- A dict describing the response retrieved

CLI Examples:

```
salt-call ipmi.set_power state=shutdown wait=True
```

```
salt.modules.ipmi.set_user_access(uid, channel=14, callback=True, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)
```

Set user access

**Parameters**

- **uid** -- user number [1:16]
- **channel** -- number [1:7]

**Parm callback** User Restricted to Callback

**False** = User Privilege Limit is determined by the **User Privilege Limit** parameter, below, for both callback and non-callback connections.

**True** = User Privilege Limit is determined by the **User Privilege Limit** parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they `call in` to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

**Parameters link\_auth** -- User Link authentication

enable/disable (used to enable whether this user's name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.

**Parameters ipmi\_msg** -- User IPMI Messaging:

(used to enable/disable whether this user's name and password information will be used for IPMI Messaging. In this case, `IPMI Messaging` refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for `activatallow_authing` the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.)

**Parameters `privilege_level` --**

User Privilege Limit. (Determines the maximum privilege level that the user is allowed to switch to on the specified channel.)

- callback
- user
- operator
- administrator
- proprietary
- no\_access

**Parameters `kwargs` --**

- `api_host=127.0.0.1`
- `api_user=admin`
- `api_pass=example`
- `api_port=623`
- `api_kg=None`

CLI Examples:

```
salt-call ipmi.set_user_access uid=2 privilege_level='operator'
```

`salt.modules.ipmi.set_user_name` (*uid*, *name*, *\*\*kwargs*)

Set user name

**Parameters**

- **uid** -- user number [1:16]
- **name** -- username (limit of 16bytes)
- **kwargs** --
  - `api_host=127.0.0.1`
  - `api_user=admin`
  - `api_pass=example`
  - `api_port=623`
  - `api_kg=None`

CLI Examples:

```
salt-call ipmi.set_user_name uid=2 name='steverweber'
```

`salt.modules.ipmi.set_user_password` (*uid*, *mode='set\_password'*, *password=None*, *\*\*kwargs*)

Set user password and (modes)

**Parameters**

- **uid** -- id number of user. see: `get_names_uid()['name']`
- **mode** --
  - `disable` = disable user connections

- enable = enable user connections
- set\_password = set or ensure password
- test\_password = test password is correct
- **password** -- max 16 char string (optional when mode is [disable or enable])
- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

**Returns** True on success when mode = test\_password, return False on bad password

CLI Example:

```
salt-call ipmi.set_user_password api_host=127.0.0.1 api_user=admin api_pass=pass
                                uid=1 password=newPass
salt-call ipmi.set_user_password uid=1 mode=enable
```

`salt.modules.ipmi.user_delete`(*uid*, *channel=14*, *\*\*kwargs*)

Delete user (helper)

**Parameters**

- **uid** -- user number [1:16]
- **channel** -- number [1:7]
- **kwargs** --
  - api\_host=127.0.0.1
  - api\_user=admin
  - api\_pass=example
  - api\_port=623
  - api\_kg=None

CLI Examples:

```
salt-call ipmi.user_delete uid=2
```

### 30.16.106 salt.modules.ipset

Support for ipset

`salt.modules.ipset.add`(*set=None*, *entry=None*, *family='ipv4'*, *\*\*kwargs*)

Append an entry to the specified set.

CLI Example:

```
salt '*' ipset.add setname 192.168.1.26
salt '*' ipset.add setname 192.168.0.3,AA:BB:CC:DD:EE:FF
```

`salt.modules.ipset.check` (*set=None, entry=None, family='ipv4'*)  
Check that an entry exists in the specified set.

CLI Example:

```
salt '*' ipset.check setname '192.168.0.1 comment "Hello"'
```

`salt.modules.ipset.check_set` (*set=None, family='ipv4'*)  
New in version 2014.7.0.

Check that given ipset set exists.

CLI Example:

```
salt '*' ipset.check_set setname
```

`salt.modules.ipset.delete` (*set=None, entry=None, family='ipv4', \*\*kwargs*)  
Delete an entry from the specified set.

CLI Example:

```
salt '*' ipset.delete setname 192.168.0.3,AA:BB:CC:DD:EE:FF
```

`salt.modules.ipset.delete_set` (*set=None, family='ipv4'*)  
New in version 2014.7.0.

Delete ipset set.

CLI Example:

```
salt '*' ipset.delete_set custom_set
```

IPv6:

```
salt '*' ipset.delete_set custom_set family=ipv6
```

`salt.modules.ipset.flush` (*set=None, family='ipv4'*)  
Flush entries in the specified set, Flush all sets if set is not specified.

CLI Example:

```
salt '*' ipset.flush
```

```
salt '*' ipset.flush set
```

IPv6:

```
salt '*' ipset.flush
```

```
salt '*' ipset.flush set
```

`salt.modules.ipset.list_sets` (*family='ipv4'*)  
New in version 2014.7.0.

List all ipset sets.

CLI Example:

```
salt '*' ipset.list_sets
```

`salt.modules.ipset.new_set` (*set=None, set\_type=None, family='ipv4', comment=False, \*\*kwargs*)  
New in version 2014.7.0.

Create new custom set

CLI Example:

```
salt '*' ipset.new_set custom_set list:set

salt '*' ipset.new_set custom_set list:set comment=True

IPv6:
salt '*' ipset.new_set custom_set list:set family=ipv6
```

`salt.modules.ipset.rename_set` (*set=None, new\_set=None, family='ipv4'*)  
New in version 2014.7.0.

Delete ipset set.

CLI Example:

```
salt '*' ipset.rename_set custom_set new_set=new_set_name

IPv6:
salt '*' ipset.rename_set custom_set new_set=new_set_name family=ipv6
```

`salt.modules.ipset.test` (*set=None, entry=None, family='ipv4', \*\*kwargs*)  
Test if an entry is in the specified set.

CLI Example:

```
salt '*' ipset.test setname 192.168.0.2

IPv6:
salt '*' ipset.test setname fd81:fc56:9ac7::/48
```

`salt.modules.ipset.version`()  
Return version from ipset --version

CLI Example:

```
salt '*' ipset.version
```

### 30.16.107 salt.modules.iptables

Support for iptables

`salt.modules.iptables.append` (*table='filter', chain=None, rule=None, family='ipv4'*)  
Append a rule to the specified table/chain.

**This function accepts a rule in a standard iptables command format**, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```
salt '*' iptables.append filter INPUT \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt '*' iptables.append filter INPUT \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' \
    family=ipv6
```

```
salt.modules.iptables.build_rule(table=None, chain=None, command=None, position='',
                                   full=None, family='ipv4', **kwargs)
```

Build a well-formatted iptables rule based on kwargs. A *table* and *chain* are not required, unless *full* is True.

If *full* is True, then *table*, *chain* and *command* are required. *command* may be specified as either a short option (*I*) or a long option (*--insert*). This will return the iptables command, exactly as it would be used from the command line.

If a position is required (as with *-I* or *-D*), it may be specified as *position*. This will only be useful if *full* is True.

If *connstate* is passed in, it will automatically be changed to *state*.

To pass in jump options that doesn't take arguments, pass in an empty string.

CLI Examples:

```
salt '*' iptables.build_rule match=state \
    connstate=RELATED,ESTABLISHED jump=ACCEPT

salt '*' iptables.build_rule filter INPUT command=I position=3 \
    full=True match=state state=RELATED,ESTABLISHED jump=ACCEPT

salt '*' iptables.build_rule filter INPUT command=A \
    full=True match=state state=RELATED,ESTABLISHED \
    source='127.0.0.1' jump=ACCEPT

.. Invert Rules
salt '*' iptables.build_rule filter INPUT command=A \
    full=True match=state state=RELATED,ESTABLISHED \
    source='! 127.0.0.1' jump=ACCEPT

salt '*' iptables.build_rule filter INPUT command=A \
    full=True match=state state=RELATED,ESTABLISHED \
    destination='not 127.0.0.1' jump=ACCEPT

IPv6:
salt '*' iptables.build_rule match=state \
    connstate=RELATED,ESTABLISHED jump=ACCEPT \
    family=ipv6
salt '*' iptables.build_rule filter INPUT command=I position=3 \
    full=True match=state state=RELATED,ESTABLISHED jump=ACCEPT \
    family=ipv6
```

```
salt.modules.iptables.check(table='filter', chain=None, rule=None, family='ipv4')
```

Check for the existence of a rule in the table and chain

This function accepts a rule in a standard iptables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```
salt '*' iptables.check filter INPUT \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt '*' iptables.check filter INPUT \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' \
    family=ipv6
```

`salt.modules.iptables.check_chain` (*table='filter', chain=None, family='ipv4'*)

New in version 2014.1.0.

Check for the existence of a chain in the table

CLI Example:

```
salt '*' iptables.check_chain filter INPUT

IPv6:
salt '*' iptables.check_chain filter INPUT family=ipv6
```

`salt.modules.iptables.delete` (*table, chain=None, position=None, rule=None, family='ipv4'*)

Delete a rule from the specified table/chain, specifying either the rule in its entirety, or the rule's position in the chain.

This function accepts a rule in a standard iptables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Examples:

```
salt '*' iptables.delete filter INPUT position=3
salt '*' iptables.delete filter INPUT \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt '*' iptables.delete filter INPUT position=3 family=ipv6
salt '*' iptables.delete filter INPUT \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' \
    family=ipv6
```

`salt.modules.iptables.delete_chain` (*table='filter', chain=None, family='ipv4'*)

New in version 2014.1.0.

Delete custom chain to the specified table.

CLI Example:

```
salt '*' iptables.delete_chain filter CUSTOM_CHAIN

IPv6:
salt '*' iptables.delete_chain filter CUSTOM_CHAIN family=ipv6
```

`salt.modules.iptables.flush` (*table='filter', chain='', family='ipv4'*)

Flush the chain in the specified table, flush all chains in the specified table if not specified chain.

CLI Example:

```
salt '*' iptables.flush filter INPUT

IPv6:
salt '*' iptables.flush filter INPUT family=ipv6
```

`salt.modules.iptables.get_policy` (*table='filter', chain=None, family='ipv4'*)

Return the current policy for the specified table/chain

CLI Example:

```
salt '*' iptables.get_policy filter INPUT
```

```
IPv6:
salt '*' iptables.get_policy filter INPUT family=ipv6
```

`salt.modules.iptables.get_rules` (*family='ipv4'*)

Return a data structure of the current, in-memory rules

CLI Example:

```
salt '*' iptables.get_rules

IPv6:
salt '*' iptables.get_rules family=ipv6
```

`salt.modules.iptables.get_saved_policy` (*table='filter', chain=None, conf\_file=None, family='ipv4'*)

Return the current policy for the specified table/chain

CLI Examples:

```
salt '*' iptables.get_saved_policy filter INPUT
salt '*' iptables.get_saved_policy filter INPUT \
    conf_file=/etc/iptables.saved

IPv6:
salt '*' iptables.get_saved_policy filter INPUT family=ipv6
salt '*' iptables.get_saved_policy filter INPUT \
    conf_file=/etc/iptables.saved family=ipv6
```

`salt.modules.iptables.get_saved_rules` (*conf\_file=None, family='ipv4'*)

Return a data structure of the rules in the conf file

CLI Example:

```
salt '*' iptables.get_saved_rules

IPv6:
salt '*' iptables.get_saved_rules family=ipv6
```

`salt.modules.iptables.insert` (*table='filter', chain=None, position=None, rule=None, family='ipv4'*)

Insert a rule into the specified table/chain, at the specified position.

**This function accepts a rule in a standard iptables command format**, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

**If the position specified is a negative number, then the insert will be performed counting from the end of the list.** For instance, a position of -1 will insert the rule as the second to last rule. To insert a rule in the last position, use the append function instead.

CLI Examples:

```
salt '*' iptables.insert filter INPUT position=3 \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt '*' iptables.insert filter INPUT position=3 \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' \
    family=ipv6
```

`salt.modules.iptables.new_chain` (*table='filter', chain=None, family='ipv4'*)

New in version 2014.1.0.

Create new custom chain to the specified table.

CLI Example:

```
salt '*' iptables.new_chain filter CUSTOM_CHAIN

IPv6:
salt '*' iptables.new_chain filter CUSTOM_CHAIN family=ipv6
```

**salt.modules.iptables.save** (*filename=None, family='ipv4'*)

Save the current in-memory rules to disk

CLI Example:

```
salt '*' iptables.save /etc/sysconfig/iptables

IPv6:
salt '*' iptables.save /etc/sysconfig/iptables family=ipv6
```

**salt.modules.iptables.set\_policy** (*table='filter', chain=None, policy=None, family='ipv4'*)

Set the current policy for the specified table/chain

CLI Example:

```
salt '*' iptables.set_policy filter INPUT ACCEPT

IPv6:
salt '*' iptables.set_policy filter INPUT ACCEPT family=ipv6
```

**salt.modules.iptables.version** (*family='ipv4'*)

Return version from iptables --version

CLI Example:

```
salt '*' iptables.version

IPv6:
salt '*' iptables.version family=ipv6
```

### 30.16.108 salt.modules.jboss7

Module for managing JBoss AS 7 through the CLI interface.

New in version 2015.5.0.

**In order to run each function, jboss\_config dictionary with the following properties must be passed:**

- `cli_path`: the path to jboss-cli script, for example: ``/opt/jboss/jboss-7.0/bin/jboss-cli.sh'`
- `controller`: the ip address and port of controller, for example: `10.11.12.13:9999`
- `cli_user`: username to connect to jboss administration console if necessary
- `cli_password`: password to connect to jboss administration console if necessary

Example:

```
jboss_config:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: 'jbossadm'
  cli_password: 'jbossadm'
```

`salt.modules.jboss7.create_datasource` (*jboss\_config*, *name*, *datasource\_properties*)

Create datasource in running jboss instance

**jboss\_config** Configuration dictionary with properties specified above.

**name** Datasource name

**datasource\_properties**

A dictionary of datasource properties to be created:

- driver-name: mysql
- connection-url: `jdbc:mysql://localhost:3306/sampleDatabase`
- jndi-name: `java:jboss/datasources/sampleDS`
- user-name: sampleuser
- password: secret
- min-pool-size: 3
- use-java-context: True

CLI Example:

```
salt '*' jboss7.create_datasource '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_v
```

`salt.modules.jboss7.create_simple_binding` (*jboss\_config*, *binding\_name*, *value*)

Create a simple jndi binding in the running jboss instance

**jboss\_config** Configuration dictionary with properties specified above.

**binding\_name** Binding name to be created

**value** Binding value

CLI Example:

```
salt '*' jboss7.create_simple_binding '{"cli_path": "integration.modules.sysmod.SysModuleTest.tes
```

`salt.modules.jboss7.deploy` (*jboss\_config*, *source\_file*)

Deploy the application on the jboss instance from the local file system where minion is running.

**jboss\_config** Configuration dictionary with properties specified above.

**source\_file** Source file to deploy from

CLI Example:

```
salt '*' jboss7.deploy '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs",
```

`salt.modules.jboss7.list_deployments` (*jboss\_config*)

List all deployments on the jboss instance

**jboss\_config**

Configuration dictionary with properties specified above.

CLI Example:

```
salt '*' jboss7.list_deployments '{"cli_path": "integration.modules.sysmod.SysModuleTest.tes
```

`salt.modules.jboss7.read_datasource` (*jboss\_config*, *name*)

Read datasource properties in the running jboss instance.

**jboss\_config** Configuration dictionary with properties specified above.

**name** Datasource name

CLI Example:

```
salt '*' jboss7.read_datasource '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_val
```

**salt.modules.jboss7.read\_simple\_binding**(*jboss\_config*, *binding\_name*)

Read jndi binding in the running jboss instance

**jboss\_config** Configuration dictionary with properties specified above.

**binding\_name** Binding name to be created

CLI Example:

```
salt '*' jboss7.read_simple_binding '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs",
  "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}'
my_binding_name
```

**salt.modules.jboss7.reload**(*jboss\_config*)

Reload running jboss instance

**jboss\_config** Configuration dictionary with properties specified above.

CLI Example:

```
salt '*' jboss7.reload '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs",
```

**salt.modules.jboss7.remove\_datasource**(*jboss\_config*, *name*)

Remove an existing datasource from the running jboss instance.

**jboss\_config** Configuration dictionary with properties specified above.

**name** Datasource name

CLI Example:

```
salt '*' jboss7.remove_datasource '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_val
```

**salt.modules.jboss7.status**(*jboss\_config*, *timeout=5*)

Get status of running jboss instance.

**jboss\_config** Configuration dictionary with properties specified above.

CLI Example:

```
salt '*' jboss7.status '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs",
```

**salt.modules.jboss7.stop\_server**(*jboss\_config*)

Stop running jboss instance

**jboss\_config** Configuration dictionary with properties specified above.

CLI Example:

```
salt '*' jboss7.stop_server '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_d
```

**salt.modules.jboss7.undeploy**(*jboss\_config*, *deployment*)

Undeploy the application from jboss instance

**jboss\_config** Configuration dictionary with properties specified above.

**deployment** Deployment name to undeploy

CLI Example:

```
salt '*' jboss7.undeploy '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs"
```

`salt.modules.jboss7.update_datasource` (*jboss\_config*, *name*, *new\_properties*)

Update an existing datasource in running jboss instance. If the property doesn't exist it will be created, if it does, it will be updated with the new value

**jboss\_config** Configuration dictionary with properties specified above.

**name** Datasource name

**new\_properties**

A dictionary of datasource properties to be updated. For example:

- driver-name: mysql
- connection-url: `jdbc:mysql://localhost:3306/sampleDatabase`
- jndi-name: `java:jboss/datasources/sampleDS`
- user-name: sampleuser
- password: secret
- min-pool-size: 3
- use-java-context: True

CLI Example:

```
salt '*' jboss7.update_datasource '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_v
```

`salt.modules.jboss7.update_simple_binding` (*jboss\_config*, *binding\_name*, *value*)

Update the simple jndi binding in the running jboss instance

**jboss\_config** Configuration dictionary with properties specified above.

**binding\_name** Binding name to be updated

**value** New binding value

CLI Example:

```
salt '*' jboss7.update_simple_binding '{"cli_path": "integration.modules.sysmod.SysModuleTest.te
```

### 30.16.109 salt.modules.jboss7\_cli

Module for low-level interaction with JbossAS7 through CLI.

This module exposes two ways of interaction with the CLI, either through commands or operations.

---

**Note:** Following JBoss documentation (<https://developer.jboss.org/wiki/CommandLineInterface>): ``Operations are considered a low level but comprehensive way to manage the AS controller, i.e. if it can't be done with operations it can't be done in any other way. Commands, on the other hand, are more user-friendly in syntax, although most of them still translate into operation requests and some of them even into a few composite operation requests, i.e. commands also simplify some management operations from the user's point of view."`

---

The difference between calling a command or operation is in handling the result. Commands return a zero return code if operation is successful or return non-zero return code and print an error to standard output in plain text, in case of an error.

Operations return a json-like structure, that contain more information about the result. In case of a failure, they also return a specific return code. This module parses the output from the operations and returns it as a dictionary so that an execution of an operation can then be verified against specific errors.

**In order to run each function, `jboss_config` dictionary with the following properties must be passed:**

- `cli_path`: the path to jboss-cli script, for example: ``/opt/jboss/jboss-7.0/bin/jboss-cli.sh'`
- `controller`: the ip address and port of controller, for example: `10.11.12.13:9999`
- `cli_user`: username to connect to jboss administration console if necessary
- `cli_password`: password to connect to jboss administration console if necessary

Example:

```
jboss_config:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: 'jbossadm'
  cli_password: 'jbossadm'
```

`salt.modules.jboss7_cli.run_command(jboss_config, command, fail_on_error=True)`

Execute a command against jboss instance through the CLI interface.

**jboss\_config** Configuration dictionary with properties specified above.

**command** Command to execute against jboss instance

**fail\_on\_error (default=True)** Is true, raise `CommandExecutionException` exception if execution fails. If false, ``success'` property of the returned dictionary is set to False

CLI Example:

```
salt '*' jboss7_cli.run_command '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_val
```

`salt.modules.jboss7_cli.run_operation(jboss_config, operation, fail_on_error=True, retries=1)`

Execute an operation against jboss instance through the CLI interface.

**jboss\_config** Configuration dictionary with properties specified above.

**operation** An operation to execute against jboss instance

**fail\_on\_error (default=True)** Is true, raise `CommandExecutionException` exception if execution fails. If false, ``success'` property of the returned dictionary is set to False

**retries**: Number of retries in case of ``JBAS012144: Could not connect to remote'` error.

CLI Example:

```
salt '*' jboss7_cli.run_operation '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_v
```

### 30.16.110 salt.modules.junos

Module for interfacing to Junos devices

ALPHA QUALITY code.

`salt.modules.junos.call_rpc()`

`salt.modules.junos.commit()`

`salt.modules.junos.diff()`

`salt.modules.junos.facts_refresh()`

Reload the facts dictionary from the device. Usually only needed if the device configuration is changed by some other actor.

`salt.modules.junos.ping()`

`salt.modules.junos.rollback()`

`salt.modules.junos.set_hostname(hostname=None, commit_change=True)`

### 30.16.111 salt.modules.key

Functions to view the minion's public key information

`salt.modules.key.finger()`

Return the minion's public key fingerprint

CLI Example:

```
salt '*' key.finger
```

`salt.modules.key.finger_master()`

Return the fingerprint of the master's public key on the minion.

CLI Example:

```
salt '*' key.finger_master
```

### 30.16.112 salt.modules.keyboard

Module for managing keyboards on supported POSIX-like systems using systemd, or such as Redhat, Debian and Gentoo.

`salt.modules.keyboard.get_sys()`

Get current system keyboard setting

CLI Example:

```
salt '*' keyboard.get_sys
```

`salt.modules.keyboard.get_x()`

Get current X keyboard setting

CLI Example:

```
salt '*' keyboard.get_x
```

`salt.modules.keyboard.set_sys(layout)`

Set current system keyboard setting

CLI Example:

```
salt '*' keyboard.set_sys dvorak
```

`salt.modules.keyboard.set_x(layout)`

Set current X keyboard setting

CLI Example:

```
salt '*' keyboard.set_x dvorak
```

### 30.16.113 salt.modules.keystone

Module for handling openstack keystone calls.

#### optdepends

- keystoneclient Python adapter

**configuration** This module is not usable until the following are specified either in a pillar or in the minion's config file:

```
keystone.user: admin
keystone.password: verybadpass
keystone.tenant: admin
keystone.tenant_id: f80919baedab48ec8931f200c65a50df
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
```

OR (for token based authentication)

```
keystone.token: 'ADMIN'
keystone.endpoint: 'http://127.0.0.1:35357/v2.0'
```

If configuration for multiple openstack accounts is required, they can be set up as different configuration profiles. For example:

```
openstack1:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.tenant_id: f80919baedab48ec8931f200c65a50df
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'

openstack2:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.tenant_id: f80919baedab48ec8931f200c65a50df
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/'
```

With this configuration in place, any of the keystone functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' keystone.tenant_list profile=openstack1
```

`salt.modules.keystone.auth(profile=None, **connection_args)`

Set up keystone credentials. Only intended to be used within Keystone-enabled modules.

CLI Example:

```
salt '*' keystone.auth
```

```
salt.modules.keystone.ec2_credentials_create(user_id=None, name=None, tenant_id=None, tenant=None, profile=None, **connection_args)
```

Create EC2-compatible credentials for user per tenant

CLI Examples:

```
salt '*' keystone.ec2_credentials_create name=admin tenant=admin
salt '*' keystone.ec2_credentials_create user_id=c965f79c4f864eaaa9c3b41904e67082 tenant_id=7227
```

```
salt.modules.keystone.ec2_credentials_delete(user_id=None, name=None, access_key=None, profile=None, **connection_args)
```

Delete EC2-compatible credentials

CLI Examples:

```
salt '*' keystone.ec2_credentials_delete 860f8c2c38ca4fab989f9bc56a061a64 access_key=5f66d2f24f6
salt '*' keystone.ec2_credentials_delete name=admin access_key=5f66d2f24f604b8bb9cd28886106f442
```

```
salt.modules.keystone.ec2_credentials_get(user_id=None, name=None, access=None, profile=None, **connection_args)
```

Return ec2\_credentials for a user (keystone ec2-credentials-get)

CLI Examples:

```
salt '*' keystone.ec2_credentials_get c965f79c4f864eaaa9c3b41904e67082 access=722787eb5408491586
salt '*' keystone.ec2_credentials_get user_id=c965f79c4f864eaaa9c3b41904e67082 access=722787eb54
salt '*' keystone.ec2_credentials_get name=nova access=722787eb540849158668370dc627ec5f
```

```
salt.modules.keystone.ec2_credentials_list(user_id=None, name=None, profile=None, **connection_args)
```

Return a list of ec2\_credentials for a specific user (keystone ec2-credentials-list)

CLI Examples:

```
salt '*' keystone.ec2_credentials_list 298ce377245c4ec9b70e1c639c89e654
salt '*' keystone.ec2_credentials_list user_id=298ce377245c4ec9b70e1c639c89e654
salt '*' keystone.ec2_credentials_list name=jack
```

```
salt.modules.keystone.endpoint_create(service, publicurl=None, internalurl=None, adminurl=None, region=None, profile=None, **connection_args)
```

Create an endpoint for an Openstack service

CLI Examples:

```
salt '*' keystone.endpoint_create nova 'http://public/url'
      'http://internal/url' 'http://adminurl/url' region
```

```
salt.modules.keystone.endpoint_delete(service, profile=None, **connection_args)
```

Delete endpoints of an Openstack service

CLI Examples:

```
salt '*' keystone.endpoint_delete nova
```

```
salt.modules.keystone.endpoint_get(service, profile=None, **connection_args)
```

Return a specific endpoint (keystone endpoint-get)

CLI Example:

```
salt '*' keystone.endpoint_get nova
```

`salt.modules.keystone.endpoint_list` (*profile=None, \*\*connection\_args*)  
Return a list of available endpoints (keystone endpoints-list)

CLI Example:

```
salt '*' keystone.endpoint_list
```

`salt.modules.keystone.role_create` (*name, profile=None, \*\*connection\_args*)  
Create a named role.

CLI Example:

```
salt '*' keystone.role_create admin
```

`salt.modules.keystone.role_delete` (*role\_id=None, name=None, profile=None, \*\*connection\_args*)

Delete a role (keystone role-delete)

CLI Examples:

```
salt '*' keystone.role_delete c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.role_delete role_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.role_delete name=admin
```

`salt.modules.keystone.role_get` (*role\_id=None, name=None, profile=None, \*\*connection\_args*)  
Return a specific roles (keystone role-get)

CLI Examples:

```
salt '*' keystone.role_get c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.role_get role_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.role_get name=nova
```

`salt.modules.keystone.role_list` (*profile=None, \*\*connection\_args*)  
Return a list of available roles (keystone role-list)

CLI Example:

```
salt '*' keystone.role_list
```

`salt.modules.keystone.service_create` (*name, service\_type, description=None, profile=None, \*\*connection\_args*)

Add service to Keystone service catalog

CLI Examples:

```
salt '*' keystone.service_create nova compute 'OpenStack Compute Service'
```

`salt.modules.keystone.service_delete` (*service\_id=None, name=None, profile=None, \*\*connection\_args*)

Delete a service from Keystone service catalog

CLI Examples:

```
salt '*' keystone.service_delete c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.service_delete name=nova
```

`salt.modules.keystone.service_get` (*service\_id=None, name=None, profile=None, \*\*connection\_args*)

Return a specific services (keystone service-get)

CLI Examples:

```
salt '*' keystone.service_get c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.service_get service_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.service_get name=nova
```

`salt.modules.keystone.service_list`(*profile=None, \*\*connection\_args*)

Return a list of available services (keystone services-list)

CLI Example:

```
salt '*' keystone.service_list
```

`salt.modules.keystone.tenant_create`(*name, description=None, enabled=True, profile=None, \*\*connection\_args*)

Create a keystone tenant

CLI Examples:

```
salt '*' keystone.tenant_create nova description='nova tenant'
salt '*' keystone.tenant_create test enabled=False
```

`salt.modules.keystone.tenant_delete`(*tenant\_id=None, name=None, profile=None, \*\*connection\_args*)

Delete a tenant (keystone tenant-delete)

CLI Examples:

```
salt '*' keystone.tenant_delete c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_delete tenant_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_delete name=demo
```

`salt.modules.keystone.tenant_get`(*tenant\_id=None, name=None, profile=None, \*\*connection\_args*)

Return a specific tenants (keystone tenant-get)

CLI Examples:

```
salt '*' keystone.tenant_get c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_get tenant_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_get name=nova
```

`salt.modules.keystone.tenant_list`(*profile=None, \*\*connection\_args*)

Return a list of available tenants (keystone tenants-list)

CLI Example:

```
salt '*' keystone.tenant_list
```

`salt.modules.keystone.tenant_update`(*tenant\_id=None, name=None, description=None, enabled=None, profile=None, \*\*connection\_args*)

Update a tenant's information (keystone tenant-update) The following fields may be updated: name, email, enabled. Can only update name if targeting by ID

CLI Examples:

```
salt '*' keystone.tenant_update name=admin enabled=True
salt '*' keystone.tenant_update c965f79c4f864eaaa9c3b41904e67082 name=admin email=admin@domain.c
```

`salt.modules.keystone.token_get`(*profile=None, \*\*connection\_args*)

Return the configured tokens (keystone token-get)

CLI Example:

```
salt '*' keystone.token_get c965f79c4f864eaaa9c3b41904e67082
```

**salt.modules.keystone.user\_create**(*name, password, email, tenant\_id=None, enabled=True, profile=None, \*\*connection\_args*)

Create a user (keystone user-create)

CLI Examples:

```
salt '*' keystone.user_create name=jack password=zero email=jack@halloweentown.org tenant_id=a28
```

**salt.modules.keystone.user\_delete**(*user\_id=None, name=None, profile=None, \*\*connection\_args*)

Delete a user (keystone user-delete)

CLI Examples:

```
salt '*' keystone.user_delete c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.user_delete user_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.user_delete name=nova
```

**salt.modules.keystone.user\_get**(*user\_id=None, name=None, profile=None, \*\*connection\_args*)

Return a specific users (keystone user-get)

CLI Examples:

```
salt '*' keystone.user_get c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.user_get user_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.user_get name=nova
```

**salt.modules.keystone.user\_list**(*profile=None, \*\*connection\_args*)

Return a list of available users (keystone user-list)

CLI Example:

```
salt '*' keystone.user_list
```

**salt.modules.keystone.user\_password\_update**(*user\_id=None, name=None, password=None, profile=None, \*\*connection\_args*)

Update a user's password (keystone user-password-update)

CLI Examples:

```
salt '*' keystone.user_password_update c965f79c4f864eaaa9c3b41904e67082 password=12345
salt '*' keystone.user_password_update user_id=c965f79c4f864eaaa9c3b41904e67082 password=12345
salt '*' keystone.user_password_update name=nova password=12345
```

**salt.modules.keystone.user\_role\_add**(*user\_id=None, user=None, tenant\_id=None, tenant=None, role\_id=None, role=None, profile=None, \*\*connection\_args*)

Add role for user in tenant (keystone user-role-add)

CLI Examples:

```
salt '*' keystone.user_role_add user_id=298ce377245c4ec9b70e1c639c89e654 tenant_id=7167a092ece84
salt '*' keystone.user_role_add user=admin tenant=admin role=admin
```

**salt.modules.keystone.user\_role\_list**(*user\_id=None, tenant\_id=None, user\_name=None, tenant\_name=None, profile=None, \*\*connection\_args*)

Return a list of available user\_roles (keystone user-roles-list)

CLI Examples:

```
salt '*' keystone.user_role_list user_id=298ce377245c4ec9b70e1c639c89e654 tenant_id=7167a092ece8
salt '*' keystone.user_role_list user_name=admin tenant_name=admin
```

`salt.modules.keystone.user_role_remove`(*user\_id=None, user=None, tenant\_id=None, tenant=None, role\_id=None, role=None, profile=None, \*\*connection\_args*)

Remove role for user in tenant (keystone user-role-remove)

CLI Examples:

```
salt '*' keystone.user_role_remove user_id=298ce377245c4ec9b70e1c639c89e654 tenant_id=7167a092ece8
salt '*' keystone.user_role_remove user=admin tenant=admin role=admin
```

`salt.modules.keystone.user_update`(*user\_id=None, name=None, email=None, enabled=None, tenant=None, profile=None, \*\*connection\_args*)

Update a user's information (keystone user-update) The following fields may be updated: name, email, enabled, tenant. Because the name is one of the fields, a valid user id is required.

CLI Examples:

```
salt '*' keystone.user_update user_id=c965f79c4f864eaaa9c3b41904e67082 name=newname
salt '*' keystone.user_update c965f79c4f864eaaa9c3b41904e67082 name=newname email=newemail@domain.com
```

`salt.modules.keystone.user_verify_password`(*user\_id=None, name=None, password=None, profile=None, \*\*connection\_args*)

Verify a user's password

CLI Examples:

```
salt '*' keystone.user_verify_password name=test password=foobar
salt '*' keystone.user_verify_password user_id=c965f79c4f864eaaa9c3b41904e67082 password=foobar
```

### 30.16.114 salt.modules.kmod

Module to manage Linux kernel modules

`salt.modules.kmod.available`()

Return a list of all available kernel modules

CLI Example:

```
salt '*' kmod.available
```

`salt.modules.kmod.check_available`(*mod*)

Check to see if the specified kernel module is available

CLI Example:

```
salt '*' kmod.check_available kvm
```

`salt.modules.kmod.is_loaded`(*mod*)

Check to see if the specified kernel module is loaded

CLI Example:

```
salt '*' kmod.is_loaded kvm
```

`salt.modules.kmod.load`(*mod, persist=False*)

Load the specified kernel module

**mod** Name of module to add

**persist** Write module to /etc/modules to make it load on system reboot

CLI Example:

```
salt '*' kmod.load kvm
```

`salt.modules.kmod.lsmod()`

Return a dict containing information about currently loaded modules

CLI Example:

```
salt '*' kmod.lsmod
```

`salt.modules.kmod.mod_list(only_persist=False)`

Return a list of the loaded module names

CLI Example:

```
salt '*' kmod.mod_list
```

`salt.modules.kmod.remove(mod, persist=False, comment=True)`

Remove the specified kernel module

**mod** Name of module to remove

**persist** Also remove module from /etc/modules

**comment** If persist is set don't remove line from /etc/modules but only comment it

CLI Example:

```
salt '*' kmod.remove kvm
```

### 30.16.115 salt.modules.launchctl

Module for the management of MacOS systems that use launchd/launchctl

---

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `'service.start' is not available`), see [here](#).

---

**depends**

- plistlib Python module

`salt.modules.launchctl.available(job_label)`

Check that the given service is available.

CLI Example:

```
salt '*' service.available com.openssh.sshd
```

`salt.modules.launchctl.get_all()`

Return all installed services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.launchctl.missing`(*job\_label*)

The inverse of `service.available` Check that the given service is not available.

CLI Example:

```
salt '*' service.missing com.openssh.sshd
```

`salt.modules.launchctl.restart`(*job\_label*, *runas=None*)

Restart the named service

CLI Example:

```
salt '*' service.restart <service label>
```

`salt.modules.launchctl.start`(*job\_label*, *runas=None*)

Start the specified service

CLI Example:

```
salt '*' service.start <service label>
salt '*' service.start org.ntp.ntpd
salt '*' service.start /System/Library/LaunchDaemons/org.ntp.ntpd.plist
```

`salt.modules.launchctl.status`(*job\_label*, *runas=None*)

Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service label>
```

`salt.modules.launchctl.stop`(*job\_label*, *runas=None*)

Stop the specified service

CLI Example:

```
salt '*' service.stop <service label>
salt '*' service.stop org.ntp.ntpd
salt '*' service.stop /System/Library/LaunchDaemons/org.ntp.ntpd.plist
```

### 30.16.116 `salt.modules.layman`

Support for Layman

`salt.modules.layman.add`(*overlay*)

Add the given overlay from the cached remote list to your locally installed overlays. Specify `ALL` to add all overlays from the remote list.

Return a list of the new overlay(s) added:

CLI Example:

```
salt '*' layman.add <overlay name>
```

`salt.modules.layman.delete`(*overlay*)

Remove the given overlay from the your locally installed overlays. Specify `ALL` to remove all overlays.

Return a list of the overlays(s) that were removed:

CLI Example:

```
salt '*' layman.delete <overlay name>
```

`salt.modules.layman.list_local()`

List the locally installed overlays.

Return a list of installed overlays:

CLI Example:

```
salt '*' layman.list_local
```

`salt.modules.layman.sync(overlay='ALL')`

Update the specified overlay. Use 'ALL' to synchronize all overlays. This is the default if no overlay is specified.

**overlay** Name of the overlay to sync. (Defaults to 'ALL')

CLI Example:

```
salt '*' layman.sync
```

### 30.16.117 salt.modules.ldapmod

Salt interface to LDAP commands

**depends**

- ldap Python module

**configuration** In order to connect to LDAP, certain configuration is required in the minion config on the LDAP server. The minimum configuration items that must be set are:

```
ldap.basedn: dc=acme,dc=com (example values, adjust to suit)
```

If your LDAP server requires authentication then you must also set:

```
ldap.anonymous: False
ldap.binddn: admin
ldap.bindpw: password
```

In addition, the following optional values may be set:

```
ldap.server: localhost (default=localhost, see warning below)
ldap.port: 389 (default=389, standard port)
ldap.tls: False (default=False, no TLS)
ldap.no_verify: False (default=False, verify TLS)
ldap.anonymous: True (default=True, bind anonymous)
ldap.scope: 2 (default=2, ldap.SCOPE_SUBTREE)
ldap.attrs: [saltAttr] (default=None, return all attributes)
```

**Warning:** At the moment this module only recommends connection to LDAP services listening on `localhost`. This is deliberate to avoid the potentially dangerous situation of multiple minions sending identical update commands to the same LDAP server. It's easy enough to override this behavior, but badness may ensue - you have been warned.

`salt.modules.ldapmod.search(filter, dn=None, scope=None, attrs=None, **kwargs)`

Run an arbitrary LDAP query and return the results.

CLI Example:

```
salt 'ldaphost' ldap.search "filter=cn=myhost"
```

Return data:

```
{'myhost': {'count': 1,
            'results': [['cn=myhost,ou=hosts,o=acme,c=gb',
                        {'saltKeyValue': ['ntpserver=ntp.acme.local',
                                          'foo=myfoo'],
                         'saltState': ['foo', 'bar']}]],
            'time': {'human': '1.2ms', 'raw': '0.00123'}}}
```

Search and connection options can be overridden by specifying the relevant option as key=value pairs, for example:

```
salt 'ldaphost' ldap.search filter=cn=myhost dn=ou=hosts,o=acme,c=gb
scope=1 attrs=' server=localhost port=7393 tls=True bindpw=ssh'
```

### 30.16.118 salt.modules.linux\_acl

Support for Linux File Access Control Lists

**salt.modules.linux\_acl.delfacl**(*acl\_type*, *acl\_name*, \*args, \*\*kwargs)

Remove specific ACL from the specified file(s)

CLI Examples:

```
salt '*' acl.delfacl user myuser /tmp/house/kitchen
salt '*' acl.delfacl default:group mygroup /tmp/house/kitchen
salt '*' acl.delfacl d:u myuser /tmp/house/kitchen
salt '*' acl.delfacl g myuser /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.delfacl user myuser /tmp/house/kitchen recursive=True
```

**salt.modules.linux\_acl.getfacl**(\*args, \*\*kwargs)

Return (extremely verbose) map of ACLs on specified file(s)

CLI Examples:

```
salt '*' acl.getfacl /tmp/house/kitchen
salt '*' acl.getfacl /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.getfacl /tmp/house/kitchen /tmp/house/livingroom recursive=True
```

**salt.modules.linux\_acl.modfacl**(*acl\_type*, *acl\_name*, *perms*, \*args, \*\*kwargs)

Add or modify a ACL for the specified file(s)

CLI Examples:

```
salt '*' acl.modfacl user myuser rwx /tmp/house/kitchen
salt '*' acl.modfacl default:group mygroup rx /tmp/house/kitchen
salt '*' acl.modfacl d:u myuser 7 /tmp/house/kitchen
salt '*' acl.modfacl g mygroup 0 /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.modfacl user myuser rwx /tmp/house/kitchen recursive=True
```

**salt.modules.linux\_acl.version**()

Return facl version from getfacl --version

CLI Example:

```
salt '*' acl.version
```

`salt.modules.linux_acl.wipefacls(*args, **kwargs)`

Remove all ACLs from the specified file(s)

CLI Examples:

```
salt '*' acl.wipefacls /tmp/house/kitchen
salt '*' acl.wipefacls /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.wipefacls /tmp/house/kitchen /tmp/house/livingroom recursive=True
```

### 30.16.119 salt.modules.linux\_lvm

Support for Linux LVM2

`salt.modules.linux_lvm.fullversion()`

Return all version info from lvm version

CLI Example:

```
salt '*' lvm.fullversion
```

`salt.modules.linux_lvm.lvcreate(lvname, vgname, size=None, extents=None, snapshot=None, pv=None, **kwargs)`

Create a new logical volume, with option for which physical volume to be used

CLI Examples:

```
salt '*' lvm.lvcreate new_volume_name vg_name size=10G
salt '*' lvm.lvcreate new_volume_name vg_name extents=100 pv=/dev/sdb
salt '*' lvm.lvcreate new_snapshot vg_name snapshot=volume_name size=3G
```

`salt.modules.linux_lvm.lvdisplay(lvname='')`

Return information about the logical volume(s)

CLI Examples:

```
salt '*' lvm.lvdisplay
salt '*' lvm.lvdisplay /dev/vg_myserver/root
```

`salt.modules.linux_lvm.lvremove(lvname, vgname)`

Remove a given existing logical volume from a named existing volume group

CLI Example:

```
salt '*' lvm.lvremove lvname vgname force=True
```

`salt.modules.linux_lvm.lvresize(size, lvm_path)`

Return information about the logical volume(s)

CLI Examples:

```
salt '*' lvm.lvresize +12M /dev/mapper/vg1-test
```

`salt.modules.linux_lvm.pvcreate(devices, **kwargs)`

Set a physical device to be used as an LVM physical volume

CLI Examples:

```
salt mymachine lvm.pvcreate /dev/sdb1,/dev/sdb2
salt mymachine lvm.pvcreate /dev/sdb1 dataalignmentoffset=7s
```

`salt.modules.linux_lvm.pvdisplay` (*pvname*=')

Return information about the physical volume(s)

CLI Examples:

```
salt '*' lvm.pvdisplay
salt '*' lvm.pvdisplay /dev/md0
```

`salt.modules.linux_lvm.pvremove` (*devices*)

Remove a physical device being used as an LVM physical volume

CLI Examples:

```
salt mymachine lvm.pvremove /dev/sdb1,/dev/sdb2
```

`salt.modules.linux_lvm.version` ()

Return LVM version from lvm version

CLI Example:

```
salt '*' lvm.version
```

`salt.modules.linux_lvm.vgcreate` (*vgname*, *devices*, *\*\*kwargs*)

Create an LVM volume group

CLI Examples:

```
salt mymachine lvm.vgcreate my_vg /dev/sdb1,/dev/sdb2
salt mymachine lvm.vgcreate my_vg /dev/sdb1 clustered=y
```

`salt.modules.linux_lvm.vgdisplay` (*vgname*=')

Return information about the volume group(s)

CLI Examples:

```
salt '*' lvm.vgdisplay
salt '*' lvm.vgdisplay nova-volumes
```

`salt.modules.linux_lvm.vgextend` (*vgname*, *devices*)

Add physical volumes to an LVM volume group

CLI Examples:

```
salt mymachine lvm.vgextend my_vg /dev/sdb1,/dev/sdb2
salt mymachine lvm.vgextend my_vg /dev/sdb1
```

`salt.modules.linux_lvm.vgremove` (*vgname*)

Remove an LVM volume group

CLI Examples:

```
salt mymachine lvm.vgremove vgname
salt mymachine lvm.vgremove vgname force=True
```

### 30.16.120 salt.modules.linux\_sysctl

Module for viewing and modifying sysctl parameters

`salt.modules.linux_sysctl.assign` (*name*, *value*)

Assign a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.assign net.ipv4.ip_forward 1
```

`salt.modules.linux_sysctl.default_config()`

Linux hosts using systemd 207 or later ignore `/etc/sysctl.conf` and only load from `/etc/sysctl.d/*.conf`. This function will do the proper checks and return a default config file which will be valid for the Minion. Hosts running systemd  $\geq$  207 will use `/etc/sysctl.d/99-salt.conf`.

CLI Example:

```
salt -G 'kernel:Linux' sysctl.default_config
```

`salt.modules.linux_sysctl.get(name)`

Return a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.get net.ipv4.ip_forward
```

`salt.modules.linux_sysctl.persist(name, value, config=None)`

Assign and persist a simple sysctl parameter for this minion. If `config` is not specified, a sensible default will be chosen using `sysctl.default_config`.

CLI Example:

```
salt '*' sysctl.persist net.ipv4.ip_forward 1
```

`salt.modules.linux_sysctl.show(config_file=False)`

Return a list of sysctl parameters for this minion

**config:** Pull the data from the system configuration file instead of the live data.

CLI Example:

```
salt '*' sysctl.show
```

### 30.16.121 salt.modules.localemod

Module for managing locales on POSIX-like systems.

`salt.modules.localemod.avail(locale)`

Check if a locale is available.

New in version 2014.7.0.

CLI Example:

```
salt '*' locale.avail 'en_US.UTF-8'
```

`salt.modules.localemod.gen_locale(locale, **kwargs)`

Generate a locale. Options:

**verbose** Show extra warnings about errors that are normally ignored.

New in version 2014.7.0.

**Parameters locale** -- Any locale listed in `/usr/share/i18n/locales` or `/usr/share/i18n/SUPPORTED` for debian and gentoo based distros

CLI Example:

```
salt '*' locale.gen_locale en_US.UTF-8
salt '*' locale.gen_locale 'en_IE@euro ISO-8859-15'
```

**salt.modules.localemod.get\_locale()**

Get the current system locale

CLI Example:

```
salt '*' locale.get_locale
```

**salt.modules.localemod.list\_avail()**

Lists available (compiled) locales

CLI Example:

```
salt '*' locale.list_avail
```

**salt.modules.localemod.set\_locale(locale)**

Sets the current system locale

CLI Example:

```
salt '*' locale.set_locale 'en_US.UTF-8'
```

### 30.16.122 salt.modules.locate

Module for using the locate utilities

**salt.modules.locate.locate**(*pattern, database=''*, *limit=0*, *\*\*kwargs*)

Performs a file lookup. Valid options (and their defaults) are:

```
basename=False
count=False
existing=False
follow=True
ignore=False
nofollow=False
wholename=True
regex=False
database=<locate's default database>
limit=<integer, not set by default>
```

See the manpage for `locate(1)` for further explanation of these options.

CLI Example:

```
salt '*' locate.locate
```

**salt.modules.locate.stats()**

Returns statistics about the locate database

CLI Example:

```
salt '*' locate.stats
```

**salt.modules.locate.updatedb()**

Updates the locate database

CLI Example:

```
salt '*' locate.updatedb
```

**salt.modules.locate.version()**

Returns the version of locate

CLI Example:

```
salt '*' locate.version
```

### 30.16.123 salt.modules.logadm

Module for managing Solaris logadm based log rotations.

**salt.modules.logadm.remove**(*name*, *conf\_file*='/etc/logadm.conf')

Remove log pattern from logadm

CLI Example:

```
salt '*' logadm.remove myapplog
```

**salt.modules.logadm.rotate**(*name*, *pattern*=False, *count*=False, *age*=False, *size*=False, *copy*=True, *conf\_file*='/etc/logadm.conf')

Set up pattern for logging.

CLI Example:

```
salt '*' logadm.rotate myapplog pattern='/var/log/myapp/*.log' count=7
```

**salt.modules.logadm.show\_conf**(*conf\_file*='/etc/logadm.conf')

Show parsed configuration

CLI Example:

```
salt '*' logadm.show_conf
```

### 30.16.124 salt.modules.logrotate

Module for managing logrotate.

**salt.modules.logrotate.set\_**(*key*, *value*, *setting*=None, *conf\_file*='/etc/logrotate.conf')

Set a new value for a specific configuration line

CLI Example:

```
salt '*' logrotate.set rotate 2
```

Can also be used to set a single value inside a multiline configuration block. For instance, to change rotate in the following block:

```
/var/log/wtmp {
    monthly
    create 0664 root root
    rotate 1
}
```

Use the following command:

```
salt '*' logrotate.set /var/log/wtmp rotate 2
```

This module also has the ability to scan files inside an include directory, and make changes in the appropriate file.

```
salt.modules.logrotate.show_conf(conf_file='/etc/logrotate.conf')
Show parsed configuration
```

CLI Example:

```
salt '*' logrotate.show_conf
```

### 30.16.125 salt.modules.lvs

Support for LVS (Linux Virtual Server)

```
salt.modules.lvs.add_server(protocol=None, service_address=None, server_address=None,
                           packet_forward_method='dr', weight=1, **kwargs)
Add a real server to a virtual service.
```

**protocol** The service protocol(only support tcp, udp and fwmark service).

**service\_address** The LVS service address.

**server\_address** The real server address.

**packet\_forward\_method** The LVS packet forwarding method(dr for direct routing, tunnel for tunneling, nat for network access translation).

**weight** The capacity of a server relative to the others in the pool.

CLI Example:

```
salt '*' lvs.add_server tcp 1.1.1.1:80 192.168.0.11:8080 nat 1
```

```
salt.modules.lvs.add_service(protocol=None, service_address=None, scheduler='wlc')
Add a virtual service.
```

**protocol** The service protocol(only support tcp, udp and fwmark service).

**service\_address** The LVS service address.

**scheduler** Algorithm for allocating TCP connections and UDP datagrams to real servers.

CLI Example:

```
salt '*' lvs.add_service tcp 1.1.1.1:80 rr
```

```
salt.modules.lvs.check_server(protocol=None, service_address=None, server_address=None,
                              **kwargs)
Check the real server exists in the specified service.
```

CLI Example:

```
salt '*' lvs.check_server tcp 1.1.1.1:80 192.168.0.11:8080
```

```
salt.modules.lvs.check_service(protocol=None, service_address=None, **kwargs)
Check the virtual service exists.
```

CLI Example:

```
salt '*' lvs.check_service tcp 1.1.1.1:80
```

`salt.modules.lvs.clear()`  
Clear the virtual server table

CLI Example:

```
salt '*' lvs.clear
```

`salt.modules.lvs.delete_server(protocol=None, service_address=None, server_address=None)`  
Delete the realserver from the virtual service.

**protocol** The service protocol(only support tcp, udp and fwmark service).

**service\_address** The LVS service address.

**server\_address** The real server address.

CLI Example:

```
salt '*' lvs.delete_server tcp 1.1.1.1:80 192.168.0.11:8080
```

`salt.modules.lvs.delete_service(protocol=None, service_address=None)`  
Delete the virtual service.

**protocol** The service protocol(only support tcp, udp and fwmark service).

**service\_address** The LVS service address.

CLI Example:

```
salt '*' lvs.delete_service tcp 1.1.1.1:80
```

`salt.modules.lvs.edit_server(protocol=None, service_address=None, server_address=None, packet_forward_method=None, weight=None, **kwargs)`  
Edit a real server to a virtual service.

**protocol** The service protocol(only support tcp, udp and fwmark service).

**service\_address** The LVS service address.

**server\_address** The real server address.

**packet\_forward\_method** The LVS packet forwarding method(dr for direct routing, tunnel for tunneling, nat for network access translation).

**weight** The capacity of a server relative to the others in the pool.

CLI Example:

```
salt '*' lvs.edit_server tcp 1.1.1.1:80 192.168.0.11:8080 nat 1
```

`salt.modules.lvs.edit_service(protocol=None, service_address=None, scheduler=None)`  
Edit the virtual service.

**protocol** The service protocol(only support tcp, udp and fwmark service).

**service\_address** The LVS service address.

**scheduler** Algorithm for allocating TCP connections and UDP datagrams to real servers.

CLI Example:

```
salt '*' lvs.edit_service tcp 1.1.1.1:80 rr
```

`salt.modules.lvs.get_rules()`

Get the virtual server rules

CLI Example:

```
salt '*' lvs.get_rules
```

`salt.modules.lvs.list_(protocol=None, service_address=None)`

List the virtual server table if `service_address` is not specified. If a `service_address` is selected, list this service only.

CLI Example:

```
salt '*' lvs.list
```

`salt.modules.lvs.zero(protocol=None, service_address=None)`

Zero the packet, byte and rate counters in a service or all services.

CLI Example:

```
salt '*' lvs.zero
```

### 30.16.126 salt.modules.lxc

Control Linux Containers via Salt

**depends** lxc package for distribution

lxc >= 1.0 (even beta alpha) is required

`salt.modules.lxc.apply_network_profile(name, network_profile, nic_opts=None)`

New in version 2015.5.0.

Apply a network profile to a container

**network\_profile** profile name or default values (dict)

**nic\_opts** values to override in defaults (dict) indexed by nic card names

CLI Examples:

```
salt 'minion' lxc.apply_network_profile web1 centos
salt 'minion' lxc.apply_network_profile web1 centos \
    nic_opts="{ 'eth0': { 'mac': 'xx:xx:xx:xx:xx:xx' } }"
salt 'minion' lxc.apply_network_profile web1 \
    "{ 'eth0': { 'mac': 'xx:xx:xx:xx:xx:yy' } }"
    nic_opts="{ 'eth0': { 'mac': 'xx:xx:xx:xx:xx:xx' } }"
```

The special case to disable use of ethernet nics:

```
salt 'minion' lxc.apply_network_profile web1 centos \
    "{eth0: {disable: true}}"
```

`salt.modules.lxc.attachable(name)`

Return True if the named container can be attached to via the lxc-attach command

CLI Example:

```
salt 'minion' lxc.attachable ubuntu
```

`salt.modules.lxc.bootstrap` (*name*, *config=None*, *approve\_key=True*, *install=True*, *pub\_key=None*, *priv\_key=None*, *bootstrap\_url=None*, *force\_install=False*, *unconditional\_install=False*, *bootstrap\_delay=None*, *bootstrap\_args=None*, *bootstrap\_shell=None*)

Install and configure salt in a container.

**config** Minion configuration options. By default, the `master` option is set to the target host's master.

**approve\_key** Request a pre-approval of the generated minion key. Requires that the salt-master be configured to either auto-accept all keys or expect a signing request from the target host. Default: `True`

**pub\_key** Explicit public key to pressed the minion with (optional). This can be either a filepath or a string representing the key

**priv\_key** Explicit private key to pressed the minion with (optional). This can be either a filepath or a string representing the key

**bootstrap\_delay** Delay in seconds between end of container creation and bootstrapping. Useful when waiting for container to obtain a DHCP lease.

New in version 2015.5.0.

**bootstrap\_url** url, content or filepath to the salt bootstrap script

**bootstrap\_args** salt bootstrap script arguments

**bootstrap\_shell** shell to execute the script into

**install** Whether to attempt a full installation of salt-minion if needed.

**force\_install** Force installation even if salt-minion is detected, this is the way to run vendor bootstrap scripts even if a salt minion is already present in the container

**unconditional\_install** Run the script even if the container seems seeded

CLI Examples:

```
salt 'minion' lxc.bootstrap container_name [config=config_data] \
    [approve_key=(True|False)] [install=(True|False)]
```

`salt.modules.lxc.clone` (*name*, *orig*, *profile=None*, *network\_profile=None*, *nic\_opts=None*, *\*\*kwargs*)  
Create a new container as a clone of another container

**name** Name of the container

**orig** Name of the original container to be cloned

**profile** Profile to use in container cloning (see `lxc.get_container_profile`). Values in a profile will be overridden by the **Container Cloning Arguments** listed below.

#### Container Cloning Arguments

**snapshot** Use Copy On Write snapshots (LVM)

**size** [1G] Size of the volume to create. Only applicable if `backing=lvm`.

**backing** The type of storage to use. Set to `lvm` to use an LVM group. Defaults to filesystem within `/var/lib/lxc`.

**network\_profile** Network profile to use for container

New in version 2015.5.2.

**nic\_opts** give extra opts overriding network profile values

New in version 2015.5.2.

CLI Examples:

```
salt '*' lxc.clone myclone orig=orig_container
salt '*' lxc.clone myclone orig=orig_container snapshot=True
```

**salt.modules.lxc.cloud\_init**(*name*, *vm\_*=None, *\*\*kwargs*)

Thin wrapper to lxc.init to be used from the saltcloud lxc driver

**name** Name of the container may be None and then guessed from saltcloud mapping

**vm\_** saltcloud mapping defaults for the vm

CLI Example:

```
salt '*' lxc.cloud_init foo
```

**salt.modules.lxc.cloud\_init\_interface**(*name*, *vm\_*=None, *\*\*kwargs*)

Interface between salt.cloud.lxc driver and lxc.init *vm\_* is a mapping of vm opts in the salt.cloud format as documented for the lxc driver.

This can be used either:

- from the salt cloud driver
- because you find the argument to give easier here than using directly lxc.init

**Warning:** BE REALLY CAREFUL CHANGING DEFAULTS !!! IT'S A RETRO COMPATIBLE INTERFACE WITH THE SALT CLOUD DRIVER (ask kiorky).

**name** name of the lxc container to create

**pub\_key** public key to preseed the minion with. Can be the keycontent or a filepath

**priv\_key** private key to preseed the minion with. Can be the keycontent or a filepath

**profile** *profile* selection

**network\_profile** *network profile* selection

**nic\_opts** per interface settings compatibles with network profile (ipv4/ipv6/link/gateway/mac/netmask)

eg:

```
- {'eth0': {'mac': '00:16:3e:01:29:40',
           'gateway': None, (default)
           'link': 'br0', (default)
           'gateway': None, (default)
           'netmask': '', (default)
           'ip': '22.1.4.25'}}
```

**unconditional\_install** given to lxc.bootstrap (see relative doc)

**force\_install** given to lxc.bootstrap (see relative doc)

**config** any extra argument for the salt minion config

**dnsservers** dns servers to set inside the container

**autostart** autostart the container at boot time

**password** administrative password for the container

**Warning:** Legacy but still supported options:

**from\_container** which container we use as a template when running lxc.clone

**image** which template do we use when we are using `lxc.create`. This is the default mode unless you specify something in `from_container`

**backing** which backing store to use. Values can be: `overlayfs`, `dir`(default), `lvm`, `zfs`, `brtfs`

**fstype** When using a blockdevice level backing store, which filesystem to use on

**size** When using a blockdevice level backing store, which size for the filesystem to use on

**snapshot** Use snapshot when cloning the container source

**vgname** if using LVM: `vgname`

**lvname** if using LVM: `lvname`

**ip** ip for the primary nic

**mac** mac address for the primary nic

**netmask** netmask for the primary nic (24) = `vm_.get('netmask', '24')`

**bridge** bridge for the primary nic (`lxbr0`)

**gateway** network gateway for the container

**additional\_ips** additional ips which will be wired on the main bridge (`br0`) which is connected to internet. Be aware that you may use manual virtual mac addresses provided by you provider (online, ovh, etc). This is a list of mappings `{ip: ``, mac: ``, netmask:``}` Set gateway to `None` and an interface with a gateway to escape from another interface that `eth0`. eg:

```
- {'mac': '00:16:3e:01:29:40',
  'gateway': None, (default)
  'link': 'br0', (default)
  'netmask': '', (default)
  'ip': '22.1.4.25'}
```

**users** administrative users for the container default: `[root]` and `[root, ubuntu]` on `ubuntu`

**default\_nic** name of the first interface, you should really not override this

CLI Example:

```
salt '*' lxc.cloud_init_interface foo
```

`salt.modules.lxc.cp`(*name, source, dest, makedirs=False*)

Copy a file or directory from the host into a container.

**name** Container name

**source** File to be copied to the container

**dest** Destination on the container. Must be an absolute path.

Changed in version 2015.5.0: If the destination is a directory, the file will be copied into that directory.

**makedirs** : `False`

Create the parent directory on the container if it does not already exist.

New in version 2015.5.0.

CLI Example:

```
salt 'minion' lxc.cp /tmp/foo /root/foo
```

`salt.modules.lxc.create`(*name*, *config=None*, *profile=None*, *network\_profile=None*, *nic\_opts=None*, *\*\*kwargs*)

Create a new container.

**name** Name of the container

**config** The config file to use for the container. Defaults to system-wide config (usually in `/etc/lxc/lxc.conf`).

**profile** Profile to use in container creation (see `lxc.get_container_profile`). Values in a profile will be overridden by the **Container Creation Arguments** listed below.

**network\_profile** Network profile to use for container

New in version 2015.5.0.

#### Container Creation Arguments

**template** The template to use. For example, `ubuntu` or `fedora`. Conflicts with the `image` argument.

**Note:** The `download` template requires the following three parameters to be defined in `options`:

- **dist** - The name of the distribution
- **release** - Release name/version
- **arch** - Architecture of the container

The available images can be listed using the `lxc.images` function.

**options** Template-specific options to pass to the `lxc-create` command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:

```
options='{"dist": "centos", "release": "6", "arch": "amd64"}'
```

**image** A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.

**backing** The type of storage to use. Set to `lvm` to use an LVM group. Defaults to filesystem within `/var/lib/lxc`.

**fstype** Filesystem type to use on LVM logical volume

**size** [1G] Size of the volume to create. Only applicable if `backing=lvm`.

**vgname** [lxc] Name of the LVM volume group in which to create the volume for this container. Only applicable if `backing=lvm`.

**lvname** Name of the LVM logical volume in which to create the volume for this container. Only applicable if `backing=lvm`.

**nic\_opts** give extra opts overriding network profile values

`salt.modules.lxc.destroy`(*name*, *stop=False*)

Destroy the named container.

**Warning:** Destroys all data associated with the container.

**stop** [False] If `True`, the container will be destroyed even if it is running/frozen.

Changed in version 2015.5.0: Default value changed to `False`. This more closely matches the behavior of `lxc-destroy(1)`, and also makes it less likely that an accidental command will destroy a running container that was being used for important things.

CLI Examples:

```
salt '*' lxc.destroy foo
salt '*' lxc.destroy foo stop=True
```

```
salt.modules.lxc.edit_conf(conf_file, out_format='simple', read_only=False, lxc_config=None,
                          **kwargs)
```

Edit an LXC configuration file. If a setting is already present inside the file, its value will be replaced. If it does not exist, it will be appended to the end of the file. Comments and blank lines will be kept in-tact if they already exist in the file.

**out\_format:** Set to simple if you need backward compatability (multiple items for a simple key is not supported)

**read\_only:** return only the edited configuration without applying it to the underlying lxc configuration file

**lxc\_config:** List of dict containning lxc configuration items For network configuration, you also need to add the device it belongs to, otherwise it will default to eth0. Also, any change to a network parameter will result in the whole network reconfiguration to avoid mismatches, be aware of that !

After the file is edited, its contents will be returned. By default, it will be returned in `simple` format, meaning an unordered dict (which may not represent the actual file order). Passing in an `out_format` of `commented` will return a data structure which accurately represents the order and content of the file.

CLI Example:

```
salt 'minion' lxc.edit_conf /etc/lxc/mycontainer.conf \
  out_format=commented lxc.network.type=veth
salt 'minion' lxc.edit_conf /etc/lxc/mycontainer.conf \
  out_format=commented \
  lxc_config="[{'lxc.network.name': 'eth0', \
               'lxc.network.ipv4': '1.2.3.4'}, \
              {'lxc.network.name': 'eth2', \
               'lxc.network.ipv4': '1.2.3.5'}, \
              {'lxc.network.gateway': '1.2.3.1'}]"
```

```
salt.modules.lxc.exists(name)
```

Returns whether the named container exists.

CLI Example:

```
salt '*' lxc.exists name
```

```
salt.modules.lxc.freeze(name, **kwargs)
```

Freeze the named container

**start** [False] If True and the container is stopped, the container will be started before attempting to freeze.

New in version 2015.5.0.

CLI Example:

```
salt '*' lxc.freeze name
```

```
salt.modules.lxc.get_container_profile(name=None, **kwargs)
```

New in version 2015.5.0.

Gather a pre-configured set of container configuration parameters. If no arguments are passed, an empty profile is returned.

Profiles can be defined in the minion or master config files, or in pillar or grains, and are loaded using `config.get`. The key under which LXC profiles must be configured is `lxc.container_profile.profile_name`. An example container profile would be as follows:

```
lxc.container_profile:
  ubuntu:
    template: ubuntu
    backing: lvm
```

```
vname: lxc
size: 1G
```

Parameters set in a profile can be overridden by passing additional container creation arguments (such as the ones passed to `lxc.create`) to this function.

A profile can be defined either as the name of the profile, or a dictionary of variable names and values. See the [LXC Tutorial](#) for more information on how to use LXC profiles.

CLI Example:

```
.. code-block:: bash
```

```
salt-call lxc.get_container_profile centos salt-call lxc.get_container_profile ubuntu template=ubuntu backing=overlayfs
```

`salt.modules.lxc.get_network_profile` (*name=None, \*\*kwargs*)

New in version 2015.5.0.

Gather a pre-configured set of network configuration parameters. If no arguments are passed, the following default profile is returned:

```
{'eth0': {'link': 'br0', 'type': 'veth', 'flags': 'up'}}
```

Profiles can be defined in the minion or master config files, or in pillar or grains, and are loaded using `config.get`. The key under which LXC profiles must be configured is `lxc.network_profile`. An example network profile would be as follows:

```
lxc.network_profile.centos:
  eth0:
    link: br0
    type: veth
    flags: up
```

To disable networking entirely:

```
lxc.network_profile.centos:
  eth0:
    disable: true
```

Parameters set in a profile can be overridden by passing additional arguments to this function.

A profile can be passed either as the name of the profile, or a dictionary of variable names and values. See the [LXC Tutorial](#) for more information on how to use network profiles.

**Warning:** The `ipv4`, `ipv6`, `gateway`, and `link` (bridge) settings in network profiles will only work if the container doesn't redefine the network configuration (for example in `/etc/sysconfig/network-scripts/ifcfg-<interface_name>` on RHEL/CentOS, or `/etc/network/interfaces` on Debian/Ubuntu/etc.)

CLI Example:

```
.. code-block:: bash
```

```
salt-call lxc.get_network_profile default
```

`salt.modules.lxc.get_parameter` (*name, parameter*)

Returns the value of a cgroup parameter for a container

CLI Example:

```
salt '*' lxc.get_parameter container_name memory.limit_in_bytes
```

`salt.modules.lxc.images` (*dist=None*)

New in version 2015.5.0.

List the available images for LXC's download template.

**dist** [None] Filter results to a single Linux distribution

CLI Examples:

```
salt myminion lxc.images
salt myminion lxc.images dist=centos
```

`salt.modules.lxc.info` (*name*)

Returns information about a container

CLI Example:

```
salt '*' lxc.info name
```

`salt.modules.lxc.init` (*name, config=None, cpuset=None, cpushare=None, memory=None, profile=None, network\_profile=None, nic=<object object>, nic\_opts=None, cpu=None, autostart=True, password=None, password\_encrypted=None, users=None, dnsservers=None, searchdomains=None, bridge=None, gateway=None, pub\_key=None, priv\_key=None, force\_install=False, unconditional\_install=False, bootstrap\_delay=None, bootstrap\_args=None, bootstrap\_shell=None, bootstrap\_url=None, \*\*kwargs*)

Initialize a new container.

This is a partial idempotent function as if it is already provisioned, we will reset a bit the lxc configuration file but much of the hard work will be escaped as markers will prevent re-execution of harmful tasks.

**name** Name of the container

**image** A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.

**cpus** Select a random number of cpu cores and assign it to the cpuset, if the cpuset option is set then this option will be ignored

**cpuset** Explicitly define the cpus this container will be bound to

**cpushare** cgroups cpu shares

**autostart** autostart container on reboot

**memory** cgroups memory limit, in MB

Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass `memory=0` to set no limit.

**gateway** the ipv4 gateway to use the default does nothing more than lxcutils does

**bridge** the bridge to use the default does nothing more than lxcutils does

**network\_profile** Network profile to use for the container

New in version 2015.5.0.

**nic** Deprecated since version 2015.5.0: Use `network_profile` instead

**nic\_opts** Extra options for network interfaces, will override

```
{ "eth0": { "hwaddr": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1", "ipv6":
"2001:db8::ff00:42:8329"}}
```

or

```
{ "eth0": { "hwaddr": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1/24",
"ipv6": "2001:db8::ff00:42:8329"}}
```

**users** Users for which the password defined in the `password` param should be set. Can be passed as a comma separated list or a python list. Defaults to just the `root` user.

**password** Set the initial password for the users defined in the `users` parameter

**password\_encrypted** [False] Set to `True` to denote a password hash instead of a plaintext password

New in version 2015.5.0.

**profile** A LXC profile (defined in `config` or `pillar`). This can be either a real profile mapping or a string to retrieve it in configuration

**start** Start the newly-created container

**dnsservers** list of dns servers to set in the container, default [] (no setting)

**seed** Seed the container with the minion config. Default: `True`

**install** If salt-minion is not already installed, install it. Default: `True`

**config** Optional config parameters. By default, the `id` is set to the name of the container.

**master** salt master (default to minion's master)

**master\_port** salt master port (default to minion's master port)

**pub\_key** Explicit public key to preseed the minion with (optional). This can be either a filepath or a string representing the key

**priv\_key** Explicit private key to preseed the minion with (optional). This can be either a filepath or a string representing the key

**approve\_key** If explicit preseeding is not used; Attempt to request key approval from the master. Default: `True`

**clone** Deprecated since version 2015.5.0: Use `clone_from` instead

**clone\_from** Original from which to use a clone operation to create the container. Default: `None`

**bootstrap\_delay** Delay in seconds between end of container creation and bootstrapping. Useful when waiting for container to obtain a DHCP lease.

New in version 2015.5.0.

**bootstrap\_url** See `lxc.bootstrap`

**bootstrap\_shell** See `lxc.bootstrap`

**bootstrap\_args** See `lxc.bootstrap`

**force\_install** Force installation even if salt-minion is detected, this is the way to run vendor bootstrap scripts even if a salt minion is already present in the container

**unconditional\_install** Run the script even if the container seems seeded

CLI Example:

```
salt 'minion' lxc.init name [cpuset=cgroups_cpuset] \
    [cpushare=cgroups_cpushare] [memory=cgroups_memory] \
    [nic=nic_profile] [profile=lxc_profile] \
    [nic_opts=nic_opts] [start=(True|False)] \
    [seed=(True|False)] [install=(True|False)] \
    [config=minion_config] [approve_key=(True|False)] \
    [clone_from=original] [autostart=True] \
    [priv_key=/path_or_content] [pub_key=/path_or_content] \
    [bridge=lxcbr0] [gateway=10.0.3.1] \
    [dnsservers[dns1,dns2]] \
    [users=[foo]] [password='secret'] \
    [password_encrypted=(True|False)]
```

`salt.modules.lxc.list_` (*extra=False, limit=None*)

List containers classified by state

**extra** Also get per-container specific info. This will change the return data. Instead of returning a list of containers, a dictionary of containers and each container's output from `lxc.info`.

**limit** Return output matching a specific state (**frozen**, **running**, or **stopped**).

New in version 2015.5.0.

CLI Examples:

```
salt '*' lxc.list
salt '*' lxc.list extra=True
salt '*' lxc.list limit=running
```

`salt.modules.lxc.ls_` (*active=None, cache=True*)

Return a list of the containers available on the minion

**active** If True, return only active (i.e. running) containers

New in version 2015.5.0.

CLI Example:

```
salt '*' lxc.ls
salt '*' lxc.ls active=True
```

`salt.modules.lxc.read_conf` (*conf\_file, out\_format='simple'*)

Read in an LXC configuration file. By default returns a simple, unsorted dict, but can also return a more detailed structure including blank lines and comments.

**out\_format**: set to 'simple' if you need the old and unsupported behavior. This wont support the multiple lxc values (eg: multiple network nics)

CLI Examples:

```
salt 'minion' lxc.read_conf /etc/lxc/mycontainer.conf
salt 'minion' lxc.read_conf /etc/lxc/mycontainer.conf out_format=commented
```

`salt.modules.lxc.restart` (*name, force=False*)

New in version 2015.5.0.

Restart the named container. If the container was not running, the container will merely be started.

**name** The name of the container

**force** [False] If True, the container will be force-stopped instead of gracefully shut down

CLI Example:

```
salt myminion lxc.restart name
```

```
salt.modules.lxc.retcode(name, cmd, no_start=False, preserve_state=True, stdin=None,
                        python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False,
                        chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')
```

New in version 2015.5.0.

Run `cmd.retcode` within a container

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stderr if the command being run does not exist. If the retcode is nonzero and not what was expected, try using `lxc.run_stderr` or `lxc.run_all`.

**name** Name of the container in which to run the command

**cmd** Command to run

**no\_start** [False] If the container is not running, don't start it

**preserve\_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output\_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.

**use\_vt** [False] Use SaltStack's `utils.vt` to stream output to console `output=all`.

**keep\_env** [http\_proxy,https\_proxy,no\_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

**chroot\_fallback** if the container is not running, try to run the command using `chroot` default: `false`

CLI Example:

```
salt myminion lxc.retcode mycontainer 'ip addr show'
```

```
salt.modules.lxc.run(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True,
                    output_loglevel='debug', use_vt=False, ignore_retcode=False, chroot_fallback=False,
                    keep_env='http_proxy, https_proxy, no_proxy')
```

New in version 2015.5.0.

Run `cmd.run` within a container

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stderr if the command being run does not exist. If no output is returned using this function, try using `lxc.run_stderr` or `lxc.run_all`.

**name** Name of the container in which to run the command

**cmd** Command to run

**no\_start** [False] If the container is not running, don't start it

**preserve\_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output\_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.

**use\_vt** [False] Use SaltStack's `utils.vt` to stream output to console. Assumes `output=all`.

**chroot\_fallback** if the container is not running, try to run the command using `chroot` default: `false`

**keep\_env** [http\_proxy,https\_proxy,no\_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

CLI Example:

```
salt myminion lxc.run mycontainer 'ifconfig -a'
```

```
salt.modules.lxc.run_all(name, cmd, no_start=False, preserve_state=True, stdin=None,
                        python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcodes=False,
                        chroot_fallback=False, keep_env='http_proxy,https_proxy,no_proxy')
```

New in version 2015.5.0.

Run `cmd.run_all` within a container

**Warning:** Many shell builtins do not work, failing with `stderr` similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in `stderr` if the command being run does not exist.

**name** Name of the container in which to run the command

**cmd** Command to run

**no\_start** [False] If the container is not running, don't start it

**preserve\_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output\_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.

**use\_vt** [False] Use SaltStack's `utils.vt` to stream output to console `output=all`.

**keep\_env** [http\_proxy,https\_proxy,no\_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

**chroot\_fallback** if the container is not running, try to run the command using `chroot` default: `false`

CLI Example:

```
salt myminion lxc.run_all mycontainer 'ip addr show'
```

```
salt.modules.lxc.run_cmd(name, cmd, no_start=False, preserve_state=True, stdin=None, stdout=True,
                        stderr=False, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcodes=False,
                        chroot_fallback=False, keep_env='http_proxy,https_proxy,no_proxy')
```

Deprecated since version 2015.5.0: Use `lxc.run` instead

`salt.modules.lxc.run_stderr`(*name*, *cmd*, *no\_start=False*, *preserve\_state=True*, *stdin=None*, *python\_shell=True*, *output\_loglevel='debug'*, *use\_vt=False*, *ignore\_retcode=False*, *chroot\_fallback=False*, *keep\_env='http\_proxy, https\_proxy, no\_proxy'*)

New in version 2015.5.0.

Run `cmd.run_stderr` within a container

<b>Warning:</b> Many shell builtins do not work, failing with stderr similar to the following:
--

<code>lxc_container: No such file or directory - failed to exec 'command'</code>
--

The same error will be displayed if the command being run does not exist.
---

**name** Name of the container in which to run the command

**cmd** Command to run

**no\_start** [False] If the container is not running, don't start it

**preserve\_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output\_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.

**use\_vt** [False] Use SaltStack's `utils.vt` to stream output to console `output=all`.

**keep\_env** [http\_proxy,https\_proxy,no\_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

**chroot\_fallback** if the container is not running, try to run the command using `chroot` default: `false`

CLI Example:

<code>salt myminion lxc.run_stderr mycontainer 'ip addr show'</code>
--

`salt.modules.lxc.run_stdout`(*name*, *cmd*, *no\_start=False*, *preserve\_state=True*, *stdin=None*, *python\_shell=True*, *output\_loglevel='debug'*, *use\_vt=False*, *ignore\_retcode=False*, *chroot\_fallback=False*, *keep\_env='http\_proxy, https\_proxy, no\_proxy'*)

New in version 2015.5.0.

Run `cmd.run_stdout` within a container

<b>Warning:</b> Many shell builtins do not work, failing with stderr similar to the following:
--

<code>lxc_container: No such file or directory - failed to exec 'command'</code>
--

The same error will be displayed in stderr if the command being run does not exist. If no output is returned using this function, try using <code>lxc.run_stderr</code> or <code>lxc.run_all</code> .
---

**name** Name of the container in which to run the command

**cmd** Command to run

**no\_start** [False] If the container is not running, don't start it

**preserve\_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output\_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.

**use\_vt** [False] Use SaltStack's `utils.vt` to stream output to console `output=all`.

**keep\_env** [http\_proxy,https\_proxy,no\_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

**chroot\_fallback** if the container is not running, try to run the command using chroot default: `false`

CLI Example:

```
salt myminion lxc.run_stdout mycontainer 'ifconfig -a'
```

**salt.modules.lxc.running\_systemd**(*name*, *cache=True*)

Determine if systemd is running

CLI Example:

```
salt '*' lxc.running_systemd ubuntu
```

**salt.modules.lxc.search\_lxc\_bridge**()

Search the first bridge which is potentially available as LXC bridge

CLI Example:

```
salt '*' lxc.search_lxc_bridge
```

**salt.modules.lxc.search\_lxc\_bridges**()

Search which bridges are potentially available as LXC bridges

CLI Example:

```
salt '*' lxc.search_lxc_bridges
```

**salt.modules.lxc.set\_dns**(*name*, *dnsservers=None*, *searchdomains=None*)

Changed in version 2015.5.0: The `dnsservers` and `searchdomains` parameters can now be passed as a comma-separated list.

Update `/etc/resolv.conf`

CLI Example:

```
salt myminion lxc.set_dns ubuntu "['8.8.8.8', '4.4.4.4']"
```

**salt.modules.lxc.set\_parameter**(*name*, *parameter*, *value*)

Set the value of a cgroup parameter for a container.

CLI Example:

```
salt '*' lxc.set_parameter name parameter value
```

**salt.modules.lxc.set\_password**(*name*, *users*, *password*, *encrypted=True*)

Changed in version 2015.5.0: Function renamed from `set_pass` to `set_password`. Additionally, this function now supports (and defaults to using) a password hash instead of a plaintext password.

Set the password of one or more system users inside containers

**users** Comma-separated list (or python list) of users to change password

**password** Password to set for the specified user(s)

**encrypted** [True] If true, password must be a password hash. Set to False to set a plaintext password (not recommended).

New in version 2015.5.0.

CLI Example:

```
salt '*' lxc.set_pass container-name root '$6$uJ2uAyLU$KoI67t8As/0fXtJ0PcHKGXmUpcoYUcVR2K6x93waL
salt '*' lxc.set_pass container-name root foo encrypted=False
```

**salt.modules.lxc.start**(*name*, *\*\*kwargs*)

Start the named container

**restart** [False] Deprecated since version 2015.5.0: Use *lxc.restart*

Restart the container if it is already running

CLI Example:

```
salt myminion lxc.start name
```

**salt.modules.lxc.state**(*name*)

Returns the state of a container.

CLI Example:

```
salt '*' lxc.state name
```

**salt.modules.lxc.stop**(*name*, *kill=False*)

Stop the named container

**kill** [False] Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop containers like this irrespective of this argument.

Changed in version 2015.5.0: Default value changed to False

CLI Example:

```
salt myminion lxc.stop name
```

**salt.modules.lxc.systemd\_running\_state**(*name*)

Get the operational state of a systemd based container

CLI Example:

```
salt myminion lxc.systemd_running_state ubuntu
```

**salt.modules.lxc.templates**()

New in version 2015.5.0.

List the available LXC template scripts installed on the minion

CLI Examples:

```
salt myminion lxc.templates
```

**salt.modules.lxc.test\_bare\_started\_state**(*name*)

Test if a non systemd container is fully started For now, it consists only to test if the container is attachable

CLI Example:

```
salt myminion lxc.test_bare_started_state ubuntu
```

`salt.modules.lxc.test_sd_started_state(name)`

Test if a systemd container is fully started

CLI Example:

```
salt myminion lxc.test_sd_started_state ubuntu
```

`salt.modules.lxc.unfreeze(name)`

Unfreeze the named container.

CLI Example:

```
salt '*' lxc.unfreeze name
```

`salt.modules.lxc.update_lxc_conf(name, lxc_conf, lxc_conf_unset)`

Edit LXC configuration options

CLI Example:

```
salt myminion lxc.update_lxc_conf ubuntu \  
    lxc_conf="{['network.ipv4.ip':'10.0.3.5']}" \  
    lxc_conf_unset=["lxc.utsname"]
```

`salt.modules.lxc.version()`

Return the actual lxc client version

New in version 2015.5.2.

CLI Example:

```
salt '*' lxc.version
```

`salt.modules.lxc.wait_started(name, timeout=300)`

Check that the system has fully initied

This is actually very important for systemd based containers

see <https://github.com/saltstack/salt/issues/23847>

CLI Example:

```
salt myminion lxc.wait_started ubuntu
```

`salt.modules.lxc.write_conf(conf_file, conf)`

Write out an LXC configuration file

This is normally only used internally. The format of the data structure must match that which is returned from `lxc.read_conf()`, with `out_format` set to `commented`.

An example might look like:

```
[  
    {'lxc.utsname': '$CONTAINER_NAME'},  
    '# This is a commented line\n',  
    '\n',  
    {'lxc.mount': '$CONTAINER_FSTAB'},  
    {'lxc.rootfs': {'comment': 'This is another test',  
                  'value': 'This is another test'}},  
    '\n',  
    {'lxc.network.type': 'veth'},  
    {'lxc.network.flags': 'up'},  
    {'lxc.network.link': 'br0'},  
    {'lxc.network.mac': '$CONTAINER_MACADDR'},
```

```

    {'lxc.network.ipv4': '$CONTAINER_IPADDR'},
    {'lxc.network.name': '$CONTAINER_DEVICENAME'},
  ]

```

CLI Example:

```

salt 'minion' lxc.write_conf /etc/lxc/mycontainer.conf \
    out_format=commented

```

### 30.16.127 salt.modules.mac\_group

Manage groups on Mac OS 10.7+

**salt.modules.mac\_group.add**(name, gid=None, \*\*kwargs)  
 Add the specified group

CLI Example:

```

salt '*' group.add foo 3456

```

**salt.modules.mac\_group.chgid**(name, gid)  
 Change the gid for a named group

CLI Example:

```

salt '*' group.chgid foo 4376

```

**salt.modules.mac\_group.delete**(name)  
 Remove the named group

CLI Example:

```

salt '*' group.delete foo

```

**salt.modules.mac\_group.getent**(refresh=False)  
 Return info on all groups

CLI Example:

```

salt '*' group.getent

```

**salt.modules.mac\_group.info**(name)  
 Return information about a group

CLI Example:

```

salt '*' group.info foo

```

### 30.16.128 salt.modules.mac\_user

Manage users on Mac OS 10.7+

---

**Important:** If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to ``user.info' is not available`), see [here](#).

---

`salt.modules.mac_user.add`(*name*, *uid=None*, *gid=None*, *groups=None*, *home=None*, *shell=None*, *full-name=None*, *createhome=True*, *\*\*kwargs*)

Add a user to the minion

CLI Example:

```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

`salt.modules.mac_user.chfullname`(*name*, *fullname*)

Change the user's Full Name

CLI Example:

```
salt '*' user.chfullname foo 'Foo Bar'
```

`salt.modules.mac_user.chgid`(*name*, *gid*)

Change the default group of the user

CLI Example:

```
salt '*' user.chgid foo 4376
```

`salt.modules.mac_user.chgroups`(*name*, *groups*, *append=False*)

Change the groups to which the user belongs. Note that the user's primary group does not have to be one of the groups passed, membership in the user's primary group is automatically assumed.

**groups** Groups to which the user should belong, can be passed either as a python list or a comma-separated string

**append** Instead of removing user from groups not included in the **groups** parameter, just add user to any groups for which they are not members

CLI Example:

```
salt '*' user.chgroups foo wheel,root
```

`salt.modules.mac_user.chhome`(*name*, *home*)

Change the home directory of the user

CLI Example:

```
salt '*' user.chhome foo /Users/foo
```

`salt.modules.mac_user.chshell`(*name*, *shell*)

Change the default shell of the user

CLI Example:

```
salt '*' user.chshell foo /bin/zsh
```

`salt.modules.mac_user.chuid`(*name*, *uid*)

Change the uid for a named user

CLI Example:

```
salt '*' user.chuid foo 4376
```

`salt.modules.mac_user.delete`(*name*, *\*args*)

Remove a user from the minion

CLI Example:

```
salt '*' user.delete foo
```

`salt.modules.mac_user.getent(refresh=False)`  
Return the list of all info for all users

CLI Example:

```
salt '*' user.getent
```

`salt.modules.mac_user.info(name)`  
Return user information

CLI Example:

```
salt '*' user.info root
```

`salt.modules.mac_user.list_groups(name)`  
Return a list of groups the named user belongs to

CLI Example:

```
salt '*' user.list_groups foo
```

`salt.modules.mac_user.list_users()`  
Return a list of all users

CLI Example:

```
salt '*' user.list_users
```

`salt.modules.mac_user.rename(name, new_name)`  
Change the username for a named user

CLI Example:

```
salt '*' user.rename name new_name
```

### 30.16.129 salt.modules.macports

Support for MacPorts under Mac OSX.

This module has some caveats.

1. Updating the database of available ports is quite resource-intensive. However, `refresh=True` is the default for all operations that need an up-to-date copy of available ports. Consider `refresh=False` when you are sure no db update is needed.

2. In some cases MacPorts doesn't always realize when another copy of itself is running and will gleefully tromp all over the available ports database. This makes MacPorts behave in undefined ways until a fresh complete copy is retrieved.

Because of 1 and 2 it is possible to get the salt-minion into a state where `salt mac-machine pkg./something/` won't want to return. Use

```
salt-run jobs.active
```

on the master to check for potentially long-running calls to `port`.

Finally, ports database updates are always handled with `port selfupdate` as opposed to `port sync`. This makes sense in the MacPorts user community but may confuse experienced Linux admins as Linux package managers don't upgrade the packaging software when doing a package database update. In other words `salt mac-machine pkg.refresh_db` is more like `apt-get update; apt-get upgrade dpkg apt-get` than simply `apt-get update`.

`salt.modules.macports.available_version(*names, **kwargs)`

Return the latest version of the named package available for upgrade or installation

Options:

**refresh** Update ports with `port selfupdate`

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

`salt.modules.macports.install(name=None, refresh=False, pkgs=None, **kwargs)`

Install the passed package(s) with `port install`

**name** The name of the formula to be installed. Note that this parameter is ignored if ``pkgs`` is passed.

CLI Example:

```
salt '*' pkg.install <package name>
```

**version** Specify a version to pkg to install. Ignored if pkgs is specified.

CLI Example:

```
salt '*' pkg.install <package name>
salt '*' pkg.install git-core version='1.8.5.5'
```

**variant** Specify a variant to pkg to install. Ignored if pkgs is specified.

CLI Example:

```
salt '*' pkg.install <package name>
salt '*' pkg.install git-core version='1.8.5.5' variant='+credential_osxkeychain+doc+pre'
```

Multiple Package Installation Options:

**pkgs** A list of formulas to install. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs=['foo',"bar"]'
salt '*' pkg.install pkgs=['foo@1.2',"bar"]'
salt '*' pkg.install pkgs=['foo@1.2+ssl',"bar@2.3"]'
```

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.install 'package package package'
```

`salt.modules.macports.latest_version(*names, **kwargs)`

Return the latest version of the named package available for upgrade or installation

Options:

**refresh** Update ports with `port selfupdate`

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

`salt.modules.macports.list_pkgs` (*versions\_as\_list=False, \*\*kwargs*)  
List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

`salt.modules.macports.list_upgrades` (*refresh=True*)  
Check whether or not an upgrade is available for all packages

Options:

**refresh** Update ports with port selfupdate

CLI Example:

```
salt '*' pkg.list_upgrades
```

`salt.modules.macports.refresh_db`()  
Update ports with port selfupdate

`salt.modules.macports.remove` (*name=None, pkgs=None, \*\*kwargs*)  
Removes packages with port uninstall.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>, <package2>, <package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

`salt.modules.macports.upgrade` (*refresh=True*)  
Run a full upgrade using MacPorts `port upgrade outdated`

Options:

**refresh** Update ports with port selfupdate

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
                'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

`salt.modules.macports.upgrade_available` (*pkg*, *refresh=True*)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

`salt.modules.macports.version` (*\*names*, *\*\*kwargs*)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3>
```

### 30.16.130 salt.modules.makeconf

Support for modifying make.conf under Gentoo

`salt.modules.makeconf.append_cflags` (*value*)

Add to or create a new CFLAGS in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_cflags '-pipe'
```

`salt.modules.makeconf.append_cxxflags` (*value*)

Add to or create a new CXXFLAGS in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_cxxflags '-pipe'
```

`salt.modules.makeconf.append_emerge_default_opts` (*value*)

Add to or create a new EMERGE\_DEFAULT\_OPTS in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_emerge_default_opts '--jobs'
```

`salt.modules.makeconf.append_features` (*value*)

Add to or create a new FEATURES in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_features 'webrsync-gpg'
```

`salt.modules.makeconf.append_gentoo_mirrors` (*value*)

Add to or create a new GENTOO\_MIRRORS in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_gentoo_mirrors 'http://distfiles.gentoo.org'
```

`salt.modules.makeconf.append_makeopts` (*value*)

Add to or create a new MAKEOPTS in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_makeopts '-j3'
```

`salt.modules.makeconf.append_var` (*var*, *value*)

Add to or create a new variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_var 'LINGUAS' 'en'
```

`salt.modules.makeconf.cflags_contains` (*value*)

Verify if CFLAGS variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.cflags_contains '-pipe'
```

`salt.modules.makeconf.chost_contains` (*value*)

Verify if CHOST variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.chost_contains 'x86_64-pc-linux-gnu'
```

`salt.modules.makeconf.cxxflags_contains(value)`

Verify if CXXFLAGS variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.cxxflags_contains '-pipe'
```

`salt.modules.makeconf.emerge_default_opts_contains(value)`

Verify if EMERGE\_DEFAULT\_OPTS variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.emerge_default_opts_contains '--jobs'
```

`salt.modules.makeconf.features_contains(value)`

Verify if FEATURES variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.features_contains 'webrsync-gpg'
```

`salt.modules.makeconf.gentoo_mirrors_contains(value)`

Verify if GENTOO\_MIRRORS variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.gentoo_mirrors_contains 'http://distfiles.gentoo.org'
```

`salt.modules.makeconf.get_cflags()`

Get the value of CFLAGS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_cflags
```

`salt.modules.makeconf.get_chost()`

Get the value of CHOST variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_chost
```

`salt.modules.makeconf.get_cxxflags()`

Get the value of CXXFLAGS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_cxxflags
```

`salt.modules.makeconf.get_emerge_default_opts()`

Get the value of EMERGE\_DEFAULT\_OPTS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_emerge_default_opts
```

`salt.modules.makeconf.get_features()`

Get the value of FEATURES variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_features
```

`salt.modules.makeconf.get_gentoo_mirrors()`

Get the value of GENTOO\_MIRRORS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_gentoo_mirrors
```

`salt.modules.makeconf.get_makeopts()`

Get the value of MAKEOPTS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_makeopts
```

`salt.modules.makeconf.get_sync()`

Get the value of SYNC variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

```
salt '*' makeconf.get_sync
```

`salt.modules.makeconf.get_var(var)`

Get the value of a variable in make.conf

Return the value of the variable or None if the variable is not in make.conf

CLI Example:

```
salt '*' makeconf.get_var 'LINGUAS'
```

`salt.modules.makeconf.makeopts_contains(value)`

Verify if MAKEOPTS variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.makeopts_contains '-j3'
```

`salt.modules.makeconf.remove_var(var)`

Remove a variable from the make.conf

Return a dict containing the new value for the variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.remove_var 'LINGUAS'
```

`salt.modules.makeconf.set_cflags(value)`

Set the CFLAGS variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_cflags '-march=native -O2 -pipe'
```

`salt.modules.makeconf.set_chost(value)`

Set the CHOST variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_chost 'x86_64-pc-linux-gnu'
```

`salt.modules.makeconf.set_cxxflags(value)`

Set the CXXFLAGS variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_cxxflags '-march=native -O2 -pipe'
```

`salt.modules.makeconf.set_emerge_default_opts(value)`

Set the EMERGE\_DEFAULT\_OPTS variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_emerge_default_opts '--jobs'
```

`salt.modules.makeconf.set_gentoo_mirrors(value)`

Set the GENTOO\_MIRRORS variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_gentoo_mirrors 'http://distfiles.gentoo.org'
```

`salt.modules.makeconf.set_makeopts`(*value*)

Set the MAKEOPTS variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_makeopts '-j3'
```

`salt.modules.makeconf.set_sync`(*value*)

Set the SYNC variable

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_sync 'rsync://rsync.namerica.gentoo.org/gentoo-portage'
```

`salt.modules.makeconf.set_var`(*var*, *value*)

Set a variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_var 'LINGUAS' 'en'
```

`salt.modules.makeconf.sync_contains`(*value*)

Verify if SYNC variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.sync_contains 'rsync://rsync.namerica.gentoo.org/gentoo-portage'
```

`salt.modules.makeconf.trim_cflags`(*value*)

Remove a value from CFLAGS variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_cflags '-pipe'
```

`salt.modules.makeconf.trim_cxxflags`(*value*)

Remove a value from CXXFLAGS variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',  
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_cxxflags '-pipe'
```

`salt.modules.makeconf.trim_emerge_default_opts`(*value*)

Remove a value from EMERGE\_DEFAULT\_OPTS variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',  
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_emerge_default_opts '--jobs'
```

`salt.modules.makeconf.trim_features`(*value*)

Remove a value from FEATURES variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',  
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_features 'webrsync-gpg'
```

`salt.modules.makeconf.trim_gentoo_mirrors`(*value*)

Remove a value from GENTOO\_MIRRORS variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',  
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_gentoo_mirrors 'http://distfiles.gentoo.org'
```

`salt.modules.makeconf.trim_makeopts`(*value*)

Remove a value from MAKEOPTS variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',  
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_makeopts '-j3'
```

`salt.modules.makeconf.trim_var`(*var*, *value*)

Remove a value from a variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_var 'LINGUAS' 'en'
```

`salt.modules.makeconf.var_contains`(*var*, *value*)

Verify if variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.var_contains 'LINGUAS' 'en'
```

### 30.16.131 salt.modules.match

The match module allows for match routines to be run and determine target specs

`salt.modules.match.compound`(*tgt*, *minion\_id=None*)

Return True if the minion ID matches the given compound target

**minion\_id** Specify the minion ID to match against the target expression

New in version 2014.7.0.

CLI Example:

```
salt '*' match.compound 'L@cheese,foo and *'
```

`salt.modules.match.data`(*tgt*)

Return True if the minion matches the given data target

CLI Example:

```
salt '*' match.data 'spam:eggs'
```

`salt.modules.match.filter_by`(*lookup*, *expr\_form='compound'*, *minion\_id=None*)

Return the first match in a dictionary of target patterns

New in version 2014.7.0.

CLI Example:

```
salt '*' match.filter_by '{foo*: Foo!, bar*: Bar!}' minion_id=bar03
```

Pillar Example:

```
{% set roles = salt['match.filter_by']({
    'web*': ['app', 'caching'],
    'db*': ['db'],
}) %}
```

`salt.modules.match.glob`(*tgt*, *minion\_id=None*)

Return True if the minion ID matches the given glob target

**minion\_id** Specify the minion ID to match against the target expression

New in version 2014.7.0.

CLI Example:

```
salt '*' match.glob '*'
```

`salt.modules.match.grain`(*tgt*, *delimiter=':'*, *delim=None*)

Return True if the minion matches the given grain target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```
salt '*' match.grain 'os:Ubuntu'
salt '*' match.grain 'ipv6|2001:db8::ff00:42:8329' delimiter='|'
```

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

**delim** Specify an alternate delimiter to use when traversing a nested dict

New in version 0.16.4.

Deprecated since version 2014.7.0.

`salt.modules.match.grain_pcre`(*tgt*, *delimiter=':'*, *delim=None*)

Return True if the minion matches the given grain\_pcre target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```
salt '*' match.grain_pcre 'os:Fedo.*'
salt '*' match.grain_pcre 'ipv6|2001:.*' delimiter='|'
```

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

**delim** Specify an alternate delimiter to use when traversing a nested dict

New in version 0.16.4.

Deprecated since version 2014.7.0.

`salt.modules.match.ipcidr`(*tgt*)

Return True if the minion matches the given ipcidr target

CLI Example:

```
salt '*' match.ipcidr '192.168.44.0/24'
```

`salt.modules.match.list_`(*tgt*, *minion\_id=None*)

Return True if the minion ID matches the given list target

**minion\_id** Specify the minion ID to match against the target expression

New in version 2014.7.0.

CLI Example:

```
salt '*' match.list 'server1,server2'
```

`salt.modules.match.pcre`(*tgt*, *minion\_id=None*)

Return True if the minion ID matches the given pcre target

**minion\_id** Specify the minion ID to match against the target expression

New in version 2014.7.0.

CLI Example:

```
salt '*' match.pcre '.*'
```

`salt.modules.match.pillar`(*tgt*, *delimiter=':'*, *delim=None*)

Return True if the minion matches the given pillar target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```
salt '*' match.pillar 'cheese:foo'
salt '*' match.pillar 'clone_url|https://github.com/saltstack/salt.git' delimiter='|'
```

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

**delim** Specify an alternate delimiter to use when traversing a nested dict

New in version 0.16.4.

Deprecated since version 2014.7.0.

`salt.modules.match.pillar_pcre`(*tgt*, *delimiter=':'*, *delim=None*)

Return True if the minion matches the given pillar\_pcre target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```
salt '*' match.pillar_pcre 'cheese:(swiss|american)'
salt '*' match.pillar_pcre 'clone_url|https://github\.\com\/.*\.git' delimiter='|'
```

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

**delim** Specify an alternate delimiter to use when traversing a nested dict

New in version 0.16.4.

Deprecated since version 2014.7.0.

### 30.16.132 salt.modules.mdadm

Salt module to manage RAID arrays with mdadm

`salt.modules.mdadm.assemble`(*name*, *devices*, *test\_mode=False*, *\*\*kwargs*)

Assemble a RAID device.

CLI Examples:

```
salt '*' raid.assemble /dev/md0 ['/dev/xvdd', '/dev/xvde']
```

---

**Note:** Adding `test_mode=True` as an argument will print out the mdadm command that would have been run.

---

**name** The name of the array to assemble.

**devices** The list of devices comprising the array to assemble.

**kwargs** Optional arguments to be passed to mdadm.

**returns**

**test\_mode=True:** Prints out the full command.

**test\_mode=False (Default):** Executes command on the host(s) and prints out the mdadm output.

For more info, read the mdadm manpage.

`salt.modules.mdadm.create` (*name, level, devices, metadata='default', test\_mode=False, \*\*kwargs*)  
Create a RAID device.

Changed in version 2014.7.0.

**Warning:** Use with CAUTION, as this function can be very destructive if not used properly!

CLI Examples:

```
salt '*' raid.create /dev/md0 level=1 chunk=256 devices="['/dev/xvdd', '/dev/xvde']" test_mode=T
```

---

**Note:** Adding `test_mode=True` as an argument will print out the mdadm command that would have been run.

---

**name** The name of the array to create.

**level** The RAID level to use when creating the raid.

**devices** A list of devices used to build the array.

**metadata** Version of metadata to use when creating the array.

**kwargs** Optional arguments to be passed to mdadm.

**returns**

**test\_mode=True:** Prints out the full command.

**test\_mode=False (Default):** Executes command on remote the host(s) and Prints out the mdadm output.

---

**Note:** It takes time to create a RAID array. You can check the progress in ``resync\_status`` field of the results from the following command:

```
salt '*' raid.detail /dev/md0
```

---

For more info, read the mdadm(8) manpage

`salt.modules.mdadm.destroy(device)`

Destroy a RAID device.

WARNING This will zero the superblock of all members of the RAID array..

CLI Example:

```
salt '*' raid.destroy /dev/md0
```

`salt.modules.mdadm.detail(device='/dev/md0')`

Show detail for a specified RAID device

CLI Example:

```
salt '*' raid.detail '/dev/md0'
```

`salt.modules.mdadm.list_()`

List the RAID devices.

CLI Example:

```
salt '*' raid.list
```

`salt.modules.mdadm.save_config()`

Save RAID configuration to config file.

Same as: `mdadm --detail --scan >> /etc/mdadm/mdadm.conf`

Fixes this issue with Ubuntu REF: <http://askubuntu.com/questions/209702/why-is-my-raid-dev-md1-showing-up-as-dev-md126-is-mdadm-conf-being-ignored>

CLI Example:

```
salt '*' raid.save_config
```

`salt.modules.mdadm.stop()`

Shut down all arrays that can be shut down (i.e. are not currently in use).

CLI Example:

```
salt '*' raid.stop
```

### 30.16.133 salt.modules.memcached

Module for Management of Memcached Keys

New in version 2014.1.0.

`salt.modules.memcached.add(key, value, host='127.0.0.1', port=11211, time=0, min_compress_len=0)`

Add a key to the memcached server, but only if it does not exist. Returns False if the key already exists.

CLI Example:

```
salt '*' memcached.add <key> <value>
```

`salt.modules.memcached.decrement(key, delta=1, host='127.0.0.1', port=11211)`

Decrement the value of a key

CLI Example:

```
salt '*' memcached.decrement <key>
salt '*' memcached.decrement <key> 2
```

`salt.modules.memcached.delete`(*key*, *host*=`127.0.0.1`, *port*=11211, *time*=0)

Delete a key from memcache server

CLI Example:

```
salt '*' memcached.delete <key>
```

`salt.modules.memcached.get`(*key*, *host*=`127.0.0.1`, *port*=11211)

Retrieve value for a key

CLI Example:

```
salt '*' memcached.get <key>
```

`salt.modules.memcached.increment`(*key*, *delta*=1, *host*=`127.0.0.1`, *port*=11211)

Increment the value of a key

CLI Example:

```
salt '*' memcached.increment <key>
salt '*' memcached.increment <key> 2
```

`salt.modules.memcached.replace`(*key*, *value*, *host*=`127.0.0.1`, *port*=11211, *time*=0, *min\_compress\_len*=0)

Replace a key on the memcached server. This only succeeds if the key already exists. This is the opposite of [memcached.add](#)

CLI Example:

```
salt '*' memcached.replace <key> <value>
```

`salt.modules.memcached.set_`(*key*, *value*, *host*=`127.0.0.1`, *port*=11211, *time*=0, *min\_compress\_len*=0)

Set a key on the memcached server, overwriting the value if it exists.

CLI Example:

```
salt '*' memcached.set <key> <value>
```

`salt.modules.memcached.status`(*host*=`127.0.0.1`, *port*=11211)

Get memcached status

CLI Example:

```
salt '*' memcached.status
```

### 30.16.134 salt.modules.mine

The function cache system allows for data to be stored on the master so it can be easily read by other minions

`salt.modules.mine.delete`(*fun*)

Remove specific function contents of minion. Returns True on success.

CLI Example:

```
salt '*' mine.delete 'network.interfaces'
```

`salt.modules.mine.flush`()

Remove all mine contents of minion. Returns True on success.

CLI Example:

```
salt '*' mine.flush
```

**salt.modules.mine.get**(*tgt, fun, expr\_form='glob'*)

Get data from the mine based on the target, function and expr\_form

Targets can be matched based on any standard matching system that can be matched on the master via these keywords:

```
glob
pcre
grain
grain_pcre
compound
pillar
pillar_pcre
```

Note that all pillar matches, whether using the compound matching system or the pillar matching system, will be exact matches, with globbing disabled.

CLI Example:

```
salt '*' mine.get '*' network.interfaces
salt '*' mine.get 'os:Fedora' network.interfaces grain
salt '*' mine.get 'os:Fedora and S@192.168.5.0/24' network.ipaddrs compound
```

**salt.modules.mine.get\_docker**(*interfaces=None, cidrs=None*)

Get all mine data for `docker.get\_containers` and run an aggregation routine. The ``interfaces`` parameter allows for specifying which network interfaces to select ip addresses from. The ``cidrs`` parameter allows for specifying a list of cidrs which the ip address must match.

CLI Example:

```
salt '*' mine.get_docker
salt '*' mine.get_docker interfaces='eth0'
salt '*' mine.get_docker interfaces='["eth0", "eth1"]'
salt '*' mine.get_docker cidrs='107.170.147.0/24'
salt '*' mine.get_docker cidrs='["107.170.147.0/24", "172.17.42.0/24"]'
salt '*' mine.get_docker interfaces='["eth0", "eth1"]' cidrs='["107.170.147.0/24", "172.17.42.0/24"]'
```

**salt.modules.mine.send**(*func, \*args, \*\*kwargs*)

Send a specific function to the mine.

CLI Example:

```
salt '*' mine.send network.ip_addrs eth0
salt '*' mine.send eth0_ip_addrs mine_function=network.ip_addrs eth0
```

**salt.modules.mine.update**(*clear=False*)

Execute the configured functions and send the data back up to the master. The functions to be executed are merged from the master config, pillar and minion config under the option ``function\_cache``:

```
mine_functions:
  network.ip_addrs:
    - eth0
  disk.usage: []
```

The function cache will be populated with information from executing these functions

CLI Example:

```
salt '*' mine.update
```

### 30.16.135 salt.modules.mod\_random

New in version 2014.7.0.

Provides access to randomness generators.

`salt.modules.mod_random.get_str` (*length=20*)

New in version 2014.7.0.

Returns a random string of the specified length.

**length** [20] Any valid number of bytes.

CLI Example:

```
salt '*' random.get_str 128
```

`salt.modules.mod_random.hash` (*value, algorithm='sha512'*)

New in version 2014.7.0.

Encodes a value with the specified encoder.

**value** The value to be hashed.

**algorithm** [sha512] The algorithm to use. May be any valid algorithm supported by hashlib.

CLI Example:

```
salt '*' random.hash 'I am a string' md5
```

`salt.modules.mod_random.rand_int` (*start=1, end=10*)

Returns a random integer number between the start and end number.

**start** [1] Any valid integer number

**end** [10] Any valid integer number

CLI Example:

```
salt '*' random.rand_int 1 10
```

`salt.modules.mod_random.shadow_hash` (*crypt\_salt=None, password=None, algorithm='sha512'*)

Generates a salted hash suitable for /etc/shadow.

**crypt\_salt** [None] Salt to be used in the generation of the hash. If one is not provided, a random salt will be generated.

**password** [None] Value to be salted and hashed. If one is not provided, a random password will be generated.

**algorithm** [sha512] Hash algorithm to use.

CLI Example:

```
salt '*' random.shadow_hash 'My5alt' 'MyP@asswd' md5
```

`salt.modules.mod_random.str_encode` (*value, encoder='base64'*)

New in version 2014.7.0.

**value** The value to be encoded.

**encoder** [base64] The encoder to use on the subsequent string.

CLI Example:

```
salt '*' random.str_encode 'I am a new string' base64
```

### 30.16.136 salt.modules.modjk

Control Modjk via the Apache Tomcat ``Status'' worker (<http://tomcat.apache.org/connectors-doc/reference/status.html>)

Below is an example of the configuration needed for this module. This configuration data can be placed either in [grains](#) or [pillar](#).

If using grains, this can be accomplished [statically](#) or via a [grain module](#).

If using pillar, the yaml configuration can be placed directly into a pillar SLS file, making this both the easier and more dynamic method of configuring this module.

```
modjk:
  default:
    url: http://localhost/jkstatus
    user: modjk
    pass: secret
    realm: authentication realm for digest passwords
    timeout: 5
  otherVhost:
    url: http://otherVhost/jkstatus
    user: modjk
    pass: secret2
    realm: authentication realm2 for digest passwords
    timeout: 600
```

**salt.modules.modjk.bulk\_activate** (*workers, lbn, profile='default'*)

Activate all the given workers in the specific load balancer

CLI Examples:

```
salt '*' modjk.bulk_activate node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_activate node1,node2,node3 loadbalancer1 other-profile

salt '*' modjk.bulk_activate ["node1","node2","node3"] loadbalancer1
salt '*' modjk.bulk_activate ["node1","node2","node3"] loadbalancer1 other-profile
```

**salt.modules.modjk.bulk\_disable** (*workers, lbn, profile='default'*)

Disable all the given workers in the specific load balancer

CLI Examples:

```
salt '*' modjk.bulk_disable node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_disable node1,node2,node3 loadbalancer1 other-profile

salt '*' modjk.bulk_disable ["node1","node2","node3"] loadbalancer1
salt '*' modjk.bulk_disable ["node1","node2","node3"] loadbalancer1 other-profile
```

**salt.modules.modjk.bulk\_recover** (*workers, lbn, profile='default'*)

Recover all the given workers in the specific load balancer

CLI Examples:

```

salt '*' modjk.bulk_recover node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_recover node1,node2,node3 loadbalancer1 other-profile

salt '*' modjk.bulk_recover ["node1","node2","node3"] loadbalancer1
salt '*' modjk.bulk_recover ["node1","node2","node3"] loadbalancer1 other-profile

```

`salt.modules.modjk.bulk_stop` (*workers, lbn, profile='default'*)

Stop all the given workers in the specific load balancer

CLI Examples:

```

salt '*' modjk.bulk_stop node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_stop node1,node2,node3 loadbalancer1 other-profile

salt '*' modjk.bulk_stop ["node1","node2","node3"] loadbalancer1
salt '*' modjk.bulk_stop ["node1","node2","node3"] loadbalancer1 other-profile

```

`salt.modules.modjk.dump_config` (*profile='default'*)

Dump the original configuration that was loaded from disk

CLI Examples:

```

salt '*' modjk.dump_config
salt '*' modjk.dump_config other-profile

```

`salt.modules.modjk.get_running` (*profile='default'*)

Get the current running config (not from disk)

CLI Examples:

```

salt '*' modjk.get_running
salt '*' modjk.get_running other-profile

```

`salt.modules.modjk.lb_edit` (*lbn, settings, profile='default'*)

Edit the loadbalancer settings

Note: <http://tomcat.apache.org/connectors-doc/reference/status.html> Data Parameters for the standard Update Action

CLI Examples:

```

salt '*' modjk.lb_edit loadbalancer1 '{"v1r': 1, 'v1t': 60}"
salt '*' modjk.lb_edit loadbalancer1 '{"v1r': 1, 'v1t': 60}" other-profile

```

`salt.modules.modjk.list_configured_members` (*lbn, profile='default'*)

Return a list of member workers from the configuration files

CLI Examples:

```

salt '*' modjk.list_configured_members loadbalancer1
salt '*' modjk.list_configured_members loadbalancer1 other-profile

```

`salt.modules.modjk.recover_all` (*lbn, profile='default'*)

Set the all the workers in lbn to recover and activate them if they are not

CLI Examples:

```

salt '*' modjk.recover_all loadbalancer1
salt '*' modjk.recover_all loadbalancer1 other-profile

```

`salt.modules.modjk.reset_stats(lbn, profile='default')`

Reset all runtime statistics for the load balancer

CLI Examples:

```
salt '*' modjk.reset_stats loadbalancer1
salt '*' modjk.reset_stats loadbalancer1 other-profile
```

`salt.modules.modjk.version(profile='default')`

Return the modjk version

CLI Examples:

```
salt '*' modjk.version
salt '*' modjk.version other-profile
```

`salt.modules.modjk.worker_activate(worker, lbn, profile='default')`

Set the worker to activate state in the lbn load balancer

CLI Examples:

```
salt '*' modjk.worker_activate node1 loadbalancer1
salt '*' modjk.worker_activate node1 loadbalancer1 other-profile
```

`salt.modules.modjk.worker_disable(worker, lbn, profile='default')`

Set the worker to disable state in the lbn load balancer

CLI Examples:

```
salt '*' modjk.worker_disable node1 loadbalancer1
salt '*' modjk.worker_disable node1 loadbalancer1 other-profile
```

`salt.modules.modjk.worker_edit(worker, lbn, settings, profile='default')`

Edit the worker settings

Note: <http://tomcat.apache.org/connectors-doc/reference/status.html> Data Parameters for the standard Update Action

CLI Examples:

```
salt '*' modjk.worker_edit node1 loadbalancer1 '{"vwf': 500, 'vwd': 60}"
salt '*' modjk.worker_edit node1 loadbalancer1 '{"vwf': 500, 'vwd': 60}" other-profile
```

`salt.modules.modjk.worker_recover(worker, lbn, profile='default')`

Set the worker to recover this module will fail if it is in OK state

CLI Examples:

```
salt '*' modjk.worker_recover node1 loadbalancer1
salt '*' modjk.worker_recover node1 loadbalancer1 other-profile
```

`salt.modules.modjk.worker_status(worker, profile='default')`

Return the state of the worker

CLI Examples:

```
salt '*' modjk.worker_status node1
salt '*' modjk.worker_status node1 other-profile
```

`salt.modules.modjk.worker_stop(worker, lbn, profile='default')`

Set the worker to stopped state in the lbn load balancer

CLI Examples:

```
salt '*' modjk.worker_activate node1 loadbalancer1
salt '*' modjk.worker_activate node1 loadbalancer1 other-profile
```

`salt.modules.modjk.workers(profile='default')`

Return a list of member workers and their status

CLI Examples:

```
salt '*' modjk.workers
salt '*' modjk.workers other-profile
```

### 30.16.137 salt.modules.mongodb

Module to provide MongoDB functionality to Salt

**configuration** This module uses PyMongo, and accepts configuration details as parameters as well as configuration settings:

```
mongodb.host: 'localhost'
mongodb.port: 27017
mongodb.user: ''
mongodb.password: ''
```

This data can also be passed into pillar. Options passed into `opts` will overwrite options passed into `pillar`.

`salt.modules.mongodb.db_exists(name, user=None, password=None, host=None, port=None)`

Checks if a database exists in MongoDB

CLI Example:

```
salt '*' mongodb.db_exists <name> <user> <password> <host> <port>
```

`salt.modules.mongodb.db_list(user=None, password=None, host=None, port=None)`

List all MongoDB databases

CLI Example:

```
salt '*' mongodb.db_list <user> <password> <host> <port>
```

`salt.modules.mongodb.db_remove(name, user=None, password=None, host=None, port=None)`

Remove a MongoDB database

CLI Example:

```
salt '*' mongodb.db_remove <name> <user> <password> <host> <port>
```

`salt.modules.mongodb.find(collection, query=None, user=None, password=None, host=None, port=None, database='admin')`

`salt.modules.mongodb.insert(objects, collection, user=None, password=None, host=None, port=None, database='admin')`

Insert an object or list of objects into a collection

CLI Example:

```
salt '*' mongodb.insert '[{"foo": "FOO", "bar": "BAR"}, {"foo": "BAZ", "bar": "BAM"}]' mycollect
```

`salt.modules.mongodb.remove`(*collection, query=None, user=None, password=None, host=None, port=None, database='admin', w=1*)

Remove an object or list of objects into a collection

CLI Example:

```
salt '*' mongodb.remove mycollection '[{"foo": "FOO", "bar": "BAR"}, {"foo": "BAZ", "bar": "BAM"}]
```

`salt.modules.mongodb.user_create`(*name, passwd, user=None, password=None, host=None, port=None, database='admin'*)

Create a Mongodb user

CLI Example:

```
salt '*' mongodb.user_create <name> <user> <password> <host> <port> <database>
```

`salt.modules.mongodb.user_exists`(*name, user=None, password=None, host=None, port=None, database='admin'*)

Checks if a user exists in Mongodb

CLI Example:

```
salt '*' mongodb.user_exists <name> <user> <password> <host> <port> <database>
```

`salt.modules.mongodb.user_list`(*user=None, password=None, host=None, port=None, database='admin'*)

List users of a Mongodb database

CLI Example:

```
salt '*' mongodb.user_list <user> <password> <host> <port> <database>
```

`salt.modules.mongodb.user_remove`(*name, user=None, password=None, host=None, port=None, database='admin'*)

Remove a Mongodb user

CLI Example:

```
salt '*' mongodb.user_remove <name> <user> <password> <host> <port> <database>
```

### 30.16.138 salt.modules.monit

Monit service module. This module will create a monit type service watcher.

`salt.modules.monit.monitor`(*name*)

monitor service via monit

CLI Example:

```
salt '*' monit.monitor <service name>
```

`salt.modules.monit.restart`(*name*)

Restart service via monit

CLI Example:

```
salt '*' monit.restart <service name>
```

`salt.modules.monit.start`(*name*)

CLI Example:

```
salt '*' monit.start <service name>
```

**salt.modules.monit.status**(*svc\_name*='')  
Display a process status from monit

CLI Example:

```
salt '*' monit.status
salt '*' monit.status <service name>
```

**salt.modules.monit.stop**(*name*)  
Stops service via monit

CLI Example:

```
salt '*' monit.stop <service name>
```

**salt.modules.monit.summary**(*svc\_name*='')  
Display a summary from monit

CLI Example:

```
salt '*' monit.summary
salt '*' monit.summary <service name>
```

**salt.modules.monit.unmonitor**(*name*)  
Unmonitor service via monit

CLI Example:

```
salt '*' monit.unmonitor <service name>
```

### 30.16.139 salt.modules.moosefs

Module for gathering and managing information about MooseFS

**salt.modules.moosefs.dirinfo**(*path*, *opts*=None)  
Return information on a directory located on the Moose

CLI Example:

```
salt '*' moosefs.dirinfo /path/to/dir/ [-[n][h|H]]
```

**salt.modules.moosefs.fileinfo**(*path*)  
Return information on a file located on the Moose

CLI Example:

```
salt '*' moosefs.fileinfo /path/to/dir/
```

**salt.modules.moosefs.getgoal**(*path*, *opts*=None)  
Return goal(s) for a file or directory

CLI Example:

```
salt '*' moosefs.getgoal /path/to/file [-[n][h|H]]
salt '*' moosefs.getgoal /path/to/dir/ [-[n][h|H][r]]
```

**salt.modules.moosefs.mounts**()  
Return a list of current MooseFS mounts

CLI Example:

```
salt '*' moosefs.mounts
```

### 30.16.140 salt.modules.mount

Salt module to manage unix mounts and the fstab file

**salt.modules.mount.active** (*extended=False*)  
List the active mounts.

CLI Example:

```
salt '*' mount.active
```

**salt.modules.mount.automaster** (*config='/etc/auto\_salt'*)  
List the contents of the fstab

CLI Example:

```
salt '*' mount.fstab
```

**salt.modules.mount.fstab** (*config='/etc/fstab'*)  
List the contents of the fstab

CLI Example:

```
salt '*' mount.fstab
```

**salt.modules.mount.is\_fuse\_exec** (*cmd*)  
Returns true if the command passed is a fuse mountable application.

CLI Example:

```
salt '*' mount.is_fuse_exec sshfs
```

**salt.modules.mount.is\_mounted** (*name*)  
New in version 2014.7.0.

Provide information if the path is mounted

CLI Example:

```
salt '*' mount.is_mounted /mnt/share
```

**salt.modules.mount.mount** (*name, device, mkmnt=False, fstype='', opts='defaults', user=None*)  
Mount a device

CLI Example:

```
salt '*' mount.mount /mnt/foo /dev/sdz1 True
```

**salt.modules.mount.remount** (*name, device, mkmnt=False, fstype='', opts='defaults', user=None*)  
Attempt to remount a device, if the device is not already mounted, mount is called

CLI Example:

```
salt '*' mount.remount /mnt/foo /dev/sdz1 True
```

**salt.modules.mount.rm\_automaster** (*name, device, config='/etc/auto\_salt'*)  
Remove the mount point from the auto\_master

CLI Example:

```
salt '*' mount.rm_automaster /mnt/foo
```

`salt.modules.mount.rm_fstab`(*name*, *device*, *config*='/etc/fstab')

Remove the mount point from the fstab

CLI Example:

```
salt '*' mount.rm_fstab /mnt/foo
```

`salt.modules.mount.set_automaster`(*name*, *device*, *fstype*, *opts*='', *config*='/etc/auto\_salt',  
*test*=False, *\*\*kwargs*)

Verify that this mount is represented in the auto\_salt, change the mount to match the data passed, or add the mount if it is not present.

CLI Example:

```
salt '*' mount.set_automaster /mnt/foo /dev/sdz1 ext4
```

`salt.modules.mount.set_fstab`(*name*, *device*, *fstype*, *opts*='defaults', *dump*=0, *pass\_num*=0, *con-*  
*fig*='/etc/fstab', *test*=False, *match\_on*='auto', *\*\*kwargs*)

Verify that this mount is represented in the fstab, change the mount to match the data passed, or add the mount if it is not present.

CLI Example:

```
salt '*' mount.set_fstab /mnt/foo /dev/sdz1 ext4
```

`salt.modules.mount.swapoff`(*name*)

Deactivate a named swap mount

CLI Example:

```
salt '*' mount.swapoff /root/swapfile
```

`salt.modules.mount.swapon`(*name*, *priority*=None)

Activate a swap disk

CLI Example:

```
salt '*' mount.swapon /root/swapfile
```

`salt.modules.mount.swaps`()

Return a dict containing information on active swap

CLI Example:

```
salt '*' mount.swaps
```

`salt.modules.mount.umount`(*name*, *device*=None, *user*=None)

Attempt to unmount a device by specifying the directory it is mounted on

CLI Example:

```
salt '*' mount.umount /mnt/foo

.. versionadded:: 2015.5.0

salt '*' mount.umount /mnt/foo /dev/xvdc1
```

### 30.16.141 salt.modules.munin

Run munin plugins/checks from salt and format the output as data.

**salt.modules.munin.list\_plugins()**

List all the munin plugins

CLI Example:

```
salt '*' munin.list_plugins
```

**salt.modules.munin.run(*plugins*)**

Run one or more named munin plugins

CLI Example:

```
salt '*' munin.run uptime
salt '*' munin.run uptime,cpu,load,memory
```

**salt.modules.munin.run\_all()**

Run all the munin plugins

CLI Example:

```
salt '*' munin.run_all
```

### 30.16.142 salt.modules.mysql

Module to provide MySQL compatibility to salt.

**depends**

- MySQLdb Python module

**Note:** On CentOS 5 (and possibly RHEL 5) both MySQL-python and python26-mysqldb need to be installed.

**configuration** In order to connect to MySQL, certain configuration is required in /etc/salt/minion on the relevant minions. Some sample configs might look like:

```
mysql.host: 'localhost'
mysql.port: 3306
mysql.user: 'root'
mysql.pass: ''
mysql.db: 'mysql'
mysql.unix_socket: '/tmp/mysql.sock'
mysql.charset: 'utf8'
```

You can also use a defaults file:

```
mysql.default_file: '/etc/mysql/debian.cnf'
```

Changed in version 2014.1.0: charset connection argument added. This is a MySQL charset, not a python one

Changed in version 0.16.2: Connection arguments from the minion config file can be overridden on the CLI by using the arguments defined [here](#). Additionally, it is now possible to setup a user with no password.

**salt.modules.mysql.db\_check(*name*, *table=None*, *\*\*connection\_args*)**

Repairs the full database or just a given table

CLI Example:

```
salt '*' mysql.db_check dbname
salt '*' mysql.db_check dbname dbtable
```

**salt.modules.mysql.db\_create**(*name*, *character\_set=None*, *collate=None*, *\*\*connection\_args*)

Adds a databases to the MySQL server.

**name** The name of the database to manage

**character\_set** The character set, if left empty the MySQL default will be used

**collate** The collation, if left empty the MySQL default will be used

CLI Example:

```
salt '*' mysql.db_create 'dbname'
salt '*' mysql.db_create 'dbname' 'utf8' 'utf8_general_ci'
```

**salt.modules.mysql.db\_exists**(*name*, *\*\*connection\_args*)

Checks if a database exists on the MySQL server.

CLI Example:

```
salt '*' mysql.db_exists 'dbname'
```

**salt.modules.mysql.db\_list**(*\*\*connection\_args*)

Return a list of databases of a MySQL server using the output from the SHOW DATABASES query.

CLI Example:

```
salt '*' mysql.db_list
```

**salt.modules.mysql.db\_optimize**(*name*, *table=None*, *\*\*connection\_args*)

Optimizes the full database or just a given table

CLI Example:

```
salt '*' mysql.db_optimize dbname
```

**salt.modules.mysql.db\_remove**(*name*, *\*\*connection\_args*)

Removes a databases from the MySQL server.

CLI Example:

```
salt '*' mysql.db_remove 'dbname'
```

**salt.modules.mysql.db\_repair**(*name*, *table=None*, *\*\*connection\_args*)

Repairs the full database or just a given table

CLI Example:

```
salt '*' mysql.db_repair dbname
```

**salt.modules.mysql.db\_tables**(*name*, *\*\*connection\_args*)

Shows the tables in the given MySQL database (if exists)

CLI Example:

```
salt '*' mysql.db_tables 'database'
```

**salt.modules.mysql.free\_slave**(*\*\*connection\_args*)

Frees a slave from its master. This is a WIP, do not use.

CLI Example:

```
salt '*' mysql.free_slave
```

`salt.modules.mysql.get_master_status(**connection_args)`

Retrieves the master status from the minion.

Returns:

```
{'host.domain.com': {'Binlog_Do_DB': '', 'Binlog_Ignore_DB': '', 'File': 'mysql-bin.000021', 'Position': 107}}
```

CLI Example:

```
salt '*' mysql.get_master_status
```

`salt.modules.mysql.get_slave_status(**connection_args)`

Retrieves the slave status from the minion.

Returns:

```
{'host.domain.com': {'Connect_Retry': 60,
    'Exec_Master_Log_Pos': 107,
    'Last_Errno': 0,
    'Last_Error': '',
    'Last_IO_Errno': 0,
    'Last_IO_Error': '',
    'Last_SQL_Errno': 0,
    'Last_SQL_Error': '',
    'Master_Host': 'comet.scion-eng.com',
    'Master_Log_File': 'mysql-bin.000021',
    'Master_Port': 3306,
    'Master_SSL_Allowed': 'No',
    'Master_SSL_CA_File': '',
    'Master_SSL_CA_Path': '',
    'Master_SSL_Cert': '',
    'Master_SSL_Cipher': '',
    'Master_SSL_Key': '',
    'Master_SSL_Verify_Server_Cert': 'No',
    'Master_Server_Id': 1,
    'Master_User': 'replu',
    'Read_Master_Log_Pos': 107,
    'Relay_Log_File': 'klo-relay-bin.000071',
    'Relay_Log_Pos': 253,
    'Relay_Log_Space': 553,
    'Relay_Master_Log_File': 'mysql-bin.000021',
    'Replicate_Do_DB': '',
    'Replicate_Do_Table': '',
    'Replicate_Ignore_DB': '',
    'Replicate_Ignore_Server_Ids': '',
    'Replicate_Ignore_Table': '',
    'Replicate_Wild_Do_Table': '',
    'Replicate_Wild_Ignore_Table': '',
    'Seconds_Behind_Master': 0,
    'Skip_Counter': 0,
    'Slave_IO_Running': 'Yes',
    'Slave_IO_State': 'Waiting for master to send event',
    'Slave_SQL_Running': 'Yes',
    'Until_Condition': 'None',
    'Until_Log_File': '',
    'Until_Log_Pos': 0}}
```

CLI Example:

```
salt '*' mysql.get_slave_status
```

`salt.modules.mysql.grant_add`(*grant*, *database*, *user*, *host*='localhost', *grant\_option*=False, *escape*=True, *ssl\_option*=False, *\*\*connection\_args*)

Adds a grant to the MySQL server.

For database, make sure you specify database.table or database.\*

CLI Example:

```
salt '*' mysql.grant_add 'SELECT,INSERT,UPDATE,...' 'database.*' 'frank' 'localhost'
```

`salt.modules.mysql.grant_exists`(*grant*, *database*, *user*, *host*='localhost', *grant\_option*=False, *escape*=True, *\*\*connection\_args*)

Checks to see if a grant exists in the database

CLI Example:

```
salt '*' mysql.grant_exists 'SELECT,INSERT,UPDATE,...' 'database.*' 'frank' 'localhost'
```

`salt.modules.mysql.grant_revoke`(*grant*, *database*, *user*, *host*='localhost', *grant\_option*=False, *escape*=True, *\*\*connection\_args*)

Removes a grant from the MySQL server.

CLI Example:

```
salt '*' mysql.grant_revoke 'SELECT,INSERT,UPDATE' 'database.*' 'frank' 'localhost'
```

`salt.modules.mysql.processlist`(*\*\*connection\_args*)

Retrieves the processlist from the MySQL server via ``SHOW FULL PROCESSLIST``.

**Returns:** a list of dicts, with each dict representing a process:

```
{'Command': 'Query', 'Host': 'localhost', 'Id': 39, 'Info': 'SHOW FULL PROCESSLIST',
  'Rows_examined': 0, 'Rows_read': 1, 'Rows_sent': 0, 'State': None, 'Time': 0, 'User': 'root',
  'db': 'mysql'}
```

CLI Example:

```
salt '*' mysql.processlist
```

`salt.modules.mysql.query`(*database*, *query*, *\*\*connection\_args*)

Run an arbitrary SQL query and return the results or the number of affected rows.

CLI Example:

```
salt '*' mysql.query mydb "UPDATE mytable set myfield=1 limit 1"
```

Return data:

```
{'query time': {'human': '39.0ms', 'raw': '0.03899'}, 'rows affected': 1L}
```

CLI Example:

```
salt '*' mysql.query mydb "SELECT id,name,cash from users limit 3"
```

Return data:

```
{'columns': ('id', 'name', 'cash'),
  'query time': {'human': '1.0ms', 'raw': '0.001'},
  'results': ((1L, 'User 1', Decimal('110.000000'))),
```

```
(2L, 'User 2', Decimal('215.636756')),
(3L, 'User 3', Decimal('0.040000')),
'rows returned': 3L}
```

CLI Example:

```
salt '*' mysql.query mydb 'INSERT into users values (null,"user 4", 5)'
```

Return data:

```
{'query time': {'human': '25.6ms', 'raw': '0.02563'}, 'rows affected': 1L}
```

CLI Example:

```
salt '*' mysql.query mydb 'DELETE from users where id = 4 limit 1'
```

Return data:

```
{'query time': {'human': '39.0ms', 'raw': '0.03899'}, 'rows affected': 1L}
```

Jinja Example: Run a query on mydb and use row 0, column 0's data.

```
{{ salt['mysql.query']('mydb', 'SELECT info from mytable limit 1')['results'][0][0] }}
```

`salt.modules.mysql.quote_identifier` (*identifier*, *for\_grants=False*)

Return an identifier name (column, table, database, etc) escaped for MySQL

This means surrounded by `` character and escaping this character inside. It also means doubling the `%` character for MySQLdb internal usage.

#### Parameters

- **identifier** -- the table, column or database identifier
- **for\_grants** -- is False by default, when using database names on grant queries you should set it to True to also escape ``\_` and ``%" characters as requested by MySQL. Note that these characters should only be escaped when requesting grants on the database level (*my\_%db.\**) but not for table level grants (*my\_%db.`foo`*)

CLI Example:

```
salt '*' mysql.quote_identifier 'foo`bar`'
```

`salt.modules.mysql.showglobal` (\*\**connection\_args*)

Retrieves the show global variables from the minion.

**Returns::** show global variables full dict

CLI Example:

```
salt '*' mysql.showglobal
```

`salt.modules.mysql.showvariables` (\*\**connection\_args*)

Retrieves the show variables from the minion.

**Returns::** show variables full dict

CLI Example:

```
salt '*' mysql.showvariables
```

`salt.modules.mysql.slave_lag(**connection_args)`

Return the number of seconds that a slave SQL server is lagging behind the master, if the host is not a slave it will return -1. If the server is configured to be a slave for replication but slave IO is not running then -2 will be returned. If there was an error connecting to the database or checking the slave status, -3 will be returned.

CLI Example:

```
salt '*' mysql.slave_lag
```

`salt.modules.mysql.status(**connection_args)`

Return the status of a MySQL server using the output from the SHOW STATUS query.

CLI Example:

```
salt '*' mysql.status
```

`salt.modules.mysql.tokenize_grant(grant)`

External wrapper function :param grant: :return: dict

CLI Example:

```
salt '*' mysql.tokenize_grant "GRANT SELECT, INSERT ON testdb.* TO 'testuser'@'localhost'"
```

`salt.modules.mysql.user_chpass(user, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=None, **connection_args)`

Change password for a MySQL user

**host** Host for which this user/password combo applies

**password** The password to set for the new user. Will take precedence over the password\_hash option if both are specified.

**password\_hash** The password in hashed form. Be sure to quote the password because YAML doesn't like the \*. A password hash can be obtained from the mysql command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+
1 row in set (0.00 sec)
```

**allow\_passwordless** If True, then password and password\_hash can be omitted (or set to None) to permit a passwordless login.

New in version 0.16.2: The allow\_passwordless option was added.

CLI Examples:

```
salt '*' mysql.user_chpass frank localhost newpassword
salt '*' mysql.user_chpass frank localhost password_hash='hash'
salt '*' mysql.user_chpass frank localhost allow_passwordless=True
```

`salt.modules.mysql.user_create(user, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=False, **connection_args)`

Creates a MySQL user

**host** Host for which this user/password combo applies

**password** The password to use for the new user. Will take precedence over the password\_hash option if both are specified.

**password\_hash** The password in hashed form. Be sure to quote the password because YAML doesn't like the \*. A password hash can be obtained from the mysql command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+
1 row in set (0.00 sec)
```

**allow\_passwordless** If True, then password and password\_hash can be omitted (or set to None) to permit a passwordless login.

**unix\_socket** If True and allow\_passwordless is True then will be used unix\_socket auth plugin.

New in version 0.16.2: The allow\_passwordless option was added.

CLI Examples:

```
salt '*' mysql.user_create 'username' 'hostname' 'password'
salt '*' mysql.user_create 'username' 'hostname' password_hash='hash'
salt '*' mysql.user_create 'username' 'hostname' allow_passwordless=True
```

**salt.modules.mysql.user\_exists**(user, host='localhost', password=None, password\_hash=None, passwordless=False, unix\_socket=False, \*\*connection\_args)

Checks if a user exists on the MySQL server. A login can be checked to see if passwordless login is permitted by omitting password and password\_hash, and using passwordless=True.

New in version 0.16.2: The passwordless option was added.

CLI Example:

```
salt '*' mysql.user_exists 'username' 'hostname' 'password'
salt '*' mysql.user_exists 'username' 'hostname' password_hash='hash'
salt '*' mysql.user_exists 'username' passwordless=True
```

**salt.modules.mysql.user\_grants**(user, host='localhost', \*\*connection\_args)

Shows the grants for the given MySQL user (if it exists)

CLI Example:

```
salt '*' mysql.user_grants 'frank' 'localhost'
```

**salt.modules.mysql.user\_info**(user, host='localhost', \*\*connection\_args)

Get full info on a MySQL user

CLI Example:

```
salt '*' mysql.user_info root localhost
```

**salt.modules.mysql.user\_list**(\*\*connection\_args)

Return a list of users on a MySQL server

CLI Example:

```
salt '*' mysql.user_list
```

**salt.modules.mysql.user\_remove**(user, host='localhost', \*\*connection\_args)

Delete MySQL user

CLI Example:

```
salt '*' mysql.user_remove frank localhost
```

`salt.modules.mysql.version(**connection_args)`

Return the version of a MySQL server using the output from the `SELECT VERSION()` query.

CLI Example:

```
salt '*' mysql.version
```

### 30.16.143 salt.modules.nacl

This module helps include encrypted passwords in pillars, grains and salt state files.

**depends** `libnacl`, <https://github.com/saltstack/libnacl>

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don't advise making your pillars public regardless if they are encrypted or not.

When generating keys and encrypting passwords use `--local` when using `salt-call` for extra security. Also consider using just the salt runner `nacl` when encrypting pillar passwords.

The `nacl` lib uses 32byte keys, these keys are base64 encoded to make your life more simple. To generate your *key* or *keyfile* you can use:

```
salt-call --local nacl.keygen keyfile=/root/.nacl
```

Now with your key, you can encrypt some data:

```
salt-call --local nacl.enc mypass keyfile=/root/.nacl
DRB7Q6/X5gGSRCTpZyxS6hX05LnIJJIIJ4ivbmUlbWj0llUA+uaVvyou3vJ4=
```

To decrypt the data:

```
salt-call --local nacl.dec data='DRB7Q6/X5gGSRCTpZyxS6hX05LnIJJIIJ4ivbmUlbWj0llUA+uaVvyou3vJ4=' keyfi
mypass
```

The following optional configurations can be defined in the minion or master config. Avoid storing the config in pillars!

```
cat /etc/salt/master.d/nacl.conf
nacl.config:
  key: None
  keyfile: /root/.nacl
```

When the key is defined in the master config you can use it from the `nacl` runner:

```
salt-run nacl.enc 'myotherpass'
```

Now you can create a pillar with protected data like:

```
pillarexample:
  user: root
  password: {{ salt.nacl.dec('DRB7Q6/X5gGSRCTpZyxS6hX05LnIJJIIJ4ivbmUlbWj0llUA+uaVvyou3vJ4=') }}
```

Or do something interesting with grains like:

```
salt-call nacl.enc minionname:dbrole
AL24Z2C50lkReer3DuQTFdrNLchLuz3NGIhGjZkLtKRYry/b/CksWM809yskLwH2AGVLoEXI5jAa
```

```

salt minionname grains.setval role 'AL24Z2C50lkReer3DuQTFdrNLchLuz3NGIhGjZkLtKRYry/b/CksWM809yskLwH2/
{%-% set r = grains.get('role') %}
{%-% set role = None %}
{%-% if r and 'nacl.dec' in salt %}
  {%-% set r = salt['nacl.dec'](r,keyfile='/root/.nacl').split(':') %}
  {%-% if opts['id'] == r[0] %}
    {%-% set role = r[1] %}
  {%-% endif %}
{%-% endif %}
base:
  {%-% if role %}
    '{{ opts['id'] }}':
      - {{ role }}
  {%-% endif %}

```

**salt.modules.nacl.dec**(*data*, *\*\*kwargs*)

Takes a key generated from *nacl.keygen* and decrypt some data.

CLI Examples:

```

salt-call --local nacl.dec pEXHQM6cuaF7A=
salt-call --local nacl.dec data='pEXHQM6cuaF7A=' keyfile=/root/.nacl
salt-call --local nacl.dec data='pEXHQM6cuaF7A=' key='cKEzd4kXsbeCE7/nLTIqXwnUiD1u1g4NoeeYcCFpd9k='

```

**salt.modules.nacl.enc**(*data*, *\*\*kwargs*)

Takes a key generated from *nacl.keygen* and encrypt some data.

CLI Examples:

```

salt-call --local nacl.enc datatoenc
salt-call --local nacl.enc datatoenc keyfile=/root/.nacl
salt-call --local nacl.enc datatoenc key='cKEzd4kXsbeCE7/nLTIqXwnUiD1u1g4NoeeYcCFpd9k='

```

**salt.modules.nacl.keygen**(*keyfile=None*)

Use libnacl to generate a private key

CLI Examples:

```

salt-call --local nacl.keygen
salt-call --local nacl.keygen keyfile=/root/.nacl
salt-call --local --out=newline_values_only nacl.keygen > /root/.nacl

```

### 30.16.144 salt.modules.nagios

Run nagios plugins/checks from salt and get the return as data.

**salt.modules.nagios.list\_plugins**()

List all the nagios plugins

CLI Example:

```

salt '*' nagios.list_plugins

```

**salt.modules.nagios.retcode**(*plugin*, *args=''*, *key\_name=None*)

Run one nagios plugin and return retcode of the execution

CLI Example:

```
salt '*' nagios.run check_apt
salt '*' nagios.run check_icmp '8.8.8.8'
```

**salt.modules.nagios.retcode\_pillar** (*pillar\_name*)

Run one or more nagios plugins from pillar data and get the result of cmd.retcode The pillar have to be in this format:

```
-----
webserver:
  Ping_google:
    - check_icmp: 8.8.8.8
    - check_icmp: google.com
  Load:
    - check_load: -w 0.8 -c 1
  APT:
    - check_apt
-----
```

webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You must to group different checks(one o more) and always it will return the highest value of all the checks

CLI Example:

```
salt '*' nagios.retcode webserver
```

**salt.modules.nagios.run** (*plugin, args=''*)

Run nagios plugin and return all the data execution with cmd.run

**salt.modules.nagios.run\_all** (*plugin, args=''*)

Run nagios plugin and return all the data execution with cmd.run\_all

**salt.modules.nagios.run\_all\_pillar** (*pillar\_name*)

Run one or more nagios plugins from pillar data and get the result of cmd.run\_all The pillar have to be in this format:

```
-----
webserver:
  Ping_google:
    - check_icmp: 8.8.8.8
    - check_icmp: google.com
  Load:
    - check_load: -w 0.8 -c 1
  APT:
    - check_apt
-----
```

webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You have to group different checks in a group

CLI Example:

```
salt '*' nagios.run webserver
```

**salt.modules.nagios.run\_pillar** (*pillar\_name*)

Run one or more nagios plugins from pillar data and get the result of cmd.run The pillar have to be in this format:

```

-----
webserver:
  Ping_google:
    - check_icmp: 8.8.8.8
    - check_icmp: google.com
  Load:
    - check_load: -w 0.8 -c 1
  APT:
    - check_apt
-----

```

webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You have to group different checks in a group

CLI Example:

```
salt '*' nagios.run webserver
```

### 30.16.145 salt.modules.netbsd\_sysctl

Module for viewing and modifying sysctl parameters

**salt.modules.netbsd\_sysctl.assign**(*name*, *value*)

Assign a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.assign net.inet.icmp.icmplim 50
```

**salt.modules.netbsd\_sysctl.get**(*name*)

Return a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.get hw.physmem
```

**salt.modules.netbsd\_sysctl.persist**(*name*, *value*, *config='/etc/sysctl.conf'*)

Assign and persist a simple sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.persist net.inet.icmp.icmplim 50
```

**salt.modules.netbsd\_sysctl.show**(*config\_file=False*)

Return a list of sysctl parameters for this minion

CLI Example:

```
salt '*' sysctl.show
```

### 30.16.146 salt.modules.netbsdservice

The service module for NetBSD

---

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to ``service.start' is not available`), see [here](#).

---

`salt.modules.netbsdservice.available(name)`  
Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available sshd
```

`salt.modules.netbsdservice.disable(name, **kwargs)`  
Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

`salt.modules.netbsdservice.disabled(name)`  
Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.disabled <service name>
```

`salt.modules.netbsdservice.enable(name, **kwargs)`  
Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

`salt.modules.netbsdservice.enabled(name, **kwargs)`  
Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.enabled <service name>
```

`salt.modules.netbsdservice.force_reload(name)`  
Force-reload the named service

CLI Example:

```
salt '*' service.force_reload <service name>
```

`salt.modules.netbsdservice.get_all()`  
Return all available boot services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.netbsdservice.get_disabled()`  
Return a set of services that are installed but disabled

CLI Example:

```
salt '*' service.get_disabled
```

`salt.modules.netbsdservice.get_enabled()`  
Return a list of service that are enabled on boot

CLI Example:

```
salt '*' service.get_enabled
```

`salt.modules.netbsdservice.missing(name)`

The inverse of `service.available`. Returns `True` if the specified service is not available, otherwise returns `False`.

CLI Example:

```
salt '*' service.missing sshd
```

`salt.modules.netbsdservice.reload_(name)`

Reload the named service

CLI Example:

```
salt '*' service.reload <service name>
```

`salt.modules.netbsdservice.restart(name)`

Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.netbsdservice.start(name)`

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.netbsdservice.status(name, sig=None)`

Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

`salt.modules.netbsdservice.stop(name)`

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.147 salt.modules.netscaler

Module to provide Citrix Netscaler compatibility to Salt (compatible with netscaler 9.2+)

New in version 2015.2.0.

**depends**

- nsnitro Python module

**Note:** You can install nsnitro using:

```
pip install nsnitro
```

**configuration** This module accepts connection configuration details either as parameters, or as configuration settings in `/etc/salt/minion` on the relevant minions

```
netcaler.host: 1.2.3.4
netcaler.user: user
netcaler.pass: password
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

**CLI Examples** Calls relying on configuration passed using /etc/salt/minion, grains, or pillars: .. code-block:: bash

```
salt-call netcaler.server_exists server_name
```

Calls passing configuration as opts .. code-block:: bash

```
salt-call netcaler.server_exists server_name netcaler_host=1.2.3.4
netcaler_user=username netcaler_pass=password salt-call netcaler.server_exists
server_name netcaler_host=1.2.3.5 netcaler_user=username2
netcaler_pass=password2 salt-call netcaler.server_enable server_name2
netcaler_host=1.2.3.5
```

`salt.modules.netcaler.server_add(s_name, s_ip, s_state=None, **connection_args)`

Add a server Note: The default server state is ENABLED

CLI Example:

```
salt '*' netcaler.server_add 'serverName' 'serverIpAddress'
salt '*' netcaler.server_add 'serverName' 'serverIpAddress' 'serverState'
```

`salt.modules.netcaler.server_delete(s_name, **connection_args)`

Delete a server

CLI Example:

```
salt '*' netcaler.server_delete 'serverName'
```

`salt.modules.netcaler.server_disable(s_name, **connection_args)`

Disable a server globally

CLI Example:

```
salt '*' netcaler.server_disable 'serverName'
```

`salt.modules.netcaler.server_enable(s_name, **connection_args)`

Enables a server globally

CLI Example:

```
salt '*' netcaler.server_enable 'serverName'
```

`salt.modules.netcaler.server_enabled(s_name, **connection_args)`

Check if a server is enabled globally

CLI Example:

```
salt '*' netcaler.server_enabled 'serverName'
```

`salt.modules.netcaler.server_exists(s_name, ip=None, s_state=None, **connection_args)`

Checks if a server exists

CLI Example:

```
salt '*' netcaler.server_exists 'serverName'
```

**salt.modules.netcaler.server\_update**(*s\_name, s\_ip, \*\*connection\_args*)  
Update a server's attributes

CLI Example:

```
salt '*' netcaler.server_update 'serverName' 'serverIP'
```

**salt.modules.netcaler.service\_disable**(*s\_name, s\_delay=None, \*\*connection\_args*)  
Disable a service

CLI Example:

```
salt '*' netcaler.service_disable 'serviceName'
salt '*' netcaler.service_disable 'serviceName' 'delayInSeconds'
```

**salt.modules.netcaler.service\_enable**(*s\_name, \*\*connection\_args*)  
Enable a service

CLI Example:

```
salt '*' netcaler.service_enable 'serviceName'
```

**salt.modules.netcaler.service\_exists**(*s\_name, \*\*connection\_args*)  
Checks if a service exists

CLI Example:

```
salt '*' netcaler.service_exists 'serviceName'
```

**salt.modules.netcaler.service\_up**(*s\_name, \*\*connection\_args*)  
Checks if a service is UP

CLI Example:

```
salt '*' netcaler.service_up 'serviceName'
```

**salt.modules.netcaler.servicegroup\_add**(*sg\_name, sg\_type='HTTP', \*\*connection\_args*)  
Add a new service group If no service type is specified, HTTP will be used. Most common service types: HTTP, SSL, and SSL\_BRIDGE

CLI Example:

```
salt '*' netcaler.servicegroup_add 'serviceGroupName'
salt '*' netcaler.servicegroup_add 'serviceGroupName' 'serviceGroupType'
```

**salt.modules.netcaler.servicegroup\_delete**(*sg\_name, \*\*connection\_args*)  
Delete a new service group

CLI Example:

```
salt '*' netcaler.servicegroup_delete 'serviceGroupName'
```

**salt.modules.netcaler.servicegroup\_exists**(*sg\_name, sg\_type=None, \*\*connection\_args*)  
Checks if a service group exists

CLI Example:

```
salt '*' netcaler.servicegroup_exists 'serviceGroupName'
```

```
salt.modules.netscaler.servicegroup_server_add(sg_name, s_name, s_port, **connection_args)
```

Add a server:port member to a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_add 'serviceGroupName' 'serverName' 'serverPort'
```

```
salt.modules.netscaler.servicegroup_server_delete(sg_name, s_name, s_port, **connection_args)
```

Remove a server:port member from a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_delete 'serviceGroupName' 'serverName' 'serverPort'
```

```
salt.modules.netscaler.servicegroup_server_disable(sg_name, s_name, s_port, **connection_args)
```

Disable a server:port member of a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_disable 'serviceGroupName' 'serverName' 'serverPort'
```

```
salt.modules.netscaler.servicegroup_server_enable(sg_name, s_name, s_port, **connection_args)
```

Enable a server:port member of a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_enable 'serviceGroupName' 'serverName' 'serverPort'
```

```
salt.modules.netscaler.servicegroup_server_exists(sg_name, s_name, s_port=None, **connection_args)
```

Check if a server:port combination is a member of a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_exists 'serviceGroupName' 'serverName' 'serverPort'
```

```
salt.modules.netscaler.servicegroup_server_up(sg_name, s_name, s_port, **connection_args)
```

Check if a server:port combination is in state UP in a servicegroup

CLI Example:

```
salt '*' netscaler.servicegroup_server_up 'serviceGroupName' 'serverName' 'serverPort'
```

```
salt.modules.netscaler.vserver_add(v_name, v_ip, v_port, v_type, **connection_args)
```

Add a new lb vserver

CLI Example:

```
salt '*' netscaler.vserver_add 'vserverName' 'vserverIP' 'vserverPort' 'vserverType'  
salt '*' netscaler.vserver_add 'alex.patate.chaude.443' '1.2.3.4' '443' 'SSL'
```

```
salt.modules.netscaler.vserver_delete(v_name, **connection_args)
```

Delete a lb vserver

CLI Example:

```
salt '*' netcaler.vserver_delete 'vserverName'
```

```
salt.modules.netcaler.vserver_exists(v_name, v_ip=None, v_port=None, v_type=None,
                                     **connection_args)
```

Checks if a vserver exists

CLI Example:

```
salt '*' netcaler.vserver_exists 'vserverName'
```

```
salt.modules.netcaler.vserver_servicegroup_add(v_name, sg_name, **connection_args)
```

Bind a servicegroup to a vserver

CLI Example:

```
salt '*' netcaler.vserver_servicegroup_add 'vserverName' 'serviceGroupName'
```

```
salt.modules.netcaler.vserver_servicegroup_delete(v_name, sg_name, **connection_args)
```

Unbind a servicegroup from a vserver

CLI Example:

```
salt '*' netcaler.vserver_servicegroup_delete 'vserverName' 'serviceGroupName'
```

```
salt.modules.netcaler.vserver_servicegroup_exists(v_name, sg_name, **connection_args)
```

Checks if a servicegroup is tied to a vserver

CLI Example:

```
salt '*' netcaler.vserver_servicegroup_exists 'vserverName' 'serviceGroupName'
```

```
salt.modules.netcaler.vserver_sslcert_add(v_name, sc_name, **connection_args)
```

Binds a SSL certificate to a vserver

CLI Example:

```
salt '*' netcaler.vserver_sslcert_add 'vserverName' 'sslCertificateName'
```

```
salt.modules.netcaler.vserver_sslcert_delete(v_name, sc_name, **connection_args)
```

Unbinds a SSL certificate from a vserver

CLI Example:

```
salt '*' netcaler.vserver_sslcert_delete 'vserverName' 'sslCertificateName'
```

```
salt.modules.netcaler.vserver_sslcert_exists(v_name, sc_name, **connection_args)
```

Checks if a SSL certificate is tied to a vserver

CLI Example:

```
salt '*' netcaler.vserver_sslcert_exists 'vserverName' 'sslCertificateName'
```

### 30.16.148 salt.modules.network

Module for gathering and managing network information

```
salt.modules.network.active_tcp()
```

Return a dict containing information on all of the running TCP connections

CLI Example:

```
salt '*' network.active_tcp
```

`salt.modules.network.arp()`

Return the arp table from the minion

CLI Example:

```
salt '*' network.arp
```

`salt.modules.network.connect(host, port=None, **kwargs)`

Test connectivity to a host using a particular port from the minion.

New in version 2014.7.0.

CLI Example:

```
salt '*' network.connect archlinux.org 80
salt '*' network.connect archlinux.org 80 timeout=3
salt '*' network.connect archlinux.org 80 timeout=3 family=ipv4
salt '*' network.connect google-public-dns-a.google.com port=53 proto=udp timeout=3
```

`salt.modules.network.default_route(family=None)`

Return default route(s) from routing table

CLI Example:

```
salt '*' network.default_route
```

`salt.modules.network.dig(host)`

Performs a DNS lookup with dig

CLI Example:

```
salt '*' network.dig archlinux.org
```

`salt.modules.network.get_bufsize(iface)`

Return network buffer sizes as a dict

CLI Example:

```
salt '*' network.getbufsize
```

`salt.modules.network.get_hostname()`

Get hostname

CLI Example:

```
salt '*' network.get_hostname
```

`salt.modules.network.get_route(ip)`

Return routing information for given destination ip

New in version 2015.5.3.

CLI Example:

```
salt '*' network.get_route 10.10.10.10
```

`salt.modules.network.hw_addr`(*iface*)

Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:

```
salt '*' network.hw_addr eth0
```

`salt.modules.network.hwaddr`(*iface*)

Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:

```
salt '*' network.hw_addr eth0
```

`salt.modules.network.in_subnet`(*cidr*)

Returns True if host is within specified subnet, otherwise False.

CLI Example:

```
salt '*' network.in_subnet 10.0.0.0/16
```

`salt.modules.network.interface`(*iface*)

Return the inet address for a given interface

New in version 2014.7.0.

CLI Example:

```
salt '*' network.interface eth0
```

`salt.modules.network.interface_ip`(*iface*)

Return the inet address for a given interface

New in version 2014.7.0.

CLI Example:

```
salt '*' network.interface_ip eth0
```

`salt.modules.network.interfaces`()

Return a dictionary of information about all the interfaces on the minion

CLI Example:

```
salt '*' network.interfaces
```

`salt.modules.network.ip_addrs`(*interface=None, include\_loopback=False, cidr=None*)

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr="10.0.0.0/8"` will return only the addresses which are within that subnet.

CLI Example:

```
salt '*' network.ip_addrs
```

`salt.modules.network.ip_addrs6`(*interface=None, include\_loopback=False*)

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:

```
salt '*' network.ip_addrs6
```

`salt.modules.network.ip_in_subnet(ip_addr, cidr)`  
Returns True if given IP is within specified subnet, otherwise False.

CLI Example:

```
salt '*' network.ip_in_subnet 172.17.0.4 172.16.0.0/12
```

`salt.modules.network.ipaddrs(interface=None, include_loopback=False, cidr=None)`  
Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr="10.0.0.0/8"` will return only the addresses which are within that subnet.

CLI Example:

```
salt '*' network.ip_addrs
```

`salt.modules.network.ipaddrs6(interface=None, include_loopback=False)`  
Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:

```
salt '*' network.ip_addrs6
```

`salt.modules.network.is_loopback(ip_addr)`  
Check if the given IP address is a loopback address

New in version 2014.7.0.

CLI Example:

```
salt '*' network.is_loopback 127.0.0.1
```

`salt.modules.network.is_private(ip_addr)`  
Check if the given IP address is a private address

New in version 2014.7.0.

CLI Example:

```
salt '*' network.is_private 10.0.0.3
```

`salt.modules.network.mod_bufsize(iface, *args, **kwargs)`  
Modify network interface buffers (currently linux only)

CLI Example:

```
salt '*' network.getBuffers
```

`salt.modules.network.mod_hostname(hostname)`  
Modify hostname

CLI Example:

```
salt '*' network.mod_hostname master.saltstack.com
```

`salt.modules.network.netstat()`  
Return information on open ports and states

---

**Note:** On BSD minions, the output contains PID info (where available) for each netstat entry, fetched from sockstat/fstat output.

---

Changed in version 2014.1.4: Added support for OpenBSD, FreeBSD, and NetBSD

CLI Example:

```
salt '*' network.netstat
```

`salt.modules.network.ping`(*host*, *timeout=False*, *return\_boolean=False*)

Performs an ICMP ping to a host

CLI Example:

```
salt '*' network.ping archlinux.org
```

New in version 2015.5.0.

Return a True or False instead of ping output.

```
salt '*' network.ping archlinux.org return_boolean=True
```

Set the time to wait for a response in seconds.

```
salt '*' network.ping archlinux.org timeout=3
```

`salt.modules.network.reverse_ip`(*ip\_addr*)

Returns the reversed IP address

CLI Example:

```
salt '*' network.reverse_ip 172.17.0.4
```

`salt.modules.network.routes`(*family=None*)

Return currently configured routes from routing table

CLI Example:

```
salt '*' network.routes
```

`salt.modules.network.subnets`()

Returns a list of subnets to which the host belongs

CLI Example:

```
salt '*' network.subnets
```

`salt.modules.network.traceroute`(*host*)

Performs a traceroute to a 3rd party host

CLI Example:

```
salt '*' network.traceroute archlinux.org
```

`salt.modules.network.wol`(*mac*, *bcast='255.255.255.255'*, *destport=9*)

Send Wake On Lan packet to a host

CLI Example:

```
salt '*' network.wol 08-00-27-13-69-77
salt '*' network.wol 080027136977 255.255.255.255 7
salt '*' network.wol 08:00:27:13:69:77 255.255.255.255 7
```

### 30.16.149 salt.modules.neutron

Module for handling OpenStack Neutron calls

#### depends

- neutronclient Python module

**configuration** This module is not usable until the user, password, tenant, and auth URL are specified either in a pillar or in the minion's config file. For example:

```
keystone.user: 'admin'
keystone.password: 'password'
keystone.tenant: 'admin'
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
keystone.region_name: 'RegionOne'
keystone.service_type: 'network'
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
  keystone.user: 'admin'
  keystone.password: 'password'
  keystone.tenant: 'admin'
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
  keystone.region_name: 'RegionOne'
  keystone.service_type: 'network'

openstack2:
  keystone.user: 'admin'
  keystone.password: 'password'
  keystone.tenant: 'admin'
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/'
  keystone.region_name: 'RegionOne'
  keystone.service_type: 'network'
```

With this configuration in place, any of the neutron functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' neutron.network_list profile=openstack1
```

**salt.modules.neutron.add\_gateway\_router** (*router, ext\_network, profile=None*)

Adds an external network gateway to the specified router

CLI Example:

```
salt '*' neutron.add_gateway_router router-name ext-network-name
```

#### Parameters

- **router** -- ID or name of the router
- **ext\_network** -- ID or name of the external network the gateway
- **profile** -- Profile to build on (Optional)

**Returns** Added Gateway router information

**salt.modules.neutron.add\_interface\_router** (*router, subnet, profile=None*)

Adds an internal network interface to the specified router

CLI Example:

```
salt '*' neutron.add_interface_router router-name subnet-name
```

#### Parameters

- **router** -- ID or name of the router
- **subnet** -- ID or name of the subnet
- **profile** -- Profile to build on (Optional)

**Returns** Added interface information

`salt.modules.neutron.create_floatingip` (*floating\_network*, *port=None*, *profile=None*)

Creates a new floatingIP

CLI Example:

```
salt '*' neutron.create_floatingip network-name port-name
```

#### Parameters

- **floating\_network** -- Network name or ID to allocate floatingIP from
- **port** -- Of the port to be associated with the floatingIP (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created floatingIP information

`salt.modules.neutron.create_ikepolicy` (*name*, *profile=None*, *\*\*kwargs*)

Creates a new IKEPolicy

CLI Example:

```
salt '*' neutron.create_ikepolicy ikepolicy-name
      phase1_negotiation_mode=main auth_algorithm=sha1
      encryption_algorithm=aes-128 pfs=group5
```

#### Parameters

- **name** -- Name of the IKE policy
- **phase1\_negotiation\_mode** -- IKE Phase1 negotiation mode in lowercase, default: main (Optional)
- **auth\_algorithm** -- Authentication algorithm in lowercase, default: sha1 (Optional)
- **encryption\_algorithm** -- Encryption algorithm in lowercase. default:aes-128 (Optional)
- **pfs** -- Perfect Forward Security in lowercase, default: group5 (Optional)
- **units** -- IKE lifetime attribute. default: seconds (Optional)
- **value** -- IKE lifetime attribute. default: 3600 (Optional)
- **ike\_version** -- IKE version in lowercase, default: v1 (Optional)
- **profile** -- Profile to build on (Optional)
- **kwargs** --

**Returns** Created IKE policy information

`salt.modules.neutron.create_ipsec_site_connection`(*name*, *ipsecpolicy*, *ikepolicy*, *vpnservice*, *peer\_cidrs*, *peer\_address*, *peer\_id*, *psk*, *admin\_state\_up=True*, *profile=None*, *\*\*kwargs*)

Creates a new IPsecSiteConnection

CLI Example:

```
salt '*' neutron.show_ipsec_site_connection connection-name
      ipsec-policy-name ikepolicy-name vpnservice-name
      192.168.XXX.XXX/24 192.168.XXX.XXX 192.168.XXX.XXX secret
```

#### Parameters

- **name** -- Set friendly name for the connection
- **ipsecpolicy** -- IPsec policy ID or name associated with this connection
- **ikepolicy** -- IKE policy ID or name associated with this connection
- **vpnservice** -- VPN service instance ID or name associated with this connection
- **peer\_cidrs** -- Remote subnet(s) in CIDR format
- **peer\_address** -- Peer gateway public IPv4/IPv6 address or FQDN
- **peer\_id** -- Peer router identity for authentication Can be IPv4/IPv6 address, e-mail address, key id, or FQDN
- **psk** -- Pre-shared key string
- **initiator** -- Initiator state in lowercase, default:bi-directional
- **admin\_state\_up** -- Set admin state up to true or false, default: True (Optional)
- **mtu** -- size for the connection, default:1500 (Optional)
- **dpd\_action** -- Dead Peer Detection attribute: hold/clear/disabled/ restart/restart-by-peer (Optional)
- **dpd\_interval** -- Dead Peer Detection attribute (Optional)
- **dpd\_timeout** -- Dead Peer Detection attribute (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created IPsec site connection information

`salt.modules.neutron.create_ipsecpolicy`(*name*, *profile=None*, *\*\*kwargs*)

Creates a new IPsecPolicy

CLI Example:

```
salt '*' neutron.create_ipsecpolicy ipsecpolicy-name
      transform_protocol=esp auth_algorithm=sha1
      encapsulation_mode=tunnel encryption_algorithm=aes-128
```

#### Parameters

- **name** -- Name of the IPsec policy
- **transform\_protocol** -- Transform protocol in lowercase, default: esp (Optional)
- **auth\_algorithm** -- Authentication algorithm in lowercase, default: sha1 (Optional)

- **encapsulation\_mode** -- Encapsulation mode in lowercase, default: tunnel (Optional)
- **encryption\_algorithm** -- Encryption algorithm in lowercase, default:aes-128 (Optional)
- **pfs** -- Prefect Forward Security in lowercase, default: group5 (Optional)
- **units** -- IPsec lifetime attribute. default: seconds (Optional)
- **value** -- IPsec lifetime attribute. default: 3600 (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created IPsec policy information

`salt.modules.neutron.create_network`(*name*, *router\_ext=False*, *profile=None*)

Creates a new network

CLI Example:

```
salt '*' neutron.create_network network-name
salt '*' neutron.create_network network-name profile=openstack1
```

#### Parameters

- **name** -- Name of network to create
- **router\_ext** -- True then if create the external network, default: False (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created network information

`salt.modules.neutron.create_port`(*name*, *network*, *device\_id=None*, *admin\_state\_up=True*, *profile=None*)

Creates a new port

CLI Example:

```
salt '*' neutron.create_port network-name port-name
```

#### Parameters

- **name** -- Name of port to create
- **network** -- Network name or ID
- **device\_id** -- ID of device (Optional)
- **admin\_state\_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created port information

`salt.modules.neutron.create_router`(*name*, *ext\_network=None*, *admin\_state\_up=True*, *profile=None*)

Creates a new router

CLI Example:

```
salt '*' neutron.create_router new-router-name
```

#### Parameters

- **name** -- Name of router to create (must be first)
- **ext\_network** -- ID or name of the external for the gateway (Optional)
- **admin\_state\_up** -- Set admin state up to true or false, default:true (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created router information

`salt.modules.neutron.create_security_group` (*name=None, description=None, profile=None*)  
Creates a new security group

CLI Example:

```
salt '*' neutron.create_security_group security-group-name description='Security'
```

#### Parameters

- **name** -- Name of security group (Optional)
- **description** -- Description of security group (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created security group information

`salt.modules.neutron.create_security_group_rule` (*security\_group, remote\_group\_id=None, direction='ingress', protocol=None, port\_range\_min=None, port\_range\_max=None, ethertype='IPv4', profile=None*)

Creates a new security group rule

CLI Example:

```
salt '*' neutron.show_security_group_rule security-group-rule-id
```

#### Parameters

- **security\_group** -- Security group name or ID to add rule
- **remote\_group\_id** -- Remote security group name or ID to apply rule (Optional)
- **direction** -- Direction of traffic: ingress/egress, default: ingress (Optional)
- **protocol** -- Protocol of packet: null/icmp/tcp/udp, default: null (Optional)
- **port\_range\_min** -- Starting port range (Optional)
- **port\_range\_max** -- Ending port range (Optional)
- **ethertype** -- IPv4/IPv6, default: IPv4 (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created security group rule information

`salt.modules.neutron.create_subnet` (*network, cidr, name=None, ip\_version=4, profile=None*)  
Creates a new subnet

CLI Example:

```
salt '*' neutron.create_subnet network-name 192.168.1.0/24
```

#### Parameters

- **network** -- Network ID or name this subnet belongs to
- **cidr** -- CIDR of subnet to create (Ex. `192.168.1.0/24`)
- **name** -- Name of the subnet to create (Optional)
- **ip\_version** -- Version to use, default is 4(IPv4) (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created subnet information

`salt.modules.neutron.create_vpnservice` (*subnet, router, name, admin\_state\_up=True, profile=None*)

Creates a new VPN service

CLI Example:

```
salt '*' neutron.create_vpnservice router-name name
```

#### Parameters

- **subnet** -- Subnet unique identifier for the VPN service deployment
- **router** -- Router unique identifier for the VPN service
- **name** -- Set a name for the VPN service
- **admin\_state\_up** -- Set admin state up to true or false, default:True (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created VPN service information

`salt.modules.neutron.delete_floatingip` (*floatingip\_id, profile=None*)

Deletes the specified floating IP

CLI Example:

```
salt '*' neutron.delete_floatingip floatingip-id
```

#### Parameters

- **floatingip\_id** -- ID of floatingIP to delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_ikepolicy` (*ikepolicy, profile=None*)

Deletes the specified IKEPolicy

CLI Example:

```
salt '*' neutron.delete_ikepolicy ikepolicy-name
```

#### Parameters

- **ikepolicy** -- ID or name of IKE policy to delete

- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_ipsec_site_connection` (*ipsec\_site\_connection*, *profile=None*)

Deletes the specified IPsecSiteConnection

CLI Example:

```
salt '*' neutron.delete_ipsec_site_connection connection-name
```

#### Parameters

- **ipsec\_site\_connection** -- ID or name of ipsec site connection to delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_ipsecpolicy` (*ipsecpolicy*, *profile=None*)

Deletes the specified IPsecPolicy

CLI Example:

```
salt '*' neutron.delete_ipsecpolicy ipsecpolicy-name
```

#### Parameters

- **ipsecpolicy** -- ID or name of IPsec policy to delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_network` (*network*, *profile=None*)

Deletes the specified network

CLI Example:

```
salt '*' neutron.delete_network network-name
salt '*' neutron.delete_network network-name profile=openstack1
```

#### Parameters

- **network** -- ID or name of network to delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_port` (*port*, *profile=None*)

Deletes the specified port

CLI Example:

```
salt '*' neutron.delete_network port-name
salt '*' neutron.delete_network port-name profile=openstack1
```

#### Parameters

- **port** -- port name or ID

- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_quota` (*tenant\_id*, *profile=None*)

Delete the specified tenant's quota value

CLI Example:

```
salt '*' neutron.update_quota tenant-id
salt '*' neutron.update_quota tenant-id profile=openstack1
```

#### Parameters

- **tenant\_id** -- ID of tenant to quota delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Delete succeed) or False(Delete failed)

`salt.modules.neutron.delete_router` (*router*, *profile=None*)

Delete the specified router

CLI Example:

```
salt '*' neutron.delete_router router-name
```

#### Parameters

- **router** -- ID or name of router to delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_security_group` (*security\_group*, *profile=None*)

Deletes the specified security group

CLI Example:

```
salt '*' neutron.delete_security_group security-group-name
```

#### Parameters

- **security\_group** -- ID or name of security group to delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_security_group_rule` (*security\_group\_rule\_id*, *profile=None*)

Deletes the specified security group rule

CLI Example:

```
salt '*' neutron.delete_security_group_rule security-group-rule-id
```

#### Parameters

- **security\_group\_rule\_id** -- ID of security group rule to delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_subnet(subnet, profile=None)`

Deletes the specified subnet

CLI Example:

```
salt '*' neutron.delete_subnet subnet-name
salt '*' neutron.delete_subnet subnet-name profile=openstack1
```

**Parameters**

- **subnet** -- ID or name of subnet to delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.delete_vpnservice(vpnservice, profile=None)`

Deletes the specified VPN service

CLI Example:

```
salt '*' neutron.delete_vpnservice vpnservice-name
```

**Parameters**

- **vpnservice** -- ID or name of vpn service to delete
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.get_quotas_tenant(profile=None)`

Fetches tenant info in server's context for following quota operation

CLI Example:

```
salt '*' neutron.get_quotas_tenant
salt '*' neutron.get_quotas_tenant profile=openstack1
```

**Parameters** **profile** -- Profile to build on (Optional)

**Returns** Quotas information

`salt.modules.neutron.list_extensions(profile=None)`

Fetches a list of all extensions on server side

CLI Example:

```
salt '*' neutron.list_extensions
salt '*' neutron.list_extensions profile=openstack1
```

**Parameters** **profile** -- Profile to build on (Optional)

**Returns** List of extensions

`salt.modules.neutron.list_floatingips` (*profile=None*)

Fetch a list of all floatingIPs for a tenant

CLI Example:

```
salt '*' neutron.list_floatingips
salt '*' neutron.list_floatingips profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of floatingIP

`salt.modules.neutron.list_ikepolicies` (*profile=None*)

Fetches a list of all configured IKEPolicies for a tenant

CLI Example:

```
salt '*' neutron.list_ikepolicies
salt '*' neutron.list_ikepolicies profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of IKE policy

`salt.modules.neutron.list_ipsec_site_connections` (*profile=None*)

Fetches all configured IPsec Site Connections for a tenant

CLI Example:

```
salt '*' neutron.list_ipsec_site_connections
salt '*' neutron.list_ipsec_site_connections profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of IPsec site connection

`salt.modules.neutron.list_ipsecpolicies` (*profile=None*)

Fetches a list of all configured IPsecPolicies for a tenant

CLI Example:

```
salt '*' neutron.list_ipsecpolicies ipsecpolicy-name
salt '*' neutron.list_ipsecpolicies ipsecpolicy-name profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of IPsec policy

`salt.modules.neutron.list_networks` (*profile=None*)

Fetches a list of all networks for a tenant

CLI Example:

```
salt '*' neutron.list_networks
salt '*' neutron.list_networks profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of network

`salt.modules.neutron.list_ports` (*profile=None*)

Fetches a list of all networks for a tenant

CLI Example:

```
salt '*' neutron.list_ports
salt '*' neutron.list_ports profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of port

`salt.modules.neutron.list_quotas` (*profile=None*)

Fetches all tenants quotas

CLI Example:

```
salt '*' neutron.list_quotas
salt '*' neutron.list_quotas profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of quotas

`salt.modules.neutron.list_routers` (*profile=None*)

Fetches a list of all routers for a tenant

CLI Example:

```
salt '*' neutron.list_routers
salt '*' neutron.list_routers profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of router

`salt.modules.neutron.list_security_group_rules` (*profile=None*)

Fetches a list of all security group rules for a tenant

CLI Example:

```
salt '*' neutron.list_security_group_rules
salt '*' neutron.list_security_group_rules profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of security group rule

`salt.modules.neutron.list_security_groups` (*profile=None*)

Fetches a list of all security groups for a tenant

CLI Example:

```
salt '*' neutron.list_security_groups
salt '*' neutron.list_security_groups profile=openstack1
```

**Parameters** `profile` -- Profile to build on (Optional)

**Returns** List of security group

`salt.modules.neutron.list_subnets` (*profile=None*)

Fetches a list of all networks for a tenant

CLI Example:

```
salt '*' neutron.list_subnets
salt '*' neutron.list_subnets profile=openstack1
```

**Parameters** **profile** -- Profile to build on (Optional)

**Returns** List of subnet

`salt.modules.neutron.list_vpnservices` (*retrive\_all=True, profile=None, \*\*kwargs*)

Fetches a list of all configured VPN services for a tenant

CLI Example:

```
salt '*' neutron.list_vpnservices
```

**Parameters**

- **retrive\_all** -- True or False, default: True (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** List of VPN service

`salt.modules.neutron.remove_gateway_router` (*router, profile=None*)

Removes an external network gateway from the specified router

CLI Example:

```
salt '*' neutron.remove_gateway_router router-name
```

**Parameters**

- **router** -- ID or name of router
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.remove_interface_router` (*router, subnet, profile=None*)

Removes an internal network interface from the specified router

CLI Example:

```
salt '*' neutron.remove_interface_router router-name subnet-name
```

**Parameters**

- **router** -- ID or name of the router
- **subnet** -- ID or name of the subnet
- **profile** -- Profile to build on (Optional)

**Returns** True(Succeed) or False

`salt.modules.neutron.show_floatingip` (*floatingip\_id*, *profile=None*)  
Fetches information of a certain floatingIP

CLI Example:

```
salt '*' neutron.show_floatingip floatingip-id
```

**Parameters**

- **floatingip\_id** -- ID of floatingIP to look up
- **profile** -- Profile to build on (Optional)

**Returns** Floating IP information

`salt.modules.neutron.show_ikepolicy` (*ikepolicy*, *profile=None*)  
Fetches information of a specific IKEPolicy

CLI Example:

```
salt '*' neutron.show_ikepolicy ikepolicy-name
```

**Parameters**

- **ikepolicy** -- ID or name of ikepolicy to look up
- **profile** -- Profile to build on (Optional)

**Returns** IKE policy information

`salt.modules.neutron.show_ipsec_site_connection` (*ipsec\_site\_connection*, *profile=None*)  
Fetches information of a specific IPsecSiteConnection

CLI Example:

```
salt '*' neutron.show_ipsec_site_connection connection-name
```

**Parameters**

- **ipsec\_site\_connection** -- ID or name of ipsec site connection to look up
- **profile** -- Profile to build on (Optional)

**Returns** IPSec site connection information

`salt.modules.neutron.show_ipsecpolicy` (*ipsecpolicy*, *profile=None*)  
Fetches information of a specific IPsecPolicy

CLI Example:

```
salt '*' neutron.show_ipsecpolicy ipsecpolicy-name
```

**Parameters**

- **ipsecpolicy** -- ID or name of IPSec policy to look up
- **profile** -- Profile to build on (Optional)

**Returns** IPSec policy information

`salt.modules.neutron.show_network`(*network*, *profile=None*)

Fetches information of a certain network

CLI Example:

```
salt '*' neutron.show_network network-name
salt '*' neutron.show_network network-name profile=openstack1
```

#### Parameters

- **network** -- ID or name of network to look up
- **profile** -- Profile to build on (Optional)

**Returns** Network information

`salt.modules.neutron.show_port`(*port*, *profile=None*)

Fetches information of a certain port

CLI Example:

```
salt '*' neutron.show_port port-id
salt '*' neutron.show_port port-id profile=openstack1
```

#### Parameters

- **port** -- ID or name of port to look up
- **profile** -- Profile to build on (Optional)

**Returns** Port information

`salt.modules.neutron.show_quota`(*tenant\_id*, *profile=None*)

Fetches information of a certain tenant's quotas

CLI Example:

```
salt '*' neutron.show_quota tenant-id
salt '*' neutron.show_quota tenant-id profile=openstack1
```

#### Parameters

- **tenant\_id** -- ID of tenant
- **profile** -- Profile to build on (Optional)

**Returns** Quota information

`salt.modules.neutron.show_router`(*router*, *profile=None*)

Fetches information of a certain router

CLI Example:

```
salt '*' neutron.show_router router-name
```

#### Parameters

- **router** -- ID or name of router to look up
- **profile** -- Profile to build on (Optional)

**Returns** Router information

`salt.modules.neutron.show_security_group`(*security\_group*, *profile=None*)

Fetches information of a certain security group

CLI Example:

```
salt '*' neutron.show_security_group security-group-name
```

**Parameters**

- **security\_group** -- ID or name of security group to look up
- **profile** -- Profile to build on (Optional)

**Returns** Security group information

`salt.modules.neutron.show_security_group_rule`(*security\_group\_rule\_id*, *profile=None*)

Fetches information of a certain security group rule

CLI Example:

```
salt '*' neutron.show_security_group_rule security-group-rule-id
```

**Parameters**

- **security\_group\_rule\_id** -- ID of security group rule to look up
- **profile** -- Profile to build on (Optional)

**Returns** Security group rule information

`salt.modules.neutron.show_subnet`(*subnet*, *profile=None*)

Fetches information of a certain subnet

CLI Example:

```
salt '*' neutron.show_subnet subnet-name
```

**Parameters**

- **subnet** -- ID or name of subnet to look up
- **profile** -- Profile to build on (Optional)

**Returns** Subnet information

`salt.modules.neutron.show_vpnservice`(*vpnservice*, *profile=None*, *\*\*kwargs*)

Fetches information of a specific VPN service

CLI Example:

```
salt '*' neutron.show_vpnservice vpnservice-name
```

**Parameters**

- **vpnservice** -- ID or name of vpn service to look up
- **profile** -- Profile to build on (Optional)

**Returns** VPN service information

`salt.modules.neutron.update_floatingip` (*floatingip\_id*, *port*, *profile=None*)

Updates a floatingIP

CLI Example:

```
salt '*' neutron.update_floatingip network-name port-name
```

#### Parameters

- **floatingip\_id** -- ID of floatingIP
- **port** -- ID or name of port
- **profile** -- Profile to build on (Optional)

**Returns** Value of updated floating IP information

`salt.modules.neutron.update_network` (*network*, *name*, *profile=None*)

Updates a network

CLI Example:

```
salt '*' neutron.update_network network-name new-network-name
```

#### Parameters

- **network** -- ID or name of network to update
- **name** -- Name of this network
- **profile** -- Profile to build on (Optional)

**Returns** Value of updated network information

`salt.modules.neutron.update_port` (*port*, *name*, *admin\_state\_up=True*, *profile=None*)

Updates a port

CLI Example:

```
salt '*' neutron.update_port port-name network-name new-port-name
```

#### Parameters

- **port** -- Port name or ID
- **name** -- Name of this port
- **admin\_state\_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Value of updated port information

`salt.modules.neutron.update_quota` (*tenant\_id*, *subnet=None*, *router=None*, *network=None*, *floatingip=None*, *port=None*, *security\_group=None*, *security\_group\_rule=None*, *profile=None*)

Update a tenant's quota

CLI Example:

```
salt '*' neutron.update_quota tenant-id subnet=40 router=50
network=10 floatingip=30 port=30
```

**Parameters**

- **tenant\_id** -- ID of tenant
- **subnet** -- Value of subnet quota (Optional)
- **router** -- Value of router quota (Optional)
- **network** -- Value of network quota (Optional)
- **floatingip** -- Value of floatingip quota (Optional)
- **port** -- Value of port quota (Optional)
- **security\_group** -- Value of security group (Optional)
- **security\_group\_rule** -- Value of security group rule (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Value of updated quota

`salt.modules.neutron.update_router`(*router*, *name=None*, *admin\_state\_up=None*, *profile=None*, *\*\*kwargs*)

Updates a router

CLI Example:

```
salt '*' neutron.update_router router_id name=new-router-name
admin_state_up=True
```

**Parameters**

- **router** -- ID or name of router to update
- **name** -- Name of this router
- **ext\_network** -- ID or name of the external for the gateway (Optional)
- **admin\_state\_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)
- **kwargs** --

**Returns** Value of updated router information

`salt.modules.neutron.update_security_group`(*security\_group*, *name=None*, *description=None*, *profile=None*)

Updates a security group

CLI Example:

```
salt '*' neutron.update_security_group security-group-name new-security-group-name
```

**Parameters**

- **security\_group** -- ID or name of security group to update
- **name** -- Name of this security group (Optional)
- **description** -- Description of security group (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Value of updated security group information

`salt.modules.neutron.update_subnet(subnet, name, profile=None)`

Updates a subnet

CLI Example:

```
salt '*' neutron.update_subnet subnet-name new-subnet-name
```

#### Parameters

- **subnet** -- ID or name of subnet to update
- **name** -- Name of this subnet
- **profile** -- Profile to build on (Optional)

**Returns** Value of updated subnet information

`salt.modules.neutron.update_vpnservice(vpnservice, desc, profile=None)`

Updates a VPN service

CLI Example:

```
salt '*' neutron.update_vpnservice vpnservice-name desc='VPN Service1'
```

#### Parameters

- **vpnservice** -- ID or name of vpn service to update
- **desc** -- Set a description for the VPN service
- **profile** -- Profile to build on (Optional)

**Returns** Value of updated VPN service information

### 30.16.150 salt.modules.nfs3

Module for managing NFS version 3.

`salt.modules.nfs3.del_export(exports='/etc/exports', path=None)`

Remove an export

CLI Example:

```
salt '*' nfs.del_export /media/storage
```

`salt.modules.nfs3.list_exports(exports='/etc/exports')`

List configured exports

CLI Example:

```
salt '*' nfs.list_exports
```

### 30.16.151 salt.modules.nftables

Support for nftables

`salt.modules.nftables.append(table='filter', chain=None, rule=None, family='ipv4')`

Append a rule to the specified table & chain.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```
salt '*' nftables.append filter input \
    rule='input tcp dport 22 log accept'

IPv6:
salt '*' nftables.append filter input \
    rule='input tcp dport 22 log accept' \
    family=ipv6
```

`salt.modules.nftables.build_rule`(*table=None, chain=None, command=None, position='*,  
*full=None, family='ipv4', \*\*kwargs*)

Build a well-formatted nftables rule based on kwargs. A *table* and *chain* are not required, unless *full* is True.

If *full* is True, then *table*, *chain* and *command* are required. *command* may be specified as either insert, append, or delete. This will return the nftables command, exactly as it would be used from the command line.

If a position is required (as with *insert* or *delete*), it may be specified as *position*. This will only be useful if *full* is True.

If *connstate* is passed in, it will automatically be changed to *state*.

CLI Examples:

```
salt '*' nftables.build_rule match=state \
    connstate=RELATED,ESTABLISHED jump=ACCEPT
salt '*' nftables.build_rule filter input command=insert position=3 \
    full=True match=state state=related,established jump=accept

IPv6:
salt '*' nftables.build_rule match=state \
    connstate=related,established jump=accept \
    family=ipv6
salt '*' nftables.build_rule filter input command=insert position=3 \
    full=True match=state state=related,established jump=accept \
    family=ipv6
```

`salt.modules.nftables.check`(*table='filter', chain=None, rule=None, family='ipv4'*)

Check for the existence of a rule in the table and chain

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```
salt '*' nftables.check filter input \
    rule='input tcp dport 22 log accept'

IPv6:
salt '*' nftables.check filter input \
    rule='input tcp dport 22 log accept' \
    family=ipv6
```

`salt.modules.nftables.check_chain`(*table='filter', chain=None, family='ipv4'*)

New in version 2014.7.0.

Check for the existence of a chain in the table

CLI Example:

```
salt '*' nftables.check_chain filter input

IPv6:
salt '*' nftables.check_chain filter input family=ipv6
```

`salt.modules.nftables.check_table`(*table=None, family='ipv4'*)  
Check for the existence of a table

CLI Example:

```
salt '*' nftables.check_table nat
```

`salt.modules.nftables.delete`(*table, chain=None, position=None, rule=None, family='ipv4'*)

Delete a rule from the specified table & chain, specifying either the rule in its entirety, or the rule's position in the chain.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Examples:

```
salt '*' nftables.delete filter input position=3

salt '*' nftables.delete filter input \
    rule='input tcp dport 22 log accept'

IPv6:
salt '*' nftables.delete filter input position=3 family=ipv6

salt '*' nftables.delete filter input \
    rule='input tcp dport 22 log accept' \
    family=ipv6
```

`salt.modules.nftables.delete_chain`(*table='filter', chain=None, family='ipv4'*)  
New in version 2014.7.0.

Delete the chain from the specified table.

CLI Example:

```
salt '*' nftables.delete_chain filter input

salt '*' nftables.delete_chain filter foo

IPv6:
salt '*' nftables.delete_chain filter input family=ipv6

salt '*' nftables.delete_chain filter foo family=ipv6
```

`salt.modules.nftables.delete_table`(*table, family='ipv4'*)  
New in version 2014.7.0.

Create new custom table.

CLI Example:

```
salt '*' nftables.delete_table filter
```

```
IPv6:
salt '*' nftables.delete_table filter family=ipv6
```

`salt.modules.nftables.flush`(*table='filter', chain='', family='ipv4'*)

Flush the chain in the specified table, flush all chains in the specified table if chain is not specified.

CLI Example:

```
salt '*' nftables.flush filter

salt '*' nftables.flush filter input

IPv6:
salt '*' nftables.flush filter input family=ipv6
```

`salt.modules.nftables.get_rule_handle`(*table='filter', chain=None, rule=None, family='ipv4'*)

Get the handle for a particular rule

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```
salt '*' nftables.get_rule_handle filter input \
    rule='input tcp dport 22 log accept'

IPv6:
salt '*' nftables.get_rule_handle filter input \
    rule='input tcp dport 22 log accept' \
    family=ipv6
```

`salt.modules.nftables.get_rules`(*family='ipv4'*)

Return a data structure of the current, in-memory rules

CLI Example:

```
salt '*' nftables.get_rules

salt '*' nftables.get_rules family=ipv6
```

`salt.modules.nftables.get_saved_rules`(*conf\_file=None, family='ipv4'*)

Return a data structure of the rules in the conf file

CLI Example:

```
salt '*' nftables.get_saved_rules
```

`salt.modules.nftables.insert`(*table='filter', chain=None, position=None, rule=None, family='ipv4'*)

Insert a rule into the specified table & chain, at the specified position.

If position is not specified, rule will be inserted in first position.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Examples:

```
salt '*' nftables.insert filter input \
    rule='input tcp dport 22 log accept'
```

```

salt '*' nftables.insert filter input position=3 \
    rule='input tcp dport 22 log accept'

IPv6:
salt '*' nftables.insert filter input \
    rule='input tcp dport 22 log accept' \
    family=ipv6

salt '*' nftables.insert filter input position=3 \
    rule='input tcp dport 22 log accept' \
    family=ipv6

```

`salt.modules.nftables.new_chain`(*table='filter', chain=None, table\_type=None, hook=None, priority=None, family='ipv4'*)

New in version 2014.7.0.

Create new chain to the specified table.

CLI Example:

```

salt '*' nftables.new_chain filter input

salt '*' nftables.new_chain filter input \
    table_type=filter hook=input priority=0

salt '*' nftables.new_chain filter foo

IPv6:
salt '*' nftables.new_chain filter input family=ipv6

salt '*' nftables.new_chain filter input \
    table_type=filter hook=input priority=0 family=ipv6

salt '*' nftables.new_chain filter foo family=ipv6

```

`salt.modules.nftables.new_table`(*table, family='ipv4'*)

New in version 2014.7.0.

Create new custom table.

CLI Example:

```

salt '*' nftables.new_table filter

IPv6:
salt '*' nftables.new_table filter family=ipv6

```

`salt.modules.nftables.save`(*filename=None, family='ipv4'*)

Save the current in-memory rules to disk

CLI Example:

```

salt '*' nftables.save /etc/nftables

```

`salt.modules.nftables.version`()

Return version from nftables --version

CLI Example:

```
salt '*' nftables.version
```

### 30.16.152 salt.modules.nginx

Support for nginx

**salt.modules.nginx.configtest()**  
test configuration and exit

CLI Example:

```
salt '*' nginx.configtest
```

**salt.modules.nginx.signal**(*signal=None*)  
Signals nginx to start, reload, reopen or stop.

CLI Example:

```
salt '*' nginx.signal reload
```

**salt.modules.nginx.status**(*url='http://127.0.0.1/status'*)  
Return the data from an Nginx status page as a dictionary. <http://wiki.nginx.org/HttpStubStatusModule>  
**url** The URL of the status page. Defaults to `'http://127.0.0.1/status'`

CLI Example:

```
salt '*' nginx.status
```

**salt.modules.nginx.version()**  
Return server version from `nginx -v`

CLI Example:

```
salt '*' nginx.version
```

### 30.16.153 salt.modules.nova

Module for handling OpenStack Nova calls

**depends**

- novaclient Python module

**configuration** This module is not usable until the user, password, tenant, and auth URL are specified either in a pillar or in the minion's config file. For example:

```
keystone.user: admin
keystone.password: verybadpass
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
# Optional
keystone.region_name: 'regionOne'
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```

openstack1:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'

openstack2:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/'

```

With this configuration in place, any of the nova functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' nova.flavor_list profile=openstack1
```

**salt.modules.nova.boot** (*name, flavor\_id=0, image\_id=0, profile=None, timeout=300*)

Boot (create) a new instance

**name** Name of the new instance (must be first)

**flavor\_id** Unique integer ID for the flavor

**image\_id** Unique integer ID for the image

**timeout** How long to wait, after creating the instance, for the provider to return information about it (default 300 seconds).

New in version 2014.1.0.

CLI Example:

```
salt '*' nova.boot myinstance flavor_id=4596 image_id=2
```

The `flavor_id` and `image_id` are obtained from `nova.flavor_list` and `nova.image_list`

```
salt '*' nova.flavor_list
salt '*' nova.image_list
```

**salt.modules.nova.delete** (*instance\_id, profile=None*)

Delete an instance

**instance\_id** ID of the instance to be deleted

CLI Example:

```
salt '*' nova.delete 1138
```

**salt.modules.nova.flavor\_create** (*name, flavor\_id=0, ram=0, disk=0, vcpus=1, profile=None*)

Add a flavor to nova (nova flavor-create). The following parameters are required:

**name** Name of the new flavor (must be first)

**flavor\_id** Unique integer ID for the new flavor

**ram** Memory size in MB

**disk** Disk size in GB

**vcpus** Number of vcpus

CLI Example:

```
salt '*' nova.flavor_create myflavor flavor_id=6 ram=4096 disk=10 vcpus=1
```

**salt.modules.nova.flavor\_delete**(*flavor\_id*, *profile=None*)  
Delete a flavor from nova by id (nova flavor-delete)

CLI Example:

```
salt '*' nova.flavor_delete 7
```

**salt.modules.nova.flavor\_list**(*profile=None*)  
Return a list of available flavors (nova flavor-list)

CLI Example:

```
salt '*' nova.flavor_list
```

**salt.modules.nova.image\_list**(*name=None*, *profile=None*)  
Return a list of available images (nova images-list + nova image-show) If a name is provided, only that image will be displayed.

CLI Examples:

```
salt '*' nova.image_list
salt '*' nova.image_list myimage
```

**salt.modules.nova.image\_meta\_delete**(*image\_id=None*, *name=None*, *keys=None*, *profile=None*)  
Delete a key=value pair from the metadata for an image (nova image-meta set)

CLI Examples:

```
salt '*' nova.image_meta_delete 6f52b2ff-0b31-4d84-8fd1-af45b84824f6 keys=cheese
salt '*' nova.image_meta_delete name=myimage keys=salad,beans
```

**salt.modules.nova.image\_meta\_set**(*image\_id=None*, *name=None*, *profile=None*, *\*\*kwargs*)  
Sets a key=value pair in the metadata for an image (nova image-meta set)

CLI Examples:

```
salt '*' nova.image_meta_set 6f52b2ff-0b31-4d84-8fd1-af45b84824f6 cheese=gruyere
salt '*' nova.image_meta_set name=myimage salad=pasta beans=baked
```

**salt.modules.nova.keypair\_add**(*name*, *pubfile=None*, *pubkey=None*, *profile=None*)  
Add a keypair to nova (nova keypair-add)

CLI Examples:

```
salt '*' nova.keypair_add mykey pubfile='/home/myuser/.ssh/id_rsa.pub'
salt '*' nova.keypair_add mykey pubkey='ssh-rsa <key> myuser@mybox'
```

**salt.modules.nova.keypair\_delete**(*name*, *profile=None*)  
Delete a keypair from nova (nova keypair-delete)

CLI Example:

```
salt '*' nova.keypair_delete mykey'
```

**salt.modules.nova.keypair\_list**(*profile=None*)  
Return a list of available keypairs (nova keypair-list)

CLI Example:

```
salt '*' nova.keypair_list
```

**salt.modules.nova.list\_**(*profile=None*)

To maintain the feel of the nova command line, this function simply calls the `server_list` function.

**salt.modules.nova.lock**(*instance\_id, profile=None*)

Lock an instance

**instance\_id** ID of the instance to be locked

CLI Example:

```
salt '*' nova.lock 1138
```

**salt.modules.nova.resume**(*instance\_id, profile=None*)

Resume an instance

**instance\_id** ID of the instance to be resumed

CLI Example:

```
salt '*' nova.resume 1138
```

**salt.modules.nova.secgroup\_create**(*name, description, profile=None*)

Add a secgroup to nova (nova secgroup-create)

CLI Example:

```
salt '*' nova.secgroup_create mygroup 'This is my security group'
```

**salt.modules.nova.secgroup\_delete**(*name, profile=None*)

Delete a secgroup to nova (nova secgroup-delete)

CLI Example:

```
salt '*' nova.secgroup_delete mygroup
```

**salt.modules.nova.secgroup\_list**(*profile=None*)

Return a list of available security groups (nova items-list)

CLI Example:

```
salt '*' nova.secgroup_list
```

**salt.modules.nova.server\_by\_name**(*name, profile=None*)

Return information about a server

**name** Server Name

CLI Example:

```
salt '*' nova.server_by_name myserver profile=openstack
```

**salt.modules.nova.server\_list**(*profile=None*)

Return list of active servers

CLI Example:

```
salt '*' nova.show
```

**salt.modules.nova.server\_list\_detailed**(*profile=None*)

Return detailed list of active servers

CLI Example:

```
salt '*' nova.server_list_detailed
```

`salt.modules.nova.server_show`(*server\_id*, *profile=None*)  
Return detailed information for an active server

CLI Example:

```
salt '*' nova.server_show <server_id>
```

`salt.modules.nova.show`(*server\_id*, *profile=None*)  
To maintain the feel of the nova command line, this function simply calls the `server_show` function.

CLI Example:

```
salt '*' nova.show
```

`salt.modules.nova.suspend`(*instance\_id*, *profile=None*)  
Suspend an instance

**instance\_id** ID of the instance to be suspended

CLI Example:

```
salt '*' nova.suspend 1138
```

`salt.modules.nova.volume_attach`(*name*, *server\_name*, *device='/dev/xvdb'*, *profile=None*, *time-out=300*)

Attach a block storage volume

**name** Name of the new volume to attach

**server\_name** Name of the server to attach to

**device** Name of the device on the server

**profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_attach myblock slice.example.com profile=openstack
salt '*' nova.volume_attach myblock server.example.com device='/dev/xvdb' profile=openstack
```

`salt.modules.nova.volume_create`(*name*, *size=100*, *snapshot=None*, *voltype=None*, *profile=None*)  
Create a block storage volume

**name** Name of the new volume (must be first)

**size** Volume size

**snapshot** Block storage snapshot id

**voltype** Type of storage

**profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_create myblock size=300 profile=openstack
```

`salt.modules.nova.volume_delete`(*name*, *profile=None*)  
Destroy the volume

**name** Name of the volume

**profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_delete myblock profile=openstack
```

`salt.modules.nova.volume_detach`(*name*, *profile=None*, *timeout=300*)

Attach a block storage volume

**name** Name of the new volume to attach

**server\_name** Name of the server to detach from

**profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_detach myblock profile=openstack
```

`salt.modules.nova.volume_list`(*search\_opts=None*, *profile=None*)

List storage volumes

**search\_opts** Dictionary of search options

**profile** Profile to use

CLI Example:

```
salt '*' nova.volume_list search_opts='{"display_name": "myblock"}'
```

`salt.modules.nova.volume_show`(*name*, *profile=None*)

Create a block storage volume

**name** Name of the volume

**profile** Profile to use

CLI Example:

```
salt '*' nova.volume_show myblock profile=openstack
```

### 30.16.154 salt.modules.npm

Manage and query NPM packages.

`salt.modules.npm.install`(*pkg=None*, *pkgs=None*, *dir=None*, *runas=None*, *registry=None*, *env=None*)

Install an NPM package.

If no directory is specified, the package will be installed globally. If no package is specified, the dependencies (from package.json) of the package in the given directory will be installed.

**pkg** A package name in any format accepted by NPM, including a version identifier

**pkgs** A list of package names in the same format as the `name` parameter

New in version 2014.7.0.

**dir** The target directory in which to install the package, or `None` for global installation

**runas** The user to run NPM with

**registry** The NPM registry to install the package from.

New in version 2014.7.0.

**env** Environment variables to set when invoking npm. Uses the same `env` format as the `cmd.run` execution function.

New in version 2014.7.0.

CLI Example:

```
salt '*' npm.install coffee-script
salt '*' npm.install coffee-script@1.0.1
```

`salt.modules.npm.list_` (*pkg=None, dir=None, runas=None, env=None*)

List installed NPM packages.

If no directory is specified, this will return the list of globally- installed packages.

**pkg** Limit package listing by name

**dir** The directory whose packages will be listed, or None for global installation

**runas** The user to run NPM with

New in version 2014.7.0.

**env** Environment variables to set when invoking npm. Uses the same `env` format as the `cmd.run` execution function.

New in version 2014.7.0.

CLI Example:

```
salt '*' npm.list
```

`salt.modules.npm.uninstall` (*pkg, dir=None, runas=None, env=None*)

Uninstall an NPM package.

If no directory is specified, the package will be uninstalled globally.

**pkg** A package name in any format accepted by NPM

**dir** The target directory from which to uninstall the package, or None for global installation

**runas** The user to run NPM with

**env** Environment variables to set when invoking npm. Uses the same `env` format as the `cmd.run` execution function.

New in version 2015.5.3.

CLI Example:

```
salt '*' npm.uninstall coffee-script
```

### 30.16.155 salt.modules.omapi

This module interacts with an ISC DHCP Server via OMAPI. `server_ip` and `server_port` params may be set in the minion config or pillar:

```
omapi.server_ip: 127.0.0.1
omapi.server_port: 7991
```

**depends** pypureomapi Python module

`salt.modules.omapi.add_host`(*mac*, *name=None*, *ip=None*, *ddns=False*, *group=None*, *super-  
sede\_host=False*)

Add a host object for the given mac.

CLI Example:

```
salt dhcp-server omapi.add_host ab:ab:ab:ab:ab:ab name=host1
```

Add ddns-hostname and a fixed-ip statements:

```
salt dhcp-server omapi.add_host ab:ab:ab:ab:ab:ab name=host1 ip=10.1.1.1 ddns=true
```

`salt.modules.omapi.delete_host`(*mac=None*, *name=None*)

Delete the host with the given mac or name.

CLI Examples:

```
salt dhcp-server omapi.delete_host name=host1
salt dhcp-server omapi.delete_host mac=ab:ab:ab:ab:ab:ab
```

### 30.16.156 salt.modules.openbsd\_sysctl

Module for viewing and modifying OpenBSD sysctl parameters

`salt.modules.openbsd_sysctl.assign`(*name*, *value*)

Assign a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.assign net.inet.ip.forwarding 1
```

`salt.modules.openbsd_sysctl.get`(*name*)

Return a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.get hw.physmem
```

`salt.modules.openbsd_sysctl.persist`(*name*, *value*, *config='/etc/sysctl.conf'*)

Assign and persist a simple sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.persist net.inet.ip.forwarding 1
```

`salt.modules.openbsd_sysctl.show`(*config\_file=False*)

Return a list of sysctl parameters for this minion

CLI Example:

```
salt '*' sysctl.show
```

### 30.16.157 salt.modules.openbsdpkg

Package support for OpenBSD

---

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

---

`salt.modules.openbsdpkg.install` (*name=None, pkgs=None, sources=None, \*\*kwargs*)

Install the passed package

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example, Install one package:

```
salt '*' pkg.install <package name>
```

CLI Example, Install more than one package:

```
salt '*' pkg.install pkgs='["<package name>", "<package name>"]'
```

CLI Example, Install more than one package from a alternate source (e.g. salt file-server, HTTP, FTP, local filesystem):

```
salt '*' pkg.install sources='[{"<pkg name>": "salt://pkgs/<pkg filename>"}]'
```

`salt.modules.openbsdpkg.latest_version` (*\*names, \*\*kwargs*)

The available version of the package in the repository

CLI Example:

```
salt '*' pkg.latest_version <package name>
```

`salt.modules.openbsdpkg.list_pkgs` (*versions\_as\_list=False, \*\*kwargs*)

List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

`salt.modules.openbsdpkg.purge` (*name=None, pkgs=None, \*\*kwargs*)

Package purges are not supported, this function is identical to `remove()`.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The **name** parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>, <package2>, <package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

`salt.modules.openbsdpkg.remove` (*name=None, pkgs=None, \*\*kwargs*)

Remove a single package with `pkg_delete`

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

`salt.modules.openbsdpkg.version(*names, **kwargs)`

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

### 30.16.158 salt.modules.openbsdrctl

The `rctl` service module for OpenBSD

`salt.modules.openbsdrctl.available(name)`

Return True if the named service is available.

CLI Example:

```
salt '*' service.available sshd
```

`salt.modules.openbsdrctl.disable(name, **kwargs)`

Disable the named service to not start at boot.

CLI Example:

```
salt '*' service.disable <service name>
```

`salt.modules.openbsdrctl.disabled(name)`

Return True if the named service is disabled at boot, False otherwise.

CLI Example:

```
salt '*' service.disabled <service name>
```

`salt.modules.openbsdrctl.enable(name, **kwargs)`

Enable the named service to start at boot.

**flags** [None] Set optional flags to run the service with.

`service.flags` can be used to change the default flags.

CLI Example:

```
salt '*' service.enable <service name>
salt '*' service.enable <service name> flags=<flags>
```

`salt.modules.openbsdrctl.enabled(name, **kwargs)`

Return True if the named service is enabled at boot and the provided flags match the configured ones (if any). Return False otherwise.

**name** Service name

CLI Example:

```
salt '*' service.enabled <service name>
salt '*' service.enabled <service name> flags=<flags>
```

**salt.modules.openbsdrctl.get\_all()**

Return all installed services.

CLI Example:

```
salt '*' service.get_all
```

**salt.modules.openbsdrctl.get\_disabled()**

Return what services are available but not enabled to start at boot.

CLI Example:

```
salt '*' service.get_disabled
```

**salt.modules.openbsdrctl.get\_enabled()**

Return what services are set to run on boot.

CLI Example:

```
salt '*' service.get_enabled
```

**salt.modules.openbsdrctl.missing(name)**

The inverse of service.available. Return True if the named service is not available.

CLI Example:

```
salt '*' service.missing sshd
```

**salt.modules.openbsdrctl.reload\_(name)**

Reload the named service.

CLI Example:

```
salt '*' service.reload <service name>
```

**salt.modules.openbsdrctl.restart(name)**

Restart the named service.

CLI Example:

```
salt '*' service.restart <service name>
```

**salt.modules.openbsdrctl.start(name)**

Start the named service.

CLI Example:

```
salt '*' service.start <service name>
```

**salt.modules.openbsdrctl.status(name, sig=None)**

Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

`salt.modules.openbsdrcctl.stop(name)`  
Stop the named service.

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.159 salt.modules.openbsdservice

The service module for OpenBSD

---

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `'service.start' is not available`), see [here](#).

---

`salt.modules.openbsdservice.available(name)`  
New in version 2014.7.0.

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available sshd
```

`salt.modules.openbsdservice.disabled(name)`  
New in version 2014.7.0.

Return True if the named service is disabled, false otherwise

CLI Example:

```
salt '*' service.disabled <service name>
```

`salt.modules.openbsdservice.enabled(name, **kwargs)`  
New in version 2014.7.0.

Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.enabled <service name>
```

`salt.modules.openbsdservice.get_all()`  
New in version 2014.7.0.

Return all available boot services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.openbsdservice.get_disabled()`  
New in version 2014.7.0.

Return a set of services that are installed but disabled

CLI Example:

```
salt '*' service.get_disabled
```

`salt.modules.openbsdservice.get_enabled()`  
New in version 2014.7.0.

Return a list of service that are enabled on boot

CLI Example:

```
salt '*' service.get_enabled
```

`salt.modules.openbsdservice.missing(name)`

New in version 2014.7.0.

The inverse of `service.available`. Returns `True` if the specified service is not available, otherwise returns `False`.

CLI Example:

```
salt '*' service.missing sshd
```

`salt.modules.openbsdservice.reload_(name)`

New in version 2014.7.0.

Reload the named service

CLI Example:

```
salt '*' service.reload <service name>
```

`salt.modules.openbsdservice.restart(name)`

Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.openbsdservice.start(name)`

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.openbsdservice.status(name, sig=None)`

Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

`salt.modules.openbsdservice.stop(name)`

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.160 salt.modules.openstack\_config

Modify, retrieve, or delete values from OpenStack configuration files.

**maintainer** Jeffrey C. Ollie <jeff@ocjtech.us>

**maturity** new

**depends**

**platform** linux

`salt.modules.openstack_config.delete`(*filename, section, parameter*)

Delete a value from an OpenStack configuration file.

**filename** The full path to the configuration file

**section** The section from which to delete the parameter

**parameter** The parameter to delete

CLI Example:

```
salt-call openstack_config.delete /etc/keystone/keystone.conf sql connection
```

`salt.modules.openstack_config.get`(*filename, section, parameter*)

Get a value from an OpenStack configuration file.

**filename** The full path to the configuration file

**section** The section from which to search for the parameter

**parameter** The parameter to return

CLI Example:

```
salt-call openstack_config.get /etc/keystone/keystone.conf sql connection
```

`salt.modules.openstack_config.set_`(*filename, section, parameter, value*)

Set a value in an OpenStack configuration file.

**filename** The full path to the configuration file

**section** The section in which the parameter will be set

**parameter** The parameter to change

**value** The value to set

CLI Example:

```
salt-call openstack_config.set /etc/keystone/keystone.conf sql connection foo
```

### 30.16.161 salt.modules.oracle

Oracle DataBase connection module

**maintainer** Vladimir Bormotov <bormotov@gmail.com>

**maturity** new

**depends** cx\_Oracle

**platform** all

**configuration** module provide connections for multiple Oracle DB instances.

**OS Environment**

ORACLE\_HOME: path to oracle product

PATH: path to Oracle Client libs need to be in PATH

**pillar**

```
oracle.dbs: list of known based
oracle.dbs.<db>.uri: connection credentials in format:
    user/password@host[:port]/sid[ as {sysdba|sysoper}]
```

**salt.modules.oracle.client\_version()**  
Oracle Client Version

CLI Example:

```
salt '*' oracle.client_version
```

**salt.modules.oracle.run\_query(*db, query*)**  
Run SQL query and return result

CLI Example:

```
salt '*' oracle.run_query my_db "select * from my_table"
```

**salt.modules.oracle.show\_dbs(*\*dbs*)**  
Show databases configuration from pillar. Filter by *\*args*

CLI Example:

```
salt '*' oracle.show_dbs
salt '*' oracle.show_dbs my_db
```

**salt.modules.oracle.show\_env()**  
Show Environment used by Oracle Client

CLI Example:

```
salt '*' oracle.show_env
```

---

**Note:** at first `_connect()` NLS\_LANG will forced to ``.AL32UTF8'`

---

**salt.modules.oracle.show\_pillar(*item=None*)**  
Show Pillar segment oracle.\* and subitem with notation ```item:subitem''`

CLI Example:

```
salt '*' oracle.show_pillar
salt '*' oracle.show_pillar dbs:my_db
```

**salt.modules.oracle.version(*\*dbs*)**  
Server Version (select banner from v\$version)

CLI Example:

```
salt '*' oracle.version
salt '*' oracle.version my_db
```

### 30.16.162 salt.modules.osxdesktop

Mac OS X implementations of various commands in the ```desktop''` interface

**salt.modules.osxdesktop.get\_output\_volume()**  
Get the output volume (range 0 to 100)

CLI Example:

```
salt '*' desktop.get_output_volume
```

`salt.modules.osxdesktop.lock()`

Lock the desktop session

CLI Example:

```
salt '*' desktop.lock
```

`salt.modules.osxdesktop.say(*words)`

Say some words.

CLI Example:

```
salt '*' desktop.say <word0> <word1> ... <wordN>
```

`salt.modules.osxdesktop.screensaver()`

Launch the screensaver

CLI Example:

```
salt '*' desktop.screensaver
```

`salt.modules.osxdesktop.set_output_volume(volume)`

Set the volume of sound (range 0 to 100)

CLI Example:

```
salt '*' desktop.set_output_volume <volume>
```

### 30.16.163 salt.modules.pacman

A module to wrap pacman calls, since Arch is the best ([https://wiki.archlinux.org/index.php/Arch\\_is\\_the\\_best](https://wiki.archlinux.org/index.php/Arch_is_the_best))

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install is not available`), see [here](#).

`salt.modules.pacman.file_dict(*packages)`

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of `_every_file` on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.pacman.file_list(*packages)`

List the files that belong to a package. Not specifying any packages will return a list of `_every_file` on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.pacman.install`(*name=None, refresh=False, sysupgrade=False, pkgs=None, sources=None, \*\*kwargs*)

Install (pacman -S) the passed package, add `refresh=True` to install with `-y`, add `sysupgrade=True` to install with `-u`.

**name** The name of the package to be installed. Note that this parameter is ignored if either `pkgs` or `sources` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `sources` option.

CLI Example:

```
salt '*' pkg.install <package name>
```

**refresh** Whether or not to refresh the package database before installing.

**sysupgrade** Whether or not to upgrade the system packages before installing.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. As with the `version` parameter above, comparison operators can be used to target a specific version of a package.

CLI Examples:

```
salt '*' pkg.install pkgs=['foo', 'bar']
salt '*' pkg.install pkgs=['foo', {'bar': '1.2.3-4'}]
salt '*' pkg.install pkgs=['foo', {'bar': '<1.2.3-4'}]
```

**sources** A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources=[{"foo": "salt://foo.pkg.tar.xz"},
```

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

`salt.modules.pacman.latest_version`(*\*names, \*\*kwargs*)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

`salt.modules.pacman.list_pkgs`(*versions\_as\_list=False, \*\*kwargs*)

List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

`salt.modules.pacman.list_upgrades` (*refresh=False*)

List all available package upgrades on this system

CLI Example:

```
salt '*' pkg.list_upgrades
```

`salt.modules.pacman.owner` (*\*paths*)

New in version 2014.7.0.

Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version` <`salt.modules.yumpkg.version`, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Example:

```
salt '*' pkg.owner /usr/bin/apachectl salt '*' pkg.owner /usr/bin/apachectl /usr/bin/zsh
```

`salt.modules.pacman.purge` (*name=None, pkgs=None, \*\*kwargs*)

Recursively remove a package and all dependencies which were installed with it, this will call a `pacman -Rsc`

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>, <package2>, <package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

`salt.modules.pacman.refresh_db` ()

Just run a `pacman -Sy`, return a dict:

```
{'<database name>': Bool}
```

CLI Example:

```
salt '*' pkg.refresh_db
```

`salt.modules.pacman.remove` (*name=None, pkgs=None, \*\*kwargs*)

Remove packages with `pacman -R`.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

**salt.modules.pacman.upgrade** (*refresh=False, \*\*kwargs*)

Run a full system upgrade, a pacman -Syu

**refresh** Whether or not to refresh the package database before installing.

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

**salt.modules.pacman.upgrade\_available** (*name*)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

**salt.modules.pacman.version** (*\*names, \*\*kwargs*)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

### 30.16.164 salt.modules.pagerduty

Module for Firing Events via PagerDuty

New in version 2014.1.0.

**configuration** This module can be used by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```
my-pagerduty-account:
  pagerduty.api_key: F3Rbyjbve43rffWf2214
  pagerduty.subdomain: mysubdomain
```

**salt.modules.pagerduty.create\_event** (*service\_key=None, description=None, details=None, incident\_key=None, profile=None*)

Create an event in PagerDuty. Designed for use in states.

CLI Example:

```
salt myminion pagerduty.create_event <service_key> <description> <details>
```

profile=my-pa

The following parameters are required:

**service\_key** This key can be found by using `pagerduty.list_services`.

**description** This is a short description of the event.

**details** This can be a more detailed description of the event.

**profile** This refers to the configuration profile to use to connect to the PagerDuty service.

`salt.modules.pagerduty.list_escalation_policies` (*profile=None, api\_key=None*)

List escalation policies belonging to this account

CLI Example:

```
salt myminion pagerduty.list_policies my-pagerduty-account salt myminion pager-
duty.list_escalation_policies my-pagerduty-account
```

`salt.modules.pagerduty.list_incidents` (*profile=None, api\_key=None*)

List incidents belonging to this account

CLI Example:

```
salt myminion pagerduty.list_incidents my-pagerduty-account
```

`salt.modules.pagerduty.list_maintenance_windows` (*profile=None, api\_key=None*)

List maintenance windows belonging to this account

CLI Example:

```
salt myminion pagerduty.list_windows my-pagerduty-account salt myminion pager-
duty.list_maintenance_windows my-pagerduty-account
```

`salt.modules.pagerduty.list_policies` (*profile=None, api\_key=None*)

List escalation policies belonging to this account

CLI Example:

```
salt myminion pagerduty.list_policies my-pagerduty-account salt myminion pager-
duty.list_escalation_policies my-pagerduty-account
```

`salt.modules.pagerduty.list_schedules` (*profile=None, api\_key=None*)

List schedules belonging to this account

CLI Example:

```
salt myminion pagerduty.list_schedules my-pagerduty-account
```

`salt.modules.pagerduty.list_services` (*profile=None, api\_key=None*)

List services belonging to this account

CLI Example:

```
salt myminion pagerduty.list_services my-pagerduty-account
```

`salt.modules.pagerduty.list_users` (*profile=None, api\_key=None*)

List users belonging to this account

CLI Example:

```
salt myminion pagerduty.list_users my-pagerduty-account
```

`salt.modules.pagerduty.list_windows` (*profile=None, api\_key=None*)

List maintenance windows belonging to this account

CLI Example:

```
salt myminion pagerduty.list_windows my-pagerduty-account salt myminion pager-
duty.list_maintenance_windows my-pagerduty-account
```

### 30.16.165 salt.modules.pam

Support for pam

`salt.modules.pam.read_file`(*file\_name*)

This is just a test function, to make sure parsing works

CLI Example:

```
salt '*' pam.read_file /etc/pam.d/login
```

### 30.16.166 salt.modules.parted

Module for managing partitions on POSIX-like systems.

**depends**

- parted, partprobe, lsblk (usually parted and util-linux packages)

Some functions may not be available, depending on your version of parted.

Check the manpage for `parted(8)` for more information, or the online docs at:

[http://www.gnu.org/software/parted/manual/html\\_chapter/parted\\_2.html](http://www.gnu.org/software/parted/manual/html_chapter/parted_2.html)

In light of parted not directly supporting partition IDs, some of this module has been written to utilize sfdisk instead. For further information, please reference the man page for `sfdisk(8)`.

`salt.modules.parted.align_check`(*device*, *part\_type*, *partition*)

`partition.align_check` *device* *part\_type* *partition*

Check if partition satisfies the alignment constraint of *part\_type*. Type must be ``minimal" or ``optimal".

CLI Example:

```
salt '*' partition.align_check /dev/sda minimal 1
```

`salt.modules.parted.check`(*device*, *minor*)

`partition.check` *device* *minor*

Checks if the file system on partition <minor> has any errors.

CLI Example:

```
salt '*' partition.check 1
```

`salt.modules.parted.cp`(*device*, *from\_minor*, *to\_minor*)

`partition.check` *device* *from\_minor* *to\_minor*

**Copies the file system on the partition <from-minor> to partition <to-minor>**, deleting the original contents of the destination partition.

CLI Example:

```
salt '*' partition.cp /dev/sda 2 3
```

`salt.modules.parted.exists`(*device*='')

`partition.exists` *device*

Check to see if the partition exists

CLI Example:

```
salt '*' partition.exists /dev/sdb1
```

### `salt.modules.parted.get_block_device()`

Retrieve a list of disk devices

New in version 2014.7.0.

CLI Example:

```
salt '*' partition.get_block_device
```

### `salt.modules.parted.get_id(device, minor)`

Prints the system ID for the partition. Some typical values are:

```
b: FAT32 (vfat)
7: HPFS/NTFS
82: Linux Swap
83: Linux
8e: Linux LVM
fd: Linux RAID Auto
```

CLI Example:

```
salt '*' partition.get_id /dev/sda 1
```

### `salt.modules.parted.list_(device, unit=None)`

partition.list device unit

Prints partition information of given <device>

CLI Examples:

```
salt '*' partition.list /dev/sda
salt '*' partition.list /dev/sda unit=s
salt '*' partition.list /dev/sda unit=kB
```

### `salt.modules.parted.mkfs(device, fs_type)`

partition.mkfs device fs\_type

Makes a file system <fs\_type> on partition <device>, destroying all data that resides on that partition. <fs\_type> must be one of ``ext2``, ``fat32``, ``fat16``, ``linux-swap`` or ``reiserfs`` (if libreiserfs is installed)

CLI Example:

```
salt '*' partition.mkfs /dev/sda2 fat32
```

### `salt.modules.parted.mklablel(device, label_type)`

partition.mklablel device label\_type

Create a new disklabel (partition table) of label\_type. Type should be one of ``aix``, ``amiga``, ``bsd``, ``dvh``, ``gpt``, ``loop``, ``mac``, ``msdos``, ``pc98``, or ``sun``.

CLI Example:

```
salt '*' partition.mklablel /dev/sda msdos
```

### `salt.modules.parted.mkpart(device, part_type, fs_type=None, start=None, end=None)`

partition.mkpart device part\_type fs\_type start end

Make a part\_type partition for filesystem fs\_type, beginning at start and ending at end (by default in megabytes). part\_type should be one of ``primary``, ``logical``, or ``extended``.

CLI Examples:

```
salt '*' partition.mkpart /dev/sda primary fs_type=fat32 start=0 end=639
salt '*' partition.mkpart /dev/sda primary start=0 end=639
```

`salt.modules.parted.mkpartfs`(*device, part\_type, fs\_type, start, end*)  
partition.mkpartfs device part\_type fs\_type start end

Make a <part\_type> partition with a new filesystem of <fs\_type>, beginning at <start> and ending at <end> (by default in megabytes). <part\_type> should be one of ``primary'', ``logical'', or ``extended''. <fs\_type> must be one of ``ext2'', ``fat32'', ``fat16'', ``linux-swap'' or ``reiserfs'' (if libreiserfs is installed)

CLI Example:

```
salt '*' partition.mkpartfs /dev/sda logical ext2 440 670
```

`salt.modules.parted.name`(*device, partition, name*)  
partition.name device partition name

Set the name of partition to name. This option works only on Mac, PC98, and GPT disklabels. The name can be placed in quotes, if necessary.

CLI Example:

```
salt '*' partition.name /dev/sda 1 'My Documents'
```

`salt.modules.parted.part_list`(*device, unit=None*)  
Deprecated. Calls partition.list.

CLI Examples:

```
salt '*' partition.part_list /dev/sda
salt '*' partition.part_list /dev/sda unit=s
salt '*' partition.part_list /dev/sda unit=kB
```

`salt.modules.parted.probe`(*\*devices, \*\*kwargs*)

Ask the kernel to update its local partition data. When no args are specified all block devices are tried.

Caution: Generally only works on devices with no mounted partitions and may take a long time to return if specified devices are in use.

CLI Examples:

```
salt '*' partition.probe
salt '*' partition.probe /dev/sda
salt '*' partition.probe /dev/sda /dev/sdb
```

`salt.modules.parted.rescue`(*device, start, end*)  
partition.rescue device start end

Rescue a lost partition that was located somewhere between start and end. If a partition is found, parted will ask if you want to create an entry for it in the partition table.

CLI Example:

```
salt '*' partition.rescue /dev/sda 0 8056
```

`salt.modules.parted.resize`(*device, minor, start, end*)  
partition.resize device minor, start, end

Resizes the partition with number <minor>. The partition will start <start> from the beginning of the disk, and end <end> from the beginning of the disk. resize never changes the minor number. Extended partitions can be resized, so long as the new extended partition completely contains all logical partitions.

CLI Example:

```
salt '*' partition.resize /dev/sda 3 200 850
```

`salt.modules.parted.rm(device, minor)`  
 partition.rm device minor

Removes the partition with number <minor>.

CLI Example:

```
salt '*' partition.rm /dev/sda 5
```

`salt.modules.parted.set_(device, minor, flag, state)`  
 partition.set device minor flag state

Changes a flag on the partition with number <minor>. A flag can be either ``on" or ``off". Some or all of these flags will be available, depending on what disk label you are using.

CLI Example:

```
salt '*' partition.set /dev/sda 1 boot on
```

`salt.modules.parted.set_id(device, minor, system_id)`  
 Sets the system ID for the partition. Some typical values are:

```
b: FAT32 (vfat)
7: HPFS/NTFS
82: Linux Swap
83: Linux
8e: Linux LVM
fd: Linux RAID Auto
```

CLI Example:

```
salt '*' partition.set_id /dev/sda 1 83
```

`salt.modules.parted.system_types()`  
 List the system types that are supported by the installed version of sfdisk

CLI Example:

```
salt '*' partition.system_types
```

`salt.modules.parted.toggle(device, partition, flag)`  
 partition.toggle device partition flag

Toggle the state of <flag> on <partition>

CLI Example:

```
salt '*' partition.name /dev/sda 1 boot
```

### 30.16.167 salt.modules.pecl

Manage PHP pecl extensions.

`salt.modules.pecl.install(pecls, defaults=False, force=False, preferred_state='stable')`  
 New in version 0.17.0.

Installs one or several pecl extensions.

**pecls** The pecl extensions to install.

**defaults** Use default answers for extensions such as `pecl_http` which ask questions before installation. Without this option, the `pecl.installed` state will hang indefinitely when trying to install these extensions.

**force** Whether to force the installed version or not

CLI Example:

```
salt '*' pecl.install fuse
```

`salt.modules.pecl.list_(channel=None)`

List installed pecl extensions.

CLI Example:

```
salt '*' pecl.list
```

`salt.modules.pecl.uninstall(pecls)`

Uninstall one or several pecl extensions.

**pecls** The pecl extensions to uninstall.

CLI Example:

```
salt '*' pecl.uninstall fuse
```

`salt.modules.pecl.update(pecls)`

Update one or several pecl extensions.

**pecls** The pecl extensions to update.

CLI Example:

```
salt '*' pecl.update fuse
```

### 30.16.168 salt.modules.pillar

Extract the pillar data for this minion

`salt.modules.pillar.ext(external, pillar=None)`

Generate the pillar and apply an explicit external pillar

CLI Example:

**pillar** [None] If specified, allows for a dictionary of pillar data to be made available to pillar and `ext_pillar` rendering. These pillar variables will also override any variables of the same name in pillar or `ext_pillar`.

New in version 2015.5.0.

```
salt '*' pillar.ext '{libvirt: _}'
```

`salt.modules.pillar.get(key, default=<type `exceptions.KeyError`>, merge=False, delimiter=':')`

New in version 0.14.

Attempt to retrieve the named value from pillar, if the named value is not available return the passed default. The default return is an empty string except `__opts__['PILLAR_RAISE_ON_MISSING']` is set to True, in which case a `KeyError` will be raised.

If the merge parameter is set to True, the default will be recursively merged into the returned pillar data.

The value can also represent a value in a nested dict using a ":" delimiter for the dict. This means that if a dict in pillar looks like this:

```
{'pkg': {'apache': 'httpd'}}
```

To retrieve the value associated with the apache key in the pkg dict this key can be passed:

```
pkg:apache
```

**merge** Specify whether or not the retrieved values should be recursively merged into the passed default.

New in version 2014.7.0.

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

CLI Example:

```
salt '*' pillar.get pkg:apache
```

**salt.modules.pillar.item**(\*args, \*\*kwargs)

New in version 0.16.2.

Return one or more pillar entries

**pillar** [none] if specified, allows for a dictionary of pillar data to be made available to pillar and ext\_pillar rendering. these pillar variables will also override any variables of the same name in pillar or ext\_pillar.

New in version 2015.5.0.

CLI Examples:

```
salt '*' pillar.item foo
salt '*' pillar.item foo bar baz
```

**salt.modules.pillar.items**(\*args, \*\*kwargs)

Calls the master for a fresh pillar and generates the pillar data on the fly

Contrast with *raw()* which returns the pillar data that is currently loaded into the minion.

**pillar** [none] if specified, allows for a dictionary of pillar data to be made available to pillar and ext\_pillar rendering. these pillar variables will also override any variables of the same name in pillar or ext\_pillar.

New in version 2015.5.0.

CLI Example:

```
salt '*' pillar.items
```

**salt.modules.pillar.raw**(key=None)

Return the raw pillar data that is currently loaded into the minion.

Contrast with *items()* which calls the master to fetch the most up-to-date Pillar.

CLI Example:

```
salt '*' pillar.raw
```

With the optional key argument, you can select a subtree of the pillar raw data.:

```
salt '*' pillar.raw key='roles'
```

### 30.16.169 salt.modules.pip

Install Python packages with pip to either the system or a virtualenv

#### Windows Support

New in version 2014.7.4.

Salt now uses a portable python. As a result the entire pip module is now functional on the salt installation itself. You can pip install dependencies for your custom modules. You can even upgrade salt itself using pip. For this to work properly, you must specify the Current Working Directory (`cwd`) and the Pip Binary (`bin_env`) salt should use. The variable `pip_bin` can be either a virtualenv path or the path to the pip binary itself.

For example, the following command will list all software installed using pip to your current salt environment:

```
salt <minion> pip.list cwd='C:\salt\bin\Scripts' bin_env='C:\salt\bin\Scripts\pip.exe'
```

Specifying the `cwd` and `bin_env` options ensures you're modifying the salt environment. If these are omitted, it will default to the local installation of python. If python is not installed locally it will fail saying it couldn't find pip.

#### State File Support

This functionality works in states as well. If you need to pip install colorama with a state, for example, the following will work:

```
install_colorama:
  pip.installed:
    - name: colorama
    - cwd: 'C:\salt\bin\scripts'
    - bin_env: 'C:\salt\bin\scripts\pip.exe'
    - upgrade: True
```

#### Upgrading Salt using Pip

You can now update salt using pip to any version from the 2014.7 branch forward. Previous version require recompiling some of the dependencies which is painful in windows.

To do this you just use pip with git to update to the version you want and then restart the service. Here is a sample state file that upgrades salt to the head of the 2015.5 branch:

```
install_salt:
  pip.installed:
    - cwd: 'C:\salt\bin\scripts'
    - bin_env: 'C:\salt\bin\scripts\pip.exe'
    - editable: git+https://github.com/saltstack/salt@2015.5#egg=salt
    - upgrade: True

restart_service:
  service.running:
    - name: salt-minion
    - enable: True
    - watch:
      - pip: install_salt
```

---

**Note:** If you're having problems, you might try doubling the back slashes. For example, `cwd: `C:\salt\bin\scripts``. Sometimes python thinks the single back slash is an escape character.

---

`salt.modules.pip.freeze`(*bin\_env=None, user=None, cwd=None, use\_vt=False*)

Return a list of installed packages either globally or in the specified virtualenv

**bin\_env** path to pip bin or path to virtualenv. If doing an uninstall from the system python and want to use a specific pip bin (pip-2.7, pip-2.6, etc..) just specify the pip bin you want. If uninstalling from a virtualenv, just use the path to the virtualenv (/home/code/path/to/virtualenv/)

**user** The user under which to run pip

**cwd** Current working directory to run pip from

CLI Example:

```
salt '*' pip.freeze /home/code/path/to/virtualenv/
```

`salt.modules.pip.install`(*pkgs=None, requirements=None, env=None, bin\_env=None, use\_wheel=False, no\_use\_wheel=False, log=None, proxy=None, timeout=None, editable=None, find\_links=None, index\_url=None, extra\_index\_url=None, no\_index=False, mirrors=None, build=None, target=None, download=None, download\_cache=None, source=None, upgrade=False, force\_reinstall=False, ignore\_installed=False, exists\_action=None, no\_deps=False, no\_install=False, no\_download=False, global\_options=None, install\_options=None, user=None, no\_chown=False, cwd=None, activate=False, pre\_releases=False, cert=None, allow\_all\_external=False, allow\_external=None, allow\_unverified=None, process\_dependency\_links=False, \_\_env\_\_=None, saltenv='base', env\_vars=None, use\_vt=False*)

Install packages with pip

Install packages individually or from a pip requirements file. Install packages globally or to a virtualenv.

**pkgs** Comma separated list of packages to install

**requirements** Path to requirements

**bin\_env** Path to pip bin or path to virtualenv. If doing a system install, and want to use a specific pip bin (pip-2.7, pip-2.6, etc..) just specify the pip bin you want.

---

**Note:** If installing into a virtualenv, just use the path to the virtualenv (e.g. /home/code/path/to/virtualenv/)

---

**env** Deprecated, use `bin_env` now

**use\_wheel** Prefer wheel archives (requires pip>=1.4)

**no\_use\_wheel** Force to not use wheel archives (requires pip>=1.4)

**log** Log file where a complete (maximum verbosity) record will be kept

**proxy** Specify a proxy in the form `user:passwd@proxy.server:port`. Note that the `user:password@` is optional and required only if you are behind an authenticated proxy. If you provide `user@proxy.server:port` then you will be prompted for a password.

**timeout** Set the socket timeout (default 15 seconds)

**editable** install something editable (e.g. `git+https://github.com/worldcompany/djangoembed.git#egg=dja`)

**find\_links** URL to search for packages

**index\_url** Base URL of Python Package Index

**extra\_index\_url** Extra URLs of package indexes to use in addition to `index_url`

**no\_index** Ignore package index

**mirrors** Specific mirror URL(s) to query (automatically adds `--use-mirrors`)

**build** Unpack packages into `build` dir

**target** Install packages into `target` dir

**download** Download packages into `download` instead of installing them

**download\_cache** Cache downloaded packages in `download_cache` dir

**source** Check out `editable` packages into `source` dir

**upgrade** Upgrade all packages to the newest available version

**force\_reinstall** When upgrading, reinstall all packages even if they are already up-to-date.

**ignore\_installed** Ignore the installed packages (reinstalling instead)

**exists\_action** Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup

**no\_deps** Ignore package dependencies

**no\_install** Download and unpack all packages, but don't actually install them

**no\_download** Don't download any packages, just install the ones already downloaded (completes an install run with `--no-install`)

**install\_options** Extra arguments to be supplied to the `setup.py` install command (e.g. like `--install-option='--install-scripts=/usr/local/bin'`). Use multiple `--install-option` options to pass multiple options to `setup.py` install. If you are using an option with a directory path, be sure to use absolute path.

**global\_options** Extra global options to be supplied to the `setup.py` call before the install command.

**user** The user under which to run pip

**no\_chown** When user is given, do not attempt to copy and `chown` a requirements file

**cwd** Current working directory to run pip from

**activate** Activates the virtual environment, if given via `bin_env`, before running install.

Deprecated since version 2014.7.2: If `bin_env` is given, pip will already be sourced from that virtualenv, making `activate` effectively a noop.

**pre\_releases** Include pre-releases in the available versions

**cert** Provide a path to an alternate CA bundle

**allow\_all\_external** Allow the installation of all externally hosted files

**allow\_external** Allow the installation of externally hosted files (comma separated list)

**allow\_unverified** Allow the installation of insecure and unverifiable files (comma separated list)

**process\_dependency\_links** Enable the processing of dependency links

**env\_vars** Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs `INCLUDE_PATH` set to pick up a header file while compiling. This must be in the form of a dictionary or a mapping.

Example:

```
salt '*' pip.install django_app env_vars="{ 'CUSTOM_PATH': '/opt/django_app' }"
```

**use\_vt** Use VT terminal emulation (see output while installing)

CLI Example:

```
salt '*' pip.install <package name>, <package2 name>
salt '*' pip.install requirements=/path/to/requirements.txt
salt '*' pip.install <package name> bin_env=/path/to/virtualenv
salt '*' pip.install <package name> bin_env=/path/to/pip_bin
```

Complicated CLI example:

```
salt '*' pip.install markdown,django editable=git+https://github.com/worldcompan
```

**salt.modules.pip.list\_** (*prefix=None, bin\_env=None, user=None, cwd=None*)

Filter list of installed apps from freeze and check to see if `prefix` exists in the list of packages installed.

CLI Example:

```
salt '*' pip.list salt
```

**salt.modules.pip.list\_upgrades** (*bin\_env=None, user=None, cwd=None*)

Check whether or not an upgrade is available for all packages

CLI Example:

```
salt '*' pip.list_upgrades
```

**salt.modules.pip.uninstall** (*pkgs=None, requirements=None, bin\_env=None, log=None, proxy=None, timeout=None, user=None, no\_chown=False, cwd=None, \_\_env\_\_=None, saltenv='base', use\_vt=False*)

Uninstall packages with pip

Uninstall packages individually or from a pip requirements file. Uninstall packages globally or from a virtualenv.

**pkgs** comma separated list of packages to install

**requirements** path to requirements.

**bin\_env** path to pip bin or path to virtualenv. If doing an uninstall from the system python and want to use a specific pip bin (pip-2.7, pip-2.6, etc..) just specify the pip bin you want. If uninstalling from a virtualenv, just use the path to the virtualenv (/home/code/path/to/virtualenv/)

**log** Log file where a complete (maximum verbosity) record will be kept

**proxy** Specify a proxy in the form `user:passwd@proxy.server:port`. Note that the `user:password@` is optional and required only if you are behind an authenticated proxy. If you provide `user@proxy.server:port` then you will be prompted for a password.

**timeout** Set the socket timeout (default 15 seconds)

**user** The user under which to run pip

**no\_chown** When user is given, do not attempt to copy and chown a requirements file (needed if the requirements file refers to other files via relative paths, as the copy-and-chown procedure does not account for such files)

**cwd** Current working directory to run pip from

**use\_vt** Use VT terminal emulation (see output while installing)

CLI Example:

```
salt '*' pip.uninstall <package name>,<package2 name>
salt '*' pip.uninstall requirements=/path/to/requirements.txt
salt '*' pip.uninstall <package name> bin_env=/path/to/virtualenv
salt '*' pip.uninstall <package name> bin_env=/path/to/pip_bin
```

**salt.modules.pip.upgrade**(*bin\_env=None, user=None, cwd=None, use\_vt=False*)  
New in version 2015.5.0.

Upgrades outdated pip packages

Returns a dict containing the changes.

```
{`<package>`: {`old`: `<old-version>`, `new`: `<new-version>`}}
```

CLI Example:

```
salt '*' pip.upgrade
```

**salt.modules.pip.upgrade\_available**(*pkg, bin\_env=None, user=None, cwd=None*)  
New in version 2015.5.0.

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pip.upgrade_available <package name>
```

**salt.modules.pip.version**(*bin\_env=None*)  
New in version 0.17.0.

Returns the version of pip. Use *bin\_env* to specify the path to a virtualenv and get the version of pip in that virtualenv.

If unable to detect the pip version, returns None.

CLI Example:

```
salt '*' pip.version
```

### 30.16.170 salt.modules.pkg\_resource

Resources needed by pkg providers

**salt.modules.pkg\_resource.add\_pkg**(*pkgs, name, version*)  
Add a package to a dict of installed packages.

CLI Example:

```
salt '*' pkg_resource.add_pkg '{}' bind 9
```

**salt.modules.pkg\_resource.check\_extra\_requirements**(*pkgname, pkgver*)  
Check if the installed package already has the given requirements. This function will simply try to call ``pkg.check\_extra\_requirements``.

CLI Example:

```
salt '*' pkg_resource.check_extra_requirements <pkgname> <extra_requirements>
```

`salt.modules.pkg_resource.pack_sources` (*sources*)

Accepts list of dicts (or a string representing a list of dicts) and packs the key/value pairs into a single dict.

'[{"foo": "salt://foo.rpm"}, {"bar": "salt://bar.rpm"}]' would become {"foo": "salt://foo.rpm", "bar": "salt://bar.rpm"}

CLI Example:

```
salt '*' pkg_resource.pack_sources '[{"foo": "salt://foo.rpm"}, {"bar": "salt://bar.rpm"}]'
```

`salt.modules.pkg_resource.parse_targets` (*name=None, pkgs=None, sources=None, saltenv='base', normalize=True, \*\*kwargs*)

Parses the input to `pkg.install` and returns back the package(s) to be installed. Returns a list of packages, as well as a string noting whether the packages are to come from a repository or a binary package.

CLI Example:

```
salt '*' pkg_resource.parse_targets
```

`salt.modules.pkg_resource.sort_pkglist` (*pkgs*)

Accepts a dict obtained from `pkg.list_pkgs()` and sorts in place the list of versions for any packages that have multiple versions installed, so that two package lists can be compared to one another.

CLI Example:

```
salt '*' pkg_resource.sort_pkglist '["3.45", "2.13"]'
```

`salt.modules.pkg_resource.stringify` (*pkgs*)

Takes a dict of package name/version information and joins each list of installed versions into a string.

CLI Example:

```
salt '*' pkg_resource.stringify 'vim: 7.127'
```

`salt.modules.pkg_resource.version` (*\*names, \*\*kwargs*)

Common interface for obtaining the version of installed packages.

CLI Example:

```
salt '*' pkg_resource.version vim
salt '*' pkg_resource.version foo bar baz
salt '*' pkg_resource.version 'python*'
```

`salt.modules.pkg_resource.version_clean` (*version*)

Clean the version string removing extra data. This function will simply try to call `pkg.version_clean`.

CLI Example:

```
salt '*' pkg_resource.version_clean <version_string>
```

### 30.16.171 salt.modules.pkgin

Package support for pkgin based systems, inspired from `freebsd/pkg` module

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

`salt.modules.pkgin.available_version` (*\*names, \*\*kwargs*)

Return the latest version of the named package available for upgrade or installation.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> ...
```

`salt.modules.pkgin.file_dict`(*package*)

List the files that belong to a package.

CLI Examples:

```
salt '*' pkg.file_list nginx
```

`salt.modules.pkgin.file_list`(*package*)

List the files that belong to a package.

CLI Examples:

```
salt '*' pkg.file_list nginx
```

`salt.modules.pkgin.install`(*name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, \*\*kwargs*)

Install the passed package

**name** The name of the package to be installed.

**refresh** Whether or not to refresh the package database before installing.

**fromrepo** Specify a package repository to install from.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs=['foo','bar']
```

**sources** A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources=[{"foo": "salt://foo.deb"}, {"bar": "salt://bar.deb"}]
```

Return a dict containing the new package names and versions:

```
{<package>: {'old': <old-version>,
              'new': <new-version>}}
```

CLI Example:

```
salt '*' pkg.install <package name>
```

`salt.modules.pkgin.latest_version`(\*names, \*\*kwargs)

Return the latest version of the named package available for upgrade or installation.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> ...
```

`salt.modules.pkgin.list_pkgs` (*versions\_as\_list=False, \*\*kwargs*)  
List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

`salt.modules.pkgin.purge` (*name=None, pkgs=None, \*\*kwargs*)  
Package purges are not supported, this function is identical to `remove()`.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs=['foo', 'bar']
```

`salt.modules.pkgin.refresh_db`()  
Use pkg update to get latest pkg\_summary

CLI Example:

```
salt '*' pkg.refresh_db
```

`salt.modules.pkgin.remove` (*name=None, pkgs=None, \*\*kwargs*)

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a list containing the removed packages.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

`salt.modules.pkgin.search` (*pkg\_name*)  
Searches for an exact match using `pkgin ^package$`

CLI Example:

```
salt '*' pkg.search 'mysql-server'
```

`salt.modules.pkgin.upgrade`()  
Run pkg upgrade, if pkgin used. Otherwise do nothing

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',  
              'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

**salt.modules.pkgin.version** (\*names, \*\*kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>  
salt '*' pkg.version <package1> <package2> <package3> ...
```

### 30.16.172 salt.modules.pkgng

Support for pkgng, the new package manager for FreeBSD

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install` is not available), see [here](#).

**Warning:** This module has been completely rewritten. Up to and including version 0.17.x, it was available as the `pkgng` module, (`pkgng.install`, `pkgng.delete`, etc.), but moving forward this module will no longer be available as `pkgng`, as it will behave like a normal Salt `pkg` provider. The documentation below should not be considered to apply to this module in versions `<= 0.17.x`. If your minion is running a 0.17.x release or older, then the documentation for this module can be viewed using the `sys.doc` function:

```
salt bsdminion sys.doc pkgng
```

This module provides an interface to `pkg(8)`. It acts as the default package provider for FreeBSD 10 and newer. For FreeBSD hosts which have been upgraded to use `pkgng`, you will need to override the `pkg` provider by setting the `providers` parameter in your Minion config file, in order to use this module to manage packages, like so:

```
providers:  
  pkg: pkgng
```

**salt.modules.pkgng.audit** (jail=None, chroot=None)

Audits installed packages against known vulnerabilities

CLI Example:

```
salt '*' pkg.audit
```

**jail** Audit packages within the specified jail

CLI Example:

```
salt '*' pkg.audit jail=<jail name or id>
```

**chroot** Audit packages within the specified chroot (ignored if `jail` is specified)

CLI Example:

```
salt '*' pkg.audit chroot=/path/to/chroot
```

`salt.modules.pkgng.autoremove` (*jail=None, chroot=None, dryrun=False*)

Delete packages which were automatically installed as dependencies and are not required anymore.

**dryrun** Dry-run mode. The list of changes to packages is always printed, but no changes are actually made.

CLI Example:

```
salt '*' pkg.autoremove
salt '*' pkg.autoremove jail=<jail name or id>
salt '*' pkg.autoremove dryrun=True
salt '*' pkg.autoremove jail=<jail name or id> dryrun=True
```

`salt.modules.pkgng.backup` (*file\_name, jail=None, chroot=None*)

Export installed packages into yaml+mtree file

CLI Example:

```
salt '*' pkg.backup /tmp/pkg
```

**jail** Backup packages from the specified jail. Note that this will run the command within the jail, and so the path to the backup file will be relative to the root of the jail

CLI Example:

```
salt '*' pkg.backup /tmp/pkg jail=<jail name or id>
```

**chroot** Backup packages from the specified chroot (ignored if `jail` is specified). Note that this will run the command within the chroot, and so the path to the backup file will be relative to the root of the chroot.

CLI Example:

```
salt '*' pkg.backup /tmp/pkg chroot=/path/to/chroot
```

`salt.modules.pkgng.check` (*jail=None, chroot=None, depends=False, recompute=False, checksum=False*)

Sanity checks installed packages

**jail** Perform the sanity check in the specified jail

CLI Example:

```
salt '*' pkg.check jail=<jail name or id>
```

**chroot** Perform the sanity check in the specified chroot (ignored if `jail` is specified)

CLI Example:

```
salt '*' pkg.check chroot=/path/to/chroot
```

Of the below, at least one must be set to `True`.

**depends** Check for and install missing dependencies.

CLI Example:

```
salt '*' pkg.check recompute=True
```

**recompute** Recompute sizes and checksums of installed packages.

CLI Example:

```
salt '*' pkg.check depends=True
```

**checksum** Find invalid checksums for installed packages.

CLI Example:

```
salt '*' pkg.check checksum=True
```

**salt.modules.pkgng.clean** (*jail=None, chroot=None*)

Cleans the local cache of fetched remote packages

CLI Example:

```
salt '*' pkg.clean
salt '*' pkg.clean jail=<jail name or id>
salt '*' pkg.clean chroot=/path/to/chroot
```

**salt.modules.pkgng.fetch** (*name, jail=None, chroot=None, fetch\_all=False, quiet=False, fromrepo=None, glob=True, regex=False, pcre=False, local=False, depends=False*)

Fetches remote packages

CLI Example:

```
salt '*' pkg.fetch <package name>
```

**jail** Fetch package in the specified jail

CLI Example:

```
salt '*' pkg.fetch <package name> jail=<jail name or id>
```

**chroot** Fetch package in the specified chroot (ignored if jail is specified)

CLI Example:

```
salt '*' pkg.fetch <package name> chroot=/path/to/chroot
```

**fetch\_all** Fetch all packages.

CLI Example:

```
salt '*' pkg.fetch <package name> fetch_all=True
```

**quiet** Quiet mode. Show less output.

CLI Example:

```
salt '*' pkg.fetch <package name> quiet=True
```

**fromrepo** Fetches packages from the given repo if multiple repo support is enabled. See `pkg.conf(5)`.

CLI Example:

```
salt '*' pkg.fetch <package name> fromrepo=repo
```

**glob** Treat `pkg_name` as a shell glob pattern.

CLI Example:

```
salt '*' pkg.fetch <package name> glob=True
```

**regex** Treat pkg\_name as a regular expression.

CLI Example:

```
salt '*' pkg.fetch <regular expression> regex=True
```

**pcre** Treat pkg\_name is an extended regular expression.

CLI Example:

```
salt '*' pkg.fetch <extended regular expression> pcre=True
```

**local** Skip updating the repository catalogs with pkg-update(8). Use the local cache only.

CLI Example:

```
salt '*' pkg.fetch <package name> local=True
```

**depends** Fetch the package and its dependencies as well.

CLI Example:

```
salt '*' pkg.fetch <package name> depends=True
```

**salt.modules.pkgng.install** (*name=None, fromrepo=None, pkgs=None, sources=None, jail=None, chroot=None, orphan=False, force=False, glob=False, local=False, dryrun=False, quiet=False, reinstall\_requires=False, regex=False, pcre=False, \*\*kwargs*)

Install package(s) from a repository

**name** The name of the package to install

CLI Example:

```
salt '*' pkg.install <package name>
```

**jail** Install the package into the specified jail

**chroot** Install the package into the specified chroot (ignored if jail is specified)

**orphan** Mark the installed package as orphan. Will be automatically removed if no other packages depend on them. For more information please refer to pkg-autoremove(8).

CLI Example:

```
salt '*' pkg.install <package name> orphan=True
```

**force** Force the reinstallation of the package if already installed.

CLI Example:

```
salt '*' pkg.install <package name> force=True
```

**glob** Treat the package names as shell glob patterns.

CLI Example:

```
salt '*' pkg.install <package name> glob=True
```

**local** Do not update the repository catalogs with `pkg-update(8)`. A value of `True` here is equivalent to using the `-U` flag with `pkg install`.

CLI Example:

```
salt '*' pkg.install <package name> local=True
```

**dryrun** Dry-run mode. The list of changes to packages is always printed, but no changes are actually made.

CLI Example:

```
salt '*' pkg.install <package name> dryrun=True
```

**quiet** Force quiet output, except when `dryrun` is used, where `pkg install` will always show packages to be installed, upgraded or deleted.

CLI Example:

```
salt '*' pkg.install <package name> quiet=True
```

**reinstall\_requires** When used with `force`, reinstalls any packages that require the given package.

CLI Example:

```
salt '*' pkg.install <package name> reinstall_requires=True force=True
```

Changed in version 2014.7.0: `require` kwarg renamed to `reinstall_requires`

**fromrepo** In multi-repo mode, override the `pkg.conf` ordering and only attempt to download packages from the named repository.

CLI Example:

```
salt '*' pkg.install <package name> fromrepo=repo
```

**regex** Treat the package names as a regular expression

CLI Example:

```
salt '*' pkg.install <regular expression> regex=True
```

**pcre** Treat the package names as extended regular expressions.

CLI Example:

```
salt '*' pkg.install <extended regular expression> pcre=True
```

`salt.modules.pkgng.latest_version(*names, **kwargs)`

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> jail=<jail name or id>
salt '*' pkg.latest_version <package name> chroot=/path/to/chroot
```

`salt.modules.pkgng.list_pkgs(versions_as_list=False, jail=None, chroot=None, with_origin=False, **kwargs)`

List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

**jail** List the packages in the specified jail

**chroot** List the packages in the specified chroot (ignored if `jail` is specified)

**with\_origin** [False] Return a nested dictionary containing both the origin name and version for each installed package.

New in version 2014.1.0.

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs jail=<jail name or id>
salt '*' pkg.list_pkgs chroot=/path/to/chroot
```

`salt.modules.pkgng.parse_config` (*file\_name='/usr/local/etc/pkg.conf'*)

Return dict of uncommented global variables.

CLI Example:

```
salt '*' pkg.parse_config
```

NOTE: not working properly right now

`salt.modules.pkgng.refresh_db` (*jail=None, chroot=None, force=False*)

Refresh PACKAGESITE contents

**Note:** This function can be accessed using `pkg.update` in addition to `pkg.refresh_db`, to more closely match the CLI usage of `pkg(8)`.

CLI Example:

```
salt '*' pkg.refresh_db
```

**jail** Refresh the pkg database within the specified jail

**chroot** Refresh the pkg database within the specified chroot (ignored if `jail` is specified)

**force** Force a full download of the repository catalog without regard to the respective ages of the local and remote copies of the catalog.

CLI Example:

```
salt '*' pkg.refresh_db force=True
```

`salt.modules.pkgng.remove` (*name=None, pkgs=None, jail=None, chroot=None, all\_installed=False, force=False, glob=False, dryrun=False, recurse=False, regex=False, pcre=False, \*\*kwargs*)

Remove a package from the database and system

**Note:** This function can be accessed using `pkg.delete` in addition to `pkg.remove`, to more closely match the CLI usage of `pkg(8)`.

**name** The package to remove

CLI Example:

```
salt '*' pkg.remove <package name>
```

**jail** Delete the package from the specified jail

**chroot** Delete the package from the specified chroot (ignored if `jail` is specified)

**all\_installed** Deletes all installed packages from the system and empties the database. USE WITH CAUTION!

CLI Example:

```
salt '*' pkg.remove all all_installed=True force=True
```

**force** Forces packages to be removed despite leaving unresolved dependencies.

CLI Example:

```
salt '*' pkg.remove <package name> force=True
```

**glob** Treat the package names as shell glob patterns.

CLI Example:

```
salt '*' pkg.remove <package name> glob=True
```

**dryrun** Dry run mode. The list of packages to delete is always printed, but no packages are actually deleted.

CLI Example:

```
salt '*' pkg.remove <package name> dryrun=True
```

**recurse** Delete all packages that require the listed package as well.

CLI Example:

```
salt '*' pkg.remove <package name> recurse=True
```

**regex** Treat the package names as regular expressions.

CLI Example:

```
salt '*' pkg.remove <regular expression> regex=True
```

**pcre** Treat the package names as extended regular expressions.

CLI Example:

```
salt '*' pkg.remove <extended regular expression> pcre=True
```

`salt.modules.pkgng.restore` (*file\_name*, *jail=None*, *chroot=None*)

Reads archive created by `pkg backup -d` and recreates the database.

CLI Example:

```
salt '*' pkg.restore /tmp/pkg
```

**jail** Restore database to the specified jail. Note that this will run the command within the jail, and so the path to the file from which the `pkg` database will be restored is relative to the root of the jail.

CLI Example:

```
salt '*' pkg.restore /tmp/pkg jail=<jail name or id>
```

**chroot** Restore database to the specified chroot (ignored if `jail` is specified). Note that this will run the command within the chroot, and so the path to the file from which the pkg database will be restored is relative to the root of the chroot.

CLI Example:

```
salt '*' pkg.restore /tmp/pkg chroot=/path/to/chroot
```

`salt.modules.pkgng.search`(*name*, *jail=None*, *chroot=None*, *exact=False*, *glob=False*, *regex=False*, *pcre=False*, *comment=False*, *desc=False*, *full=False*, *depends=False*, *size=False*, *quiet=False*, *origin=False*, *prefix=False*)

Searches in remote package repositories

CLI Example:

```
salt '*' pkg.search pattern
```

**jail** Perform the search using the `pkg.conf(5)` from the specified jail

CLI Example:

```
salt '*' pkg.search pattern jail=<jail name or id>
```

**chroot** Perform the search using the `pkg.conf(5)` from the specified chroot (ignored if `jail` is specified)

CLI Example:

```
salt '*' pkg.search pattern chroot=/path/to/chroot
```

**exact** Treat pattern as exact pattern.

CLI Example:

```
salt '*' pkg.search pattern exact=True
```

**glob** Treat pattern as a shell glob pattern.

CLI Example:

```
salt '*' pkg.search pattern glob=True
```

**regex** Treat pattern as a regular expression.

CLI Example:

```
salt '*' pkg.search pattern regex=True
```

**pcre** Treat pattern as an extended regular expression.

CLI Example:

```
salt '*' pkg.search pattern pcre=True
```

**comment** Search for pattern in the package comment one-line description.

CLI Example:

```
salt '*' pkg.search pattern comment=True
```

**desc** Search for pattern in the package description.

CLI Example:

```
salt '*' pkg.search pattern desc=True
```

**full** Displays full information about the matching packages.

CLI Example:

```
salt '*' pkg.search pattern full=True
```

**depends** Displays the dependencies of pattern.

CLI Example:

```
salt '*' pkg.search pattern depends=True
```

**size** Displays the size of the package

CLI Example:

```
salt '*' pkg.search pattern size=True
```

**quiet** Be quiet. Prints only the requested information without displaying many hints.

CLI Example:

```
salt '*' pkg.search pattern quiet=True
```

**origin** Displays pattern origin.

CLI Example:

```
salt '*' pkg.search pattern origin=True
```

**prefix** Displays the installation prefix for each package matching pattern.

CLI Example:

```
salt '*' pkg.search pattern prefix=True
```

`salt.modules.pkgng.stats` (*local=False, remote=False, jail=None, chroot=None*)

Return pkgng stats.

CLI Example:

```
salt '*' pkg.stats
```

**local** Display stats only for the local package database.

CLI Example:

```
salt '*' pkg.stats local=True
```

**remote** Display stats only for the remote package database(s).

CLI Example:

```
salt '*' pkg.stats remote=True
```

**jail** Retrieve stats from the specified jail.

CLI Example:

```

salt '*' pkg.stats jail=<jail name or id>
salt '*' pkg.stats jail=<jail name or id> local=True
salt '*' pkg.stats jail=<jail name or id> remote=True

```

**chroot** Retrieve stats from the specified chroot (ignored if `jail` is specified).

CLI Example:

```

salt '*' pkg.stats chroot=/path/to/chroot
salt '*' pkg.stats chroot=/path/to/chroot local=True
salt '*' pkg.stats chroot=/path/to/chroot remote=True

```

`salt.modules.pkgng.update_package_site(new_url)`

Updates remote package repo URL, `PACKAGESITE` var to be exact.

Must use `http://`, `ftp://`, or `https://` protocol

CLI Example:

```

salt '*' pkg.update_package_site http://127.0.0.1/

```

`salt.modules.pkgng.updating(name, jail=None, chroot=None, filedate=None, filename=None)`

` Displays UPDATING entries of software packages

CLI Example:

```

salt '*' pkg.updating foo

```

**jail** Perform the action in the specified jail

CLI Example:

```

salt '*' pkg.updating foo jail=<jail name or id>

```

**chroot** Perform the action in the specified chroot (ignored if `jail` is specified)

CLI Example:

```

salt '*' pkg.updating foo chroot=/path/to/chroot

```

**filedate** Only entries newer than date are shown. Use a YYYYMMDD date format.

CLI Example:

```

salt '*' pkg.updating foo filedate=20130101

```

**filename** Defines an alternative location of the UPDATING file.

CLI Example:

```

salt '*' pkg.updating foo filename=/tmp/UPDATING

```

`salt.modules.pkgng.upgrade(*names, **kwargs)`

Upgrade named or all packages (run a `pkg upgrade`). If `<package name>` is omitted, the operation is executed on all packages.

CLI Example:

```

salt '*' pkg.upgrade <package name>

```

**jail** Audit packages within the specified jail

CLI Example:

```
salt '*' pkg.upgrade <package name> jail=<jail name or id>
```

**chroot** Audit packages within the specified chroot (ignored if jail is specified)

CLI Example:

```
salt '*' pkg.upgrade <package name> chroot=/path/to/chroot
```

Any of the below options can also be used with jail or chroot.

**force** Force reinstalling/upgrading the whole set of packages.

CLI Example:

```
salt '*' pkg.upgrade <package name> force=True
```

**local** Do not update the repository catalogs with pkg-update(8). A value of True here is equivalent to using the -U flag with pkg upgrade.

CLI Example:

```
salt '*' pkg.upgrade <package name> local=True
```

**dryrun** Dry-run mode: show what packages have updates available, but do not perform any upgrades. Repository catalogs will be updated as usual unless the local option is also given.

CLI Example:

```
salt '*' pkg.upgrade <package name> dryrun=True
```

**salt.modules.pkgng.version** (\*names, \*\*kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

---

**Note:** This function can be accessed using `pkg.info` in addition to `pkg.version`, to more closely match the CLI usage of `pkg(8)`.

---

**jail** Get package version information for the specified jail

**chroot** Get package version information for the specified chroot (ignored if jail is specified)

**with\_origin** [False] Return a nested dictionary containing both the origin name and version for each specified package.

New in version 2014.1.0.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package name> jail=<jail name or id>
salt '*' pkg.version <package1> <package2> <package3> ...
```

**salt.modules.pkgng.which** (path, jail=None, chroot=None, origin=False, quiet=False)

Displays which package installed a specific file

CLI Example:

```
salt '*' pkg.which <file name>
```

**jail** Perform the check in the specified jail

CLI Example:

```
salt '*' pkg.which <file name> jail=<jail name or id>
```

**chroot** Perform the check in the specified chroot (ignored if jail is specified)

CLI Example:

```
salt '*' pkg.which <file name> chroot=/path/to/chroot
```

**origin** Shows the origin of the package instead of name-version.

CLI Example:

```
salt '*' pkg.which <file name> origin=True
```

**quiet** Quiet output.

CLI Example:

```
salt '*' pkg.which <file name> quiet=True
```

### 30.16.173 salt.modules.pkgutil

Pkgutil support for Solaris

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

**salt.modules.pkgutil.install**(*name=None, refresh=False, version=None, pkgs=None, \*\*kwargs*)  
Install packages using the pkgutil tool.

CLI Example:

```
salt '*' pkg.install <package_name>
salt '*' pkg.install SMClgcc346
```

Multiple Package Installation Options:

**pkgs** A list of packages to install from OpenCSW. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3"}]'
```

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

**salt.modules.pkgutil.latest\_version**(*\*names, \*\*kwargs*)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkgutil.latest_version CSWpython
salt '*' pkgutil.latest_version <package1> <package2> <package3> ...
```

`salt.modules.pkgutil.list_pkgs` (*versions\_as\_list=False*, *\*\*kwargs*)

List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

`salt.modules.pkgutil.list_upgrades` (*refresh=True*)

List all available package upgrades on this system

CLI Example:

```
salt '*' pkgutil.list_upgrades
```

`salt.modules.pkgutil.purge` (*name=None*, *pkgs=None*, *\*\*kwargs*)

Package purges are not supported, this function is identical to `remove()`.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>, <package2>, <package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

`salt.modules.pkgutil.refresh_db`()

Updates the pkgutil repo database (pkgutil -U)

CLI Example:

```
salt '*' pkgutil.refresh_db
```

`salt.modules.pkgutil.remove` (*name=None*, *pkgs=None*, *\*\*kwargs*)

Remove a package and all its dependencies which are not in use by other packages.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

`salt.modules.pkgutil.upgrade(refresh=True)`

Upgrade all of the packages to the latest available version.

Returns a dict containing the changes:

```
{<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkgutil.upgrade
```

`salt.modules.pkgutil.upgrade_available(name)`

Check if there is an upgrade available for a certain package

CLI Example:

```
salt '*' pkgutil.upgrade_available CSWpython
```

`salt.modules.pkgutil.version(*names, **kwargs)`

Returns a version if the package is installed, else returns an empty string

CLI Example:

```
salt '*' pkgutil.version CSWpython
```

### 30.16.174 salt.modules.portage\_config

Configure portage(5)

`salt.modules.portage_config.append_to_package_conf(conf, atom='`', flags=None, string='`', overwrite=False)`

Append a string or a list of flags for a given package or DEPEND atom to a given configuration file.

CLI Example:

```
salt '*' portage_config.append_to_package_conf use string="app-admin/salt ldap -libvirt"
salt '*' portage_config.append_to_package_conf use atom="> = app-admin/salt-0.14.1" flags="['lda
```

`salt.modules.portage_config.append_use_flags(atom, uses=None, overwrite=False)`

Append a list of use flags for a given package or DEPEND atom

CLI Example:

```
salt '*' portage_config.append_use_flags "app-admin/salt[ldap, -libvirt]"
salt '*' portage_config.append_use_flags ">=app-admin/salt-0.14.1" ["ldap', '-libvirt']"
```

`salt.modules.portage_config.enforce_nice_config()`

Enforce a nice tree structure for /etc/portage/package.\* configuration files.

See also:

[`salt.modules.ebuild.ex\_mod\_init\(\)`](#) for information on automatically running this when pkg is used.

CLI Example:

```
salt '*' portage_config.enforce_nice_config
```

`salt.modules.portage_config.get_flags_from_package_conf(conf, atom)`

Get flags for a given package or DEPEND atom. Warning: This only works if the configuration files tree is in the correct format (the one enforced by `enforce_nice_config`)

CLI Example:

```
salt '*' portage_config.get_flags_from_package_conf license salt
```

`salt.modules.portage_config.get_missing_flags(conf, atom, flags)`

Find out which of the given flags are currently not set. CLI Example:

```
salt '*' portage_config.get_missing_flags use salt "['ldap', '-libvirt', 'openssl']"
```

`salt.modules.portage_config.has_flag(conf, atom, flag)`

Verify if the given package or DEPEND atom has the given flag. Warning: This only works if the configuration files tree is in the correct format (the one enforced by `enforce_nice_config`)

CLI Example:

```
salt '*' portage_config.has_flag license salt Apache-2.0
```

`salt.modules.portage_config.has_use(atom, use)`

Verify if the given package or DEPEND atom has the given use flag. Warning: This only works if the configuration files tree is in the correct format (the one enforced by `enforce_nice_config`)

CLI Example:

```
salt '*' portage_config.has_use salt libvirt
```

`salt.modules.portage_config.is_present(conf, atom)`

Tell if a given package or DEPEND atom is present in the configuration files tree. Warning: This only works if the configuration files tree is in the correct format (the one enforced by `enforce_nice_config`)

CLI Example:

```
salt '*' portage_config.is_present unmask salt
```

### 30.16.175 salt.modules.postfix

Support for Postfix

This module is currently little more than a config file viewer and editor. It is able to read the `master.cf` file (which is one style) and files in the style of `main.cf` (which is a different style, that is used in multiple postfix configuration files).

The design of this module is such that when files are edited, a minimum of changes are made to them. Each file should look as if it has been edited by hand; order, comments and whitespace are all preserved.

`salt.modules.postfix.delete(queue_id)`

Delete message(s) from the mail queue

CLI Example:

```
salt '*' postfix.delete 5C33CA0DEA
```

```
salt '*' postfix.delete ALL
```

`salt.modules.postfix.hold(queue_id)`  
Put message(s) on hold from the mail queue

CLI Example:

```
salt '*' postfix.hold 5C33CA0DEA

salt '*' postfix.hold ALL
```

`salt.modules.postfix.requeue(queue_id)`  
Requeue message(s) in the mail queue

CLI Example:

```
salt '*' postfix.requeue 5C33CA0DEA

salt '*' postfix.requeue ALL
```

`salt.modules.postfix.set_main(key, value, path='/etc/postfix/main.cf')`

Set a single config value in the main.cf file. If the value does not already exist, it will be appended to the end.

CLI Example:

```
salt <minion> postfix.set_main mailq_path /usr/bin/mailq
```

`salt.modules.postfix.set_master(service, conn_type, private='y', unpriv='y', chroot='y', wakeup='n', maxproc='100', command='', write_conf=True, path='/etc/postfix/master.cf')`

Set a single config value in the master.cf file. If the value does not already exist, it will be appended to the end.

Because of shell parsing issues, `` cannot be set as a value, as is normal in the master.cf file; either `y`, `n` or a number should be used when calling this function from the command line. If the value used matches the default, it will internally be converted to a ``. Calling this function from the Python API is not affected by this limitation

The settings and their default values, in order, are: service (required), conn\_type (required), private (y), unpriv (y), chroot (y), wakeup (n), maxproc (100), command (required).

By default, this function will write out the changes to the master.cf file, and then returns the full contents of the file. By setting the `write_conf` option to `False`, it will skip writing the file.

CLI Example:

```
salt <minion> postfix.set_master smtp inet n y n n 100 smtpd
```

`salt.modules.postfix.show_main(path='/etc/postfix/main.cf')`

Return a dict of active config values. This does not include comments, spacing or order. Bear in mind that order is functionally important in the main.cf file, since keys can be referred to as variables. This means that the data returned from this function should not be used for direct modification of the main.cf file; other functions are available for that.

CLI Examples:

```
salt <minion> postfix.show_main salt <minion> postfix.show_main path=/path/to/main.cf
```

`salt.modules.postfix.show_master(path='/etc/postfix/master.cf')`

Return a dict of active config values. This does not include comments, spacing or order.

The data returned from this function should not be used for direct modification of the main.cf file; other functions are available for that.

CLI Examples:

```
salt <minion> postfix.show_master salt <minion> postfix.show_master path=/path/to/master.cf
```

`salt.modules.postfix.show_queue()`

Show contents of the mail queue

CLI Example:

```
salt '*' postfix.show_queue
```

`salt.modules.postfix.unhold(queue_id)`

Set held message(s) in the mail queue to unheld

CLI Example:

```
salt '*' postfix.unhold 5C33CA0DEA
```

```
salt '*' postfix.unhold ALL
```

### 30.16.176 salt.modules.postgres

Module to provide Postgres compatibility to salt.

**configuration** In order to connect to Postgres, certain configuration is required in `/etc/salt/minion` on the relevant minions. Some sample configs might look like:

```
postgres.host: 'localhost'
postgres.port: '5432'
postgres.user: 'postgres' -> db user
postgres.pass: ''
postgres.maintenance_db: 'postgres'
```

The default for the `maintenance_db` is `'postgres'` and in most cases it can be left at the default setting. This data can also be passed into pillar. Options passed into `opts` will overwrite options passed into pillar

**note** This module uses MD5 hashing which may not be compliant with certain security audits.

`salt.modules.postgres.available_extensions` (*user=None, host=None, port=None, maintenance\_db=None, password=None, runas=None*)

List available postgresql extensions

CLI Example:

```
salt '*' postgres.available_extensions
```

`salt.modules.postgres.create_extension` (*name, if\_not\_exists=None, schema=None, ext\_version=None, from\_version=None, user=None, host=None, port=None, maintenance\_db=None, password=None, runas=None*)

Install a postgresql extension

CLI Example:

```
salt '*' postgres.create_extension 'adminpack'
```

`salt.modules.postgres.create_metadata` (*name, ext\_version=None, schema=None, user=None, host=None, port=None, maintenance\_db=None, password=None, runas=None*)

Get lifecycle information about an extension

CLI Example:

```
salt '*' postgres.create_metadata adminpack
```

`salt.modules.postgres.db_alter` (*name*, *user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *tablespace=None*, *owner=None*, *runas=None*)

Change tablespace or/and owner of database.

CLI Example:

```
salt '*' postgres.db_alter dbname owner=otheruser
```

`salt.modules.postgres.db_create` (*name*, *user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *tablespace=None*, *encoding=None*, *lc\_collate=None*, *lc\_ctype=None*, *owner=None*, *template=None*, *runas=None*)

Adds a databases to the Postgres server.

CLI Example:

```
salt '*' postgres.db_create 'dbname'
```

```
salt '*' postgres.db_create 'dbname' template=template_postgis
```

`salt.modules.postgres.db_exists` (*name*, *user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *runas=None*)

Checks if a database exists on the Postgres server.

CLI Example:

```
salt '*' postgres.db_exists 'dbname'
```

`salt.modules.postgres.db_list` (*user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *runas=None*)

Return dictionary with information about databases of a Postgres server.

CLI Example:

```
salt '*' postgres.db_list
```

`salt.modules.postgres.db_remove` (*name*, *user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *runas=None*)

Removes a databases from the Postgres server.

CLI Example:

```
salt '*' postgres.db_remove 'dbname'
```

`salt.modules.postgres.drop_extension` (*name*, *if\_exists=None*, *restrict=None*, *cascade=None*, *user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *runas=None*)

Drop an installed postgresql extension

CLI Example:

```
salt '*' postgres.drop_extension 'adminpack'
```

`salt.modules.postgres.get_available_extension` (*name*, *user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *runas=None*)

Get info about an available postgresql extension

CLI Example:

```
salt '*' postgres.get_available_extension plpgsql
```

```
salt.modules.postgres.get_installed_extension(name, user=None, host=None, port=None,
                                              maintenance_db=None, password=None,
                                              runas=None)
```

Get info about an installed postgresql extension

CLI Example:

```
salt '*' postgres.get_installed_extension plpgsql
```

```
salt.modules.postgres.group_create(groupname, user=None, host=None, port=None, main-
                                  tenance_db=None, password=None, createdb=None,
                                  createuser=None, createroles=None, encrypted=None,
                                  login=None, inherit=None, superuser=None, repli-
                                  cation=None, rolepassword=None, groups=None,
                                  runas=None)
```

Creates a Postgres group. A group in postgres is similar to a user, but cannot login.

CLI Example:

```
salt '*' postgres.group_create 'groupname' user='user' \
                               host='hostname' port='port' password='password' \
                               rolepassword='rolepassword'
```

```
salt.modules.postgres.group_remove(groupname, user=None, host=None, port=None, mainte-
                                   nance_db=None, password=None, runas=None)
```

Removes a group from the Postgres server.

CLI Example:

```
salt '*' postgres.group_remove 'groupname'
```

```
salt.modules.postgres.group_update(groupname, user=None, host=None, port=None, main-
                                   tenance_db=None, password=None, createdb=None,
                                   createroles=None, createuser=None, encrypted=None, in-
                                   inherit=None, login=None, superuser=None, replication=None,
                                   rolepassword=None, groups=None, runas=None)
```

Updates a postgres group

CLI Examples:

```
salt '*' postgres.group_update 'username' user='user' \
                               host='hostname' port='port' password='password' \
                               rolepassword='rolepassword'
```

```
salt.modules.postgres.installed_extensions(user=None, host=None, port=None,
                                           maintenance_db=None, password=None,
                                           runas=None)
```

List installed postgresql extensions

CLI Example:

```
salt '*' postgres.installed_extensions
```

```
salt.modules.postgres.is_available_extension(name, user=None, host=None, port=None,
                                             maintenance_db=None, password=None,
                                             runas=None)
```

Test if a specific extension is available

CLI Example:

```
salt '*' postgres.is_available_extension
```

`salt.modules.postgres.is_installed_extension`(*name*, *user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *runas=None*)

Test if a specific extension is installed

CLI Example:

```
salt '*' postgres.is_installed_extension
```

`salt.modules.postgres.owner_to`(*dbname*, *ownername*, *user=None*, *host=None*, *port=None*, *password=None*, *runas=None*)

Set the owner of all schemas, functions, tables, views and sequences to the given username.

CLI Example:

```
salt '*' postgres.owner_to 'dbname' 'username'
```

`salt.modules.postgres.psql_query`(*query*, *user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *runas=None*)

Run an SQL-Query and return the results as a list. This command only supports SELECT statements. This limitation can be worked around with a query like this:

```
WITH updated AS (UPDATE pg_authid SET rolconnlimit = 2000 WHERE rolname = 'rolename' RETURNING rolconnlimit) SELECT * FROM updated;
```

CLI Example:

```
salt '*' postgres.psql_query 'select * from pg_stat_activity'
```

`salt.modules.postgres.role_get`(*name*, *user=None*, *host=None*, *port=None*, *maintenance\_db=None*, *password=None*, *runas=None*, *return\_password=False*)

Return a dict with information about users of a Postgres server.

Set `return_password` to True to get password hash in the result.

CLI Example:

```
salt '*' postgres.role_get postgres
```

`salt.modules.postgres.schema_create`(*dbname*, *name*, *owner=None*, *user=None*, *db\_user=None*, *db\_password=None*, *db\_host=None*, *db\_port=None*)

Creates a Postgres schema.

CLI Example:

```
salt '*' postgres.schema_create dbname name owner='owner' \
    user='user' \
    db_user='user' db_password='password' \
    db_host='hostname' db_port='port'
```

`salt.modules.postgres.schema_exists`(*dbname*, *name*, *db\_user=None*, *db\_password=None*, *db\_host=None*, *db\_port=None*)

Checks if a schema exists on the Postgres server.

CLI Example:

```
salt '*' postgres.schema_exists dbname schemaname
```

**dbname** Database name we query on

**name** Schema name we look for

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

```
salt.modules.postgres.schema_get(dbname, name, db_user=None, db_password=None,  
                                   db_host=None, db_port=None)
```

Return a dict with information about schemas in a database.

CLI Example:

```
salt '*' postgres.schema_get dbname name
```

**dbname** Database name we query on

**name** Schema name we look for

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

```
salt.modules.postgres.schema_list(dbname, db_user=None, db_password=None, db_host=None,  
                                   db_port=None)
```

Return a dict with information about schemas in a Postgres database.

CLI Example:

```
salt '*' postgres.schema_list dbname
```

**dbname** Database name we query on

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

```
salt.modules.postgres.schema_remove(dbname, name, user=None, db_user=None,  
                                       db_password=None, db_host=None, db_port=None)
```

Removes a schema from the Postgres server.

CLI Example:

```
salt '*' postgres.schema_remove dbname schemaname
```

**dbname** Database name we work on

**schemaname** The schema's name we'll remove

**user** System user all operations should be performed on behalf of

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

**salt.modules.postgres.user\_create**(*username, user=None, host=None, port=None, maintenance\_db=None, password=None, createdb=None, createuser=None, createroles=None, inherit=None, login=None, connlimit=None, encrypted=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None*)

Creates a Postgres user.

CLI Examples:

```
salt '*' postgres.user_create 'username' user='user' \
    host='hostname' port='port' password='password' \
    rolepassword='rolepassword'
```

**salt.modules.postgres.user\_exists**(*name, user=None, host=None, port=None, maintenance\_db=None, password=None, runas=None*)

Checks if a user exists on the Postgres server.

CLI Example:

```
salt '*' postgres.user_exists 'username'
```

**salt.modules.postgres.user\_list**(*user=None, host=None, port=None, maintenance\_db=None, password=None, runas=None, return\_password=False*)

Return a dict with information about users of a Postgres server.

Set `return_password` to True to get password hash in the result.

CLI Example:

```
salt '*' postgres.user_list
```

**salt.modules.postgres.user\_remove**(*username, user=None, host=None, port=None, maintenance\_db=None, password=None, runas=None*)

Removes a user from the Postgres server.

CLI Example:

```
salt '*' postgres.user_remove 'username'
```

**salt.modules.postgres.user\_update**(*username, user=None, host=None, port=None, maintenance\_db=None, password=None, createdb=None, createuser=None, createroles=None, encrypted=None, superuser=None, inherit=None, login=None, connlimit=None, replication=None, rolepassword=None, groups=None, runas=None*)

Updates a Postgres user.

CLI Examples:

```
salt '*' postgres.user_update 'username' user='user' \
    host='hostname' port='port' password='password' \
    rolepassword='rolepassword'
```

**salt.modules.postgres.version**(*user=None, host=None, port=None, maintenance\_db=None, password=None, runas=None*)

Return the version of a Postgres server.

CLI Example:

```
salt '*' postgres.version
```

### 30.16.177 salt.modules.poudriere

Support for poudriere

**salt.modules.poudriere.bulk\_build**(*jail, pkg\_file, keep=False*)

Run bulk build on poudriere server.

Return number of pkg builds, failures, and errors, on error dump to CLI

CLI Example:

```
salt -N buildbox_group poudriere.bulk_build 90amd64 /root/pkg_list
```

**salt.modules.poudriere.create\_jail**(*name, arch, version='9.0-RELEASE'*)

Creates a new poudriere jail if one does not exist

*NOTE* creating a new jail will take some time the master is not hanging

CLI Example:

```
salt '*' poudriere.create_jail 90amd64 amd64
```

**salt.modules.poudriere.create\_ports\_tree**()

Not working need to run portfetch non interactive

**salt.modules.poudriere.delete\_jail**(*name*)

Deletes poudriere jail with *name*

CLI Example:

```
salt '*' poudriere.delete_jail 90amd64
```

**salt.modules.poudriere.is\_jail**(*name*)

Return True if jail exists False if not

CLI Example:

```
salt '*' poudriere.is_jail <jail name>
```

**salt.modules.poudriere.list\_jails**()

Return a list of current jails managed by poudriere

CLI Example:

```
salt '*' poudriere.list_jails
```

**salt.modules.poudriere.list\_ports**()

Return a list of current port trees managed by poudriere

CLI Example:

```
salt '*' poudriere.list_ports
```

**salt.modules.poudriere.make\_pkgng\_aware**(*jname*)

Make jail *jname* pkgng aware

CLI Example:

```
salt '*' poudriere.make_pkgng_aware <jail name>
```

`salt.modules.poudriere.parse_config`(*config\_file=None*)  
Returns a dict of poudriere main configuration definitions

CLI Example:

```
salt '*' poudriere.parse_config
```

`salt.modules.poudriere.update_jail`(*name*)  
Run freebsd-update on *name* poudriere jail

CLI Example:

```
salt '*' poudriere.update_jail freebsd:10:x86:64
```

`salt.modules.poudriere.update_ports_tree`(*ports\_tree*)  
Updates the ports tree, either the default or the *ports\_tree* specified

CLI Example:

```
salt '*' poudriere.update_ports_tree staging
```

`salt.modules.poudriere.version`()  
Return poudriere version

CLI Example:

```
salt '*' poudriere.version
```

### 30.16.178 salt.modules.powerpath

powerpath support.

Assumes RedHat

`salt.modules.powerpath.add_license`(*key*)  
Add a license

`salt.modules.powerpath.has_powerpath`()

`salt.modules.powerpath.list_licenses`()  
returns a list of applied powerpath license keys

`salt.modules.powerpath.remove_license`(*key*)  
Remove a license

### 30.16.179 salt.modules.publish

Publish a command from a minion to a target

`salt.modules.publish.full_data`(*tgt, fun, arg=None, expr\_form='glob', returner='', timeout=5*)  
Return the full data about the publication, this is invoked in the same way as the publish function

CLI Example:

```
salt system.example.com publish.full_data '*' cmd.run 'ls -la /tmp'
```

**Attention**

If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:

```
salt '*' publish.full_data test.kwarg arg='cheese=spam'
```

---

`salt.modules.publish.publish`(*tgt, fun, arg=None, expr\_form='glob', returner='', timeout=5*)

Publish a command from the minion out to other minions.

Publications need to be enabled on the Salt master and the minion needs to have permission to publish the command. The Salt master will also prevent a recursive publication loop, this means that a minion cannot command another minion to command another minion as that would create an infinite command loop.

The `expr_form` argument is used to pass a target other than a glob into the execution, the available options are:

- glob
- pcre
- grain
- grain\_pcre
- pillar
- pillar\_pcre
- ipcidr
- range
- compound

Note that for pillar matches must be exact, both in the pillar matcher and the compound matcher. No globbing is supported.

The arguments sent to the minion publish function are separated with commas. This means that for a minion executing a command with multiple args it will look like this:

```
salt system.example.com publish.publish '*' user.add 'foo,1020,1020'  
salt system.example.com publish.publish 'os:Fedora' network.interfaces '' grain
```

CLI Example:

```
salt system.example.com publish.publish '*' cmd.run 'ls -la /tmp'
```

---

**Attention**

If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:

```
salt '*' publish.publish test.kwarg arg='cheese=spam'
```

Multiple keyword arguments should be passed as a list.

```
salt '*' publish.publish test.kwarg arg="['cheese=spam', 'spam=cheese']"
```

---

`salt.modules.publish.runner`(*fun, arg=None, timeout=5*)

Execute a runner on the master and return the data from the runner function

CLI Example:

```
salt publish.runner manage.down
```

### 30.16.180 salt.modules.puppet

Execute puppet routines

**salt.modules.puppet.disable**(*message=None*)

New in version 2014.7.0.

Disable the puppet agent

**message** New in version 2015.5.2.

Disable message to send to puppet

CLI Example:

```
salt '*' puppet.disable
salt '*' puppet.disable 'Disabled, contact XYZ before enabling'
```

**salt.modules.puppet.enable**()

New in version 2014.7.0.

Enable the puppet agent

CLI Example:

```
salt '*' puppet.enable
```

**salt.modules.puppet.fact**(*name, puppet=False*)

Run facter for a specific fact

CLI Example:

```
salt '*' puppet.fact kernel
```

**salt.modules.puppet.facts**(*puppet=False*)

Run facter and return the results

CLI Example:

```
salt '*' puppet.facts
```

**salt.modules.puppet.noop**(\*args, \*\*kwargs)

Execute a puppet noop run and return a dict with the stderr, stdout, return code, etc. Usage is the same as for puppet.run.

CLI Example:

```
salt '*' puppet.noop
salt '*' puppet.noop tags=basefiles::edit,apache::server
salt '*' puppet.noop debug
salt '*' puppet.noop apply /a/b/manifest.pp modulepath=/a/b/modules tags=basefiles::edit,apache::
```

**salt.modules.puppet.run**(\*args, \*\*kwargs)

Execute a puppet run and return a dict with the stderr, stdout, return code, etc. The first positional argument given is checked as a subcommand. Following positional arguments should be ordered with arguments required by the subcommand first, followed by non-keyword arguments. Tags are specified by a tag keyword and comma separated list of values. -- [http://docs.puppetlabs.com/puppet/latest/reference/lang\\_tags.html](http://docs.puppetlabs.com/puppet/latest/reference/lang_tags.html)

CLI Examples:

```
salt '*' puppet.run
salt '*' puppet.run tags=basefiles::edit,apache::server
salt '*' puppet.run agent onetime no-daemonize no-usecacheonfailure no-splay ignorecache
salt '*' puppet.run debug
salt '*' puppet.run apply /a/b/manifest.pp modulepath=/a/b/modules tags=basefiles::edit,apache::
```

**salt.modules.puppet.status()**

New in version 2014.7.0.

Display puppet agent status

CLI Example:

```
salt '*' puppet.status
```

**salt.modules.puppet.summary()**

New in version 2014.7.0.

Show a summary of the last puppet agent run

CLI Example:

```
salt '*' puppet.summary
```

### 30.16.181 salt.modules.pw\_group

Manage groups on FreeBSD

---

**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `'group.info' is not available`), see [here](#).

---

**salt.modules.pw\_group.add**(*name*, *gid=None*, *\*\*kwargs*)

Add the specified group

CLI Example:

```
salt '*' group.add foo 3456
```

**salt.modules.pw\_group.chgid**(*name*, *gid*)

Change the gid for a named group

CLI Example:

```
salt '*' group.chgid foo 4376
```

**salt.modules.pw\_group.delete**(*name*)

Remove the named group

CLI Example:

```
salt '*' group.delete foo
```

**salt.modules.pw\_group.getent**(*refresh=False*)

Return info on all groups

CLI Example:

```
salt '*' group.getent
```

`salt.modules.pw_group.info`(*name*)  
Return information about a group

CLI Example:

```
salt '*' group.info foo
```

`salt.modules.pw_group.members`(*name, members\_list*)  
Replaces members of the group with a provided list.

New in version 2015.5.4.

CLI Example:

```
salt '*' group.members foo `user1,user2,user3,...`
```

Replaces a membership list for a local group ``foo``. `foo:x:1234:user1,user2,user3,...`

### 30.16.182 salt.modules.pw\_user

Manage users with the useradd command

---

**Important:** If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to ``user.info` is not available`), see [here](#).

---

`salt.modules.pw_user.add`(*name, uid=None, gid=None, groups=None, home=None, shell=None, unique=True, fullname='', roomnumber='', workphone='', homephone='', createhome=True, \*\*kwargs*)

Add a user to the minion

CLI Example:

```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

`salt.modules.pw_user.chfullname`(*name, fullname*)  
Change the user's Full Name

CLI Example:

```
salt '*' user.chfullname foo "Foo Bar"
```

`salt.modules.pw_user.chgid`(*name, gid*)  
Change the default group of the user

CLI Example:

```
salt '*' user.chgid foo 4376
```

`salt.modules.pw_user.chgroups`(*name, groups, append=False*)  
Change the groups this user belongs to, add append to append the specified groups

CLI Example:

```
salt '*' user.chgroups foo wheel,root True
```

`salt.modules.pw_user.chhome`(*name, home, persist=False*)  
Change the home directory of the user, pass true for persist to copy files to the new home dir

CLI Example:

```
salt '*' user.chhome foo /home/users/foo True
```

`salt.modules.pw_user.chhomephone` (*name, homephone*)  
Change the user's Home Phone

CLI Example:

```
salt '*' user.chhomephone foo "7735551234"
```

`salt.modules.pw_user.chroomnumber` (*name, roomnumber*)  
Change the user's Room Number

CLI Example:

```
salt '*' user.chroomnumber foo 123
```

`salt.modules.pw_user.chshell` (*name, shell*)  
Change the default shell of the user

CLI Example:

```
salt '*' user.chshell foo /bin/zsh
```

`salt.modules.pw_user.chuid` (*name, uid*)  
Change the uid for a named user

CLI Example:

```
salt '*' user.chuid foo 4376
```

`salt.modules.pw_user.chworkphone` (*name, workphone*)  
Change the user's Work Phone

CLI Example:

```
salt '*' user.chworkphone foo "7735550123"
```

`salt.modules.pw_user.delete` (*name, remove=False, force=False*)  
Remove a user from the minion

CLI Example:

```
salt '*' user.delete name remove=True force=True
```

`salt.modules.pw_user.getent` (*refresh=False*)  
Return the list of all info for all users

CLI Example:

```
salt '*' user.getent
```

`salt.modules.pw_user.info` (*name*)  
Return user information

CLI Example:

```
salt '*' user.info root
```

`salt.modules.pw_user.list_groups` (*name*)  
Return a list of groups the named user belongs to

CLI Example:

```
salt '*' user.list_groups foo
```

**salt.modules.pw\_user.list\_users()**

Return a list of all users

CLI Example:

```
salt '*' user.list_users
```

**salt.modules.pw\_user.rename(name, new\_name)**

Change the username for a named user

CLI Example:

```
salt '*' user.rename name new_name
```

### 30.16.183 salt.modules.pyenv

Manage python installations with pyenv.

New in version v2014.04.

**salt.modules.pyenv.default**(python=None, runas=None)

Returns or sets the currently defined default python.

**python=None** The version to set as the default. Should match one of the versions listed by *pyenv.versions*. Leave blank to return the current default.

CLI Example:

```
salt '*' pyenv.default
salt '*' pyenv.default 2.0.0-p0
```

**salt.modules.pyenv.do**(cmdline=None, runas=None)

Execute a python command with pyenv's shims from the user or the system.

CLI Example:

```
salt '*' pyenv.do 'gem list bundler'
salt '*' pyenv.do 'gem list bundler' deploy
```

**salt.modules.pyenv.do\_with\_python**(python, cmdline, runas=None)

Execute a python command with pyenv's shims using a specific python version.

CLI Example:

```
salt '*' pyenv.do_with_python 2.0.0-p0 'gem list bundler'
salt '*' pyenv.do_with_python 2.0.0-p0 'gem list bundler' deploy
```

**salt.modules.pyenv.install**(runas=None, path=None)

Install pyenv systemwide

CLI Example:

```
salt '*' pyenv.install
```

**salt.modules.pyenv.install\_python**(python, runas=None)

Install a python implementation.

**python** The version of python to install, should match one of the versions listed by *pyenv.list*

CLI Example:

```
salt '*' pyenv.install_python 2.0.0-p0
```

`salt.modules.pyenv.is_installed` (*runas=None*)

Check if pyenv is installed.

CLI Example:

```
salt '*' pyenv.is_installed
```

`salt.modules.pyenv.list_` (*runas=None*)

List the installable versions of python.

CLI Example:

```
salt '*' pyenv.list
```

`salt.modules.pyenv.rehash` (*runas=None*)

Run pyenv rehash to update the installed shims.

CLI Example:

```
salt '*' pyenv.rehash
```

`salt.modules.pyenv.uninstall_python` (*python, runas=None*)

Uninstall a python implementation.

**python** The version of python to uninstall. Should match one of the versions listed by `pyenv.versions`

CLI Example:

```
salt '*' pyenv.uninstall_python 2.0.0-p0
```

`salt.modules.pyenv.update` (*runas=None, path=None*)

Updates the current versions of pyenv and python-Build

CLI Example:

```
salt '*' pyenv.update
```

`salt.modules.pyenv.versions` (*runas=None*)

List the installed versions of python.

CLI Example:

```
salt '*' pyenv.versions
```

### 30.16.184 salt.modules.qemu\_img

#### Qemu-img Command Wrapper

The qemu img command is wrapped for specific functions

**depends** qemu-img

`salt.modules.qemu_img.make_image` (*location, size, fmt*)

Create a blank virtual machine image file of the specified size in megabytes. The image can be created in any format supported by qemu

CLI Example:

```
salt '*' qemu_img.make_image /tmp/image.qcow 2048 qcow2
salt '*' qemu_img.make_image /tmp/image.raw 10240 raw
```

### 30.16.185 salt.modules.qemu\_nbd

Qemu Command Wrapper

The qemu system comes with powerful tools, such as qemu-img and qemu-nbd which are used here to build up kvm images.

**salt.modules.qemu\_nbd.clear**(*mnt*)

Pass in the mnt dict returned from nbd\_mount to unmount and disconnect the image from nbd. If all of the partitions are unmounted return an empty dict, otherwise return a dict containing the still mounted partitions

CLI Example:

```
salt '*' qemu_nbd.clear '{"mnt/foo": "/dev/nbd0p1"}'
```

**salt.modules.qemu\_nbd.connect**(*image*)

Activate nbd for an image file.

CLI Example:

```
salt '*' qemu_nbd.connect /tmp/image.raw
```

**salt.modules.qemu\_nbd.init**(*image*)

Mount the named image via qemu-nbd and return the mounted roots

CLI Example:

```
salt '*' qemu_nbd.init /srv/image.qcow2
```

**salt.modules.qemu\_nbd.mount**(*nbd*)

Pass in the nbd connection device location, mount all partitions and return a dict of mount points

CLI Example:

```
salt '*' qemu_nbd.mount /dev/nbd0
```

### 30.16.186 salt.modules.quota

Module for managing quotas on POSIX-like systems.

**salt.modules.quota.get\_mode**(*device*)

Report whether the quota system for this device is on or off

CLI Example:

```
salt '*' quota.get_mode
```

**salt.modules.quota.off**(*device*)

Turns off the quota system

CLI Example:

```
salt '*' quota.off
```

`salt.modules.quota.on` (*device*)

Turns on the quota system

CLI Example:

```
salt '*' quota.on
```

`salt.modules.quota.report` (*mount*)

Report on quotas for a specific volume

CLI Example:

```
salt '*' quota.report /media/data
```

`salt.modules.quota.set_` (*device, \*\*kwargs*)

Calls out to `setquota`, for a specific user or group

CLI Example:

```
salt '*' quota.set /media/data user=larry block-soft-limit=1048576
salt '*' quota.set /media/data group=painters file-hard-limit=1000
```

`salt.modules.quota.stats` ()

Runs the `quotastats` command, and returns the parsed output

CLI Example:

```
salt '*' quota.stats
```

`salt.modules.quota.warn` ()

Runs the `warnquota` command, to send warning emails to users who are over their quota limit.

CLI Example:

```
salt '*' quota.warn
```

### 30.16.187 `salt.modules.rabbitmq`

Module to provide RabbitMQ compatibility to Salt. Todo: A lot, need to add cluster support, logging, and minion configuration data.

`salt.modules.rabbitmq.add_user` (*name, password=None, runas=None*)

Add a rabbitMQ user via `rabbitmqctl user_add <user> <password>`

CLI Example:

```
salt '*' rabbitmq.add_user rabbit_user password
```

`salt.modules.rabbitmq.add_vhost` (*vhost, runas=None*)

Adds a vhost via `rabbitmqctl add_vhost`.

CLI Example:

```
salt '*' rabbitmq add_vhost '<vhost_name>'
```

`salt.modules.rabbitmq.change_password` (*name, password, runas=None*)

Changes a user's password.

CLI Example:

```
salt '*' rabbitmq.change_password rabbit_user password
```

`salt.modules.rabbitmq.clear_password`(*name*, *runas=None*)  
Removes a user's password.

CLI Example:

```
salt '*' rabbitmq.clear_password rabbit_user
```

`salt.modules.rabbitmq.cluster_status`(*runas=None*)  
return rabbitmq cluster\_status

CLI Example:

```
salt '*' rabbitmq.cluster_status
```

`salt.modules.rabbitmq.delete_policy`(*vhost*, *name*, *runas=None*)  
Delete a policy based on rabbitmqctl clear\_policy.

Reference: <http://www.rabbitmq.com/ha.html>

CLI Example:

```
salt '*' rabbitmq.delete_policy / HA'
```

`salt.modules.rabbitmq.delete_user`(*name*, *runas=None*)  
Deletes a user via rabbitmqctl delete\_user.

CLI Example:

```
salt '*' rabbitmq.delete_user rabbit_user
```

`salt.modules.rabbitmq.delete_vhost`(*vhost*, *runas=None*)  
Deletes a vhost rabbitmqctl delete\_vhost.

CLI Example:

```
salt '*' rabbitmq.delete_vhost '<vhost_name>'
```

`salt.modules.rabbitmq.disable_plugin`(*name*, *runas=None*)  
Disable a RabbitMQ plugin via the rabbitmq-plugins command.

CLI Example:

```
salt '*' rabbitmq.disable_plugin foo
```

`salt.modules.rabbitmq.enable_plugin`(*name*, *runas=None*)  
Enable a RabbitMQ plugin via the rabbitmq-plugins command.

CLI Example:

```
salt '*' rabbitmq.enable_plugin foo
```

`salt.modules.rabbitmq.force_reset`(*runas=None*)  
Forcefully Return a RabbitMQ node to its virgin state

CLI Example:

```
salt '*' rabbitmq.force_reset
```

`salt.modules.rabbitmq.join_cluster`(*host*, *user='rabbit'*, *ram\_node=None*, *runas=None*)  
Join a rabbit cluster

CLI Example:

```
salt '*' rabbitmq.join_cluster 'rabbit.example.com' 'rabbit'
```

`salt.modules.rabbitmq.list_permissions` (*vhost*, *runas=None*)

Lists permissions for vhost via rabbitmqctl list\_permissions

CLI Example:

```
salt '*' rabbitmq.list_permissions '/myvhost'
```

`salt.modules.rabbitmq.list_policies` (*runas=None*)

Return a dictionary of policies nested by vhost and name based on the data returned from rabbitmqctl list\_policies.

Reference: <http://www.rabbitmq.com/ha.html>

CLI Example:

```
salt '*' rabbitmq.list_policies'
```

`salt.modules.rabbitmq.list_queues` (*runas=None*, *\*kwargs*)

Returns queue details of the / virtual host

CLI Example:

```
salt '*' rabbitmq.list_queues messages consumers
```

`salt.modules.rabbitmq.list_queues_vhost` (*vhost*, *runas=None*, *\*kwargs*)

Returns queue details of specified virtual host. This command will consider first parameter as the vhost name and rest will be treated as queueinfoitem. For getting details on vhost /, use `list_queues` instead).

CLI Example:

```
salt '*' rabbitmq.list_queues messages consumers
```

`salt.modules.rabbitmq.list_user_permissions` (*name*, *runas=None*)

List permissions for a user via rabbitmqctl list\_user\_permissions

CLI Example:

```
salt '*' rabbitmq.list_user_permissions 'user'.
```

`salt.modules.rabbitmq.list_users` (*runas=None*)

Return a list of users based off of rabbitmqctl user\_list.

CLI Example:

```
salt '*' rabbitmq.list_users
```

`salt.modules.rabbitmq.list_vhosts` (*runas=None*)

Return a list of vhost based on rabbitmqctl list\_vhosts.

CLI Example:

```
salt '*' rabbitmq.list_vhosts
```

`salt.modules.rabbitmq.plugin_is_enabled` (*name*, *runas=None*)

Return whether the plugin is enabled.

CLI Example:

```
salt '*' rabbitmq.plugin_is_enabled foo
```

`salt.modules.rabbitmq.policy_exists` (*vhost, name, runas=None*)  
Return whether the policy exists based on rabbitmqctl list\_policies.

Reference: <http://www.rabbitmq.com/ha.html>

CLI Example:

```
salt '*' rabbitmq.policy_exists / HA
```

`salt.modules.rabbitmq.reset` (*runas=None*)  
Return a RabbitMQ node to its virgin state

CLI Example:

```
salt '*' rabbitmq.reset
```

`salt.modules.rabbitmq.set_permissions` (*vhost, user, conf='\*', write='\*', read='\*', runas=None*)  
Sets permissions for vhost via rabbitmqctl set\_permissions

CLI Example:

```
salt '*' rabbitmq.set_permissions 'myvhost' 'myuser'
```

`salt.modules.rabbitmq.set_policy` (*vhost, name, pattern, definition, priority=None, runas=None*)  
Set a policy based on rabbitmqctl set\_policy.

Reference: <http://www.rabbitmq.com/ha.html>

CLI Example:

```
salt '*' rabbitmq.set_policy / HA '.*' '{"ha-mode": "all"}'
```

`salt.modules.rabbitmq.set_user_tags` (*name, tags, runas=None*)  
Add user tags via rabbitmqctl set\_user\_tags

CLI Example:

```
salt '*' rabbitmq.set_user_tags 'myadmin' 'administrator'
```

`salt.modules.rabbitmq.start_app` (*runas=None*)  
Start the RabbitMQ application.

CLI Example:

```
salt '*' rabbitmq.start_app
```

`salt.modules.rabbitmq.status` (*runas=None*)  
return rabbitmq status

CLI Example:

```
salt '*' rabbitmq.status
```

`salt.modules.rabbitmq.stop_app` (*runas=None*)  
Stops the RabbitMQ application, leaving the Erlang node running.

CLI Example:

```
salt '*' rabbitmq.stop_app
```

`salt.modules.rabbitmq.user_exists`(*name*, *runas=None*)

Return whether the user exists based on `rabbitmqctl list_users`.

CLI Example:

```
salt '*' rabbitmq.user_exists rabbit_user
```

`salt.modules.rabbitmq.vhost_exists`(*name*, *runas=None*)

Return whether the vhost exists based on `rabbitmqctl list_vhosts`.

CLI Example:

```
salt '*' rabbitmq.vhost_exists rabbit_host
```

### 30.16.188 `salt.modules.raet_publish`

Publish a command from a minion to a target

`salt.modules.raet_publish.full_data`(*tgt*, *fun*, *arg=None*, *expr\_form='glob'*, *returner=''*, *timeout=5*)

Return the full data about the publication, this is invoked in the same way as the `publish` function

CLI Example:

```
salt system.example.com publish.full_data '*' cmd.run 'ls -la /tmp'
```

---

#### Attention

If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:

```
salt '*' publish.full_data test.kwarg arg='cheese=spam'
```

---

`salt.modules.raet_publish.publish`(*tgt*, *fun*, *arg=None*, *expr\_form='glob'*, *returner=''*, *timeout=5*)

Publish a command from the minion out to other minions.

Publications need to be enabled on the Salt master and the minion needs to have permission to publish the command. The Salt master will also prevent a recursive publication loop, this means that a minion cannot command another minion to command another minion as that would create an infinite command loop.

The `expr_form` argument is used to pass a target other than a glob into the execution, the available options are:

- glob
- pcre
- grain
- grain\_pcre
- pillar
- pillar\_pcre
- ipcidr
- range
- compound

The arguments sent to the minion publish function are separated with commas. This means that for a minion executing a command with multiple args it will look like this:

```
salt system.example.com publish.publish '*' user.add 'foo,1020,1020'
salt system.example.com publish.publish 'os:Fedora' network.interfaces ' ' grain
```

CLI Example:

```
salt system.example.com publish.publish '*' cmd.run 'ls -la /tmp'
```

#### Attention

If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:

```
salt '*' publish.publish test.kwarg arg='cheese=spam'
```

`salt.modules.raet_publish.runner` (*fun, arg=None, timeout=5*)

Execute a runner on the master and return the data from the runner function

CLI Example:

```
salt publish.runner manage.down
```

### 30.16.189 salt.modules.random\_org

Module for retrieving random information from Random.org

New in version 2015.5.0.

**configuration** This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
random_org:
  api_key: 7be1402d-5719-5bd3-a306-3def9f135da5
  api_version: 1
```

`salt.modules.random_org.generateBlobs` (*api\_key=None, api\_version=None, \*\*kwargs*)

List all Slack users. :param api\_key: The Random.org api key. :param api\_version: The Random.org api version. :param format: Specifies the format in which the

blobs will be returned. Values allowed are base64 and hex.

**Returns** The user list.

CLI Example:

```
salt '*' get_integers number=5 min=1 max=6
salt '*' get_integers number=5 min=1 max=6
```

`salt.modules.random_org.generateDecimalFractions` (*api\_key=None, api\_version=None, \*\*kwargs*)

Generates true random decimal fractions

**Parameters**

- **api\_key** -- The Random.org api key.
- **api\_version** -- The Random.org api version.
- **number** -- How many random decimal fractions you need. Must be within the [1,1e4] range.
- **decimalPlaces** -- The number of decimal places to use. Must be within the [1,20] range.
- **replacement** -- Specifies whether the random numbers should be picked with replacement. The default (true) will cause the numbers to be picked with replacement, i.e., the resulting numbers may contain duplicate values (like a series of dice rolls). If you want the numbers picked to be unique (like raffle tickets drawn from a container), set this value to false.

**Returns** A list of decimal fraction

CLI Example:

```
salt '*' random_org.generateDecimalFractions number=10 decimalPlaces=4
salt '*' random_org.generateDecimalFractions number=10 decimalPlaces=4 replacement=True
```

`salt.modules.random_org.generateGaussians` (*api\_key=None, api\_version=None, \*\*kwargs*)  
This method generates true random numbers from a Gaussian distribution (also known as a normal distribution).

**Parameters**

- **api\_key** -- The Random.org api key.
- **api\_version** -- The Random.org api version.
- **number** -- How many random numbers you need. Must be within the [1,1e4] range.
- **mean** -- The distribution's mean. Must be within the [-1e6,1e6] range.
- **standardDeviation** -- The distribution's standard deviation. Must be within the [-1e6,1e6] range.
- **significantDigits** -- The number of significant digits to use. Must be within the [2,20] range.

**Returns** The user list.

CLI Example:

```
salt '*' random_org.generateGaussians number=10 mean=0.0 standardDeviation=1.0 significantDigits
```

`salt.modules.random_org.generateIntegers` (*api\_key=None, api\_version=None, \*\*kwargs*)  
Generate random integers

**Parameters**

- **api\_key** -- The Random.org api key.
- **api\_version** -- The Random.org api version.
- **number** -- The number of integers to generate
- **minimum** -- The lower boundary for the range from which the random numbers will be picked. Must be within the [-1e9,1e9] range.
- **maximum** -- The upper boundary for the range from which the random numbers will be picked. Must be within the [-1e9,1e9] range.

- **replacement** -- Specifies whether the random numbers should be picked with replacement. The default (true) will cause the numbers to be picked with replacement, i.e., the resulting numbers may contain duplicate values (like a series of dice rolls). If you want the numbers picked to be unique (like raffle tickets drawn from a container), set this value to false.
- **base** -- Specifies the base that will be used to display the numbers. Values allowed are 2, 8, 10 and 16. This affects the JSON types and formatting of the resulting data as discussed below.

**Returns** A list of integers.

CLI Example:

```
salt '*' random_org.generateIntegers number=5 minimum=1 maximum=6

salt '*' random_org.generateIntegers number=5 minimum=2 maximum=255 base=2
```

`salt.modules.random_org.generateStrings` (*api\_key=None, api\_version=None, \*\*kwargs*)  
Generate random strings.

**Parameters**

- **api\_key** -- The Random.org api key.
- **api\_version** -- The Random.org api version.
- **number** -- The number of strings to generate.
- **length** -- The length of each string. Must be within the [1,20] range. All strings will be of the same length
- **characters** -- A string that contains the set of characters that are allowed to occur in the random strings. The maximum number of characters is 80.
- **replacement** -- Specifies whether the random strings should be picked with replacement. The default (true) will cause the strings to be picked with replacement, i.e., the resulting list of strings may contain duplicates (like a series of dice rolls). If you want the strings to be unique (like raffle tickets drawn from a container), set this value to false.

**Returns** A list of strings.

CLI Example:

```
salt '*' random_org.generateStrings number=5 length=8 characters='abcdefghijklmnopqrstuvwxyz'

salt '*' random_org.generateStrings number=10 length=16 characters'abcdefghijklmnopqrstuvwxyz'
```

`salt.modules.random_org.generateUUIDs` (*api\_key=None, api\_version=None, \*\*kwargs*)  
Generate a list of random UUIDs

**Parameters**

- **api\_key** -- The Random.org api key.
- **api\_version** -- The Random.org api version.
- **number** -- How many random UUIDs you need. Must be within the [1,1e3] range.

**Returns** A list of UUIDs

CLI Example:

```
salt '*' random_org.generateUUIDs number=5
```

`salt.modules.random_org.getUsage` (*api\_key=None, api\_version=None*)  
Show current usages statistics

**Parameters**

- **api\_key** -- The Random.org api key.
- **api\_version** -- The Random.org api version.

**Returns** The current usage statistics.

CLI Example:

```
salt '*' random_org.getUsage
```

```
salt '*' random_org.getUsage api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=1
```

### 30.16.190 salt.modules.rbenv

Manage ruby installations with rbenv. Rbenv is supported on Linux and Mac OS X. Rbenv doesn't work on Windows (and isn't really necessary on Windows as there is no system Ruby on Windows). On Windows, the RubyInstaller and/or Pik are both good alternatives to work with multiple versions of Ruby on the same box.

<http://misheska.com/blog/2013/06/15/using-rbenv-to-manage-multiple-versions-of-ruby/>

New in version 0.16.0.

`salt.modules.rbenv.default` (*ruby=None, runas=None*)  
Returns or sets the currently defined default ruby.

**ruby=None** The version to set as the default. Should match one of the versions listed by `rbenv.versions`.  
Leave blank to return the current default.

CLI Example:

```
salt '*' rbenv.default
salt '*' rbenv.default 2.0.0-p0
```

`salt.modules.rbenv.do` (*cmdline=None, runas=None*)  
Execute a ruby command with rbenv's shims from the user or the system.

CLI Example:

```
salt '*' rbenv.do 'gem list bundler'
salt '*' rbenv.do 'gem list bundler' deploy
```

`salt.modules.rbenv.do_with_ruby` (*ruby, cmdline, runas=None*)  
Execute a ruby command with rbenv's shims using a specific ruby version.

CLI Example:

```
salt '*' rbenv.do_with_ruby 2.0.0-p0 'gem list bundler'
salt '*' rbenv.do_with_ruby 2.0.0-p0 'gem list bundler' deploy
```

`salt.modules.rbenv.install` (*runas=None, path=None*)  
Install Rbenv systemwide

CLI Example:

```
salt '*' rbenv.install
```

`salt.modules.rbenv.install_ruby` (*ruby*, *runas=None*)

Install a ruby implementation.

**ruby** The version of Ruby to install, should match one of the versions listed by `rbenv.list`

Additional environment variables can be configured in pillar / grains / master:

```
rbenv:
  build_env: 'CONFIGURE_OPTS="--no-tcmalloc" CFLAGS="-fno-tree-dce"'
```

CLI Example:

```
salt '*' rbenv.install_ruby 2.0.0-p0
```

`salt.modules.rbenv.is_installed` (*runas=None*)

Check if Rbenv is installed.

CLI Example:

```
salt '*' rbenv.is_installed
```

`salt.modules.rbenv.list` (*runas=None*)

List the installable versions of ruby.

CLI Example:

```
salt '*' rbenv.list
```

`salt.modules.rbenv.rehash` (*runas=None*)

Run rbenv rehash to update the installed shims.

CLI Example:

```
salt '*' rbenv.rehash
```

`salt.modules.rbenv.uninstall_ruby` (*ruby*, *runas=None*)

Uninstall a ruby implementation.

**ruby** The version of ruby to uninstall. Should match one of the versions listed by `rbenv.versions`

CLI Example:

```
salt '*' rbenv.uninstall_ruby 2.0.0-p0
```

`salt.modules.rbenv.update` (*runas=None*, *path=None*)

Updates the current versions of Rbenv and Ruby-Build

CLI Example:

```
salt '*' rbenv.update
```

`salt.modules.rbenv.versions` (*runas=None*)

List the installed versions of ruby.

CLI Example:

```
salt '*' rbenv.versions
```

### 30.16.191 salt.modules.rdp

Manage RDP Service on Windows servers

`salt.modules.rdp.disable()`

Disable RDP the service on the server

CLI Example:

```
salt '*' rdp.disable
```

`salt.modules.rdp.enable()`

Enable RDP the service on the server

CLI Example:

```
salt '*' rdp.enable
```

`salt.modules.rdp.status()`

Show if rdp is enabled on the server

CLI Example:

```
salt '*' rdp.status
```

### 30.16.192 salt.modules.redis

Module to provide redis functionality to Salt

New in version 2014.7.0.

**configuration** This module requires the redis python module and uses the following defaults which may be overridden in the minion configuration:

```
redis.host: 'localhost'  
redis.port: 6379  
redis.db: 0  
redis.password: None
```

`salt.modules.redismod.bgrewriteaof` (*host=None, port=None, db=None, password=None*)

Asynchronously rewrite the append-only file

CLI Example:

```
salt '*' redis.bgrewriteaof
```

`salt.modules.redismod.bgsave` (*host=None, port=None, db=None, password=None*)

Asynchronously save the dataset to disk

CLI Example:

```
salt '*' redis.bgsave
```

`salt.modules.redismod.config_get` (*pattern='\*', host=None, port=None, db=None, password=None*)

Get redis server configuration values

CLI Example:

```
salt '*' redis.config_get  
salt '*' redis.config_get port
```

`salt.modules.redismod.config_set`(*name*, *value*, *host=None*, *port=None*, *db=None*, *password=None*)

Set redis server configuration values

CLI Example:

```
salt '*' redis.config_set masterauth luv_kittens
```

`salt.modules.redismod.dbsize`(*host=None*, *port=None*, *db=None*, *password=None*)

Return the number of keys in the selected database

CLI Example:

```
salt '*' redis.dbsize
```

`salt.modules.redismod.delete`(\**keys*, \*\**connection\_args*)

Deletes the keys from redis, returns number of keys deleted

CLI Example:

```
salt '*' redis.delete foo
```

`salt.modules.redismod.exists`(*key*, *host=None*, *port=None*, *db=None*, *password=None*)

Return true if the key exists in redis

CLI Example:

```
salt '*' redis.exists foo
```

`salt.modules.redismod.expire`(*key*, *seconds*, *host=None*, *port=None*, *db=None*, *password=None*)

Set a keys time to live in seconds

CLI Example:

```
salt '*' redis.expire foo 300
```

`salt.modules.redismod.expireat`(*key*, *timestamp*, *host=None*, *port=None*, *db=None*, *password=None*)

Set a keys expire at given UNIX time

CLI Example:

```
salt '*' redis.expireat foo 1400000000
```

`salt.modules.redismod.flushall`(*host=None*, *port=None*, *db=None*, *password=None*)

Remove all keys from all databases

CLI Example:

```
salt '*' redis.flushall
```

`salt.modules.redismod.flushdb`(*host=None*, *port=None*, *db=None*, *password=None*)

Remove all keys from the selected database

CLI Example:

```
salt '*' redis.flushdb
```

`salt.modules.redismod.get_key`(*key*, *host=None*, *port=None*, *db=None*, *password=None*)

Get redis key value

CLI Example:

```
salt '*' redis.get_key foo
```

`salt.modules.redismod.hget` (*key, field, host=None, port=None, db=None, password=None*)  
Get specific field value from a redis hash, returns dict

CLI Example:

```
salt '*' redis.hget foo_hash bar_field
```

`salt.modules.redismod.hgetall` (*key, host=None, port=None, db=None, password=None*)  
Get all fields and values from a redis hash, returns dict

CLI Example:

```
salt '*' redis.hgetall foo_hash
```

`salt.modules.redismod.info` (*host=None, port=None, db=None, password=None*)  
Get information and statistics about the server

CLI Example:

```
salt '*' redis.info
```

`salt.modules.redismod.key_type` (*key, host=None, port=None, db=None, password=None*)  
Get redis key type

CLI Example:

```
salt '*' redis.type foo
```

`salt.modules.redismod.keys` (*pattern='\*', host=None, port=None, db=None, password=None*)  
Get redis keys, supports glob style patterns

CLI Example:

```
salt '*' redis.keys  
salt '*' redis.keys test*
```

`salt.modules.redismod.lastsave` (*host=None, port=None, db=None, password=None*)  
Get the UNIX time in seconds of the last successful save to disk

CLI Example:

```
salt '*' redis.lastsave
```

`salt.modules.redismod.llen` (*key, host=None, port=None, db=None, password=None*)  
Get the length of a list in Redis

CLI Example:

```
salt '*' redis.llen foo_list
```

`salt.modules.redismod.lrange` (*key, start, stop, host=None, port=None, db=None, password=None*)  
Get a range of values from a list in Redis

CLI Example:

```
salt '*' redis.lrange foo_list 0 10
```

`salt.modules.redismod.ping` (*host=None, port=None, db=None, password=None*)  
Ping the server, returns False on connection errors

CLI Example:

```
salt '*' redis.ping
```

`salt.modules.redismod.save` (*host=None, port=None, db=None, password=None*)  
Synchronously save the dataset to disk

CLI Example:

```
salt '*' redis.save
```

`salt.modules.redismod.set_key` (*key, value, host=None, port=None, db=None, password=None*)  
Set redis key value

CLI Example:

```
salt '*' redis.set_key foo bar
```

`salt.modules.redismod.shutdown` (*host=None, port=None, db=None, password=None*)  
Synchronously save the dataset to disk and then shut down the server

CLI Example:

```
salt '*' redis.shutdown
```

`salt.modules.redismod.slaveof` (*master\_host=None, master\_port=None, host=None, port=None, db=None, password=None*)

Make the server a slave of another instance, or promote it as master

CLI Example:

```
# Become slave of redis-n01.example.com:6379
salt '*' redis.slaveof redis-n01.example.com 6379
salt '*' redis.slaveof redis-n01.example.com
# Become master
salt '*' redis.slaveof
```

`salt.modules.redismod.smembers` (*key, host=None, port=None, db=None, password=None*)  
Get members in a Redis set

CLI Example:

```
salt '*' redis.smembers foo_set
```

`salt.modules.redismod.time` (*host=None, port=None, db=None, password=None*)  
Return the current server UNIX time in seconds

CLI Example:

```
salt '*' redis.time
```

`salt.modules.redismod.zcard` (*key, host=None, port=None, db=None, password=None*)  
Get the length of a sorted set in Redis

CLI Example:

```
salt '*' redis.zcard foo_sorted
```

`salt.modules.redismod.zrange` (*key, start, stop, host=None, port=None, db=None, password=None*)  
Get a range of values from a sorted set in Redis by index

CLI Example:

```
salt '*' redis.zrange foo_sorted 0 10
```

### 30.16.193 salt.modules.reg

#### Manage the Windows registry

The read\_key and set\_key functions will be updated in Boron to reflect proper registry usage. The registry has three main components. Hives, Keys, and Values.

##### Hives

Hives are the main sections of the registry and all begin with the word HKEY. - HKEY\_LOCAL\_MACHINE - HKEY\_CURRENT\_USER - HKEY\_USER

##### Keys

Keys are the folders in the registry. Keys can have many nested subkeys. Keys can have a value assigned to them under the (Default)

##### Values or Entries

Values/Entries are name/data pairs. There can be many values in a key. The (Default) value corresponds to the Key, the rest are their own value pairs.

##### depends

- winreg Python module

class salt.modules.reg.**Registry**

Delay `'_winreg'` usage until this module is used

salt.modules.reg.**create\_key**(hkey, path, key=None, value=None, reflection=True)

**\* Incorrect Usage \*** The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

<https://github.com/saltstack/salt/issues/25618>

In order to not break existing state files this function will call the set\_value function if key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release path will be removed and key will be the path. You will not pass value. **\*\*\***

Create a registry key

CLI Example:

```
salt '*' reg.create_key HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version' '0.97'
```

salt.modules.reg.**delete\_key**(hkey, path, key=None, reflection=True, force=False)

**\* Incorrect Usage \*** The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

<https://github.com/saltstack/salt/issues/25618>

In order to not break existing state files this function will call the `delete_value` function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release path will be removed and key will be the path. reflection will also be removed. \*\*\*

Delete a registry key

CLI Example:

```
salt '*' reg.delete_key HKEY_CURRENT_USER 'SOFTWARE\Salt'
```

#### Parameters

- **hkey** (*str*) -- (will be changed to hive) The name of the hive. Can be one of the following - HKEY\_LOCAL\_MACHINE or HKLM - HKEY\_CURRENT\_USER or HKCU - HKEY\_USER or HKU
- **path** (*str*) -- (will be changed to key) The key (looks like a path) to remove.
- **key** (*str*) -- (used incorrectly) Will be removed in Boron
- **reflection** (*bool*) -- A boolean value indicating that the value should also be removed from the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

Only applies to delete value. If the key parameter is passed, this function calls `delete_value` instead. Will be changed in Boron.

- **force** (*bool*) -- A boolean value indicating that all subkeys should be removed as well. If this is set to False (default) and there are subkeys, the `delete_key` function will fail.

**Returns** Returns True if successful, False if not. If `force=True`, the results of `delete_key_recursive` are returned.

**Return type** `bool`

`salt.modules.reg.delete_key_recursive(hive, key)`

New in version 2015.5.4.

Delete a registry key to include all subkeys.

#### Parameters

- **hive** -- The name of the hive. Can be one of the following - HKEY\_LOCAL\_MACHINE or HKLM - HKEY\_CURRENT\_USER or HKCU - HKEY\_USER or HKU
- **key** -- The key to remove (looks like a path)

**Returns** A dictionary listing the keys that deleted successfully as well as those that failed to delete.

**Return type** `dict`

The following example will remove `salt` and all its subkeys from the `SOFTWARE` key in `HKEY_LOCAL_MACHINE`:

CLI Example:

```
salt '*' reg.delete_key_recursive HKLM SOFTWARE\salt
```

`salt.modules.reg.delete_value(hive, key, vname=None, reflection=True)`

Delete a registry value entry or the default value for a key.

#### Parameters

- **hive** (*str*) -- The name of the hive. Can be one of the following - HKEY\_LOCAL\_MACHINE or HKLM - HKEY\_CURRENT\_USER or HKCU - HKEY\_USER or HKU
- **key** (*str*) -- The key (looks like a path) to the value name.
- **vname** (*str*) -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be deleted.
- **reflection** (*bool*) -- A boolean value indicating that the value should also be set in the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

**Returns** Returns True if successful, False if not

**Return type** `bool`

CLI Example:

```
salt '*' reg.delete_value HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version'
```

`salt.modules.reg.read_key(hkey, path, key=None)`

**\* Incorrect Usage \*** The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

<https://github.com/saltstack/salt/issues/25618>

In order to not break existing state files this function will call the `read_value` function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release this function will be removed in favor of `read_value`. \*\*\*

Read registry key value

Returns the first unnamed value (Default) as a string. Returns none if first unnamed value is empty. Returns False if key not found.

CLI Example:

```
salt '*' reg.read_key HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version'
```

`salt.modules.reg.read_value(hive, key, vname=None)`

Reads a registry value entry or the default value for a key.

#### Parameters

- **hive** (*str*) -- The name of the hive. Can be one of the following - HKEY\_LOCAL\_MACHINE or HKLM - HKEY\_CURRENT\_USER or HKCU - HKEY\_USER or HKU
- **key** (*str*) -- The key (looks like a path) to the value name.
- **vname** (*str*) -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be returned

#### Returns

A dictionary containing the passed settings as well as the `value_data` if successful. If unsuccessful, sets `success` to False

If `vname` is not passed: - Returns the first unnamed value (Default) as a string. - Returns none if first unnamed value is empty. - Returns False if key not found.

**Return type** `dict`

CLI Example:

```
salt '*' reg.read_value HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version'
```

`salt.modules.reg.set_key` (*hkey*, *path*, *value*, *key=None*, *vtype='REG\_DWORD'*, *reflection=True*)

\* **Incorrect Usage** \* The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

<https://github.com/saltstack/salt/issues/25618>

In order to not break existing state files this function will call the `set_value` function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release this function will be removed in favor of `set_value`. \*\*\*

Set a registry key

*vtype*: [http://docs.python.org/2/library/\\_winreg.html#value-types](http://docs.python.org/2/library/_winreg.html#value-types)

CLI Example:

```
salt '*' reg.set_key HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version' '0.97' REG_DWORD
```

`salt.modules.reg.set_value` (*hive*, *key*, *vname=None*, *vdata=None*, *vtype='REG\_SZ'*, *reflection=True*)

Sets a registry value entry or the default value for a key.

#### Parameters

- **hive** (*str*) -- The name of the hive. Can be one of the following - HKEY\_LOCAL\_MACHINE or HKLM - HKEY\_CURRENT\_USER or HKCU - HKEY\_USER or HKU
- **key** (*str*) -- The key (looks like a path) to the value name.
- **vname** (*str*) -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be set.
- **vdata** (*str*) -- The value data to be set.
- **vtype** (*str*) -- The value type. Can be one of the following: - REG\_BINARY - REG\_DWORD - REG\_EXPAND\_SZ - REG\_MULTI\_SZ - REG\_SZ
- **reflection** (*bool*) -- A boolean value indicating that the value should also be set in the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

**Returns** Returns True if successful, False if not

**Return type** `bool`

CLI Example:

```
salt '*' reg.set_value HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version' '2015.5.2'
```

### 30.16.194 salt.modules.rest\_package

Service support for the REST example

`salt.modules.rest_package.install` (*name=None*, *refresh=False*, *fromrepo=None*, *pkgs=None*, *sources=None*, *\*\*kwargs*)

```
salt.modules.rest_package.installed(name, version=None, refresh=False, fromrepo=None, skip_verify=False, pkgs=None, sources=None, **kwargs)
```

```
salt.modules.rest_package.list_pkgs(versions_as_list=False, **kwargs)
```

```
salt.modules.rest_package.remove(name=None, pkgs=None, **kwargs)
```

```
salt.modules.rest_package.version(*names, **kwargs)
```

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

### 30.16.195 salt.modules.rest\_sample

Module for interfacing to the REST example

pre-pre-ALPHA QUALITY code.

```
salt.modules.rest_sample.grains_refresh()
```

Refresh the cache.

```
salt.modules.rest_sample.ping()
```

### 30.16.196 salt.modules.rest\_service

Service support for the REST example

```
salt.modules.rest_service.list_()
```

List services.

CLI Example:

```
salt '*' rest_service.list <service name>
```

```
salt.modules.rest_service.restart(name)
```

Restart the named service

CLI Example:

```
salt '*' rest_service.restart <service name>
```

```
salt.modules.rest_service.start(name)
```

Start the specified service

CLI Example:

```
salt '*' rest_service.start <service name>
```

```
salt.modules.rest_service.status(name)
```

Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' rest_service.status <service name>
```

`salt.modules.rest_service.stop(name)`

Stop the specified service

CLI Example:

```
salt '*' rest_service.stop <service name>
```

### 30.16.197 salt.modules.ret

Module to integrate with the returner system and retrieve data sent to a salt returner

`salt.modules.ret.get_fun(returner, fun)`

Return info about last time fun was called on each minion

CLI Example:

```
salt '*' ret.get_fun mysql network.interfaces
```

`salt.modules.ret.get_jid(returner, jid)`

Return the information for a specified job id

CLI Example:

```
salt '*' ret.get_jid redis 20421104181954700505
```

`salt.modules.ret.get_jids(returner)`

Return a list of all job ids

CLI Example:

```
salt '*' ret.get_jids mysql
```

`salt.modules.ret.get_minions(returner)`

Return a list of all minions

CLI Example:

```
salt '*' ret.get_minions mysql
```

### 30.16.198 salt.modules.rh\_ip

The networking module for RHEL/Fedora based distros

`salt.modules.rh_ip.apply_network_settings(**settings)`

Apply global network configuration.

CLI Example:

```
salt '*' ip.apply_network_settings
```

`salt.modules.rh_ip.build_bond(iface, **settings)`

Create a bond script in /etc/modprobe.d with the passed settings and load the bonding kernel module.

CLI Example:

```
salt '*' ip.build_bond bond0 mode=balance-alb
```

`salt.modules.rh_ip.build_interface`(*iface*, *iface\_type*, *enabled*, *\*\*settings*)  
Build an interface script for a network interface.

CLI Example:

```
salt '*' ip.build_interface eth0 eth <settings>
```

`salt.modules.rh_ip.build_network_settings`(*\*\*settings*)  
Build the global network script.

CLI Example:

```
salt '*' ip.build_network_settings <settings>
```

`salt.modules.rh_ip.build_routes`(*iface*, *\*\*settings*)  
Build a route script for a network interface.

CLI Example:

```
salt '*' ip.build_routes eth0 <settings>
```

`salt.modules.rh_ip.down`(*iface*, *iface\_type*)  
Shutdown a network interface

CLI Example:

```
salt '*' ip.down eth0
```

`salt.modules.rh_ip.get_bond`(*iface*)  
Return the content of a bond script

CLI Example:

```
salt '*' ip.get_bond bond0
```

`salt.modules.rh_ip.get_interface`(*iface*)  
Return the contents of an interface script

CLI Example:

```
salt '*' ip.get_interface eth0
```

`salt.modules.rh_ip.get_network_settings`()  
Return the contents of the global network script.

CLI Example:

```
salt '*' ip.get_network_settings
```

`salt.modules.rh_ip.get_routes`(*iface*)  
Return the contents of the interface routes script.

CLI Example:

```
salt '*' ip.get_routes eth0
```

`salt.modules.rh_ip.up`(*iface*, *iface\_type*)  
Start up a network interface

CLI Example:

```
salt '*' ip.up eth0
```

### 30.16.199 salt.modules.rh\_service

Service support for RHEL-based systems, including support for both upstart and sysvinit

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `'service.start' is not available`), see [here](#).

**salt.modules.rh\_service.available**(*name*, *limit*='')

Return True if the named service is available. Use the `limit` param to restrict results to services of that type.

CLI Examples:

```
salt '*' service.available sshd
salt '*' service.available sshd limit=upstart
salt '*' service.available sshd limit=sysvinit
```

**salt.modules.rh\_service.disable**(*name*, **\*\*kwargs**)

Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

**salt.modules.rh\_service.disabled**(*name*)

Check to see if the named service is disabled to start on boot

CLI Example:

```
salt '*' service.disabled <service name>
```

**salt.modules.rh\_service.enable**(*name*, **\*\*kwargs**)

Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

**salt.modules.rh\_service.enabled**(*name*, **\*\*kwargs**)

Check to see if the named service is enabled to start on boot

CLI Example:

```
salt '*' service.enabled <service name>
```

**salt.modules.rh\_service.get\_all**(*limit*='')

Return all installed services. Use the `limit` param to restrict results to services of that type.

CLI Example:

```
salt '*' service.get_all
salt '*' service.get_all limit=upstart
salt '*' service.get_all limit=sysvinit
```

**salt.modules.rh\_service.get\_disabled**(*limit*='')

Return the disabled services. Use the `limit` param to restrict results to services of that type.

CLI Example:

```
salt '*' service.get_disabled
salt '*' service.get_disabled limit=upstart
salt '*' service.get_disabled limit=sysvinit
```

`salt.modules.rh_service.get_enabled(limit='')`

Return the enabled services. Use the `limit` param to restrict results to services of that type.

CLI Examples:

```
salt '*' service.get_enabled
salt '*' service.get_enabled limit=upstart
salt '*' service.get_enabled limit=sysvinit
```

`salt.modules.rh_service.missing(name, limit='')`

The inverse of `service.available`. Return True if the named service is not available. Use the `limit` param to restrict results to services of that type.

CLI Examples:

```
salt '*' service.missing sshd
salt '*' service.missing sshd limit=upstart
salt '*' service.missing sshd limit=sysvinit
```

`salt.modules.rh_service.reload_(name)`

Reload the named service

CLI Example:

```
salt '*' service.reload <service name>
```

`salt.modules.rh_service.restart(name)`

Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.rh_service.start(name)`

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.rh_service.status(name, sig=None)`

Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

`salt.modules.rh_service.stop(name)`

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.200 salt.modules.riak

#### Riak Salt Module

Author: David Boucha <boucha@gmail.com>

`salt.modules.riak.cluster_commit()`

Commit Cluster Changes

CLI Example:

```
salt '*' riak.cluster_commit
```

`salt.modules.riak.cluster_join(riak_user=None, riak_host=None)`

Join a Riak cluster

CLI Example:

```
salt '*' riak.cluster_join <user> <host>
```

`salt.modules.riak.cluster_plan()`

Review Cluster Plan

CLI Example:

```
salt '*' riak.cluster_plan
```

`salt.modules.riak.member_status()`

Get cluster member status

CLI Example:

```
salt '*' riak.member_status
```

`salt.modules.riak.start()`

Start Riak

CLI Example:

```
salt '*' riak.start
```

`salt.modules.riak.stop()`

Stop Riak

CLI Example:

```
salt '*' riak.stop
```

### 30.16.201 salt.modules.rpm

Support for rpm

`salt.modules.rpm.diff(package, path)`

Return a formatted diff between current file and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

#### Parameters

- **package** -- The name of the package
- **path** -- Full path to the installed file

**Returns** Difference or empty string. For binary files only a notification.

CLI example:

```
salt '*' lowpkg.diff apache2 /etc/apache2/httpd.conf
```

`salt.modules.rpm.file_dict(*packages)`

List the files that belong to a package, sorted by group. Not specifying any packages will return a list of `_every_file` on the system's rpm database (not generally recommended).

CLI Examples:

```
salt '*' lowpkg.file_dict httpd
salt '*' lowpkg.file_dict httpd postfix
salt '*' lowpkg.file_dict
```

`salt.modules.rpm.file_list(*packages)`

List the files that belong to a package. Not specifying any packages will return a list of `_every_file` on the system's rpm database (not generally recommended).

CLI Examples:

```
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

`salt.modules.rpm.list_pkgs(*packages)`

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' lowpkg.list_pkgs
```

`salt.modules.rpm.modified(*packages, **flags)`

List the modified files that belong to a package. Not specifying any packages will return a list of `_all_modified` files on the system's RPM database.

New in version 2015.5.0.

CLI examples:

```
salt '*' lowpkg.modified httpd
salt '*' lowpkg.modified httpd postfix
salt '*' lowpkg.modified
```

`salt.modules.rpm.owner(*paths)`

Return the name of the package that owns the file. Multiple file paths can be passed. If a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:

```
salt '*' lowpkg.owner /usr/bin/apachectl
salt '*' lowpkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```

`salt.modules.rpm.verify(*package, **kwargs)`

Runs an `rpm -Va` on a system, and returns the results in a dict

Files with an attribute of `config`, `doc`, `ghost`, `license` or `readme` in the package header can be ignored using the `ignore_types` keyword argument

CLI Example:

```
salt '*' lowpkg.verify
salt '*' lowpkg.verify httpd
salt '*' lowpkg.verify 'httpd postfix'
salt '*' lowpkg.verify 'httpd postfix' ignore_types=['config','doc']
```

### 30.16.202 salt.modules.rsync

Wrapper for `rsync`

New in version 2014.1.0.

This data can also be passed into `pillar`. Options passed into `opts` will overwrite options passed into `pillar`.

`salt.modules.rsync.config(configfile='/etc/rsyncd.conf')`

Return `rsync` config

CLI Example:

```
salt '*' rsync.config
```

`salt.modules.rsync.rsync(src, dst, delete=False, force=False, update=False, passwordfile=None, exclude=None, excludefrom=None)`

Rsync files from `src` to `dst`

CLI Example:

```
salt '*' rsync.rsync {src} {dst} {delete=True} {update=True} {passwordfile=/etc/pass.crt} {exclude}
salt '*' rsync.rsync {src} {dst} {delete=True} {excludefrom=/xx.ini}
```

`salt.modules.rsync.version()`

Return `rsync` version

CLI Example:

```
salt '*' rsync.version
```

### 30.16.203 salt.modules.runit

`runit` service module

This module is compatible with the `service` states, so it can be used to maintain services using the `provider` argument:

```
myservice:
  service:
    - running
    - provider: runit
```

Note that the `enabled` argument is not available with this provider.

`salt.modules.runit.available(name)`

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' runit.available foo
```

`salt.modules.runit.full_restart(name)`

Calls `runit.restart()` function

CLI Example:

```
salt '*' runit.full_restart <service name>
```

`salt.modules.runit.get_all()`

Return a list of all available services

CLI Example:

```
salt '*' runit.get_all
```

`salt.modules.runit.missing(name)`

The inverse of `runit.available`. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' runit.missing foo
```

`salt.modules.runit.reload_(name)`

Send a HUP to service via `runit`

CLI Example:

```
salt '*' runit.reload <service name>
```

`salt.modules.runit.restart(name)`

Restart service via `runit`. This will stop/start service

CLI Example:

```
salt '*' runit.restart <service name>
```

`salt.modules.runit.start(name)`

Starts service via `runit`

CLI Example:

```
salt '*' runit.start <service name>
```

`salt.modules.runit.status(name, sig=None)`

Return the status for a service via `runit`, return pid if running

CLI Example:

```
salt '*' runit.status <service name>
```

`salt.modules.runit.stop(name)`

Stops service via `runit`

CLI Example:

```
salt '*' runit.stop <service name>
```

`salt.modules.runit.term(name)`

Send a TERM to service via runit

CLI Example:

```
salt '*' runit.term <service name>
```

### 30.16.204 salt.modules.rvm

Manage ruby installations and gemsets with RVM, the Ruby Version Manager.

`salt.modules.rvm.do(ruby, command, runas=None, cwd=None)`

Execute a command in an RVM controlled environment.

**ruby:** The ruby to use.

**command:** The command to execute.

**runas** [None] The user to run rvm as.

**cwd** [None] The current working directory.

CLI Example:

```
salt '*' rvm.do 2.0.0 <command>
```

`salt.modules.rvm.gemset_copy(source, destination, runas=None)`

Copy all gems from one gemset to another.

**source** The name of the gemset to copy, complete with ruby version.

**destination** The destination gemset.

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.gemset_copy foobar bazquo
```

`salt.modules.rvm.gemset_create(ruby, gemset, runas=None)`

Creates a gemset.

**ruby** The ruby version to create the gemset for.

**gemset** The name of the gemset to create.

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.gemset_create 2.0.0 foobar
```

`salt.modules.rvm.gemset_delete(ruby, gemset, runas=None)`

Deletes a gemset.

**ruby** The ruby version the gemset belongs to.

**gemset** The gemset to delete.

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.gemset_delete 2.0.0 foobar
```

`salt.modules.rvm.gemset_empty`(*ruby*, *gemset*, *runas=None*)

Remove all gems from a gemset.

**ruby** The ruby version the gemset belongs to.

**gemset** The gemset to empty.

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.gemset_empty 2.0.0 foobar
```

`salt.modules.rvm.gemset_list`(*ruby='default'*, *runas=None*)

List all gemsets for the given ruby.

**ruby** [default] The ruby version to list the gemsets for

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.gemset_list
```

`salt.modules.rvm.gemset_list_all`(*runas=None*)

List all gemsets for all installed rubies.

Note that you must have set a default ruby before this can work.

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.gemset_list_all
```

`salt.modules.rvm.get`(*version='stable'*, *runas=None*)

Update RVM.

**version** [stable] Which version of RVM to install, e.g. stable or head.

**ruby** The version of ruby to reinstall.

CLI Example:

```
salt '*' rvm.get
```

`salt.modules.rvm.install`(*runas=None*)

Install RVM system wide.

CLI Example:

```
salt '*' rvm.install
```

`salt.modules.rvm.install_ruby`(*ruby*, *runas=None*)

Install a ruby implementation.

**ruby** The version of ruby to install.

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.install_ruby 1.9.3-p385
```

`salt.modules.rvm.is_installed`(*runas=None*)

Check if RVM is installed.

CLI Example:

```
salt '*' rvm.is_installed
```

`salt.modules.rvm.list`(*runas=None*)

List all rvm installed rubies.

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.list
```

`salt.modules.rvm.reinstall_ruby`(*ruby, runas=None*)

Reinstall a ruby implementation.

**ruby** The version of ruby to reinstall.

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.reinstall_ruby 1.9.3-p385
```

`salt.modules.rvm.rubygems`(*ruby, version, runas=None*)

Installs a specific rubygems version in the given ruby.

**ruby** The ruby to install rubygems for.

**version** The version of rubygems to install or 'remove' to use the version that ships with 1.9

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.rubygems 2.0.0 1.8.24
```

`salt.modules.rvm.set_default`(*ruby, runas=None*)

Set the default ruby.

**ruby** The version of ruby to make the default.

**runas** [None] The user to run rvm as.

CLI Example:

```
salt '*' rvm.set_default 2.0.0
```

`salt.modules.rvm.wrapper`(*ruby\_string, wrapper\_prefix, runas=None, \*binaries*)

Install RVM wrapper scripts.

**ruby\_string** Ruby/gemset to install wrappers for.

**wrapper\_prefix** What to prepend to the name of the generated wrapper binaries.

**runas** [None] The user to run rvm as.

**binaries** [None] The names of the binaries to create wrappers for. When nothing is given, wrappers for ruby, gem, rake, irb, rdoc, ri and testrb are generated.

CLI Example:

```
salt '*' rvm.wrapper <ruby_string> <wrapper_prefix>
```

### 30.16.205 salt.modules.s3

Connection module for Amazon S3

**configuration** This module accepts explicit s3 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
s3.keyid: GKTADJGHEIQSXMKKRBJ08H
s3.key: askdjghsdfjkghWupUjasdfklkfklgsdfjajkghs
```

A service\_url may also be specified in the configuration:

```
s3.service_url: s3.amazonaws.com
```

If a service\_url is not specified, the default is s3.amazonaws.com. This may appear in various documentation as an "endpoint". A comprehensive list for Amazon S3 may be found at:

```
http://docs.aws.amazon.com/general/latest/gr/rande.html#s3\_region
```

The service\_url will form the basis for the final endpoint that is used to query the service.

SSL verification may also be turned off in the configuration:

```
s3.verify_ssl: False
```

This is required if using S3 bucket names that contain a period, as these will not match Amazon's S3 wildcard certificates. Certificate verification is enabled by default.

AWS region may be specified in the configuration:

```
s3.location: eu-central-1
```

Default is us-east-1.

This module should be usable to query other S3-like services, such as Eucalyptus.

**depends** requests

**salt.modules.s3.delete** (*bucket*, *path=None*, *action=None*, *key=None*, *keyid=None*, *service\_url=None*, *verify\_ssl=None*, *location=None*)

Delete a bucket, or delete an object from a bucket.

CLI Example to delete a bucket:

```
salt myminion s3.delete mybucket
```

CLI Example to delete an object from a bucket:

```
salt myminion s3.delete mybucket remoteobject
```

`salt.modules.s3.get`(*bucket=None, path=None, return\_bin=False, action=None, local\_file=None, key=None, keyid=None, service\_url=None, verify\_ssl=None, location=None*)

List the contents of a bucket, or return an object from a bucket. Set `return_bin` to `True` in order to retrieve an object wholesale. Otherwise, Salt will attempt to parse an XML response.

CLI Example to list buckets:

```
salt myminion s3.get
```

CLI Example to list the contents of a bucket:

```
salt myminion s3.get mybucket
```

CLI Example to return the binary contents of an object:

```
salt myminion s3.get mybucket myfile.png return_bin=True
```

CLI Example to save the binary contents of an object to a local file:

```
salt myminion s3.get mybucket myfile.png local_file=/tmp/myfile.png
```

It is also possible to perform an action on a bucket. Currently, S3 supports the following actions:

```
acl
cors
lifecycle
policy
location
logging
notification
tagging
versions
requestPayment
versioning
website
```

To perform an action on a bucket:

```
salt myminion s3.get mybucket myfile.png action=acl
```

`salt.modules.s3.head`(*bucket, path=None, key=None, keyid=None, service\_url=None, verify\_ssl=None, location=None*)

Return the metadata for a bucket, or an object in a bucket.

CLI Examples:

```
salt myminion s3.head mybucket
salt myminion s3.head mybucket myfile.png
```

`salt.modules.s3.put`(*bucket, path=None, return\_bin=False, action=None, local\_file=None, key=None, keyid=None, service\_url=None, verify\_ssl=None, location=None*)

Create a new bucket, or upload an object to a bucket.

CLI Example to create a bucket:

```
salt myminion s3.put mybucket
```

CLI Example to upload an object to a bucket:

```
salt myminion s3.put mybucket remotepath local_file=/path/to/file
```

### 30.16.206 salt.modules.saltcloudmod

Control a salt cloud system

`salt.modules.saltcloudmod.create(name, profile)`

Create the named vm

CLI Example:

```
salt <minion-id> saltcloud.create webserver rackspace_centos_512
```

### 30.16.207 salt.modules.saltutil

The Saltutil module is used to manage the state of the salt minion itself. It is used to manage minion modules as well as automate updates to the salt minion.

**depends**

- esky Python module for update functionality

`salt.modules.saltutil.clear_cache()`

Forcibly removes all caches on a minion.

New in version 2014.7.0.

WARNING: The safest way to clear a minion cache is by first stopping the minion and then deleting the cache files before restarting it.

CLI Example:

```
salt '*' saltutil.clear_cache
```

`salt.modules.saltutil.cmd(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='', kwarg=None, ssh=False, **kwargs)`

Assuming this minion is a master, execute a salt command

CLI Example:

```
salt '*' saltutil.cmd
```

`salt.modules.saltutil.cmd_iter(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='', kwarg=None, ssh=False, **kwargs)`

Assuming this minion is a master, execute a salt command

CLI Example:

```
salt '*' saltutil.cmd_iter
```

`salt.modules.saltutil.find_cached_job(jid)`

Return the data for a specific cached job id

CLI Example:

```
salt '*' saltutil.find_cached_job <job id>
```

`salt.modules.saltutil.find_job(jid)`

Return the data for a specific job id

CLI Example:

```
salt '*' saltutil.find_job <job id>
```

`salt.modules.saltutil.is_running(fun)`

If the named function is running return the data associated with it/them. The argument can be a glob

CLI Example:

```
salt '*' saltutil.is_running state.highstate
```

`salt.modules.saltutil.kill_job(jid)`

Sends a kill signal (SIGKILL 9) to the named salt job's process

CLI Example:

```
salt '*' saltutil.kill_job <job id>
```

`salt.modules.saltutil.mmodule(saltenv, fun, *args, **kwargs)`

Loads minion modules from an environment so that they can be used in pillars for that environment

CLI Example:

```
salt '*' saltutil.mmodule base test.ping
```

`salt.modules.saltutil.pillar_refresh()`

Signal the minion to refresh the pillar data.

CLI Example:

```
salt '*' saltutil.refresh_pillar
```

`salt.modules.saltutil.refresh_beacons()`

Signal the minion to refresh the beacons.

CLI Example:

```
salt '*' saltutil.refresh_beacons
```

`salt.modules.saltutil.refresh_modules()`

Signal the minion to refresh the module and grain data

CLI Example:

```
salt '*' saltutil.refresh_modules
```

`salt.modules.saltutil.refresh_pillar()`

Signal the minion to refresh the pillar data.

CLI Example:

```
salt '*' saltutil.refresh_pillar
```

`salt.modules.saltutil.regen_keys()`

Used to regenerate the minion keys.

CLI Example:

```
salt '*' saltutil.regen_keys
```

`salt.modules.saltutil.revoke_auth(preserve_minion_cache=False)`

The minion sends a request to the master to revoke its own key. Note that the minion session will be revoked and the minion may not be able to return the result of this command back to the master.

If the `'preserve_minion_cache'` flag is set to True, the master cache for this minion will not be removed.

CLI Example:

```
salt '*' saltutil.revoke_auth
```

**salt.modules.saltutil.runner**(*\_fun, \*\*kwargs*)  
Execute a runner module (this function must be run on the master)

New in version 2014.7.0.

**name** The name of the function to run

**kwargs** Any keyword arguments to pass to the runner function

CLI Example:

```
salt '*' saltutil.runner jobs.list_jobs
```

**salt.modules.saltutil.running**()  
Return the data on all running salt processes on the minion

CLI Example:

```
salt '*' saltutil.running
```

**salt.modules.saltutil.signal\_job**(*jid, sig*)  
Sends a signal to the named salt job's process

CLI Example:

```
salt '*' saltutil.signal_job <job id> 15
```

**salt.modules.saltutil.sync\_all**(*saltenv=None, refresh=True*)  
Sync down all of the dynamic modules from the file server for a specific environment. This function synchronizes custom modules, states, beacons, grains, returners, output modules, renderers, and utils.

**refresh** [True] Also refresh the execution modules available to the minion.

CLI Example:

```
salt '*' saltutil.sync_all
```

**salt.modules.saltutil.sync\_beacons**(*saltenv=None, refresh=True*)  
Sync the beacons from the `_beacons` directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the `_beacons` directory, `base` is the default environment.

New in version 2015.5.1.

CLI Example:

```
salt '*' saltutil.sync_beacons
```

**salt.modules.saltutil.sync\_grains**(*saltenv=None, refresh=True*)  
Sync the grains from the `_grains` directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the `_grains` directory, `base` is the default environment.

CLI Example:

```
salt '*' saltutil.sync_grains
```

**salt.modules.saltutil.sync\_modules**(*saltenv=None, refresh=True*)  
Sync the modules from the `_modules` directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the `_modules` directory, `base` is the default environment.

New in version 2015.5.1.

CLI Example:

```
salt '*' saltutil.sync_modules
```

`salt.modules.saltutil.sync_output` (*saltenv=None, refresh=True*)

Sync the output modules from the `_output` directory on the salt master file server. This function is environment aware. Pass the desired environment to grab the contents of the `_output` directory. Base is the default environment.

CLI Example:

```
salt '*' saltutil.sync_output
```

`salt.modules.saltutil.sync_outputters` (*saltenv=None, refresh=True*)

Sync the output modules from the `_output` directory on the salt master file server. This function is environment aware. Pass the desired environment to grab the contents of the `_output` directory. Base is the default environment.

CLI Example:

```
salt '*' saltutil.sync_output
```

`salt.modules.saltutil.sync_renderers` (*saltenv=None, refresh=True*)

Sync the renderers from the `_renderers` directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the `_renderers` directory, base is the default environment.

CLI Example:

```
salt '*' saltutil.sync_renderers
```

`salt.modules.saltutil.sync_returners` (*saltenv=None, refresh=True*)

Sync the returners from the `_returners` directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the `_returners` directory, base is the default environment.

CLI Example:

```
salt '*' saltutil.sync_returners
```

`salt.modules.saltutil.sync_sdb` (*saltenv=None, refresh=False*)

Sync sdb modules from the `_sdb` directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the `_sdb` directory, base is the default environment.

New in version 2015.5.7.

CLI Example:

```
salt '*' saltutil.sync_sdb
```

`salt.modules.saltutil.sync_states` (*saltenv=None, refresh=True*)

Sync the states from the `_states` directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the `_states` directory, base is the default environment.

CLI Example:

```
salt '*' saltutil.sync_states
```

`salt.modules.saltutil.sync_utils` (*saltenv=None, refresh=True*)

Sync utility source files from the `_utils` directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the `_utils` directory, base is the default environment.

CLI Example:

```
salt '*' saltutil.sync_utils
```

`salt.modules.saltutil.term_job` (*jid*)

Sends a termination signal (SIGTERM 15) to the named salt job's process

CLI Example:

```
salt '*' saltutil.term_job <job id>
```

`salt.modules.saltutil.update` (*version=None*)

Update the salt minion from the URL defined in `opts['update_url']` SaltStack, Inc provides the latest builds here: `update_url`: <http://docs.saltstack.com/downloads/>

Be aware that as of 2014-8-11 there's a bug in esky such that only the latest version available in the `update_url` can be downloaded and installed.

This feature requires the minion to be running a `bdist_esky` build.

The version number is optional and will default to the most recent version available at `opts['update_url']`.

Returns details about the transaction upon completion.

CLI Example:

```
salt '*' saltutil.update
salt '*' saltutil.update 0.10.3
```

`salt.modules.saltutil.wheel` (*\_fun, \*\*kwargs*)

Execute a wheel module (this function must be run on the master)

New in version 2014.7.0.

**name** The name of the function to run

**kwargs** Any keyword arguments to pass to the wheel function

CLI Example:

```
salt '*' saltutil.wheel key.accept match=jerry
```

### 30.16.208 salt.modules.schedule

Module for managing the Salt schedule on a minion

New in version 2014.7.0.

`salt.modules.schedule.add` (*name, \*\*kwargs*)

Add a job to the schedule

CLI Example:

```
salt '*' schedule.add job1 function='test.ping' seconds=3600
# If function have some arguments, use job_args
salt '*' schedule.add job2 function='cmd.run' job_args=["'date >> /tmp/date.log'"] seconds=60
```

`salt.modules.schedule.build_schedule_item(name, **kwargs)`  
Build a schedule job

CLI Example:

```
salt '*' schedule.build_schedule_item job1 function='test.ping' seconds=3600
```

`salt.modules.schedule.copy(name, target, **kwargs)`  
Copy scheduled job to another minion or minions.

CLI Example:

```
salt '*' schedule.copy jobname target
```

`salt.modules.schedule.delete(name, **kwargs)`  
Delete a job from the minion's schedule

CLI Example:

```
salt '*' schedule.delete job1
```

`salt.modules.schedule.disable(**kwargs)`  
Disable all scheduled jobs on the minion

CLI Example:

```
salt '*' schedule.disable
```

`salt.modules.schedule.disable_job(name, **kwargs)`  
Disable a job in the minion's schedule

CLI Example:

```
salt '*' schedule.disable_job job1
```

`salt.modules.schedule.enable(**kwargs)`  
Enable all scheduled jobs on the minion

CLI Example:

```
salt '*' schedule.enable
```

`salt.modules.schedule.enable_job(name, **kwargs)`  
Enable a job in the minion's schedule

CLI Example:

```
salt '*' schedule.enable_job job1
```

`salt.modules.schedule.is_enabled(name)`  
List a Job only if its enabled

New in version 2015.5.3.

CLI Example:

```
salt '*' schedule.is_enabled name=job_name
```

`salt.modules.schedule.list_(show_all=False, return_yaml=True)`  
List the jobs currently scheduled on the minion

CLI Example:

```
salt '*' schedule.list  
salt '*' schedule.list show_all=True
```

**salt.modules.schedule.modify**(*name*, *\*\*kwargs*)  
Modify an existing job in the schedule

CLI Example:

```
salt '*' schedule.modify job1 function='test.ping' seconds=3600
```

**salt.modules.schedule.move**(*name*, *target*, *\*\*kwargs*)  
Move scheduled job to another minion or minions.

CLI Example:

```
salt '*' schedule.move jobname target
```

**salt.modules.schedule.purge**(*\*\*kwargs*)  
Purge all the jobs currently scheduled on the minion

CLI Example:

```
salt '*' schedule.purge
```

**salt.modules.schedule.reload\_**()  
Reload saved scheduled jobs on the minion

CLI Example:

```
salt '*' schedule.reload
```

**salt.modules.schedule.run\_job**(*name*, *force=False*)  
Run a scheduled job on the minion immediately

CLI Example:

```
salt '*' schedule.run_job job1  
  
salt '*' schedule.run_job job1 force=True  
Force the job to run even if it is disabled.
```

**salt.modules.schedule.save**()  
Save all scheduled jobs on the minion

CLI Example:

```
salt '*' schedule.save
```

### 30.16.209 salt.modules.scsi

SCSI administration module

**salt.modules.scsi.ls\_**(*get\_size=True*)  
List SCSI devices, with details

CLI Examples:

```
salt '*' scsi.ls  
salt '*' scsi.ls get_size=False
```

**get\_size** [True] Get the size information for scsi devices. This option should be set to False for older OS distributions (RHEL6 and older) due to lack of support for the `-s` option in `lsscsi`.

New in version 2015.5.10.

`salt.modules.scsi.rescan_all(host)`

List scsi devices

CLI Example:

```
salt '*' scsi.rescan_all(0)
```

### 30.16.210 salt.modules.sdb

#### Module for Manipulating Data via the Salt DB API

`salt.modules.sdb.get(uri)`

Get a value from a db, using a uri in the form of `sdb://<profile>/<key>`. If the uri provided does not start with `sdb://`, then it will be returned as-is.

CLI Example:

```
salt '*' sdb.get sdb://mymemcached/foo
```

`salt.modules.sdb.set_(uri, value)`

Set a value in a db, using a uri in the form of `sdb://<profile>/<key>`. If the uri provided does not start with `sdb://` or the value is not successfully set, return False.

CLI Example:

```
salt '*' sdb.set sdb://mymemcached/foo bar
```

### 30.16.211 salt.modules.seed

Virtual machine image management tools

`salt.modules.seed.apply_(path, id=None, config=None, approve_key=True, install=True, prep_install=False)`

Seed a location (disk image, directory, or block device) with the minion config, approve the minion's key, and/or install salt-minion.

CLI Example:

```
salt 'minion' seed.apply path id [config=config_data] \
    [gen_key=(true|false)] [approve_key=(true|false)] \
    [install=(true|false)]
```

**path** Full path to the directory, device, or disk image on the target minion's file system.

**id** Minion id with which to seed the path.

**config** Minion configuration options. By default, the `master` option is set to the target host's `master`.

**approve\_key** Request a pre-approval of the generated minion key. Requires that the salt-master be configured to either auto-accept all keys or expect a signing request from the target host. Default: true.

**install** Install salt-minion, if absent. Default: true.

**prep\_install** Prepare the bootstrap script, but don't run it. Default: false

**salt.modules.seed.mkconfig**(*config=None, tmp=None, id\_=None, approve\_key=True, pub\_key=None, priv\_key=None*)

Generate keys and config and put them in a tmp directory.

**pub\_key** absolute path or file content of an optional preseeded salt key

**priv\_key** absolute path or file content of an optional preseeded salt key

CLI Example:

```
salt 'minion' seed.mkconfig [config=config_data] [tmp=tmp_dir] \  
[id_=minion_id] [approve_key=(true|false)]
```

**salt.modules.seed.prep\_bootstrap**(*mpt*)

Update and get the random script to a random place

CLI Example:

```
salt '*' seed.prep_bootstrap /tmp
```

### 30.16.212 salt.modules.selinux

Execute calls on selinux

---

**Note:** This module requires the `semanage` and `setsebool` commands to be available on the minion. On RHEL-based distributions, ensure that the `policycoreutils-python` package is installed. On Fedora 23 and up, ensure that the `policycoreutils-python-utils` package is installed. If not on a Fedora or RHEL-based distribution, consult the selinux documentation for your distro to ensure that the proper packages are installed.

---

**salt.modules.selinux.getenforce**()

Return the mode selinux is running in

CLI Example:

```
salt '*' selinux.getenforce
```

**salt.modules.selinux.getsebool**(*boolean*)

Return the information on a specific selinux boolean

CLI Example:

```
salt '*' selinux.getsebool virt_use_usb
```

**salt.modules.selinux.list\_sebool**()

Return a structure listing all of the selinux booleans on the system and what state they are in

CLI Example:

```
salt '*' selinux.list_sebool
```

**salt.modules.selinux.selinux\_fs\_path**(*\*args*)

Return the location of the SELinux VFS directory

CLI Example:

```
salt '*' selinux.selinux_fs_path
```

`salt.modules.selinux.setenforce(mode)`

Set the SELinux enforcing mode

CLI Example:

```
salt '*' selinux.setenforce enforcing
```

`salt.modules.selinux.setsebool(boolean, value, persist=False)`

Set the value for a boolean

CLI Example:

```
salt '*' selinux.setsebool virt_use_usb off
```

`salt.modules.selinux.setsebools(pairs, persist=False)`

Set the value of multiple booleans

CLI Example:

```
salt '*' selinux.setsebools '{virt_use_usb: on, squid_use_tproxy: off}'
```

### 30.16.213 salt.modules.sensors

Read lm-sensors

New in version 2014.1.3.

`salt.modules.sensors.sense(chip, fahrenheit=False)`

Gather lm-sensors data from a given chip

To determine the chip to query, use the `sensors` command and see the leading line in the block.

Example:

```
/usr/bin/sensors
```

```
coretemp-isa-0000 Adapter: ISA adapter Physical id 0: +56.0°C (high = +87.0°C, crit = +105.0°C) Core 0: +52.0°C (high = +87.0°C, crit = +105.0°C) Core 1: +50.0°C (high = +87.0°C, crit = +105.0°C) Core 2: +56.0°C (high = +87.0°C, crit = +105.0°C) Core 3: +53.0°C (high = +87.0°C, crit = +105.0°C)
```

Given the above, the chip is `coretemp-isa-0000`.

### 30.16.214 salt.modules.serverdensity\_device

#### Wrapper around Server Density API

New in version 2014.7.0.

`salt.modules.serverdensity_device.create(name, **params)`

Function to create device in Server Density. For more info, see the [API docs](#).

CLI Example:

```
salt '*' serverdensity_device.create lama
salt '*' serverdensity_device.create rich_lama group=lama_band installedRAM=32768
```

`salt.modules.serverdensity_device.delete(device_id)`

Delete a device from Server Density. For more information, see the [API docs](#).

CLI Example:

```
salt '*' serverdensity_device.delete 51f7eafcdba4bb235e000ae4
```

`salt.modules.serverdensity_device.get_sd_auth(val, sd_auth_pillar_name='serverdensity')`  
Returns requested Server Density authentication value from pillar.

CLI Example:

```
salt '*' serverdensity_device.get_sd_auth <val>
```

`salt.modules.serverdensity_device.install_agent(agent_key)`  
Function downloads Server Density installation agent, and installs sd-agent with agent\_key.

CLI Example:

```
salt '*' serverdensity_device.install_agent c2bbdd6689ff46282bdaa07555641498
```

`salt.modules.serverdensity_device.ls(**params)`  
List devices in Server Density

Results will be filtered by any params passed to this function. For more information, see the API docs on [listing](#) and [searching](#).

CLI Example:

```
salt '*' serverdensity_device.ls
salt '*' serverdensity_device.ls name=lama
salt '*' serverdensity_device.ls name=lama group=lama_band installedRAM=32768
```

`salt.modules.serverdensity_device.update(device_id, **params)`  
Updates device information in Server Density. For more information see the [API docs](#).

CLI Example:

```
salt '*' serverdensity_device.update 51f7eafcdba4bb235e000ae4 name=lama group=lama_band
salt '*' serverdensity_device.update 51f7eafcdba4bb235e000ae4 name=better_lama group=rock_lamas
```

### 30.16.215 salt.modules.service

service is a virtual module that is fulfilled by one of the following modules:

Execution Module	Used for
<code>debian_service</code>	Debian Wheezy and earlier
<code>freebsd_service</code>	FreeBSD-based OSes using <code>service(8)</code>
<code>gentoo_service</code>	Gentoo Linux using <code>sysvinit</code> and <code>rc-update(8)</code>
<code>launchctl</code>	Mac OS hosts using <code>launchctl(1)</code>
<code>netbsd_service</code>	NetBSD-based OSes
<code>openbsd_service</code>	OpenBSD-based OSes
<code>rh_service</code>	RedHat-based distros and derivatives using <code>service(8)</code> and <code>chkconfig(8)</code> . Supports both pure <code>sysvinit</code> and mixed <code>sysvinit/upstart</code> systems.
<code>service</code>	Fallback which simply wraps <code>sysvinit</code> scripts
<code>smf</code>	Solaris-based OSes which use SMF
<code>systemd</code>	Linux distros which use <code>systemd</code>
<code>upstart</code>	Ubuntu-based distros using <code>upstart</code>
<code>win_service</code>	Windows

If Salt's OS detection does not identify a different virtual service module, the minion will fall back to using this basic module, which simply wraps `sysvinit` scripts.

`salt.modules.service.available(name)`

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available sshd
```

`salt.modules.service.get_all()`

Return a list of all available services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.service.missing(name)`

The inverse of `service.available`. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing sshd
```

`salt.modules.service.reload_(name)`

Refreshes config files by calling `service reload`. Does not perform a full restart.

CLI Example:

```
salt '*' service.reload <service name>
```

`salt.modules.service.restart(name)`

Restart the specified service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.service.start`(*name*)

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.service.status`(*name*, *sig=None*)

Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps

CLI Example:

```
salt '*' service.status <service name> [service signature]
```

`salt.modules.service.stop`(*name*)

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.216 salt.modules.shadow

shadow is a virtual module that is fulfilled by one of the following modules:

Execution Module	Used for
<i>shadow</i>	Linux
<i>bsd_shadow</i>	FreeBSD, OpenBSD, NetBSD
<i>solaris_shadow</i>	Solaris-based OSes
<i>win_shadow</i>	Windows

Manage the shadow file on Linux systems

---

**Important:** If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `'shadow.info' is not available`), see [here](#).

---

`salt.modules.shadow.default_hash`()

Returns the default hash used for unset passwords

CLI Example:

```
salt '*' shadow.default_hash
```

`salt.modules.shadow.del_password`(*name*)

New in version 2014.7.0.

Delete the password from name user

CLI Example:

```
salt '*' shadow.del_password username
```

`salt.modules.shadow.gen_password`(*password*, *crypt\_salt=None*, *algorithm='sha512'*)

New in version 2014.7.0.

Generate hashed password

**Note:** When called this function is called directly via remote-execution, the password argument may be displayed in the system's process list. This may be a security risk on certain systems.

**password** Plaintext password to be hashed.

**crypt\_salt** Cryptographic salt. If not given, a random 8-character salt will be generated.

**algorithm** The following hash algorithms are supported:

- md5
- blowfish (not in mainline glibc, only available in distros that add it)
- sha256
- sha512 (default)

CLI Example:

```
salt '*' shadow.gen_password 'I_am_password'
salt '*' shadow.gen_password 'I_am_password' crypt_salt'I_am_salt' algorithm=sha256
```

`salt.modules.shadow.info`(*name*)

Return information for the specified user

CLI Example:

```
salt '*' shadow.info root
```

`salt.modules.shadow.set_date`(*name*, *date*)

Sets the value for the date the password was last changed to days since the epoch (January 1, 1970). See man chage.

CLI Example:

```
salt '*' shadow.set_date username 0
```

`salt.modules.shadow.set_expire`(*name*, *expire*)

Changed in version 2014.7.0.

Sets the value for the date the account expires as days since the epoch (January 1, 1970). Using a value of -1 will clear expiration. See man chage.

CLI Example:

```
salt '*' shadow.set_expire username -1
```

`salt.modules.shadow.set_inactdays`(*name*, *inactdays*)

Set the number of days of inactivity after a password has expired before the account is locked. See man chage.

CLI Example:

```
salt '*' shadow.set_inactdays username 7
```

`salt.modules.shadow.set_maxdays`(*name*, *maxdays*)

Set the maximum number of days during which a password is valid. See man chage.

CLI Example:

```
salt '*' shadow.set_maxdays username 90
```

`salt.modules.shadow.set_mindays`(*name*, *mindays*)

Set the minimum number of days between password changes. See man chage.

CLI Example:

```
salt '*' shadow.set_mindays username 7
```

`salt.modules.shadow.set_password`(*name*, *password*, *use\_usermod=False*)

Set the password for a named user. The password must be a properly defined hash. The password hash can be generated with this command:

```
python -c "import crypt; print crypt.crypt('password', '\$6\$\$SALTsalt')"
```

SALTsalt is the 8-character cryptographic salt. Valid characters in the salt are ., /, and any alphanumeric character.

Keep in mind that the \$6 represents a sha512 hash, if your OS is using a different hashing algorithm this needs to be changed accordingly

CLI Example:

```
salt '*' shadow.set_password root '$1$UYCIxa628.9qXjpQCjM4a..'
```

`salt.modules.shadow.set_warndays`(*name*, *warndays*)

Set the number of days of warning before a password change is required. See man chage.

CLI Example:

```
salt '*' shadow.set_warndays username 7
```

### 30.16.217 salt.modules.slack\_notify

Module for sending messages to Slack

New in version 2015.5.0.

**configuration** This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
slack:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

`salt.modules.slack_notify.find_room`(*name*, *api\_key=None*)

Find a room by name and return it. :param name: The room name. :param api\_key: The Slack admin api key. :return: The room object.

CLI Example:

```
salt '*' slack.find_room name="random"

salt '*' slack.find_room name="random" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

`salt.modules.slack_notify.find_user` (*name*, *api\_key=None*)

Find a user by name and return it. :param name: The user name. :param api\_key: The Slack admin api key. :return: The user object.

CLI Example:

```
salt '*' slack.find_user name="ThomasHatch"

salt '*' slack.find_user name="ThomasHatch" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

`salt.modules.slack_notify.list_rooms` (*api\_key=None*)

List all Slack rooms.

**Parameters** `api_key` -- The Slack admin api key.

**Returns** The room list.

CLI Example:

```
salt '*' slack.list_rooms

salt '*' slack.list_rooms api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

`salt.modules.slack_notify.list_users` (*api\_key=None*)

List all Slack users. :param api\_key: The Slack admin api key. :return: The user list.

CLI Example:

```
salt '*' slack.list_users

salt '*' slack.list_users api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

`salt.modules.slack_notify.post_message` (*channel*, *message*, *from\_name*, *api\_key=None*)

Send a message to a Slack channel. :param channel: The channel name, either will work. :param message: The message to send to the HipChat room. :param from\_name: Specify who the message is from. :param api\_key: The Slack api key, if not specified in the configuration. :return: Boolean if message was sent successfully.

CLI Example:

```
salt '*' slack.send_message channel="Development Room" message="Build is done" from_name="Build
```

### 30.16.218 salt.modules.smartos\_imgadm

Module for running imgadm command on SmartOS

`salt.modules.smartos_imgadm.avail` (*search=None*)

Return a list of available images

CLI Example:

```
salt '*' imgadm.avail [percona]
```

`salt.modules.smartos_imgadm.delete` (*uuid=None*)

Remove an installed image

CLI Example:

```
salt '*' imgadm.delete e42f8c84-bbea-11e2-b920-078fab2aab1f
```

`salt.modules.smartos_imgadm.get(uuid=None)`  
Return info on an installed image

CLI Example:

```
salt '*' imgadm.get e42f8c84-bbea-11e2-b920-078fab2aab1f
```

`salt.modules.smartos_imgadm.import_image(uuid=None)`  
Import an image from the repository

CLI Example:

```
salt '*' imgadm.import_image e42f8c84-bbea-11e2-b920-078fab2aab1f
```

`salt.modules.smartos_imgadm.list_installed()`  
Return a list of installed images

CLI Example:

```
salt '*' imgadm.list_installed
```

`salt.modules.smartos_imgadm.show(uuid=None)`  
Show manifest of a given image

CLI Example:

```
salt '*' imgadm.show e42f8c84-bbea-11e2-b920-078fab2aab1f
```

`salt.modules.smartos_imgadm.update_installed()`  
Gather info on unknown images (locally installed)

CLI Example:

```
salt '*' imgadm.update_installed()
```

`salt.modules.smartos_imgadm.version()`  
Return imgadm version

CLI Example:

```
salt '*' imgadm.version
```

### 30.16.219 salt.modules.smartos\_vmadm

Module for managing VMs on SmartOS

`salt.modules.smartos_vmadm.destroy(uuid=None)`  
Hard power down the virtual machine, this is equivalent to pulling the power

CLI Example:

```
salt '*' virt.destroy <uuid>
```

`salt.modules.smartos_vmadm.get_macs(uuid=None)`  
Return a list off MAC addresses from the named VM

CLI Example:

```
salt '*' virt.get_macs <uuid>
```

`salt.modules.smartos_vmadm.init(**kwargs)`

Initialize a new VM

CLI Example:

```
salt '*' virt.init image_uuid='...' alias='...' [...]
```

`salt.modules.smartos_vmadm.list_active_vms()`

Return a list of uuids for active virtual machine on the minion

CLI Example:

```
salt '*' virt.list_active_vms
```

`salt.modules.smartos_vmadm.list_inactive_vms()`

Return a list of uuids for inactive virtual machine on the minion

CLI Example:

```
salt '*' virt.list_inactive_vms
```

`salt.modules.smartos_vmadm.list_vms()`

Return a list of virtual machine names on the minion

CLI Example:

```
salt '*' virt.list_vms
```

`salt.modules.smartos_vmadm.reboot(uuid=None)`

Reboot a domain via ACPI request

CLI Example:

```
salt '*' virt.reboot <uuid>
```

`salt.modules.smartos_vmadm.setmem(uuid, memory)`

Change the amount of memory allocated to VM. <memory> is to be specified in MB.

Note for KVM : this would require a restart of the VM.

CLI Example:

```
salt '*' virt.setmem <uuid> 512
```

`salt.modules.smartos_vmadm.shutdown(uuid=None)`

Send a soft shutdown signal to the named vm

CLI Example:

```
salt '*' virt.shutdown <uuid>
```

`salt.modules.smartos_vmadm.start(uuid=None)`

Start a defined domain

CLI Example:

```
salt '*' virt.start <uuid>
```

`salt.modules.smartos_vmadm.vm_info(uuid=None)`

Return a dict with information about the specified VM on this CN

CLI Example:

```
salt '*' virt.vm_info <uuid>
```

`salt.modules.smartos_vmadm.virt_type`(*uuid=None*)  
Return VM virtualization type : OS or KVM

CLI Example:

```
salt '*' virt.vm_virt_type <uuid>
```

### 30.16.220 salt.modules.smf

Service support for Solaris 10 and 11, should work with other systems that use SMF also. (e.g. SmartOS)

---

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `'service.start' is not available`), see [here](#).

---

`salt.modules.smf.available`(*name*)  
Returns True if the specified service is available, otherwise returns False.

We look up the name with the `svcs` command to get back the FMRI This allows users to use simpler service names

CLI Example:

```
salt '*' service.available net-snmp
```

`salt.modules.smf.disable`(*name, \*\*kwargs*)  
Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

`salt.modules.smf.disabled`(*name*)  
Check to see if the named service is disabled to start on boot

CLI Example:

```
salt '*' service.disabled <service name>
```

`salt.modules.smf.enable`(*name, \*\*kwargs*)  
Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

`salt.modules.smf.enabled`(*name, \*\*kwargs*)  
Check to see if the named service is enabled to start on boot

CLI Example:

```
salt '*' service.enabled <service name>
```

`salt.modules.smf.get_all`()  
Return all installed services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.smf.get_disabled()`

Return the disabled services

CLI Example:

```
salt '*' service.get_disabled
```

`salt.modules.smf.get_enabled()`

Return the enabled services

CLI Example:

```
salt '*' service.get_enabled
```

`salt.modules.smf.get_running()`

Return the running services

CLI Example:

```
salt '*' service.get_running
```

`salt.modules.smf.get_stopped()`

Return the stopped services

CLI Example:

```
salt '*' service.get_stopped
```

`salt.modules.smf.missing(name)`

The inverse of `service.available`. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing net-snmp
```

`salt.modules.smf.reload_(name)`

Reload the named service

CLI Example:

```
salt '*' service.reload <service name>
```

`salt.modules.smf.restart(name)`

Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.smf.start(name)`

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.smf.status(name, sig=None)`

Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

**salt.modules.smf.stop**(*name*)

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.221 salt.modules.smtp

Module for Sending Messages via SMTP

New in version 2014.7.0.

#### depends

- smtplib python module

**configuration** This module can be used by either passing a jid and password directly to `send_message`, or by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```
my-smtp-login:
  smtp.server: smtp.domain.com
  smtp.tls: True
  smtp.sender: admin@domain.com
  smtp.username: myuser
  smtp.password: verybadpass
```

The resourcename refers to the resource that is using this account. It is user-definable, and optional. The following configurations are both valid:

```
my-smtp-login:
  smtp.server: smtp.domain.com
  smtp.tls: True
  smtp.sender: admin@domain.com
  smtp.username: myuser
  smtp.password: verybadpass

another-smtp-login:
  smtp.server: smtp.domain.com
  smtp.tls: True
  smtp.sender: admin@domain.com
  smtp.username: myuser
  smtp.password: verybadpass
```

**salt.modules.smtp.send\_msg**(*recipient*, *message*, *subject*='Message from Salt', *sender*=None, *server*=None, *use\_ssl*='True', *username*=None, *password*=None, *profile*=None)

Send a message to an SMTP recipient. Designed for use in states.

CLI Examples:

```
smtp.send_msg 'admin@example.com' 'This is a salt module test'
smtp.send_msg 'admin@example.com' 'This is a salt module test'
profile='my-smtp-acco
username='myuser' pas
```

### 30.16.222 salt.modules.softwareupdate

Support for the softwareupdate command on MacOS.

**salt.modules.softwareupdate.download**(\*updates)

Download a named update so that it can be installed later with the install or upgrade function. It returns a list of all updates that are now downloaded.

CLI Example:

```
salt '*' softwareupdate.download <update name>
salt '*' softwareupdate.download "<update with whitespace>"
salt '*' softwareupdate.download <update1> <update2> <update3>
```

**salt.modules.softwareupdate.download\_all**(rec=False, restart=True)

Download all available updates so that they can be installed later with the install or upgrade function. It returns a list of updates that are now downloaded.

CLI Example:

```
salt '*' softwareupdate.download_all
```

**salt.modules.softwareupdate.ignore**(\*updates)

Ignore a specific program update. When an update is ignored the '-' and version number at the end will be omitted, so 'SecUpd2014-001-1.0' becomes 'SecUpd2014-001'. It will be removed automatically if present. An update is successfully ignored when it no longer shows up after list\_upgrades.

CLI Example:

```
salt '*' softwareupdate.ignore <update-name>
salt '*' softwareupdate.ignore "<update with whitespace>"
salt '*' softwareupdate.ignore <update1> <update2> <update3>
```

**salt.modules.softwareupdate.install**(\*updates)

Install a named upgrade. Returns a dictionary containing the name of the update and the status of its installation.

Return values: - True: The update was installed. - False: The update was not installed. - None: There is no update available with that name.

CLI Example:

```
salt '*' softwareupdate.install <update-name>
salt '*' softwareupdate.install "<update with whitespace>"
salt '*' softwareupdate.install <update1> <update2> <update3>
```

**salt.modules.softwareupdate.list\_downloads**()

Return a list of all updates that have been downloaded locally.

CLI Example:

```
salt '*' softwareupdate.list_downloads
```

**salt.modules.softwareupdate.list\_ignored**()

List all upgrades that has been ignored. Ignored updates are shown without the '-' and version number at the end, this is how the softwareupdate command works.

CLI Example:

```
salt '*' softwareupdate.list_ignored
```

`salt.modules.softwareupdate.list_upgrades` (*rec=False, restart=False*)

List all available updates.

**rec** Return only the recommended updates.

**restart** Return only the updates that require a restart.

CLI Example:

```
salt '*' softwareupdate.list_upgrades
```

`salt.modules.softwareupdate.reset_ignored`()

Make sure the ignored updates are not ignored anymore, returns a list of the updates that are no longer ignored.

CLI Example:

```
salt '*' softwareupdate.reset_ignored
```

`salt.modules.softwareupdate.schedule` (*\*status*)

Decide if automatic checking for upgrades should be on or off. If no arguments are given it will return the current status. Append on or off to change the status.

Return values: - True: Automatic checking is now on, - False: Automatic checking is now off, - None: Invalid argument.

CLI Example:

```
salt '*' softwareupdate.schedule
salt '*' softwareupdate.schedule on|off
```

`salt.modules.softwareupdate.upgrade` (*rec=False, restart=True*)

Install all available upgrades. Returns a dictionary containing the name of the update and the status of its installation.

Return values: - True: The update was installed. - False: The update was not installed.

**rec** If set to True, only install all the recommended updates.

**restart** Set this to False if you do not want to install updates that require a restart.

CLI Example:

```
salt '*' softwareupdate.upgrade
```

`salt.modules.softwareupdate.upgrade_available` (*update*)

Check whether or not an upgrade is available with a given name.

CLI Example:

```
salt '*' softwareupdate.upgrade_available <update-name>
salt '*' softwareupdate.upgrade_available "<update with whitespace>"
```

### 30.16.223 salt.modules.solaris\_group

Manage groups on Solaris

---

**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `'group.info' is not available`), see [here](#).

---

`salt.modules.solaris_group.add(name, gid=None, **kwargs)`  
Add the specified group

CLI Example:

```
salt '*' group.add foo 3456
```

`salt.modules.solaris_group.chgid(name, gid)`  
Change the gid for a named group

CLI Example:

```
salt '*' group.chgid foo 4376
```

`salt.modules.solaris_group.delete(name)`  
Remove the named group

CLI Example:

```
salt '*' group.delete foo
```

`salt.modules.solaris_group.getent(refresh=False)`  
Return info on all groups

CLI Example:

```
salt '*' group.getent
```

`salt.modules.solaris_group.info(name)`  
Return information about a group

CLI Example:

```
salt '*' group.info foo
```

### 30.16.224 salt.modules.solaris\_shadow

Manage the password database on Solaris systems

---

**Important:** If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `'shadow.info' is not available`), see [here](#).

---

`salt.modules.solaris_shadow.default_hash()`  
Returns the default hash used for unset passwords

CLI Example:

```
salt '*' shadow.default_hash
```

`salt.modules.solaris_shadow.info(name)`  
Return information for the specified user

CLI Example:

```
salt '*' shadow.info root
```

`salt.modules.solaris_shadow.set_maxdays(name, maxdays)`  
Set the maximum number of days during which a password is valid. See man passwd.

CLI Example:

```
salt '*' shadow.set_maxdays username 90
```

`salt.modules.solaris_shadow.set_mindays`(*name*, *mindays*)  
Set the minimum number of days between password changes. See man passwd.

CLI Example:

```
salt '*' shadow.set_mindays username 7
```

`salt.modules.solaris_shadow.set_password`(*name*, *password*)  
Set the password for a named user. The password must be a properly defined hash, the password hash can be generated with this command: `openssl passwd -1 <plaintext password>`

CLI Example:

```
salt '*' shadow.set_password root $1$UYCIxa628.9qXjpQCjM4a..
```

`salt.modules.solaris_shadow.set_warndays`(*name*, *warndays*)  
Set the number of days of warning before a password change is required. See man passwd.

CLI Example:

```
salt '*' shadow.set_warndays username 7
```

### 30.16.225 salt.modules.solaris\_user

Manage users with the useradd command

---

**Important:** If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `'user.info' is not available`), see [here](#).

---

`salt.modules.solaris_user.add`(*name*, *uid=None*, *gid=None*, *groups=None*, *home=None*, *shell=None*, *unique=True*, *fullname=''*, *roomnumber=''*, *workphone=''*, *home-phone=''*, *createhome=True*, *\*\*kwargs*)

Add a user to the minion

CLI Example:

```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

`salt.modules.solaris_user.chfullname`(*name*, *fullname*)  
Change the user's Full Name

CLI Example:

```
salt '*' user.chfullname foo "Foo Bar"
```

`salt.modules.solaris_user.chgid`(*name*, *gid*)  
Change the default group of the user

CLI Example:

```
salt '*' user.chgid foo 4376
```

`salt.modules.solaris_user.chgroups`(*name*, *groups*, *append=False*)  
Change the groups this user belongs to, add append to append the specified groups

CLI Example:

```
salt '*' user.chgroups foo wheel,root True
```

`salt.modules.solaris_user.chhome` (*name, home, persist=False*)

Change the home directory of the user, pass true for persist to copy files to the new home dir

CLI Example:

```
salt '*' user.chhome foo /home/users/foo True
```

`salt.modules.solaris_user.chhomephone` (*name, homephone*)

Change the user's Home Phone

CLI Example:

```
salt '*' user.chhomephone foo "7735551234"
```

`salt.modules.solaris_user.chroomnumber` (*name, roomnumber*)

Change the user's Room Number

CLI Example:

```
salt '*' user.chroomnumber foo 123
```

`salt.modules.solaris_user.chshell` (*name, shell*)

Change the default shell of the user

CLI Example:

```
salt '*' user.chshell foo /bin/zsh
```

`salt.modules.solaris_user.chuid` (*name, uid*)

Change the uid for a named user

CLI Example:

```
salt '*' user.chuid foo 4376
```

`salt.modules.solaris_user.chworkphone` (*name, workphone*)

Change the user's Work Phone

CLI Example:

```
salt '*' user.chworkphone foo "7735550123"
```

`salt.modules.solaris_user.delete` (*name, remove=False, force=False*)

Remove a user from the minion

CLI Example:

```
salt '*' user.delete name remove=True force=True
```

`salt.modules.solaris_user.getent` (*refresh=False*)

Return the list of all info for all users

CLI Example:

```
salt '*' user.getent
```

`salt.modules.solaris_user.info` (*name*)

Return user information

CLI Example:

```
salt '*' user.info root
```

**salt.modules.solaris\_user.list\_groups**(*name*)

Return a list of groups the named user belongs to

CLI Example:

```
salt '*' user.list_groups foo
```

**salt.modules.solaris\_user.rename**(*name*, *new\_name*)

Change the username for a named user

CLI Example:

```
salt '*' user.rename name new_name
```

### 30.16.226 salt.modules.solarisips

IPS pkg support for Solaris

---

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

---

This module provides support for Solaris 11 new package management - IPS (Image Packaging System). This is the default pkg module for Solaris 11 (and later).

If you want to use also other packaging module (e.g. pkgutil) together with IPS, you need to override the pkg provider in sls for each package:

```
mypackage:
  pkg.installed:
    - provider: solarisips
```

Or you can override it globally by setting the *providers* parameter in your Minion config file like this:

```
providers:
  pkg: pkgutil
```

**salt.modules.solarisips.available\_version**(*name*, *\*\*kwargs*)

The available version of the package in the repository. In case of multiple match, it returns list of all matched packages. Accepts full or partial FMRI. Please use `pkg.latest_version` as `pkg.available_version` is being deprecated.

CLI Example:

```
salt '*' pkg.latest_version pkg://solaris/entire
```

**salt.modules.solarisips.get\_fmri**(*name*, *\*\*kwargs*)

Returns FMRI from partial name. Returns empty string (``) if not found. In case of multiple match, the function returns list of all matched packages.

CLI Example:

```
salt '*' pkg.get_fmri bash
```

**salt.modules.solarisips.install**(*name=None*, *refresh=False*, *pkgs=None*, *version=None*, *test=False*, *\*\*kwargs*)

Install the named package using the IPS pkg command. Accepts full or partial FMRI.

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
                'new': '<new-version>'}}
```

Multiple Package Installation Options:

**pkgs** A list of packages to install. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install vim
salt '*' pkg.install pkg://solaris/editor/vim
salt '*' pkg.install pkg://solaris/editor/vim refresh=True
salt '*' pkg.install pkgs=['foo', 'bar']
```

**salt.modules.solarisips.is\_installed**(*name*, *\*\*kwargs*)

Returns True if the package is installed. Otherwise returns False. Name can be full or partial FMRI. In case of multiple match from partial FMRI name, it returns True.

CLI Example:

```
salt '*' pkg.is_installed bash
```

**salt.modules.solarisips.latest\_version**(*name*, *\*\*kwargs*)

The available version of the package in the repository. In case of multiple match, it returns list of all matched packages. Accepts full or partial FMRI. Please use `pkg.latest_version` as `pkg.available_version` is being deprecated.

CLI Example:

```
salt '*' pkg.latest_version pkg://solaris/entire
```

**salt.modules.solarisips.list\_pkgs**(*versions\_as\_list=False*, *\*\*kwargs*)

List the currently installed packages as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

**salt.modules.solarisips.list\_upgrades**(*refresh=False*)

Lists all packages available for update. When run in global zone, it reports only upgradable packages for the global zone. When run in non-global zone, it can report more upgradable packages than `pkg update -vn` because `pkg update` hides packages that require newer version of `pkg://solaris/entire` (which means that they can be upgraded only from global zone). Simply said: if you see `pkg://solaris/entire` in the list of upgrades, you should upgrade the global zone to get all possible updates. You can force full pkg DB refresh before listing.

CLI Example:

```
salt '*' pkg.list_upgrades
salt '*' pkg.list_upgrades refresh=True
```

**salt.modules.solarisips.normalize\_name**(*name*, *\*\*kwargs*)

Internal function. Normalizes pkg name to full FMRI before running `pkg.install`. In case of multiple match or no match, it returns the name without modifications and lets the `pkg install` to decide what to do.

CLI Example:

```
salt '*' pkg.normalize_name vim
```

`salt.modules.solarisips.purge`(*name*, *\*\*kwargs*)

Remove specified package. Accepts full or partial FMRI.

Returns a list containing the removed packages.

CLI Example:

```
salt '*' pkg.purge <package name>
```

`salt.modules.solarisips.refresh_db`(*full=False*)

Updates the remote repos database. You can force the full pkg DB refresh from all publishers regardless the last refresh time.

CLI Example:

```
salt '*' pkg.refresh_db
salt '*' pkg.refresh_db full=True
```

`salt.modules.solarisips.remove`(*name=None*, *pkgs=None*, *\*\*kwargs*)

Remove specified package. Accepts full or partial FMRI. In case of multiple match, the command fails and won't modify the OS.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The **name** parameter will be ignored if this option is passed.

Returns a list containing the removed packages.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove tcsh
salt '*' pkg.remove pkg://solaris/shell/tcsh
salt '*' pkg.remove pkgs=['foo', 'bar']
```

`salt.modules.solarisips.search`(*name*, *versions\_as\_list=False*, *\*\*kwargs*)

Searches the repository for given pkg name. The name can be full or partial FMRI. All matches are printed. Globs are also supported.

CLI Example:

```
salt '*' pkg.search bash
```

`salt.modules.solarisips.upgrade`(*refresh=False*, *\*\*kwargs*)

Upgrade all packages to the latest possible version. When run in global zone, it updates also all non-global zones. In non-global zones upgrade is limited by dependency constrains linked to the version of `pkg://solaris/entire`.

Returns also a raw output of ``pkg update`` command (because if update creates a new boot environment, no immediate changes are visible in ``pkg list``).

CLI Example:

```
salt '*' pkg.upgrade
```

`salt.modules.solarisips.upgrade_available(name)`

Check if there is an upgrade available for a certain package. Accepts full or partial FMRI. Returns all matches found.

CLI Example:

```
salt '*' pkg.upgrade_available apache-22
```

`salt.modules.solarisips.version(*names, **kwargs)`

Common interface for obtaining the version of installed packages. Accepts full or partial FMRI. If called using `pkg_resource`, full FMRI is required.

CLI Example:

```
salt '*' pkg.version vim
salt '*' pkg.version foo bar baz
salt '*' pkg_resource.version pkg://solaris/entire
```

### 30.16.227 salt.modules.solarispkg

Package support for Solaris

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

`salt.modules.solarispkg.install(name=None, sources=None, saltenv='base', **kwargs)`

Install the passed package. Can install packages from the following sources:

- \* Locally (package already exists on the minion)
- \* HTTP/HTTPS server
- \* FTP server
- \* Salt master

Returns a dict containing the new package names and versions:

```
{'package': {'old': '<old-version>',
              'new': '<new-version>'}}
```

CLI Example, installing a data stream pkg that already exists on the minion:

```
salt '*' pkg.install sources='[{"<pkg name>": "/dir/on/minion/<pkg filename>"}]'
salt '*' pkg.install sources='[{"SMClgcc346": "/var/spool/pkg/gcc-3.4.6-sol10-sparc-local.pkg"}]'
```

CLI Example, installing a data stream pkg that exists on the salt master:

```
salt '*' pkg.install sources='[{"<pkg name>": "salt://pkgs/<pkg filename>"}]'
salt '*' pkg.install sources='[{"SMClgcc346": "salt://pkgs/gcc-3.4.6-sol10-sparc-local.pkg"}]'
```

CLI Example, installing a data stream pkg that exists on a HTTP server:

```
salt '*' pkg.install sources='[{"<pkg name>": "http://packages.server.com/<pkg filename>"}]'
salt '*' pkg.install sources='[{"SMClgcc346": "http://packages.server.com/gcc-3.4.6-sol10-sparc-"}]'
```

If working with solaris zones and you want to install a package only in the global zone you can pass `'current_zone_only=True'` to salt to have the package only installed in the global zone. (Behind the scenes this is passing `'-G'` to the `pkgadd` command.) Solaris default when installing a package in the global zone is to install it in all zones. This overrides that and installs the package only in the global.

CLI Example, installing a data stream package only in the global zone:

```
salt 'global_zone' pkg.install sources='[{"SMClgcc346": "/var/spool/pkg/gcc-3.4.6-sol10-sparc-local.pkg"}']
```

By default salt automatically provides an adminfile, to automate package installation, with these options set:

```
email=
instance=quit
partial=nocheck
runlevel=nocheck
idepend=nocheck
rdepend=nocheck
space=nocheck
setuid=nocheck
conflict=nocheck
action=nocheck
basedir=default
```

You can override any of these options in two ways. First you can optionally pass any of the options as a kwarg to the module/state to override the default value or you can optionally pass the `admin\_source` option providing your own adminfile to the minions.

Note: You can find all of the possible options to provide to the adminfile by reading the admin man page:

```
man -s 4 admin
```

CLI Example - Overriding the `instance` adminfile option when calling the module directly:

```
salt '*' pkg.install sources='[{"<pkg name>": "salt://pkgs/<pkg filename>"}]' instance="overwrite"
```

CLI Example - Overriding the `instance` adminfile option when used in a state:

```
SMClgcc346:
  pkg.installed:
    - sources:
      - SMClgcc346: salt://srv/salt/pkgs/gcc-3.4.6-sol10-sparc-local.pkg
    - instance: overwrite
```

Note: the ID declaration is ignored, as the package name is read from the ``sources`` parameter.

CLI Example - Providing your own adminfile when calling the module directly:

```
salt '*' pkg.install sources='[{"<pkg name>": "salt://pkgs/<pkg filename>"}]' admin_source='salt://adminfile'
```

CLI Example - Providing your own adminfile when using states:

```
<pkg name>:
  pkg.installed:
    - sources:
      - <pkg name>: salt://pkgs/<pkg filename>
    - admin_source: salt://pkgs/<adminfile filename>
```

Note: the ID declaration is ignored, as the package name is read from the ``sources`` parameter.

`salt.modules.solarispkg.latest_version(*names, **kwargs)`

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

NOTE: As package repositories are not presently supported for Solaris pkgadd, this function will always return an empty string for a given package.

`salt.modules.solarispkg.list_pkgs` (*versions\_as\_list=False, \*\*kwargs*)

List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

`salt.modules.solarispkg.purge` (*name=None, pkgs=None, \*\*kwargs*)

Package purges are not supported, this function is identical to `remove()`.

**name** The name of the package to be deleted

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>, <package2>, <package3>
salt '*' pkg.purge pkgs=['foo', 'bar']
```

`salt.modules.solarispkg.remove` (*name=None, pkgs=None, saltenv='base', \*\*kwargs*)

Remove packages with `pkgrm`

**name** The name of the package to be deleted

By default salt automatically provides an adminfile, to automate package removal, with these options set:

```
email=
instance=quit
partial=nocheck
runlevel=nocheck
idepend=nocheck
rdepend=nocheck
space=nocheck
setuid=nocheck
conflict=nocheck
action=nocheck
basedir=default
```

You can override any of these options in two ways. First you can optionally pass any of the options as a kwarg to the module/state to override the default value or you can optionally pass the `admin_source` option providing your own adminfile to the minions.

Note: You can find all of the possible options to provide to the adminfile by reading the admin man page:

```
man -s 4 admin
```

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The **name** parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove SUNWgit
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

**salt.modules.solarispkg.upgrade\_available**(*name*)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

**salt.modules.solarispkg.version**(\**names*, \*\**kwargs*)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

### 30.16.228 salt.modules.solr

Apache Solr Salt Module

Author: Jed Glazner Version: 0.2.1 Modified: 12/09/2011

This module uses HTTP requests to talk to the apache solr request handlers to gather information and report errors. Because of this the minion doesn't necessarily need to reside on the actual slave. However if you want to use the signal function the minion must reside on the physical solr host.

This module supports multi-core and standard setups. Certain methods are master/slave specific. Make sure you set the **solr.type**. If you have questions or want a feature request please ask.

#### Coming Features in 0.3

1. Add command for checking for replication failures on slaves
2. Improve **match\_index\_versions** since it's pointless on busy solr masters
3. Add additional local fs checks for backups to make sure they succeeded

#### Override these in the minion config

**solr.cores** A list of core names e.g. ['core1','core2']. An empty list indicates non-multicore setup.

**solr.baseurl** The root level URL to access solr via HTTP

**solr.request\_timeout** The number of seconds before timing out an HTTP/HTTPS/FTP request. If nothing is specified then the python global timeout setting is used.

**solr.type** Possible values are `master` or `slave`

**solr.backup\_path** The path to store your backups. If you are using cores and you can specify to append the core name to the path in the backup method.

**solr.num\_backups** For versions of solr >= 3.5. Indicates the number of backups to keep. This option is ignored if your version is less.

**solr.init\_script** The full path to your init script with start/stop options

**solr.dih.options** A list of options to pass to the DIH.

### Required Options for DIH

**clean** [False] Clear the index before importing

**commit** [True] Commit the documents to the index upon completion

**optimize** [True] Optimize the index after commit is complete

**verbose** [True] Get verbose output

**salt.modules.solr.abort\_import** (*handler, host=None, core\_name=None, verbose=False*)

MASTER ONLY Aborts an existing import command to the specified handler. This command can only be run if the minion is configured with solr.type=master

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core** [str (None)] The core the handler belongs to.

**verbose** [boolean (False)] Run the command with verbose output.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.abort_import dataimport None music {'clean':True}
```

**salt.modules.solr.backup** (*host=None, core\_name=None, append\_core\_to\_path=False*)

Tell solr make a backup. This method can be mis-leading since it uses the backup API. If an error happens during the backup you are not notified. The status: `OK` in the response simply means that solr received the request successfully.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

**append\_core\_to\_path** [boolean (False)] If True add the name of the core to the backup path. Assumes that minion backup path is not None.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.backup music
```

`salt.modules.solr.core_status` (*host=None, core\_name=None*)  
MULTI-CORE HOSTS ONLY Get the status for a given core or all cores if no core is specified

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str] The name of the core to reload

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.core_status None music
```

`salt.modules.solr.delta_import` (*handler, host=None, core\_name=None, options=None, extra=None*)  
Submits an import command to the specified handler using specified options. This command can only be run if the minion is configured with `solr.type=master`

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core** [str (None)] The core the handler belongs to.

**options** [dict (`__opts__`)] A list of options such as clean, optimize commit, verbose, and pause\_replication. leave blank to use `__opts__` defaults. options will be merged with `__opts__`

**extra** [dict ({})] Extra name value pairs to pass to the handler. e.g. ["name=value"]

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.delta_import dataimport None music {'clean':True}
```

`salt.modules.solr.full_import` (*handler, host=None, core\_name=None, options=None, extra=None*)  
MASTER ONLY Submits an import command to the specified handler using specified options. This command can only be run if the minion is configured with `solr.type=master`

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core** [str (None)] The core the handler belongs to.

**options** [dict (`__opts__`)] A list of options such as clean, optimize commit, verbose, and pause\_replication. leave blank to use `__opts__` defaults. options will be merged with `__opts__`

**extra** [dict ({})] Extra name value pairs to pass to the handler. e.g. ["name=value"]

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.full_import dataimport None music {'clean':True}
```

`salt.modules.solr.import_status` (*handler, host=None, core\_name=None, verbose=False*)  
Submits an import command to the specified handler using specified options. This command can only be run if the minion is configured with `solr.type: `master``

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core** [str (None)] The core the handler belongs to.

**verbose** [boolean (False)] Specifies verbose output

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.import_status dataimport None music False
```

`salt.modules.solr.is_replication_enabled`(*host=None, core\_name=None*)

SLAVE CALL Check for errors, and determine if a slave is replicating or not.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.is_replication_enabled music
```

`salt.modules.solr.lucene_version`(*core\_name=None*)

Gets the lucene version that solr is using. If you are running a multi-core setup you should specify a core name since all the cores run under the same servlet container, they will all have the same version.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.lucene_version
```

`salt.modules.solr.match_index_versions`(*host=None, core\_name=None*)

SLAVE CALL Verifies that the master and the slave versions are in sync by comparing the index version. If you are constantly pushing updates the index the master and slave versions will seldom match. A solution to this is pause indexing every so often to allow the slave to replicate and then call this method before allowing indexing to resume.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.match_index_versions music
```

**salt.modules.solr.optimize**(*host=None, core\_name=None*)

Search queries fast, but it is a very expensive operation. The ideal process is to run this with a master/slave configuration. Then you can optimize the master, and push the optimized index to the slaves. If you are running a single solr instance, or if you are going to run this on a slave be aware that search performance will be horrible while this command is being run. Additionally it can take a LONG time to run and your HTTP request may timeout. If that happens adjust your timeout settings.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.optimize music
```

**salt.modules.solr.ping**(*host=None, core\_name=None*)

Does a health check on solr, makes sure solr can talk to the indexes.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.ping music
```

**salt.modules.solr.reload\_core**(*host=None, core\_name=None*)

MULTI-CORE HOSTS ONLY Load a new core from the same configuration as an existing registered core. While the ``new`` core is initializing, the ``old`` one will continue to accept requests. Once it has finished, all new request will go to the ``new`` core, and the ``old`` core will be unloaded.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str] The name of the core to reload

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.reload_core None music
```

Return data is in the following format:

```
{'success':bool, 'data':dict, 'errors':list, 'warnings':list}
```

`salt.modules.solr.reload_import_config`(*handler*, *host=None*, *core\_name=None*, *verbose=False*)  
 MASTER ONLY re-loads the handler config XML file. This command can only be run if the minion is a `master` type

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core** [str (None)] The core the handler belongs to.

**verbose** [boolean (False)] Run the command with verbose output.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.reload_import_config dataimport None music {'clean':True}
```

`salt.modules.solr.replication_details`(*host=None*, *core\_name=None*)

Get the full replication details.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.replication_details music
```

`salt.modules.solr.set_is_polling`(*polling*, *host=None*, *core\_name=None*)

SLAVE CALL Prevent the slaves from polling the master for updates.

**polling** [boolean] True will enable polling. False will disable it.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.set_is_polling False
```

`salt.modules.solr.set_replication_enabled`(*status*, *host=None*, *core\_name=None*)

MASTER ONLY Sets the master to ignore poll requests from the slaves. Useful when you don't want the slaves replicating during indexing or when clearing the index.

**status** [boolean] Sets the replication status to the specified state.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to set the status on all cores.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.set_replication_enabled false, None, music
```

`salt.modules.solr.signal` (*signal=None*)

Signals Apache Solr to start, stop, or restart. Obviously this is only going to work if the minion resides on the solr host. Additionally Solr doesn't ship with an init script so one must be created.

**signal** [str (None)] The command to pass to the apache solr init valid values are `start`, `stop`, and `restart`

CLI Example:

```
salt '*' solr.signal restart
```

`salt.modules.solr.version` (*core\_name=None*)

Gets the solr version for the core specified. You should specify a core here as all the cores will run under the same servlet container and so will all have the same version.

**core\_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```
salt '*' solr.version
```

### 30.16.229 salt.modules.splunk\_search

Module for interop with the Splunk API

New in version 2015.5.0.

#### depends

- splunk-sdk python module

**configuration** Configure this module by specifying the name of a configuration profile in the minion config, minion pillar, or master config. The module will use the `splunk` key by default, if defined.

For example:

```
splunk:
  username: alice
  password: abc123
  host: example.splunkcloud.com
  port: 8080
```

`salt.modules.splunk_search.create` (*name, profile='splunk', \*\*kwargs*)

Create a splunk search

CLI Example:

```
splunk_search.create `my search name' search='error msg'
```

`salt.modules.splunk_search.delete` (*name*, *profile='splunk'*)

Delete a splunk search

CLI Example:

```
splunk_search.delete `my search name'
```

`salt.modules.splunk_search.get` (*name*, *profile='splunk'*)

Get a splunk search

CLI Example:

```
splunk_search.get `my search name'
```

`salt.modules.splunk_search.list` (*profile='splunk'*)

List splunk searches (names only)

CLI Example: `splunk_search.list`

`salt.modules.splunk_search.list_all` (*prefix=None*, *app=None*, *owner=None*, *description\_contains=None*, *name\_not\_contains=None*, *profile='splunk'*)

Get all splunk search details. Produces results that can be used to create an sls file.

if `app` or `owner` are specified, results will be limited to matching saved searches.

if `description_contains` is specified, results will be limited to those where `description_contains` in `description` is true if `name_not_contains` is specified, results will be limited to those where `name_not_contains` not in `name` is true.

If `prefix` parameter is given, alarm names in the output will be prepended with the prefix; alarms that have the prefix will be skipped. This can be used to convert existing alarms to be managed by salt, as follows:

CLI example:

1. **Make a ``backup'' of all existing searches** `$ salt-call splunk_search.list_all --out=txt | sed ``s/local: //' > legacy_searches.sls`
2. **Get all searches with new prefixed names** `$ salt-call splunk_search.list_all ``prefix=**MANAGED BY SALT** " --out=txt | sed ``s/local: //' > managed_searches.sls`
3. **Insert the managed searches into splunk** `$ salt-call state.sls managed_searches.sls`
4. Manually verify that the new searches look right
5. **Delete the original searches** `$ sed s/present/absent/ legacy_searches.sls > remove_legacy_searches.sls $ salt-call state.sls remove_legacy_searches.sls`
6. **Get all searches again, verify no changes** `$ salt-call splunk_search.list_all --out=txt | sed ``s/local: //' > final_searches.sls $ diff final_searches.sls managed_searches.sls`

`salt.modules.splunk_search.update` (*name*, *profile='splunk'*, *\*\*kwargs*)

Update a splunk search

CLI Example:

```
splunk_search.update `my search name' sharing=app
```

### 30.16.230 salt.modules.sqlite3

Support for SQLite3

`salt.modules.sqlite3.fetch` (*db=None, sql=None*)  
Retrieve data from an sqlite3 db (returns all rows, be careful!)

CLI Example:

```
salt '*' sqlite3.fetch /root/test.db 'SELECT * FROM test;'
```

`salt.modules.sqlite3.indexes` (*db=None*)  
Show all indices in the database, for people with poor spelling skills

CLI Example:

```
salt '*' sqlite3.indexes /root/test.db
```

`salt.modules.sqlite3.indices` (*db=None*)  
Show all indices in the database

CLI Example:

```
salt '*' sqlite3.indices /root/test.db
```

`salt.modules.sqlite3.modify` (*db=None, sql=None*)  
Issue an SQL query to sqlite3 (with no return data), usually used to modify the database in some way (insert, delete, create, etc)

CLI Example:

```
salt '*' sqlite3.modify /root/test.db 'CREATE TABLE test(id INT, testdata TEXT);'
```

`salt.modules.sqlite3.sqlite_version` ()  
Return version of sqlite

CLI Example:

```
salt '*' sqlite3.sqlite_version
```

`salt.modules.sqlite3.tables` (*db=None*)  
Show all tables in the database

CLI Example:

```
salt '*' sqlite3.tables /root/test.db
```

`salt.modules.sqlite3.version` ()  
Return version of pysqlite

CLI Example:

```
salt '*' sqlite3.version
```

### 30.16.231 salt.modules.ssh

Manage client ssh components

---

**Note:** This module requires the use of MD5 hashing. Certain security audits may not permit the use of MD5. For those cases, this module should be disabled or removed.

---

`salt.modules.ssh.auth_keys` (*user=None, config='ssh/authorized\_keys'*)  
Return the authorized keys for users

CLI Example:

```
salt '*' ssh.auth_keys
salt '*' ssh.auth_keys root
salt '*' ssh.auth_keys user=root
salt '*' ssh.auth_keys user="[user1, user2]"
```

`salt.modules.ssh.check_key`(*user*, *key*, *enc*, *comment*, *options*, *config*='.ssh/authorized\_keys', *cache\_keys*=None)

Check to see if a key needs updating, returns ``update``, ``add`` or ``exists``

CLI Example:

```
salt '*' ssh.check_key <user> <key> <enc> <comment> <options>
```

`salt.modules.ssh.check_key_file`(*user*, *source*, *config*='.ssh/authorized\_keys', *saltenv*='base', *env*=None)

Check a keyfile from a source destination against the local keys and return the keys to change

CLI Example:

```
salt '*' root salt://ssh/keyfile
```

`salt.modules.ssh.check_known_host`(*user*=None, *hostname*=None, *key*=None, *fingerprint*=None, *config*=None, *port*=None)

Check the record in known\_hosts file, either by its value or by fingerprint (it's enough to set up either key or fingerprint, you don't need to set up both).

If provided key or fingerprint doesn't match with stored value, return ``update``, if no value is found for a given host, return ``add``, otherwise return ``exists``.

If neither key, nor fingerprint is defined, then additional validation is not performed.

CLI Example:

```
salt '*' ssh.check_known_host <user> <hostname> key='AAAA...FAaQ=='
```

`salt.modules.ssh.get_known_host`(*user*, *hostname*, *config*=None, *port*=None)

Return information about known host from the configfile, if any. If there is no such key, return None.

CLI Example:

```
salt '*' ssh.get_known_host <user> <hostname>
```

`salt.modules.ssh.hash_known_hosts`(*user*=None, *config*=None)

Hash all the hostnames in the known hosts file.

New in version 2014.7.0.

**user** hash known hosts of this user

**config** path to known hosts file: can be absolute or relative to user's home directory

CLI Example:

```
salt '*' ssh.hash_known_hosts
```

`salt.modules.ssh.host_keys`(*keydir*=None)

Return the minion's host keys

CLI Example:

```
salt '*' ssh.host_keys
```

```
salt.modules.ssh.recv_known_host(hostname, enc=None, port=None, hash_hostname=True,
                                  hash_known_hosts=True)
```

Retrieve information about host public key from remote server

**hostname** The name of the remote host (e.g. ``github.com``)

**enc** Defines what type of key is being used, can be ed25519, ecdsa ssh-rsa or ssh-dss

**port** optional parameter, denoting the port of the remote host, which will be used in case, if the public key will be requested from it. By default the port 22 is used.

**hash\_hostname** [True] Hash all hostnames and addresses in the known hosts file.

Deprecated since version Carbon: Please use hash\_known\_hosts instead.

**hash\_known\_hosts** [True] Hash all hostnames and addresses in the known hosts file.

CLI Example:

```
salt '*' ssh.recv_known_host <hostname> enc=<enc> port=<port>
```

```
salt.modules.ssh.rm_auth_key(user, key, config='.ssh/authorized_keys')
```

Remove an authorized key from the specified user's authorized key file

CLI Example:

```
salt '*' ssh.rm_auth_key <user> <key>
```

```
salt.modules.ssh.rm_known_host(user=None, hostname=None, config=None, port=None)
```

Remove all keys belonging to hostname from a known\_hosts file.

CLI Example:

```
salt '*' ssh.rm_known_host <user> <hostname>
```

```
salt.modules.ssh.set_auth_key(user, key, enc='ssh-rsa', comment='', options=None,
                              config='.ssh/authorized_keys', cache_keys=None)
```

Add a key to the authorized\_keys file. The ``key`` parameter must only be the string of text that is the encoded key. If the key begins with ``ssh-rsa`` or ends with `user@host`, remove those from the key before passing it to this function.

CLI Example:

```
salt '*' ssh.set_auth_key <user> '<key>' enc='dsa'
```

```
salt.modules.ssh.set_auth_key_from_file(user, source, config='.ssh/authorized_keys',
                                       saltenv='base', env=None)
```

Add a key to the authorized\_keys file, using a file as the source.

CLI Example:

```
salt '*' ssh.set_auth_key_from_file <user> salt://ssh_keys/<user>.id_rsa.pub
```

```
salt.modules.ssh.set_known_host(user=None, hostname=None, fingerprint=None, key=None,
                                 port=None, enc=None, hash_hostname=True, config=None,
                                 hash_known_hosts=True)
```

Download SSH public key from remote host ``hostname``, optionally validate its fingerprint against ``fingerprint`` variable and save the record in the known\_hosts file.

If such a record does already exists in there, do nothing.

**user** The user who owns the ssh authorized keys file to modify

**hostname** The name of the remote host (e.g. ``github.com``)

**fingerprint** The fingerprint of the key which must be presented in the known\_hosts file (optional if key specified)

**key** The public key which must be presented in the known\_hosts file (optional if fingerprint specified)

**port** optional parameter, denoting the port of the remote host, which will be used in case, if the public key will be requested from it. By default the port 22 is used.

**enc** Defines what type of key is being used, can be ed25519, ecdsa ssh-rsa or ssh-dss

**hash\_hostname** [True] Hash all hostnames and addresses in the known hosts file.  
 Deprecated since version Carbon: Please use hash\_known\_hosts instead.

**config** The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/known\_hosts". If no user is specified, defaults to ``/etc/ssh/ssh\_known\_hosts``. If present, must be an absolute path when a user is not specified.

**hash\_known\_hosts** [True] Hash all hostnames and addresses in the known hosts file.

CLI Example:

```
salt '*' ssh.set_known_host <user> fingerprint='xx:xx:..:xx' enc='ssh-rsa' config='.ssh/known_hosts'
```

`salt.modules.ssh.user_keys` (*user=None, pubfile=None, prvfile=None*)

Return the user's ssh keys on the minion

New in version 2014.7.0.

CLI Example:

```
salt '*' ssh.user_keys
salt '*' ssh.user_keys user=user1
salt '*' ssh.user_keys user=user1 pubfile=/home/user1/.ssh/id_rsa.pub prvfile=/home/user1/.ssh/id_rsa
salt '*' ssh.user_keys user=user1 prvfile=False
salt '*' ssh.user_keys user=["'user1','user2'] pubfile=id_rsa.pub prvfile=id_rsa
```

As you can see you can tell Salt not to read from the user's private (or public) key file by setting the file path to False. This can be useful to prevent Salt from publishing private data via Salt Mine or others.

### 30.16.232 salt.modules.state

Control the state system on the minion.

#### State Caching

When a highstate is called, the minion automatically caches a copy of the last high data. If you then run a highstate with `cache=True` it will use that cached highdata and won't hit the fileserver except for `salt://` links in the states themselves.

`salt.modules.state.apply_` (*mods=None, \*\*kwargs*)

New in version 2015.5.0.

This function will call `state.highstate` or `state.sls` based on the arguments passed to this function. It exists as a more intuitive way of applying states.

### APPLYING ALL STATES CONFIGURED IN TOP.SLS (A.K.A. *HIGHSTATE*)

To apply all configured states, simply run `state.apply`:

```
salt '*' state.apply
```

The following additional arguments are also accepted when applying all states configured in `top.sls`:

**test** Run states in test-only (dry-run) mode

**pillar** Custom Pillar values, passed as a dictionary of key-value pairs

```
salt '*' state.apply test pillar='{"foo": "bar"}'
```

---

**Note:** Values passed this way will override Pillar values set via `pillar_roots` or an external Pillar source.

---

**queue** [False] Instead of failing immediately when another state run is in progress, queue the new state run to begin running once the other has finished.

This option starts a new thread for each queued state run, so use this option sparingly.

**localconfig** Optionally, instead of using the minion config, load minion opts from the file specified by this argument, and then merge them with the options from the minion config. This functionality allows for specific states to be run with their own custom minion configuration, including different pillars, `file_roots`, etc.

```
salt '*' state.apply localconfig=/path/to/minion.yml
```

### APPLYING INDIVIDUAL SLS FILES (A.K.A. *STATE.SLS*)

To apply individual SLS files, pass them as a comma-separated list:

```
# Run the states configured in salt://test.sls (or salt://test/init.sls)
salt '*' state.apply test
# Run the states configured in salt://test.sls (or salt://test/init.sls)
# and salt://pkgs.sls (or salt://pkgs/init.sls).
salt '*' state.apply test,pkgs
```

The following additional arguments are also accepted when applying individual SLS files:

**test** Run states in test-only (dry-run) mode

**pillar** Custom Pillar values, passed as a dictionary of key-value pairs

```
salt '*' state.apply test pillar='{"foo": "bar"}'
```

---

**Note:** Values passed this way will override Pillar values set via `pillar_roots` or an external Pillar source.

---

**queue** [False] Instead of failing immediately when another state run is in progress, queue the new state run to begin running once the other has finished.

This option starts a new thread for each queued state run, so use this option sparingly.

**concurrent** [False] Execute state runs concurrently instead of serially

**Warning:** This flag is potentially dangerous. It is designed for use when multiple state runs can safely be run at the same time. Do *not* use this flag for performance optimization.

**saltenv** [None] Specify a salt fileserver environment to be used when applying states

Changed in version 0.17.0: Argument name changed from `env` to `saltenv`

Changed in version 2014.7.0: If no `saltenv` is specified, the minion config will be checked for a `saltenv` parameter and if found, it will be used. If none is found, `base` will be used. In prior releases, the minion config was not checked and `base` would always be assumed when the `saltenv` was not explicitly set.

**pillarenv** Specify a Pillar environment to be used when applying states. By default, all Pillar environments will be merged together and used.

**localconfig** Optionally, instead of using the minion config, load minion opts from the file specified by this argument, and then merge them with the options from the minion config. This functionality allows for specific states to be run with their own custom minion configuration, including different pillars, `file_roots`, etc.

```
salt '*' state.apply test localconfig=/path/to/minion.yml
```

**salt.modules.state.check\_request** (*name=None*)

New in version 2015.5.0.

Return the state request information, if any

CLI Example:

```
salt '*' state.check_request
```

**salt.modules.state.clear\_cache** ()

Clear out cached state files, forcing even cache runs to refresh the cache on the next state execution.

Remember that the state cache is completely disabled by default, this execution only applies if `cache=True` is used in states

CLI Example:

```
salt '*' state.clear_cache
```

**salt.modules.state.clear\_request** (*name=None*)

New in version 2015.5.0.

Clear out the state execution request without executing it

CLI Example:

```
salt '*' state.clear_request
```

**salt.modules.state.disable** (*states*)

Disable state runs.

CLI Example:

```
salt '*' state.disable highstate
salt '*' state.disable highstate,test.succeed_without_changes
```

**Note:** To disable a state file from running provide the same name that would be passed in a `state.sls` call.

```
salt '*' state.disable bind.config
```

`salt.modules.state.enable(states)`

Enable state function or sls run

CLI Example:

```
salt '*' state.enable highstate

salt '*' state.enable test.succeed_without_changes
```

---

**Note:** To enable a state file from running provide the same name that would be passed in a state.sls call.

```
salt '*' state.disable bind.config
```

---

`salt.modules.state.high(data, test=False, queue=False, **kwargs)`

Execute the compound calls stored in a single set of high data

This function is mostly intended for testing the state system and is not likely to be needed in everyday usage.

CLI Example:

```
salt '*' state.high '{"vim": {"pkg": ["installed"]}]'
```

`salt.modules.state.highstate(test=None, queue=False, **kwargs)`

Retrieve the state data from the salt master for this minion and execute it

**test** Run states in test-only (dry-run) mode

**pillar** Custom Pillar values, passed as a dictionary of key-value pairs

```
salt '*' state.apply test pillar='{"foo": "bar"}'
```

---

**Note:** Values passed this way will override Pillar values set via `pillar_roots` or an external Pillar source.

---

**queue** [False] Instead of failing immediately when another state run is in progress, queue the new state run to begin running once the other has finished.

This option starts a new thread for each queued state run, so use this option sparingly.

**localconfig** Optionally, instead of using the minion config, load minion opts from the file specified by this argument, and then merge them with the options from the minion config. This functionality allows for specific states to be run with their own custom minion configuration, including different pillars, `file_roots`, etc.

CLI Examples:

```
salt '*' state.highstate

salt '*' state.highstate whitelist=sls1_to_run,sls2_to_run
salt '*' state.highstate exclude=sls_to_exclude
salt '*' state.highstate exclude="[{'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]"

salt '*' state.highstate pillar="{foo: 'Foo!', bar: 'Bar!'}"
```

`salt.modules.state.list_disabled()`

List the states which are currently disabled

CLI Example:

```
salt '*' state.list_disabled
```

`salt.modules.state.low`(*data*, *queue=False*, *\*\*kwargs*)

Execute a single low data call

This function is mostly intended for testing the state system and is not likely to be needed in everyday usage.

CLI Example:

```
salt '*' state.low '{"state": "pkg", "fun": "installed", "name": "vi"}'
```

`salt.modules.state.pkg`(*pkg\_path*, *pkg\_sum*, *hash\_type*, *test=False*, *\*\*kwargs*)

Execute a packaged state run, the packaged state run will exist in a tarball available locally. This packaged state can be generated using salt-ssh.

CLI Example:

```
salt '*' state.pkg /tmp/state_pkg.tgz
```

`salt.modules.state.request`(*mods=None*, *\*\*kwargs*)

New in version 2015.5.0.

Request that the local admin execute a state run via `salt-call state.run_request` All arguments match `state.apply`

CLI Example:

```
salt '*' state.request
salt '*' state.request test
salt '*' state.request test,pkgs
```

`salt.modules.state.run_request`(*name='default'*, *\*\*kwargs*)

New in version 2015.5.0.

Execute the pending state request

CLI Example:

```
salt '*' state.run_request
```

`salt.modules.state.running`(*concurrent=False*)

Return a list of strings that contain state return data if a state function is already running. This function is used to prevent multiple state calls from being run at the same time.

CLI Example:

```
salt '*' state.running
```

`salt.modules.state.show_highstate`(*queue=False*, *\*\*kwargs*)

Retrieve the highstate data from the salt master and display it

Custom Pillar data can be passed with the `pillar` kwarg.

CLI Example:

```
salt '*' state.show_highstate
```

`salt.modules.state.show_low_sls`(*mods*, *saltenv='base'*, *test=None*, *queue=False*, *env=None*, *\*\*kwargs*)

Display the low data from a specific sls. The default environment is `base`, use `saltenv` (`env` in Salt 0.17.x and older) to specify a different environment.

CLI Example:

```
salt '*' state.show_low_sls foo
```

`salt.modules.state.show_lowstate` (*queue=False, \*\*kwargs*)  
List out the low data that will be applied to this minion

CLI Example:

```
salt '*' state.show_lowstate
```

`salt.modules.state.show_sls` (*mods, saltenv='base', test=None, queue=False, env=None, \*\*kwargs*)  
Display the state data from a specific sls or list of sls files on the master. The default environment is base, use `saltenv` (`env` in Salt 0.17.x and older) to specify a different environment.

This function does not support topfiles. For `top.sls` please use `show_top` instead.

Custom Pillar data can be passed with the `pillar` kwarg.

CLI Example:

```
salt '*' state.show_sls core,edit.vim dev
```

`salt.modules.state.show_top` (*queue=False, \*\*kwargs*)  
Return the top data that the minion will use for a highstate

CLI Example:

```
salt '*' state.show_top
```

`salt.modules.state.single` (*fun, name, test=None, queue=False, \*\*kwargs*)  
Execute a single state function with the named kwargs, returns False if insufficient data is sent to the command  
By default, the values of the kwargs will be parsed as YAML. So, you can specify lists values, or lists of single entry key-value maps, as you would in a YAML salt file. Alternatively, JSON format of keyword values is also supported.

CLI Example:

```
salt '*' state.single pkg.installed name=vim
```

`salt.modules.state.sls` (*mods, saltenv=None, test=None, exclude=None, queue=False, env=None, pillarenv=None, \*\*kwargs*)

Execute the states in one or more SLS files

**test** Run states in test-only (dry-run) mode

**pillar** Custom Pillar values, passed as a dictionary of key-value pairs

```
salt '*' state.apply test pillar='{"foo": "bar"}'
```

---

**Note:** Values passed this way will override Pillar values set via `pillar_roots` or an external Pillar source.

---

**queue** [False] Instead of failing immediately when another state run is in progress, queue the new state run to begin running once the other has finished.

This option starts a new thread for each queued state run, so use this option sparingly.

**concurrent** [False] Execute state runs concurrently instead of serially

**Warning:** This flag is potentially dangerous. It is designed for use when multiple state runs can safely be run at the same time. Do *not* use this flag for performance optimization.

**saltenv** [None] Specify a salt filesrv environment to be used when applying states

Changed in version 0.17.0: Argument name changed from `env` to `saltenv`

Changed in version 2014.7.0: If no `saltenv` is specified, the minion config will be checked for a `saltenv` parameter and if found, it will be used. If none is found, `base` will be used. In prior releases, the minion config was not checked and `base` would always be assumed when the `saltenv` was not explicitly set.

**pillarenv** Specify a Pillar environment to be used when applying states. By default, all Pillar environments will be merged together and used.

**localconfig**

Optionally, instead of using the minion config, load minion opts from the file specified by this argument, and then merge them with the options from the minion config. This functionality allows for specific states to be run with their own custom minion configuration, including different pillars, `file_roots`, etc.

CLI Example:

```
salt '*' state.sls core,edit.vim dev
salt '*' state.sls core exclude="{ 'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]"

salt '*' state.sls myslsfile pillar="{foo: 'Foo!', bar: 'Bar!'}"
```

**salt.modules.state.sls\_id**(*id\_*, *mods*, *saltenv='base'*, *test=None*, *queue=False*, *\*\*kwargs*)

Call a single ID from the named module(s) and handle all requisites

New in version 2014.7.0.

CLI Example:

```
salt '*' state.sls_id apache http
```

**salt.modules.state.template**(*tem*, *queue=False*, *\*\*kwargs*)

Execute the information stored in a template file on the minion.

This function does not ask a master for a SLS file to render but instead directly processes the file at the provided path on the minion.

CLI Example:

```
salt '*' state.template '<Path to template on the minion>'
```

**salt.modules.state.template\_str**(*tem*, *queue=False*, *\*\*kwargs*)

Execute the information stored in a string from an sls template

CLI Example:

```
salt '*' state.template_str '<Template String>'
```

**salt.modules.state.top**(*topfn*, *test=None*, *queue=False*, *saltenv=None*, *\*\*kwargs*)

Execute a specific top file instead of the default

CLI Example:

```
salt '*' state.top reverse_top.sls
salt '*' state.top reverse_top.sls exclude=sls_to_exclude
salt '*' state.top reverse_top.sls exclude="{ 'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]"
```

### 30.16.233 salt.modules.status

Module for returning various status data about a minion. These data can be useful for compiling into stats later.

`salt.modules.status.all_status()`

Return a composite of all status data and info for this minion. Warning: There is a LOT here!

CLI Example:

```
salt '*' status.all_status
```

`salt.modules.status.cpuinfo()`

Return the CPU info for this minion

CLI Example:

```
salt '*' status.cpuinfo
```

`salt.modules.status.cputats()`

Return the CPU stats for this minion

CLI Example:

```
salt '*' status.cputats
```

`salt.modules.status.custom()`

Return a custom composite of status data and info for this minion, based on the minion config file. An example config like might be:

```
status.cputats.custom: [ 'cpu', 'ctxt', 'btime', 'processes' ]
```

Where status refers to status.py, cputats is the function where we get our data, and custom is this function It is followed by a list of keys that we want returned.

This function is meant to replace all\_status(), which returns anything and everything, which we probably don't want.

By default, nothing is returned. Warning: Depending on what you include, there can be a LOT here!

CLI Example:

```
salt '*' status.custom
```

`salt.modules.status.diskstats()`

Return the disk stats for this minion

CLI Example:

```
salt '*' status.diskstats
```

`salt.modules.status.diskusage(*args)`

Return the disk usage for this minion

Usage:

```
salt '*' status.diskusage [paths and/or filesystem types]
```

CLI Example:

```
salt '*' status.diskusage           # usage for all filesystems
salt '*' status.diskusage / /tmp    # usage for / and /tmp
salt '*' status.diskusage ext?      # usage for ext[234] filesystems
salt '*' status.diskusage / ext?    # usage for / and all ext filesystems
```

`salt.modules.status.loadavg()`

Return the load averages for this minion

CLI Example:

```
salt '*' status.loadavg
```

`salt.modules.status.master(master=None, connected=True)`

New in version 2014.7.0.

Fire an event if the minion gets disconnected from its master. This function is meant to be run via a scheduled job from the minion. If `master_ip` is an FQDN/Hostname, it must be resolvable to a valid IPv4 address.

CLI Example:

```
salt '*' status.master
```

`salt.modules.status.meminfo()`

Return the memory info for this minion

CLI Example:

```
salt '*' status.meminfo
```

`salt.modules.status.netdev()`

Return the network device stats for this minion

CLI Example:

```
salt '*' status.netdev
```

`salt.modules.status.netstats()`

Return the network stats for this minion

CLI Example:

```
salt '*' status.netstats
```

`salt.modules.status.nproc()`

Return the number of processing units available on this system

CLI Example:

```
salt '*' status.nproc
```

`salt.modules.status.pid(sig)`

Return the PID or an empty string if the process is running or not. Pass a signature to use to find the process via ps. Note you can pass a Python-compatible regular expression to return all pids of processes matching the regexp.

CLI Example:

```
salt '*' status.pid <sig>
```

`salt.modules.status.procs()`

Return the process data

CLI Example:

```
salt '*' status.procs
```

`salt.modules.status.uptime()`

Return the uptime for this minion

CLI Example:

```
salt '*' status.uptime
```

`salt.modules.status.version()`

Return the system version for this minion

CLI Example:

```
salt '*' status.version
```

`salt.modules.status.vmstats()`

Return the virtual memory stats for this minion

CLI Example:

```
salt '*' status.vmstats
```

`salt.modules.status.w()`

Return a list of logged in users for this minion, using the w command

CLI Example:

```
salt '*' status.w
```

### 30.16.234 salt.modules.sudo

Allow for the calling of execution modules via sudo.

This module is invoked by the minion if the `sudo_user` minion config is present.

Example minion config:

```
sudo_user: saltdev
```

Once this setting is made, any execution module call done by the minion will be run under `sudo -u <sudo_user> salt-call`. For example, with the above minion config,

```
salt sudo_minion cmd.run 'cat /etc/sudoers'
```

is equivalent to

```
sudo -u saltdev salt-call cmd.run 'cat /etc/sudoers'
```

being run on `sudo_minion`.

`salt.modules.sudo.salt_call(runas, fun, *args, **kwargs)`

Wrap a shell execution out to salt call with sudo

Example:

`/etc/salt/minion`

```
sudo_user: saltdev
```

```
salt '*' test.ping # is run as saltdev user
```

### 30.16.235 salt.modules.supervisord

Provide the service module for system supervisord or supervisord in a virtualenv

`salt.modules.supervisord.add`(*name*, *user=None*, *conf\_file=None*, *bin\_env=None*)

Activates any updates in config for process/group.

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisord.add <name>
```

`salt.modules.supervisord.custom`(*command*, *user=None*, *conf\_file=None*, *bin\_env=None*)

Run any custom supervisord command

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisord.custom "mstop '*gunicorn*'"
```

`salt.modules.supervisord.options`(*name*, *conf\_file=None*)

New in version 2014.1.0.

Read the config file and return the config options for a given process

**name** Name of the configured process

**conf\_file** path to supervisord config file

CLI Example:

```
salt '*' supervisord.options foo
```

`salt.modules.supervisord.remove`(*name*, *user=None*, *conf\_file=None*, *bin\_env=None*)

Removes process/group from active config

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisord.remove <name>
```

`salt.modules.supervisord.reread`(*user=None*, *conf\_file=None*, *bin\_env=None*)

Reload the daemon's configuration files

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisorctl.reread
```

**salt.modules.supervisord.restart** (*name='all', user=None, conf\_file=None, bin\_env=None*)  
Restart the named service. Process group names should not include a trailing asterisk.

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisorctl.restart <service>
salt '*' supervisorctl.restart <group>:
```

**salt.modules.supervisord.start** (*name='all', user=None, conf\_file=None, bin\_env=None*)  
Start the named service. Process group names should not include a trailing asterisk.

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisorctl.start <service>
salt '*' supervisorctl.start <group>:
```

**salt.modules.supervisord.status** (*name=None, user=None, conf\_file=None, bin\_env=None*)  
List programs and its state

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisorctl.status
```

**salt.modules.supervisord.status\_raw** (*name=None, user=None, conf\_file=None, bin\_env=None*)  
Display the raw output of status

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisorctl.status_raw
```

**salt.modules.supervisord.stop** (*name='all', user=None, conf\_file=None, bin\_env=None*)  
Stop the named service. Process group names should not include a trailing asterisk.

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisorctl.stop <service>
salt '*' supervisorctl.stop <group>:
```

`salt.modules.supervisord.update` (*user=None, conf\_file=None, bin\_env=None*)

Reload config and add/remove as necessary

**user** user to run supervisorctl as

**conf\_file** path to supervisord config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisorctl.update
```

### 30.16.236 salt.modules.svn

Subversion SCM

`salt.modules.svn.add` (*cwd, targets, user=None, username=None, password=None, \*opts*)

Add files to be tracked by the Subversion working-copy checkout

**cwd** The path to the Subversion repository

**targets** [None] files and directories to pass to the command as arguments

**user** [None] Run svn as a user other than what the minion runs as

**username** [None] Connect to the Subversion server as another user

**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.add /path/to/repo /path/to/new/file
```

`salt.modules.svn.checkout` (*cwd, remote, target=None, user=None, username=None, password=None, \*opts*)

Download a working copy of the remote Subversion repository directory or file

**cwd** The path to the Subversion repository

**remote** [None] URL to checkout

**target** [None] The name to give the file or directory working copy Default: svn uses the remote basename

**user** [None] Run svn as a user other than what the minion runs as

**username** [None] Connect to the Subversion server as another user

**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.checkout /path/to/repo svn://remote/repo
```

`salt.modules.svn.commit`(*cwd*, *targets=None*, *msg=None*, *user=None*, *username=None*, *password=None*, *\*opts*)

Commit the current directory, files, or directories to the remote Subversion repository

**cwd** The path to the Subversion repository

**targets** [None] files and directories to pass to the command as arguments Default: svn uses `.`

**msg** [None] Message to attach to the commit log

**user** [None] Run svn as a user other than what the minion runs as

**username** [None] Connect to the Subversion server as another user

**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.commit /path/to/repo
```

`salt.modules.svn.diff`(*cwd*, *targets=None*, *user=None*, *username=None*, *password=None*, *\*opts*)

Return the diff of the current directory, files, or directories from the remote Subversion repository

**cwd** The path to the Subversion repository

**targets** [None] files and directories to pass to the command as arguments Default: svn uses `.`

**user** [None] Run svn as a user other than what the minion runs as

**username** [None] Connect to the Subversion server as another user

**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.diff /path/to/repo
```

`salt.modules.svn.export`(*cwd*, *remote*, *target=None*, *user=None*, *username=None*, *password=None*, *revision='HEAD'*, *\*opts*)

Create an unversioned copy of a tree.

**cwd** The path to the Subversion repository

**remote** [None] URL and path to file or directory checkout

**target** [None] The name to give the file or directory working copy Default: svn uses the remote basename

**user** [None] Run svn as a user other than what the minion runs as

**username** [None] Connect to the Subversion server as another user

**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.export /path/to/repo svn://remote/repo
```

`salt.modules.svn.info`(*cwd*, *targets=None*, *user=None*, *username=None*, *password=None*, *fmt='str'*)

Display the Subversion information from the checkout.

**cwd** The path to the Subversion repository

**targets** [None] files, directories, and URLs to pass to the command as arguments svn uses ``!`` by default

**user** [None] Run svn as a user other than what the minion runs as

**username** [None] Connect to the Subversion server as another user

**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

**fmt** [str] How to fmt the output from info. (str, xml, list, dict)

CLI Example:

```
salt '*' svn.info /path/to/svn/repo
```

`salt.modules.svn.remove`(*cwd*, *targets*, *msg=None*, *user=None*, *username=None*, *password=None*, *\*opts*)

Remove files and directories from the Subversion repository

**cwd** The path to the Subversion repository

**targets** [None] files, directories, and URLs to pass to the command as arguments

**msg** [None] Message to attach to the commit log

**user** [None] Run svn as a user other than what the minion runs as

**username** [None] Connect to the Subversion server as another user

**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.remove /path/to/repo /path/to/repo/remove
```

`salt.modules.svn.status`(*cwd*, *targets=None*, *user=None*, *username=None*, *password=None*, *\*opts*)

Display the status of the current directory, files, or directories in the Subversion repository

**cwd** The path to the Subversion repository

**targets** [None] files, directories, and URLs to pass to the command as arguments Default: svn uses ``!``

**user** [None] Run svn as a user other than what the minion runs as

**username** [None] Connect to the Subversion server as another user

**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.status /path/to/repo
```

`salt.modules.svn.switch`(*cwd*, *remote*, *target=None*, *user=None*, *username=None*, *password=None*, *\*opts*)

New in version 2014.1.0.

Switch a working copy of a remote Subversion repository directory

**cwd** The path to the Subversion repository

**remote** [None] URL to switch

**target** [None] The name to give the file or directory working copy Default: svn uses the remote basename

**user** [None] Run svn as a user other than what the minion runs as

**username** [None] Connect to the Subversion server as another user

**password** [None] Connect to the Subversion server with this password

CLI Example:

```
salt '*' svn.switch /path/to/repo svn://remote/repo
```

**salt.modules.svn.update**(*cwd*, *targets=None*, *user=None*, *username=None*, *password=None*, *\*opts*)

Update the current directory, files, or directories from the remote Subversion repository

**cwd** The path to the Subversion repository

**targets** [None] files and directories to pass to the command as arguments Default: svn uses `!`

**user** [None] Run svn as a user other than what the minion runs as

**password** [None] Connect to the Subversion server with this password

New in version 0.17.0.

**username** [None] Connect to the Subversion server as another user

CLI Example:

```
salt '*' svn.update /path/to/repo
```

### 30.16.237 salt.modules.swift

Module for handling OpenStack Swift calls Author: Anthony Stanton <[anthony.stanton@gmail.com](mailto:anthony.stanton@gmail.com)>

Inspired by the S3 and Nova modules

#### depends

- swiftclient Python module

**configuration** This module is not usable until the user, tenant, auth URL, and password or auth\_key are specified either in a pillar or in the minion's config file. For example:

```
keystone.user: admin
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
keystone.password: verybadpass
# or
keystone.auth_key: 203802934809284k2j34lkj2l3kj43k
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
  keystone.user: admin
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
  keystone.password: verybadpass
# or
  keystone.auth_key: 203802934809284k2j34lkj2l3kj43k

openstack2:
  keystone.user: admin
```

```

keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.2:5000/v2.0/'
keystone.password: verybadpass
# or
keystone.auth_key: 303802934809284k2j34lkj2l3kj43k

```

With this configuration in place, any of the swift functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' swift.get mycontainer myfile /tmp/file profile=openstack1
```

NOTE: For Rackspace cloud files setting `keystone.auth_version = 1` is recommended.

`salt.modules.swift.delete` (*cont*, *path=None*, *profile=None*)

Delete a container, or delete an object from a container.

CLI Example to delete a container:

```
salt myminion swift.delete mycontainer
```

CLI Example to delete an object from a container:

```
salt myminion swift.delete mycontainer remoteobject
```

`salt.modules.swift.get` (*cont=None*, *path=None*, *local\_file=None*, *return\_bin=False*, *profile=None*)

List the contents of a container, or return an object from a container. Set `return_bin` to True in order to retrieve an object wholesale. Otherwise, Salt will attempt to parse an XML response.

CLI Example to list containers:

```
salt myminion swift.get
```

CLI Example to list the contents of a container:

```
salt myminion swift.get mycontainer
```

CLI Example to return the binary contents of an object:

```
salt myminion swift.get mycontainer myfile.png return_bin=True
```

CLI Example to save the binary contents of an object to a local file:

```
salt myminion swift.get mycontainer myfile.png local_file=/tmp/myfile.png
```

`salt.modules.swift.head`()

`salt.modules.swift.put` (*cont*, *path=None*, *local\_file=None*, *profile=None*)

Create a new container, or upload an object to a container.

CLI Example to create a container:

```
salt myminion swift.put mycontainer
```

CLI Example to upload an object to a container:

```
salt myminion swift.put mycontainer remotepath local_file=/path/to/file
```

### 30.16.238 salt.modules.sysbench

The `sysbench` module is used to analyze the performance of the minions, right from the master! It measures various system parameters such as CPU, Memory, File I/O, Threads and Mutex.

`salt.modules.sysbench.cpu()`

Tests for the CPU performance of minions.

CLI Examples:

```
salt '*' sysbench.cpu
```

`salt.modules.sysbench.fileio()`

This tests for the file read and write operations Various modes of operations are

- sequential write
- sequential rewrite
- sequential read
- random read
- random write
- random read and write

The test works with 32 files with each file being 1Gb in size The test consumes a lot of time. Be patient!

CLI Examples:

```
salt '*' sysbench.fileio
```

`salt.modules.sysbench.memory()`

This tests the memory for read and write operations.

CLI Examples:

```
salt '*' sysbench.memory
```

`salt.modules.sysbench.mutex()`

Tests the implementation of mutex

CLI Examples:

```
salt '*' sysbench.mutex
```

`salt.modules.sysbench.ping()`

`salt.modules.sysbench.threads()`

This tests the performance of the processor's scheduler

CLI Example:

```
salt '*' sysbench.threads
```

### 30.16.239 salt.modules.syslog\_ng

Module for getting information about syslog-ng

**maintainer** Tibor Benke <btibi@sch.bme.hu>

**maturity** new

**depends** cmd

**platform** all

This module is capable of managing syslog-ng instances which were installed via a package manager or from source. Users can use a directory as a parameter in the case of most functions, which contains the syslog-ng and syslog-ng-ctl binaries.

Syslog-ng can be installed via a package manager or from source. In the latter case, the syslog-ng and syslog-ng-ctl binaries are not available from the PATH, so users should set location of the/sbin directory with `syslog-ng.set_binary_path`.

Similarly, users can specify the location of the configuration file with `syslog-ng.set_config_file`, then the module will use it. If it is not set, syslog-ng uses the default configuration file.

class salt.modules.syslog\_ng.**Argument**(value='')

A TypedParameterValue has one or more Arguments. For example this can be the value of key\_file.

Does not need examples.

**build**()

class salt.modules.syslog\_ng.**Buildable**(iterable, join\_body\_on='', append\_extra\_newline=True)

Base class of most classes, which have a build method.

It contains a common build function.

Does not need examples.

**build**()

Builds the textual representation of the whole configuration object with it's children.

**build\_body**()

Builds the body of a syslog-ng configuration object.

**build\_header**()

Builds the header of a syslog-ng configuration object.

**build\_tail**()

Builds the tail of a syslog-ng configuration object.

class salt.modules.syslog\_ng.**GivenStatement**(value, add\_newline=True)

This statement returns a string without modification. It can be used to use existing configuration snippets.

Does not need examples.

**build**()

class salt.modules.syslog\_ng.**NamedStatement**(type, id='', options=None)

It represents a configuration statement, which has a name, e.g. a source.

Does not need examples.

class salt.modules.syslog\_ng.**Option**(type='', params=None)

A Statement class contains Option instances.

An instance of Option can represent a file(), tcp(), udp(), etc. option.

Does not need examples.

**add\_parameter**(param)

**build**()

**class** `salt.modules.syslog_ng.Parameter` (*iterable=None, join\_body\_on=''*)  
An Option has one or more Parameter instances.

Does not need examples.

**class** `salt.modules.syslog_ng.ParameterValue` (*iterable=None, join\_body\_on=''*)  
A TypedParameter can have one or more values.

Does not need examples.

**class** `salt.modules.syslog_ng.SimpleParameter` (*value=''*)  
A Parameter is a SimpleParameter, if it's just a simple type, like a string.

For example:

```
destination d_file {
    file(
        "/var/log/messages"
    );
};
```

`/var/log/messages` is a SimpleParameter.

Does not need examples.

**build()**

**class** `salt.modules.syslog_ng.SimpleParameterValue` (*value=''*)  
A ParameterValue which holds a simple type, like a string or a number.

For example in `ip(127.0.0.1)` `127.0.0.1` is a SimpleParameterValue.

Does not need examples.

**build()**

**class** `salt.modules.syslog_ng.Statement` (*type, id='', options=None, has\_name=True*)  
It represents a syslog-ng configuration statement, e.g. source, destination, filter.

Does not need examples.

**add\_child** (*option*)

**build\_header** ()

**build\_tail** ()

**exception** `salt.modules.syslog_ng.SyslogNgError`

**class** `salt.modules.syslog_ng.TypedParameter` (*type='', values=None*)  
A Parameter, which has a type:

```
destination d_tcp {
    tcp(
        ip(127.0.0.1)
    );
};
```

`ip(127.0.0.1)` is a TypedParameter.

Does not need examples.

**add\_value** (*value*)

**build** ()

class salt.modules.syslog\_ng.**TypedParameterValue**(*type=''*, *arguments=None*)

We have to go deeper..

A TypedParameter can have a 'parameter', which also have a type. For example key\_file and cert\_file:

```
source demo_tls_source {
    tcp(
        ip(0.0.0.0)
        port(1999)
        tls(
            key_file("/opt/syslog-ng/etc/syslog-ng/key.d/syslog-ng.key")
            cert_file("/opt/syslog-ng/etc/syslog-ng/cert.d/syslog-ng.cert")
        )
    );
};
```

Does not need examples.

**add\_argument**(*arg*)

**build**()

class salt.modules.syslog\_ng.**UnnamedStatement**(*type*, *options=None*)

It represents a configuration statement, which doesn't have a name, e.g. a log path.

Does not need examples.

salt.modules.syslog\_ng.**config**(*name*, *config*, *write=True*)

Builds syslog-ng configuration. This function is intended to be used from the state module, users should not use it directly!

name : the id of the Salt document or it is the format of <statement name>.id  
 config : the parsed YAML code  
 write : if True, it writes the config into the configuration file, otherwise just returns it

CLI Example:

```
salt '*' syslog_ng.config name="s_local" config="{ 'tcp': [ { 'ip': '127.0.0.1' }, { 'port': 1233 } ] }"
```

salt.modules.syslog\_ng.**config\_test**(*syslog\_ng\_sbin\_dir=None*, *cfgfile=None*)

Runs syntax check against cfgfile. If syslog\_ng\_sbin\_dir is specified, it is added to the PATH during the test.

CLI Example:

```
salt '*' syslog_ng.config_test
salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin
salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin /etc/syslog-ng/syslog-ng.conf
```

salt.modules.syslog\_ng.**get\_config\_file**()

Returns the configuration directory, which contains syslog-ng.conf.

CLI Example:

```
salt '*' syslog_ng.get_config_file
```

salt.modules.syslog\_ng.**modules**(*syslog\_ng\_sbin\_dir=None*)

Returns the available modules. If syslog\_ng\_sbin\_dir is specified, it is added to the PATH during the execution of the command syslog-ng.

CLI Example:

```
salt '*' syslog_ng.modules
salt '*' syslog_ng.modules /home/user/install/syslog-ng/sbin
```

`salt.modules.syslog_ng.reload_(name)`

Reloads syslog-ng. This function is intended to be used from states.

If `syslog_ng.set_config_file`, is called before, this function will use the set binary path.

CLI Example:

```
salt '*' syslog_ng.reload
```

`salt.modules.syslog_ng.set_binary_path(name)`

Sets the path, where the syslog-ng binary can be found. This function is intended to be used from states.

If syslog-ng is installed via a package manager, users don't need to use this function.

CLI Example:

```
salt '*' syslog_ng.set_binary_path name="/usr/sbin"
```

`salt.modules.syslog_ng.set_config_file(name)`

Sets the configuration's name. This function is intended to be used from states.

CLI Example:

```
salt '*' syslog_ng.set_config_file name="/etc/syslog-ng"
```

`salt.modules.syslog_ng.set_parameters(version=None, binary_path=None, config_file=None, *args, **kwargs)`

Sets variables.

CLI Example:

```
salt '*' syslog_ng.set_parameters version="3.6"
salt '*' syslog_ng.set_parameters binary_path="/home/user/install/syslog-ng/sbin" config_file="
```

`salt.modules.syslog_ng.start(name=None, user=None, group=None, chroot=None, caps=None, no_caps=False, pidfile=None, enable_core=False, fd_limit=None, verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None)`

Ensures, that syslog-ng is started via the given parameters. This function is intended to be used from the state module.

Users shouldn't use this function, if the service module is available on their system. If `syslog_ng.set_config_file`, is called before, this function will use the set binary path.

CLI Example:

```
salt '*' syslog_ng.start
```

`salt.modules.syslog_ng.stats(syslog_ng_sbin_dir=None)`

Returns statistics from the running syslog-ng instance. If `syslog_ng_sbin_dir` is specified, it is added to the PATH during the execution of the command `syslog-ng-ctl`.

CLI Example:

```
salt '*' syslog_ng.stats
salt '*' syslog_ng.stats /home/user/install/syslog-ng/sbin
```

`salt.modules.syslog_ng.stop(name=None)`

Kills syslog-ng. This function is intended to be used from the state module.

Users shouldn't use this function, if the service module is available on their system. If `syslog_ng.set_config_file` is called before, this function will use the set binary path.

CLI Example:

```
salt '*' syslog-ng.stop
```

`salt.modules.syslog-ng.version`(*syslog\_ng\_sbin\_dir=None*)

Returns the version of the installed syslog-ng. If `syslog_ng_sbin_dir` is specified, it is added to the PATH during the execution of the command `syslog-ng`.

CLI Example:

```
salt '*' syslog-ng.version
salt '*' syslog-ng.version /home/user/install/syslog-ng/sbin
```

`salt.modules.syslog-ng.write_config`(*config, newlines=2*)

Writes the given parameter `config` into the config file. This function is intended to be used from states.

If `syslog-ng.set_config_file`, is called before, this function will use the set config file.

CLI Example:

```
salt '*' syslog-ng.write_config config="# comment"
```

`salt.modules.syslog-ng.write_version`(*name*)

Removes the previous configuration file, then creates a new one and writes the name line. This function is intended to be used from states.

If `syslog-ng.set_config_file`, is called before, this function will use the set config file.

CLI Example:

```
salt '*' syslog-ng.write_version name="3.6"
```

### 30.16.240 salt.modules.sysmod

The `sys` module provides information about the available functions on the minion

`salt.modules.sysmod.argspec`(*module=""*)

Return the argument specification of functions in Salt execution modules.

CLI Example:

```
salt '*' sys.argspec pkg.install
salt '*' sys.argspec sys
salt '*' sys.argspec
```

Module names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.argspec 'pkg.*'
```

`salt.modules.sysmod.doc`(\*args)

Return the docstrings for all modules. Optionally, specify a module or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple modules/functions can be specified.

CLI Example:

```
salt '*' sys.doc
salt '*' sys.doc sys
salt '*' sys.doc sys.doc
salt '*' sys.doc network.traceroute user.info
```

Modules can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.doc 'sys.*'
salt '*' sys.doc 'sys.list_*'
```

**salt.modules.sysmod.list\_functions**(\*args, \*\*kwargs)

List the functions for all modules. Optionally, specify a module or modules from which to list.

CLI Example:

```
salt '*' sys.list_functions
salt '*' sys.list_functions sys
salt '*' sys.list_functions sys user
```

Function names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_functions 'sys.list_*'
```

**salt.modules.sysmod.list\_modules**(\*args)

List the modules loaded on the minion

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.list_modules
```

Module names can be specified as globs.

```
salt '*' sys.list_modules 's*'
```

**salt.modules.sysmod.list\_renderers**(\*args)

List the renderers loaded on the minion

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.list_renderers
```

Render names can be specified as globs.

```
salt '*' sys.list_renderers 'yaml*'
```

**salt.modules.sysmod.list\_returner\_functions**(\*args, \*\*kwargs)

List the functions for all returner modules. Optionally, specify a returner module or modules from which to list.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_returner_functions
salt '*' sys.list_returner_functions mysql
salt '*' sys.list_returner_functions mysql etcd
```

Returner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_returner_functions 'sqlite3.get*'
```

**salt.modules.sysmod.list\_returners**(*\*args*)

List the returners loaded on the minion

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_returners
```

Returner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_returners 's*'
```

**salt.modules.sysmod.list\_runner\_functions**(*\*args*, *\*\*kwargs*)

List the functions for all runner modules. Optionally, specify a runner module or modules from which to list.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_runner_functions
salt '*' sys.list_runner_functions state
salt '*' sys.list_runner_functions state virt
```

Runner function names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_runner_functions 'state.*' 'virt.*'
```

**salt.modules.sysmod.list\_runners**(*\*args*)

List the runners loaded on the minion

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_runners
```

Runner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_runners 'm*'
```

**salt.modules.sysmod.list\_state\_functions**(*\*args*, *\*\*kwargs*)

List the functions for all state modules. Optionally, specify a state module or modules from which to list.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_state_functions
salt '*' sys.list_state_functions file
salt '*' sys.list_state_functions pkg user
```

State function names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_state_functions 'file.*'
salt '*' sys.list_state_functions 'file.s*'
```

**salt.modules.sysmod.list\_state\_modules(\*args)**

List the modules loaded on the minion

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.list_state_modules
```

State module names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.list_state_modules 'mysql_*'
```

**salt.modules.sysmod.reload\_modules()**

Tell the minion to reload the execution modules

CLI Example:

```
salt '*' sys.reload_modules
```

**salt.modules.sysmod.renderer\_doc(\*args)**

Return the docstrings for all renderers. Optionally, specify a renderer or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple renderers can be specified.

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.renderer_doc
salt '*' sys.renderer_doc cheetah
salt '*' sys.renderer_doc jinja json
```

Renderer names can be specified as globs.

```
salt '*' sys.renderer_doc 'c*' 'j*'
```

**salt.modules.sysmod.returner\_argspec(module='')**

Return the argument specification of functions in Salt returner modules.

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.returner_argspec xmpp
salt '*' sys.returner_argspec xmpp smtp
salt '*' sys.returner_argspec
```

Returner names can be specified as globs.

```
salt '*' sys.returner_argspec 'sqlite3.*'
```

`salt.modules.sysmod.returner_doc(*args)`

Return the docstrings for all returners. Optionally, specify a returner or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple returners/functions can be specified.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.returner_doc
salt '*' sys.returner_doc sqlite3
salt '*' sys.returner_doc sqlite3.get_fun
salt '*' sys.returner_doc sqlite3.get_fun etcd.get_fun
```

Returner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.returner_doc 'sqlite3.get_*'
```

`salt.modules.sysmod.runner_argspec(module='')`

Return the argument specification of functions in Salt runner modules.

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.runner_argspec state
salt '*' sys.runner_argspec http
salt '*' sys.runner_argspec
```

Runner names can be specified as globs.

```
salt '*' sys.runner_argspec 'winrepo.*'
```

`salt.modules.sysmod.runner_doc(*args)`

Return the docstrings for all runners. Optionally, specify a runner or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple runners/functions can be specified.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.runner_doc
salt '*' sys.runner_doc cache
salt '*' sys.runner_doc cache.grains
salt '*' sys.runner_doc cache.grains mine.get
```

Runner names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.runner_doc 'cache.clear_*'
```

`salt.modules.sysmod.state_argspec` (*module=''*)

Return the argument specification of functions in Salt state modules.

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.state_argspec pkg.installed
salt '*' sys.state_argspec file
salt '*' sys.state_argspec
```

State names can be specified as globs.

```
salt '*' sys.state_argspec 'pkg.*'
```

`salt.modules.sysmod.state_doc` (*\*args*)

Return the docstrings for all states. Optionally, specify a state or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple states/functions can be specified.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.state_doc
salt '*' sys.state_doc service
salt '*' sys.state_doc service.running
salt '*' sys.state_doc service.running ipables.append
```

State names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.state_doc 'service.*' 'iptables.*'
```

### 30.16.241 `salt.modules.sysrc`

`sysrc` module for FreeBSD

`salt.modules.sysrc.get` (*\*\*kwargs*)

Return system rc configuration variables

CLI Example:

```
salt '*' sysrc.get includeDefaults=True
```

`salt.modules.sysrc.remove` (*name, \*\*kwargs*)

Remove system rc configuration variables

CLI Example:

```
salt '*' sysrc.remove name=sshd_enable
```

`salt.modules.sysrc.set_` (*name, value, \*\*kwargs*)

Set system rc configuration variables

CLI Example:

```
salt '*' sysrc.remove name=sshd_enable
```

### 30.16.242 salt.modules.system

Support for reboot, shutdown, etc

**salt.modules.system.halt()**

Halt a running system

CLI Example:

```
salt '*' system.halt
```

**salt.modules.system.init(*runlevel*)**

Change the system runlevel on sysV compatible systems

CLI Example:

```
salt '*' system.init 3
```

**salt.modules.system.poweroff()**

Poweroff a running system

CLI Example:

```
salt '*' system.poweroff
```

**salt.modules.system.reboot()**

Reboot the system using the `reboot` command

CLI Example:

```
salt '*' system.reboot
```

**salt.modules.system.shutdown(*at\_time=None*)**

Shutdown a running system

CLI Example:

```
salt '*' system.shutdown
```

### 30.16.243 salt.modules.system\_profiler

System Profiler Module

Interface with Mac OSX's command-line System Profiler utility to get information about package receipts and installed applications.

New in version 2015.5.0.

**salt.modules.system\_profiler.applications()**

Return the results of a call to `system_profiler -xml -detail full SPApplicationsDataType` as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

Note that this can take a long time depending on how many applications are installed on the target Mac.

CLI Example:

```
salt '*' systemprofiler.applications
```

`salt.modules.system_profiler.receipts()`

Return the results of a call to `system_profiler -xml -detail full SPInstallHistoryDataType` as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

CLI Example:

```
salt '*' systemprofiler.receipts
```

### 30.16.244 salt.modules.systemd

Provide the service module for systemd

---

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `'service.start' is not available`), see [here](#).

---

`salt.modules.systemd.available(name)`

Check that the given service is available taking into account template units.

CLI Example:

```
salt '*' service.available sshd
```

`salt.modules.systemd.disable(name, **kwargs)`

Disable the named service to not start when the system boots

CLI Example:

```
salt '*' service.disable <service name>
```

`salt.modules.systemd.disabled(name)`

Return if the named service is disabled to start on boot

CLI Example:

```
salt '*' service.disabled <service name>
```

`salt.modules.systemd.enable(name, **kwargs)`

Enable the named service to start when the system boots

CLI Example:

```
salt '*' service.enable <service name>
```

`salt.modules.systemd.enabled(name, **kwargs)`

Return if the named service is enabled to start on boot

CLI Example:

```
salt '*' service.enabled <service name>
```

`salt.modules.systemd.execs()`

Return a list of all files specified as `ExecStart` for all services.

CLI Example:

```
salt '*' service.execs
```

`salt.modules.systemd.force_reload(name)`

Force-reload the specified service with systemd

CLI Example:

```
salt '*' service.force_reload <service name>
```

`salt.modules.systemd.get_all()`

Return a list of all available services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.systemd.get_disabled()`

Return a list of all disabled services

CLI Example:

```
salt '*' service.get_disabled
```

`salt.modules.systemd.get_enabled()`

Return a list of all enabled services

CLI Example:

```
salt '*' service.get_enabled
```

`salt.modules.systemd.mask(name)`

Mask the specified service with systemd

CLI Example:

```
salt '*' service.mask <service name>
```

`salt.modules.systemd.missing(name)`

The inverse of `service.available`. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing sshd
```

`salt.modules.systemd.reload_(name)`

Reload the specified service with systemd

CLI Example:

```
salt '*' service.reload <service name>
```

`salt.modules.systemd.restart(name)`

Restart the specified service with systemd

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.systemd.show(name)`

Show properties of one or more units/jobs or the manager

CLI Example:

```
salt '*' service.show <service name>
```

`salt.modules.systemd.start(name)`

Start the specified service with systemd

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.systemd.status`(*name*, *sig=None*)

Return the status for a service via systemd, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

`salt.modules.systemd.stop`(*name*)

Stop the specified service with systemd

CLI Example:

```
salt '*' service.stop <service name>
```

`salt.modules.systemd.systemctl_reload`()

Reloads systemctl, an action needed whenever unit files are updated.

CLI Example:

```
salt '*' service.systemctl_reload
```

`salt.modules.systemd.unmask`(*name*)

Unmask the specified service with systemd

CLI Example:

```
salt '*' service.unmask <service name>
```

### 30.16.245 salt.modules.test

Module for running arbitrary tests

`salt.modules.test.arg`(*\*args*, *\*\*kwargs*)

Print out the data passed into the function *\*args* and *`kwargs*, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns `{`args': args, `kwargs': kwargs}`.

CLI Example:

```
salt '*' test.arg 1 "two" 3.1 txt="hello" wow='{a: 1, b: "hello"}'
```

`salt.modules.test.arg_repr`(*\*args*, *\*\*kwargs*)

Print out the data passed into the function *\*args* and *`kwargs*, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns `{`args': repr(args), `kwargs': repr(kwargs)}`.

CLI Example:

```
salt '*' test.arg_repr 1 "two" 3.1 txt="hello" wow='{a: 1, b: "hello"}'
```

`salt.modules.test.arg_type`(*\*args*, *\*\*kwargs*)

Print out the types of the args and kwargs. This is used to test the types of the args and kwargs passed down to the minion

CLI Example:

```
salt '*' test.arg_type 1 'int'
```

`salt.modules.test.assertion(assertion)`

Assert the given argument

CLI Example:

```
salt '*' test.assert False
```

`salt.modules.test.attr_call()`

Call grains.items via the attribute

CLI Example:

```
.. code-block:: bash
```

```
salt '*' test.attr_call
```

`salt.modules.test.collatz(start)`

Execute the collatz conjecture from the passed starting number, returns the sequence and the time it took to compute. Used for performance tests.

CLI Example:

```
salt '*' test.collatz 3
```

`salt.modules.test.conf_test()`

Return the value for test.foo in the minion configuration file, or return the default value

CLI Example:

```
salt '*' test.conf_test
```

`salt.modules.test.cross_test(func, args=None)`

Execute a minion function via the `__salt__` object in the test module, used to verify that the minion functions can be called via the `__salt__` module.

CLI Example:

```
salt '*' test.cross_test file.gid_to_group 0
```

`salt.modules.test.echo(text)`

Return a string - used for testing the connection

CLI Example:

```
salt '*' test.echo 'foo bar baz quo qux'
```

`salt.modules.test.exception(message='Test Exception')`

Raise an exception

Optionally provide an error message or output the full stack.

CLI Example:

```
salt '*' test.exception 'Oh noes!'
```

`salt.modules.test.fib(num)`

Return a Fibonacci sequence up to the passed number, and the time it took to compute in seconds. Used for performance tests

CLI Example:

```
salt '*' test.fib 3
```

**salt.modules.test.get\_opts()**

Return the configuration options passed to this minion

CLI Example:

```
salt '*' test.get_opts
```

**salt.modules.test.kwarg(\*\*kwargs)**

Print out the data passed into the function **\*\*kwargs**, this is used to both test the publication data and cli kwarg passing, but also to display the information available within the publication data.

CLI Example:

```
salt '*' test.kwarg num=1 txt="two" env='{a: 1, b: "hello"}'
```

**salt.modules.test.missing\_func()**

**salt.modules.test.module\_report()**

Return a dict containing all of the execution modules with a report on the overall availability via different references

CLI Example:

```
.. code-block:: bash
```

```
    salt '*' test.module_report
```

**salt.modules.test.not\_loaded()**

List the modules that were not loaded by the salt loader system

CLI Example:

```
salt '*' test.not_loaded
```

**salt.modules.test.opts\_pkg()**

Return an opts package with the grains and opts for this minion. This is primarily used to create the options used for master side state compiling routines

CLI Example:

```
salt '*' test.opts_pkg
```

**salt.modules.test.outputter(data)**

Test the outputter, pass in data to return

CLI Example:

```
salt '*' test.outputter foobar
```

**salt.modules.test.ping()**

Used to make sure the minion is up and responding. Not an ICMP ping.

Returns True.

CLI Example:

```
salt '*' test.ping
```

`salt.modules.test.provider(module)`

Pass in a function name to discover what provider is being used

CLI Example:

```
salt '*' test.provider service
```

`salt.modules.test.providers()`

Return a dict of the provider names and the files that provided them

CLI Example:

```
salt '*' test.providers
```

`salt.modules.test.rand_sleep(max=60)`

Sleep for a random number of seconds, used to test long-running commands and minions returning at differing intervals

CLI Example:

```
salt '*' test.rand_sleep 60
```

`salt.modules.test.rand_str(size=999999999)`

Return a random string

CLI Example:

```
salt '*' test.rand_str
```

`salt.modules.test.retcode(code=42)`

Test that the returncode system is functioning correctly

CLI Example:

```
salt '*' test.retcode 42
```

`salt.modules.test.sleep(length)`

Instruct the minion to initiate a process that will sleep for a given period of time.

CLI Example:

```
salt '*' test.sleep 20
```

`salt.modules.test.stack()`

Return the current stack trace

CLI Example:

```
salt '*' test.stack
```

`salt.modules.test.try_(module, return_try_exception=False, **kwargs)`

Try to run a module command. On an exception return None. If *return\_try\_exception* is set True return the exception. This can be helpful in templates where running a module might fail as expected.

CLI Example:

```
<pre>
{% for i in range(0,230) %}
    {{ salt['test.try'](module='ipmi.get_users', bmc_host='172.2.2.'+i)|yaml(False) }}
{% endfor %}
</pre>
```

`salt.modules.test.tty(*args, **kwargs)`  
Deprecated! Moved to cmdmod.

CLI Example:

```
salt '*' test.tty tty0 'This is a test'
salt '*' test.tty pts3 'This is a test'
```

`salt.modules.test.version()`  
Return the version of salt on the minion

CLI Example:

```
salt '*' test.version
```

`salt.modules.test.versions_information()`  
Returns versions of components used by salt as a dict

CLI Example:

```
salt '*' test.versions_information
```

`salt.modules.test.versions_report()`  
Returns versions of components used by salt

CLI Example:

```
salt '*' test.versions_report
```

### 30.16.246 `salt.modules.test_virtual`

Module for running arbitrary tests with a `__virtual__` function

`salt.modules.test_virtual.ping()`

### 30.16.247 `salt.modules.timezone`

Module for managing timezone on POSIX-like systems.

`salt.modules.timezone.get_hwclock()`  
Get current hardware clock setting (UTC or localtime)

CLI Example:

```
salt '*' timezone.get_hwclock
```

`salt.modules.timezone.get_offset()`  
Get current numeric timezone offset from UCT (i.e. -0700)

CLI Example:

```
salt '*' timezone.get_offset
```

`salt.modules.timezone.get_zone()`  
Get current timezone (i.e. America/Denver)

CLI Example:

```
salt '*' timezone.get_zone
```

`salt.modules.timezone.get_zonecode()`

Get current timezone (i.e. PST, MDT, etc)

CLI Example:

```
salt '*' timezone.get_zonecode
```

`salt.modules.timezone.set_hwclock(clock)`

Sets the hardware clock to be either UTC or localtime

CLI Example:

```
salt '*' timezone.set_hwclock UTC
```

`salt.modules.timezone.set_zone(timezone)`

Unlinks, then symlinks /etc/localtime to the set timezone.

The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever you system uses as its cron and syslog daemons). This will not be automagically done and must be done manually!

CLI Example:

```
salt '*' timezone.set_zone 'America/Denver'
```

`salt.modules.timezone.zone_compare(timezone)`

Checks the hash sum between the given timezone, and the one set in /etc/localtime. Returns True if they match, and False if not. Mostly useful for running state checks.

CLI Example:

```
salt '*' timezone.zone_compare 'America/Denver'
```

### 30.16.248 salt.modules.tls

A salt module for SSL/TLS. Can create a Certificate Authority (CA) or use Self-Signed certificates.

**depends**

- PyOpenSSL Python module (0.10 or later, 0.14 or later for X509 extension support)

**configuration** Add the following values in /etc/salt/minion for the CA module to function properly:

```
ca.cert_base_path: '/etc/pki'
```

CLI Example #1 Creating a CA, a server request and its signed certificate:

```
# salt-call tls.create_ca my_little days=5 CN='My Little CA' C=US ST=Utah L=Salt
Created Private Key: "/etc/pki/my_little/my_little_ca_cert.key"
Created CA "my_little_ca": "/etc/pki/my_little_ca/my_little_ca_cert.crt"

# salt-call tls.create_csr my_little CN=www.thisisnot.coms
Created Private Key: "/etc/pki/my_little/certs/www.thisisnot.coms.key"
Created CSR for "www.thisisnot.coms": "/etc/pki/my_little/certs/www.thisisnot.coms.csr"

# salt-call tls.create_ca_signed_cert my_little CN=www.thisisnot.coms
Created Certificate for "www.thisisnot.coms": /etc/pki/my_little/certs/www.thisisnot.coms.crt"
```

CLI Example #2: Creating a client request and its signed certificate

```
# salt-call tls.create_csr my_little CN=DBReplica_No.1 cert_type=client
Created Private Key: "/etc/pki/my_little/certs/DBReplica_No.1.key."
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.csr."

# salt-call tls.create_ca_signed_cert my_little CN=DBReplica_No.1
Created Certificate for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.crt"
```

CLI Example #3: Creating both a server and client req + cert for the same CN

```
# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 cert_type=client
Created Private Key: "/etc/pki/my_little/certs/MasterDBReplica_No.2.key."
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/MasterDBReplica_No.2.csr."

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2
Created Certificate for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.crt"

# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 cert_type=server
Certificate "MasterDBReplica_No.2" already exists

(doh!)

# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 cert_type=server type_ext=True
Created Private Key: "/etc/pki/my_little/certs/DBReplica_No.1_client.key."
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1_client.csr."

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2
Certificate "MasterDBReplica_No.2" already exists

(DOH!)

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2 cert_type=server type_ext=True
Created Certificate for "MasterDBReplica_No.2": "/etc/pki/my_little/certs/MasterDBReplica_No.2_server.crt"
```

CLI Example #4: Create a server req + cert with non-CN filename for the cert

```
# salt-call tls.create_csr my_little CN=www.anothersometh.ing cert_type=server type_ext=True
Created Private Key: "/etc/pki/my_little/certs/www.anothersometh.ing_server.key."
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/www.anothersometh.ing_server.csr."

# salt-call tls.create_ca_signed_cert my_little CN=www.anothersometh.ing cert_type=server type_ext=True
Created Certificate for "www.anothersometh.ing": "/etc/pki/my_little/certs/something_completely_different.crt"
```

**salt.modules.tls.ca\_exists**(*ca\_name*, *ca\_cert\_path*=None, *ca\_filename*=None)

Verify whether a Certificate Authority (CA) already exists

**ca\_name** name of the CA

**ca\_cert\_path** absolute path to ca certificates root directory

**ca\_filename** alternative filename for the CA

New in version 2015.5.3.

CLI Example:

```
salt '*' tls.ca_exists test_ca /etc/certs
```

**salt.modules.tls.cert\_base\_path**(*ca\_cert\_path*=None)

Return the base path for certs from CLI or from options

**cacert\_path** absolute path to ca certificates root directory

CLI Example:

```
salt '*' tls.cert_base_path
```

`salt.modules.tls.cert_info(cert_path, digest='sha256')`

Return information for a particular certificate

**cert\_path** path to the cert file

**digest** what digest to use for fingerprinting

CLI Example:

```
salt '*' tls.cert_info /dir/for/certs/cert.pem
```

`salt.modules.tls.create_ca(ca_name, bits=2048, days=365, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', fix-mode=False, cacert_path=None, ca_filename=None, digest='sha256', on-lyif=None, unless=None, replace=False)`

Create a Certificate Authority (CA)

**ca\_name** name of the CA

**bits** number of RSA key bits, default is 2048

**days** number of days the CA will be valid, default is 365

**CN** common name in the request, default is ``localhost``

**C** country, default is ``US``

**ST** state, default is ``Utah``

**L** locality, default is ``Centerville``, the city where SaltStack originated

**O** organization, default is ``SaltStack``

**OU** organizational unit, default is None

**emailAddress** email address for the CA owner, default is `xyz@pdq.net`

**cacert\_path** absolute path to ca certificates root directory

**ca\_filename** alternative filename for the CA

New in version 2015.5.3.

**digest** The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL (by `EVP_get_digestbyname`, specifically). For example, ``md5`` or ``sha1``. Default: `sha256`

**replace** Replace this certificate even if it exists

New in version 2015.5.1.

Writes out a CA certificate based upon defined config values. If the file already exists, the function just returns assuming the CA certificate already exists.

If the following values were set:

```
ca.cert_base_path='/etc/pki'
ca_name='koji'
```

the resulting CA, and corresponding key, would be written in the following location:

```
/etc/pki/koji/koji_ca_cert.crt
/etc/pki/koji/koji_ca_cert.key
```

CLI Example:

```
salt '*' tls.create_ca test_ca
```

```
salt.modules.tls.create_ca_signed_cert(ca_name, CN, days=365, cacert_path=None,
                                       ca_filename=None, cert_path=None,
                                       cert_filename=None, digest='sha256', cert_type=None,
                                       type_ext=False, replace=False)
```

Create a Certificate (CERT) signed by a named Certificate Authority (CA)

If the certificate file already exists, the function just returns assuming the CERT already exists.

The CN *must* match an existing CSR generated by create\_csr. If it does not, this method does nothing.

**ca\_name** name of the CA

**CN** common name matching the certificate signing request

**days** number of days certificate is valid, default is 365 (1 year)

**cacert\_path** absolute path to ca certificates root directory

**ca\_filename** alternative filename for the CA

New in version 2015.5.3.

**cert\_path** full path to the certificates directory

**cert\_filename** alternative filename for the certificate, useful when using special characters in the CN. If this option is set it will override the certificate filename output effects of cert\_type. type\_ext will be completely overridden.

New in version 2015.5.3.

**digest** The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL (by EVP\_get\_digestbyname, specifically). For example, ``md5`` or ``sha1``. Default: ``sha256``

**replace** Replace this certificate even if it exists

New in version 2015.5.1.

**cert\_type** string. Either ``server`` or ``client`` (see create\_csr() for details).

If create\_csr(type\_ext=True) this function **must** be called with the same cert\_type so it can find the CSR file.

---

**Note:** create\_csr() defaults to cert\_type='server'; therefore, if it was also called with type\_ext, cert\_type becomes a required argument for create\_ca\_signed\_cert()

---

**type\_ext** bool. If set True, use cert\_type as an extension to the CN when formatting the filename.

e.g.: some\_subject\_CN\_server.crt or some\_subject\_CN\_client.crt

This facilitates the context where both types are required for the same subject

If cert\_filename is *not None*, setting type\_ext has no effect

If the following values were set:

```
ca.cert_base_path='/etc/pki'
ca_name='koji'
CN='test.egavas.org'
```

the resulting signed certificate would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.crt
```

CLI Example:

```
salt '*' tls.create_ca_signed_cert test localhost
```

```
salt.modules.tls.create_csr(ca_name, bits=2048, CN='localhost', C='US', ST='Utah', L='Salt
Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net',
subjectAltName=None, cacert_path=None, ca_filename=None,
csr_path=None, csr_filename=None, digest='sha256', type_ext=False,
cert_type='server', replace=False)
```

Create a Certificate Signing Request (CSR) for a particular Certificate Authority (CA)

**ca\_name** name of the CA

**bits** number of RSA key bits, default is 2048

**CN** common name in the request, default is ``localhost``

**C** country, default is ``US``

**ST** state, default is ``Utah``

**L** locality, default is ``Centerville``, the city where SaltStack originated

**O** organization, default is ``SaltStack`` NOTE: Must the same as CA certificate or an error will be raised

**OU** organizational unit, default is None

**emailAddress** email address for the request, default is `xyz@pdq.net`

**subjectAltName** valid subjectAltNames in full form, e.g. to add DNS entry you would call this function with this value:

```
examples: ['DNS:somednsname.com', `DNS:1.2.3.4`, `IP:1.2.3.4`, `IP:2001:4801:7821:77:be76:4eff:fe11:e51`,
`email:me@i.like.pie.com`]
```

**Note:** some libraries do not properly query IP: prefixes, instead looking for the given req. source with a DNS: prefix. To be thorough, you may want to include both DNS: and IP: entries if you are using subjectAltNames for destinations for your TLS connections.

e.g.: requests to <https://1.2.3.4> will fail from python's requests library w/out the second entry in the above list

New in version Beryllium.

**cert\_type** Specify the general certificate type. Can be either *server* or *client*. Indicates the set of common extensions added to the CSR.

```
server: { `basicConstraints`: `CA:FALSE`, `extendedKeyUsage`: `serverAuth`, `keyUsage`: `digitalSignature, keyEncipherment`
}
```

```
client: { `basicConstraints`: `CA:FALSE`, `extendedKeyUsage`: `clientAuth`, `keyUsage`: `nonRepudiation, digitalSignature, keyEncipherment`
}
```

```
}

```

**type\_ext** boolean. Whether or not to extend the filename with CN\_[cert\_type] This can be useful if a server and client certificate are needed for the same CN. Defaults to False to avoid introducing an unexpected file naming pattern

The files normally named some\_subject\_CN.csr and some\_subject\_CN.key will then be saved

**replace** Replace this signing request even if it exists

New in version 2015.5.1.

Writes out a Certificate Signing Request (CSR) If the file already exists, the function just returns assuming the CSR already exists.

If the following values were set:

```
ca.cert_base_path='/etc/pki'
ca_name='koji'
CN='test.egavas.org'
```

the resulting CSR, and corresponding key, would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.csr
/etc/pki/koji/certs/test.egavas.org.key
```

CLI Example:

```
salt '*' tls.create_csr test
```

```
salt.modules.tls.create_empty_crl(ca_name, cacert_path=None, ca_filename=None,
                                crl_file=None)
```

Create an empty Certificate Revocation List.

New in version Beryllium.

**ca\_name** name of the CA

**cacert\_path** absolute path to ca certificates root directory

**ca\_filename** alternative filename for the CA

New in version 2015.5.3.

**crl\_file** full path to the CRL file

CLI Example:

```
salt '*' tls.create_empty_crl ca_name='koji' ca_filename='ca'
```

```
salt.modules.tls.create_pkcs12(ca_name, CN, passphrase='', cacert_path=None, replace=False)
```

Create a PKCS#12 browser certificate for a particular Certificate (CN)

**ca\_name** name of the CA

**CN** common name matching the certificate signing request

**passphrase** used to unlock the PKCS#12 certificate when loaded into the browser

**cacert\_path** absolute path to ca certificates root directory

**replace** Replace this certificate even if it exists

New in version 2015.5.1.

If the following values were set:

```
ca.cert_base_path='/etc/pki'
ca_name='koji'
CN='test.egavas.org'
```

the resulting signed certificate would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.p12
```

CLI Example:

```
salt '*' tls.create_pkcs12 test localhost
```

```
salt.modules.tls.create_self_signed_cert(tls_dir='tls', bits=2048, days=365, CN='localhost',
C='US', ST='Utah', L='Salt Lake City',
O='SaltStack', OU=None, emailAddress='xyz@pdq.net',
cacert_path=None, cert_filename=None, digest='sha256', replace=False)
```

Create a Self-Signed Certificate (CERT)

**tls\_dir** location appended to the ca.cert\_base\_path, default is 'tls'

**bits** number of RSA key bits, default is 2048

**CN** common name in the request, default is 'localhost'

**C** country, default is 'US'

**ST** state, default is 'Utah'

**L** locality, default is 'Centerville', the city where SaltStack originated

**O** organization, default is 'SaltStack' NOTE: Must be the same as CA certificate or an error will be raised

**OU** organizational unit, default is None

**emailAddress** email address for the request, default is 'xyz@pdq.net'

**cacert\_path** absolute path to ca certificates root directory

**digest** The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL (by EVP\_get\_digestbyname, specifically). For example, 'md5' or 'sha1'. Default: 'sha256'

**replace** Replace this certificate even if it exists

New in version 2015.5.1.

Writes out a Self-Signed Certificate (CERT). If the file already exists, the function just returns.

If the following values were set:

```
ca.cert_base_path='/etc/pki'
tls_dir='koji'
CN='test.egavas.org'
```

the resulting CERT, and corresponding key, would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.crt
/etc/pki/koji/certs/test.egavas.org.key
```

CLI Example:

```
salt '*' tls.create_self_signed_cert
```

Passing options from the command line:

```
salt 'minion' tls.create_self_signed_cert CN='test.mysite.org'
```

`salt.modules.tls.get_ca`(*ca\_name*, *as\_text=False*, *cacert\_path=None*)

Get the certificate path or content

**ca\_name** name of the CA

**as\_text** if true, return the certificate content instead of the path

**cacert\_path** absolute path to ca certificates root directory

CLI Example:

```
salt '*' tls.get_ca test_ca as_text=False cacert_path=/etc/certs
```

`salt.modules.tls.get_ca_signed_cert`(*ca\_name*, *CN='localhost'*, *as\_text=False*, *cacert\_path=None*, *cert\_filename=None*)

Get the certificate path or content

**ca\_name** name of the CA

**CN** common name of the certificate

**as\_text** if true, return the certificate content instead of the path

**cacert\_path** absolute path to certificates root directory

**cert\_filename** alternative filename for the certificate, useful when using special characters in the CN

New in version 2015.5.3.

CLI Example:

```
salt '*' tls.get_ca_signed_cert test_ca CN=localhost as_text=False cacert_path=/etc/certs
```

`salt.modules.tls.get_ca_signed_key`(*ca\_name*, *CN='localhost'*, *as\_text=False*, *cacert\_path=None*, *key\_filename=None*)

Get the certificate path or content

**ca\_name** name of the CA

**CN** common name of the certificate

**as\_text** if true, return the certificate content instead of the path

**cacert\_path** absolute path to certificates root directory

**key\_filename** alternative filename for the key, useful when using special characters

New in version 2015.5.3.

in the CN

CLI Example:

```
salt '*' tls.get_ca_signed_key test_ca CN=localhost as_text=False
```

`salt.modules.tls.get_extensions`(*cert\_type*)

Fetch X509 and CSR extension definitions from `tls:extensions:` (`common|server|client`) or set them to standard defaults.

New in version Beryllium.

**cert\_type:** The type of certificate such as `server` or `client`.

CLI Example:

```
salt '*' tls.get_extensions client
```

`salt.modules.tls.maybe_fix_ssl_version`(*ca\_name*, *cacert\_path*=None, *ca\_filename*=None)

Check that the X509 version is correct (was incorrectly set in previous salt versions). This will fix the version if needed.

**ca\_name** ca authority name

**cacert\_path** absolute path to ca certificates root directory

**ca\_filename** alternative filename for the CA

New in version 2015.5.3.

CLI Example:

```
salt '*' tls.maybe_fix_ssl_version test_ca /etc/certs
```

`salt.modules.tls.revoke_cert`(*ca\_name*, *CN*, *cacert\_path*=None, *ca\_filename*=None, *cert\_path*=None, *cert\_filename*=None, *crl\_file*=None)

Revoke a certificate.

New in version Beryllium.

**ca\_name** Name of the CA.

**CN** Common name matching the certificate signing request.

**cacert\_path** Absolute path to ca certificates root directory.

**ca\_filename** Alternative filename for the CA.

**cert\_path** Path to the cert file.

**cert\_filename** Alternative filename for the certificate, useful when using special characters in the CN.

**crl\_file** Full path to the CRL file.

CLI Example:

```
salt '*' tls.revoke_cert ca_name='koji' ca_filename='ca'
```

`salt.modules.tls.set_ca_path`(*cacert\_path*)

If wanted, store the aforementioned *cacert\_path* in context to be used as the basepath for further operations

CLI Example:

```
salt '*' tls.set_ca_path /etc/certs
```

### 30.16.249 salt.modules.tomcat

Support for Tomcat

This module uses the manager webapp to manage Apache tomcat webapps. If the manager webapp is not configured some of the functions won't work.

**Note:** The config format was changed in 2014.7.0, but backwards compatibility for the old-style config will be in the 2014.7.1 release.

The following grains/pillar should be set:

```
tomcat-manager:  
  user: <username>  
  passwd: <password>
```

or the old format:

```
tomcat-manager.user: <username>  
tomcat-manager.passwd: <password>
```

Also configure a user in the conf/tomcat-users.xml file:

```
<?xml version='1.0' encoding='utf-8'?>  
<tomcat-users>  
  <role rolename="manager-script"/>  
  <user username="tomcat" password="tomcat" roles="manager-script"/>  
</tomcat-users>
```

---

**Note:**

- More information about tomcat manager: <http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html>
- if you use only this module for deployments you've might want to strict access to the manager only from localhost for more info: [http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring\\_Manager\\_Application\\_Access](http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access)

- Tested on:

**JVM Vendor:** Sun Microsystems Inc.

**JVM Version:** 1.6.0\_43-b01

**OS Architecture:** amd64

**OS Name:** Linux

**OS Version:** 2.6.32-358.el6.x86\_64

**Tomcat Version:** Apache Tomcat/7.0.37

---

```
salt.modules.tomcat.deploy_war(war, context, force='no', url='http://localhost:8080/manager',  
                               saltenv='base', timeout=180, env=None,  
                               temp_war_location=None)
```

Deploy a WAR file

**war** absolute path to WAR file (should be accessible by the user running tomcat) or a path supported by the salt.modules.cp.get\_file function

**context** the context path to deploy

**force** [False] set True to deploy the webapp even one is deployed in the context

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**saltenv** [base] the environment for WAR file in used by salt.modules.cp.get\_url function

**timeout** [180] timeout for HTTP request

**temp\_war\_location** [None] use another location to temporarily copy to war file by default the system's temp directory is used

CLI Examples:

cp module

```
salt '*' tomcat.deploy_war salt://application.war /api
salt '*' tomcat.deploy_war salt://application.war /api no
salt '*' tomcat.deploy_war salt://application.war /api yes http://localhost:8080/manager
```

minion local file system

```
salt '*' tomcat.deploy_war /tmp/application.war /api
salt '*' tomcat.deploy_war /tmp/application.war /api no
salt '*' tomcat.deploy_war /tmp/application.war /api yes http://localhost:8080/manager
```

### salt.modules.tomcat.fullversion()

Return all server information from catalina.sh version

CLI Example:

```
salt '*' tomcat.fullversion
```

### salt.modules.tomcat.leaks(url='http://localhost:8080/manager', timeout=180)

Find memory leaks in tomcat

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.leaks
```

### salt.modules.tomcat.ls(url='http://localhost:8080/manager', timeout=180)

list all the deployed webapps

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.ls
salt '*' tomcat.ls http://localhost:8080/manager
```

### salt.modules.tomcat.passwd(pwd, user='', alg='md5', realm=None)

This function replaces the \$CATALINA\_HOME/bin/digest.sh script convert a clear-text password to the \$CATALINA\_BASE/conf/tomcat-users.xml format

CLI Examples:

```
salt '*' tomcat.passwd secret
salt '*' tomcat.passwd secret tomcat sha1
salt '*' tomcat.passwd secret tomcat sha1 'Protected Realm'
```

### salt.modules.tomcat.reload\_(app, url='http://localhost:8080/manager', timeout=180)

Reload the webapp

**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.reload /jenkins
salt '*' tomcat.reload /jenkins http://localhost:8080/manager
```

`salt.modules.tomcat.serverinfo` (*url*='http://localhost:8080/manager', *timeout*=180)  
return details about the server

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.serverinfo
salt '*' tomcat.serverinfo http://localhost:8080/manager
```

`salt.modules.tomcat.sessions` (*app*, *url*='http://localhost:8080/manager', *timeout*=180)  
return the status of the webapp sessions

**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.sessions /jenkins
salt '*' tomcat.sessions /jenkins http://localhost:8080/manager
```

`salt.modules.tomcat.signal` (*signal*=None)  
Signals catalina to start, stop, securestart, forcestop.

CLI Example:

```
salt '*' tomcat.signal start
```

`salt.modules.tomcat.start` (*app*, *url*='http://localhost:8080/manager', *timeout*=180)  
Start the webapp

**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.start /jenkins
salt '*' tomcat.start /jenkins http://localhost:8080/manager
```

`salt.modules.tomcat.status` (*url*='http://localhost:8080/manager', *timeout*=180)  
Used to test if the tomcat manager is up

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.status
salt '*' tomcat.status http://localhost:8080/manager
```

`salt.modules.tomcat.status_webapp` (*app*, *url*='http://localhost:8080/manager', *timeout*=180)  
return the status of the webapp (stopped | running | missing)

**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.status_webapp /jenkins
salt '*' tomcat.status_webapp /jenkins http://localhost:8080/manager
```

**salt.modules.tomcat.stop**(*app*, *url*='http://localhost:8080/manager', *timeout*=180)

Stop the webapp

**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.stop /jenkins
salt '*' tomcat.stop /jenkins http://localhost:8080/manager
```

**salt.modules.tomcat.undeploy**(*app*, *url*='http://localhost:8080/manager', *timeout*=180)

Undeploy a webapp

**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.undeploy /jenkins
salt '*' tomcat.undeploy /jenkins http://localhost:8080/manager
```

**salt.modules.tomcat.version**()

Return server version from catalina.sh version

CLI Example:

```
salt '*' tomcat.version
```

### 30.16.250 salt.modules.twilio\_notify

Module for notifications via Twilio

New in version 2014.7.0.

**depends**

- twilio python module

**configuration** Configure this module by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```
my-twilio-account:
  twilio.account_sid: AC32a3c83990934481add5ce1659f04d2
  twilio.auth_token: mytoken
```

`salt.modules.twilio_notify.send_sms(profile, body, to, from_)`

Send an sms

CLI Example:

```
twilio.send_sms twilio-account 'Test sms' '+1801999999' '+18011111111'
```

### 30.16.251 salt.modules.upstart

Module for the management of upstart systems. The Upstart system only supports service starting, stopping and restarting.

---

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `'service.start' is not available`), see [here](#).

---

Currently (as of Ubuntu 12.04) there is no tool available to disable Upstart services (like `update-rc.d`). This[1] is the recommended way to disable an Upstart service. So we assume that all Upstart services that have not been disabled in this manner are enabled.

But this is broken because we do not check to see that the dependent services are enabled. Otherwise we would have to do something like parse the output of `initctl show-config` to determine if all service dependencies are enabled to start on boot. For example, see the `start on` condition for the `lightdm` service below[2]. And this would be too hard. So we wait until the upstart developers have solved this problem. :) This is to say that an Upstart service that is enabled may not really be enabled.

Also, when an Upstart service is enabled, should the dependent services be enabled too? Probably not. But there should be a notice about this, at least.

[1] <http://upstart.ubuntu.com/cookbook/#disabling-a-job-from-automatically-starting>

[2] example upstart configuration file:

```
lightdm
emits login-session-start
emits desktop-session-start
emits desktop-shutdown
start on (((filesystem and runlevel [!06]) and started dbus) and (drm-device-added card0 PRIMARY_DEV
stop on runlevel [016]
```

**Warning:** This module should not be used on Red Hat systems. For these, the `rh_service` module should be used, as it supports the hybrid upstart/sysvinit system used in RHEL/CentOS 6.

`salt.modules.upstart.available(name)`

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available sshd
```

`salt.modules.upstart.disable(name, **kwargs)`

Disable the named service from starting on boot

CLI Example:

```
salt '*' service.disable <service name>
```

`salt.modules.upstart.disabled(name)`

Check to see if the named service is disabled to start on boot

CLI Example:

```
salt '*' service.disabled <service name>
```

`salt.modules.upstart.enable`(*name*, *\*\*kwargs*)  
Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

`salt.modules.upstart.enabled`(*name*, *\*\*kwargs*)  
Check to see if the named service is enabled to start on boot

CLI Example:

```
salt '*' service.enabled <service name>
```

`salt.modules.upstart.force_reload`(*name*)  
Force-reload the named service

CLI Example:

```
salt '*' service.force_reload <service name>
```

`salt.modules.upstart.full_restart`(*name*)  
Do a full restart (stop/start) of the named service

CLI Example:

```
salt '*' service.full_restart <service name>
```

`salt.modules.upstart.get_all`()  
Return all installed services

CLI Example:

```
salt '*' service.get_all
```

`salt.modules.upstart.get_disabled`()  
Return the disabled services

CLI Example:

```
salt '*' service.get_disabled
```

`salt.modules.upstart.get_enabled`()  
Return the enabled services

CLI Example:

```
salt '*' service.get_enabled
```

`salt.modules.upstart.missing`(*name*)  
The inverse of `service.available`. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing sshd
```

`salt.modules.upstart.reload_`(*name*)  
Reload the named service

CLI Example:

```
salt '*' service.reload <service name>
```

`salt.modules.upstart.restart(name)`

Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.upstart.start(name)`

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.upstart.status(name, sig=None)`

Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

`salt.modules.upstart.stop(name)`

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.252 salt.modules.useradd

Manage users with the useradd command

---

**Important:** If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to ``user.info' is not available`), see [here](#).

---

`salt.modules.useradd.add(name, uid=None, gid=None, groups=None, home=None, shell=None, unique=True, system=False, fullname='', roomnumber='', workphone='', homephone='', createhome=True, loginclass=None)`

Add a user to the minion

CLI Example:

```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

`salt.modules.useradd.chfullname(name, fullname)`

Change the user's Full Name

CLI Example:

```
salt '*' user.chfullname foo "Foo Bar"
```

`salt.modules.useradd.chgid(name, gid)`

Change the default group of the user

CLI Example:

```
salt '*' user.chgid foo 4376
```

`salt.modules.useradd.chgroups` (*name, groups, append=False*)

Change the groups to which this user belongs

**name** User to modify

**groups** Groups to set for the user

**append** [False] If True, append the specified group(s). Otherwise, this function will replace the user's groups with the specified group(s).

CLI Examples:

```
salt '*' user.chgroups foo wheel,root
salt '*' user.chgroups foo wheel,root append=True
```

`salt.modules.useradd.chhome` (*name, home, persist=False*)

Change the home directory of the user, pass True for persist to move files to the new home directory if the old home directory exist.

CLI Example:

```
salt '*' user.chhome foo /home/users/foo True
```

`salt.modules.useradd.chhomephone` (*name, homephone*)

Change the user's Home Phone

CLI Example:

```
salt '*' user.chhomephone foo 7735551234
```

`salt.modules.useradd.chloginclass` (*name, loginclass*)

Change the default login class of the user

---

**Note:** This function only applies to OpenBSD systems.

---

CLI Example:

```
salt '*' user.chloginclass foo staff
```

`salt.modules.useradd.chroomnumber` (*name, roomnumber*)

Change the user's Room Number

CLI Example:

```
salt '*' user.chroomnumber foo 123
```

`salt.modules.useradd.chshell` (*name, shell*)

Change the default shell of the user

CLI Example:

```
salt '*' user.chshell foo /bin/zsh
```

`salt.modules.useradd.chuid` (*name, uid*)

Change the uid for a named user

CLI Example:

```
salt '*' user.chuid foo 4376
```

`salt.modules.useradd.chworkphone` (*name*, *workphone*)  
Change the user's Work Phone

CLI Example:

```
salt '*' user.chworkphone foo 7735550123
```

`salt.modules.useradd.delete` (*name*, *remove=False*, *force=False*)  
Remove a user from the minion

CLI Example:

```
salt '*' user.delete name remove=True force=True
```

`salt.modules.useradd.get_loginclass` (*name*)  
Get the login class of the user

---

**Note:** This function only applies to OpenBSD systems.

---

CLI Example:

```
salt '*' user.get_loginclass foo
```

`salt.modules.useradd.getent` (*refresh=False*)  
Return the list of all info for all users

CLI Example:

```
salt '*' user.getent
```

`salt.modules.useradd.info` (*name*)  
Return user information

CLI Example:

```
salt '*' user.info root
```

`salt.modules.useradd.list_groups` (*name*)  
Return a list of groups the named user belongs to

CLI Example:

```
salt '*' user.list_groups foo
```

`salt.modules.useradd.list_users` ()  
Return a list of all users

CLI Example:

```
salt '*' user.list_users
```

`salt.modules.useradd.rename` (*name*, *new\_name*)  
Change the username for a named user

CLI Example:

```
salt '*' user.rename name new_name
```

### 30.16.253 salt.modules.uwsgi

uWSGI stats server <http://uwsgi-docs.readthedocs.org/en/latest/StatsServer.html>

**maintainer** Peter Baumgartner <pete@lincolnloop.com>

**maturity** new

**platform** all

**salt.modules.uwsgi.stats**(*socket*)

Return the data from `uwsgi --connect-and-read` as a dictionary.

**socket** The socket the uWSGI stats server is listening on

CLI Example:

```
salt '*' uwsgi.stats /var/run/mystatsserver.sock
```

```
salt '*' uwsgi.stats 127.0.0.1:5050
```

### 30.16.254 salt.modules.varnish

Support for Varnish

New in version 2014.7.0.

---

**Note:** These functions are designed to work with all implementations of Varnish from 3.x onwards

---

**salt.modules.varnish.ban**(*ban\_expression*)

Add ban to the varnish cache

CLI Example:

```
salt '*' varnish.ban ban_expression
```

**salt.modules.varnish.ban\_list**()

List varnish cache current bans

CLI Example:

```
salt '*' varnish.ban_list
```

**salt.modules.varnish.param\_set**(*param, value*)

Set a param in varnish cache

CLI Example:

```
salt '*' varnish.param_set param value
```

**salt.modules.varnish.param\_show**(*param=None*)

Show params of varnish cache

CLI Example:

```
salt '*' varnish.param_show param
```

**salt.modules.varnish.purge**()

Purge the varnish cache

CLI Example:

```
salt '*' varnish.purge
```

**salt.modules.varnish.version()**  
Return server version from varnishd -V

CLI Example:

```
salt '*' varnish.version
```

### 30.16.255 salt.modules.vbox\_guest

VirtualBox Guest Additions installer

**salt.modules.vbox\_guest.additions\_install(\*args, \*\*kwargs)**  
Install VirtualBox Guest Additions. Uses the CD, connected by VirtualBox.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host` is usually `Right Ctrl`).

See <https://www.virtualbox.org/manual/ch04.html#idp52733088> for more details.

CLI Example:

```
salt '*' vbox_guest.additions_install
salt '*' vbox_guest.additions_install reboot=True
salt '*' vbox_guest.additions_install upgrade_os=True
```

#### Parameters

- **reboot** (*bool*) -- reboot computer to complete installation
- **upgrade\_os** (*bool*) -- upgrade OS (to ensure the latests version of kernel and developer tools are installed)

**Returns** version of VirtualBox Guest Additions or string with error

**salt.modules.vbox\_guest.additions\_mount()**  
Mount VirtualBox Guest Additions CD to the temp directory.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host` is usually `Right Ctrl`).

CLI Example:

```
salt '*' vbox_guest.additions_mount
```

**Returns** True or OSError exception

**salt.modules.vbox\_guest.additions\_remove(\*\*kwargs)**  
Remove VirtualBox Guest Additions.

Firstly it tries to uninstall itself by executing `/opt/VBoxGuestAdditions-VERSION/uninstall.run uninstall`. It uses the CD, connected by VirtualBox if it fails.

CLI Example:

```
salt '*' vbox_guest.additions_remove
salt '*' vbox_guest.additions_remove force=True
```

**Parameters** **force** (*bool*) -- force VirtualBox Guest Additions removing

**Returns** True if VirtualBox Guest Additions were removed successfully else False

`salt.modules.vbox_guest.additions_umount(mount_point)`

Unmount VirtualBox Guest Additions CD from the temp directory.

CLI Example:

```
salt '*' vbox_guest.additions_umount
```

**Parameters** **mount\_point** -- directory VirtualBox Guest Additions is mounted to

**Returns** True or an string with error

`salt.modules.vbox_guest.additions_version()`

Check VirtualBox Guest Additions version.

CLI Example:

```
salt '*' vbox_guest.additions_version
```

**Returns** version of VirtualBox Guest Additions or False if they are not installed

`salt.modules.vbox_guest.grant_access_to_shared_folders_to(name, users=None)`

Grant access to auto-mounted shared folders to the users.

User is specified by it's name. To grant access for several users use argument *users*. Access will be denied to the users not listed in *users* argument.

See [https://www.virtualbox.org/manual/ch04.html#sf\\_mount\\_auto](https://www.virtualbox.org/manual/ch04.html#sf_mount_auto) for more details.

CLI Example:

```
salt '*' vbox_guest.grant_access_to_shared_folders_to fred
salt '*' vbox_guest.grant_access_to_shared_folders_to users ['fred', 'roman']
```

#### Parameters

- **name** (*str*) -- name of the user to grant access to auto-mounted shared folders to
- **users** (*list of str*) -- list of names of users to grant access to auto-mounted shared folders to (if specified, *name* will not be taken into account)

**Returns** list of users who have access to auto-mounted shared folders

`salt.modules.vbox_guest.list_shared_folders_users()`

List users who have access to auto-mounted shared folders.

See [https://www.virtualbox.org/manual/ch04.html#sf\\_mount\\_auto](https://www.virtualbox.org/manual/ch04.html#sf_mount_auto) for more details.

CLI Example:

```
salt '*' vbox_guest.list_shared_folders_users
```

**Returns** list of users who have access to auto-mounted shared folders

### 30.16.256 salt.modules.virt

Work with virtual machines managed by libvirt

**depends** libvirt Python module

**salt.modules.virt.create**(*vm\_*)

Start a defined domain

CLI Example:

```
salt '*' virt.create <vm name>
```

**salt.modules.virt.create\_xml\_path**(*path*)

Start a domain based on the XML-file path passed to the function

CLI Example:

```
salt '*' virt.create_xml_path <path to XML file on the node>
```

**salt.modules.virt.create\_xml\_str**(*xml*)

Start a domain based on the XML passed to the function

CLI Example:

```
salt '*' virt.create_xml_str <XML in string format>
```
