**salt.modules.virt.ctrl\_alt\_del**(*vm\_*)

Sends CTRL+ALT+DEL to a VM

CLI Example:

```
salt '*' virt.ctrl_alt_del <vm name>
```

**salt.modules.virt.define\_vol\_xml\_path**(*path*)

Define a volume based on the XML-file path passed to the function

CLI Example:

```
salt '*' virt.define_vol_xml_path <path to XML file on the node>
```

**salt.modules.virt.define\_vol\_xml\_str**(*xml*)

Define a volume based on the XML passed to the function

CLI Example:

```
salt '*' virt.define_vol_xml_str <XML in string format>
```

**salt.modules.virt.define\_xml\_path**(*path*)

Define a domain based on the XML-file path passed to the function

CLI Example:

```
salt '*' virt.define_xml_path <path to XML file on the node>
```

**salt.modules.virt.define\_xml\_str**(*xml*)

Define a domain based on the XML passed to the function

CLI Example:

```
salt '*' virt.define_xml_str <XML in string format>
```

`salt.modules.virt.destroy(vm_)`

Hard power down the virtual machine, this is equivalent to pulling the power

CLI Example:

```
salt '*' virt.destroy <vm name>
```

`salt.modules.virt.freecpu()`

Return an int representing the number of unallocated cpus on this hypervisor

CLI Example:

```
salt '*' virt.freecpu
```

`salt.modules.virt.freemem()`

Return an int representing the amount of memory that has not been given to virtual machines on this node

CLI Example:

```
salt '*' virt.freemem
```

`salt.modules.virt.full_info()`

Return the node\_info, vm\_info and freemem

CLI Example:

```
salt '*' virt.full_info
```

`salt.modules.virt.get_disks(vm_)`

Return the disks of a named vm

CLI Example:

```
salt '*' virt.get_disks <vm name>
```

`salt.modules.virt.get_graphics(vm_)`

Returns the information on vnc for a given vm

CLI Example:

```
salt '*' virt.get_graphics <vm name>
```

`salt.modules.virt.get_macs(vm_)`

Return a list off MAC addresses from the named vm

CLI Example:

```
salt '*' virt.get_macs <vm name>
```

`salt.modules.virt.get_nics(vm_)`

Return info about the network interfaces of a named vm

CLI Example:

```
salt '*' virt.get_nics <vm name>
```

`salt.modules.virt.get_profiles(hypervisor=None)`

Return the virt profiles for hypervisor.

Currently there are profiles for:

- nic
- disk

CLI Example:

```
salt '*' virt.get_profiles
salt '*' virt.get_profiles hypervisor=esxi
```

**salt.modules.virt.get\_xml**(*vm\_*)

Returns the XML for a given vm

CLI Example:

```
salt '*' virt.get_xml <vm name>
```

**salt.modules.virt.init**(*name, cpu, mem, image=None, nic='default', hypervisor='kvm', start=True, disk='default', saltenv='base', \*\*kwargs*)

Initialize a new vm

CLI Example:

```
salt 'hypervisor' virt.init vm_name 4 512 salt://path/to/image.raw
salt 'hypervisor' virt.init vm_name 4 512 nic=profile disk=profile
```

**salt.modules.virt.is\_hyper**()

Returns a bool whether or not this node is a hypervisor of any kind

CLI Example:

```
salt '*' virt.is_hyper
```

**salt.modules.virt.is\_kvm\_hyper**()

Returns a bool whether or not this node is a KVM hypervisor

CLI Example:

```
salt '*' virt.is_kvm_hyper
```

**salt.modules.virt.is\_xen\_hyper**()

Returns a bool whether or not this node is a XEN hypervisor

CLI Example:

```
salt '*' virt.is_xen_hyper
```

**salt.modules.virt.list\_active\_vms**()

Return a list of names for active virtual machine on the minion

CLI Example:

```
salt '*' virt.list_active_vms
```

**salt.modules.virt.list\_inactive\_vms**()

Return a list of names for inactive virtual machine on the minion

CLI Example:

```
salt '*' virt.list_inactive_vms
```

**salt.modules.virt.list\_vms**()

Return a list of virtual machine names on the minion

CLI Example:

```
salt '*' virt.list_vms
```

**salt.modules.virt.migrate**(*vm\_*, *target*, *ssh=False*)  
Shared storage migration

CLI Example:

```
salt '*' virt.migrate <vm name> <target hypervisor>
```

**salt.modules.virt.migrate\_non\_shared**(*vm\_*, *target*, *ssh=False*)  
Attempt to execute non-shared storage ``all" migration

CLI Example:

```
salt '*' virt.migrate_non_shared <vm name> <target hypervisor>
```

**salt.modules.virt.migrate\_non\_shared\_inc**(*vm\_*, *target*, *ssh=False*)  
Attempt to execute non-shared storage ``all" migration

CLI Example:

```
salt '*' virt.migrate_non_shared_inc <vm name> <target hypervisor>
```

**salt.modules.virt.node\_info**()  
Return a dict with information about this node

CLI Example:

```
salt '*' virt.node_info
```

**salt.modules.virt.pause**(*vm\_*)  
Pause the named vm

CLI Example:

```
salt '*' virt.pause <vm name>
```

**salt.modules.virt.purge**(*vm\_*, *dirs=False*)  
Recursively destroy and delete a virtual machine, pass True for dir's to also delete the directories containing the virtual machine disk images - USE WITH EXTREME CAUTION!

CLI Example:

```
salt '*' virt.purge <vm name>
```

**salt.modules.virt.reboot**(*vm\_*)  
Reboot a domain via ACPI request

CLI Example:

```
salt '*' virt.reboot <vm name>
```

**salt.modules.virt.reset**(*vm\_*)  
Reset a VM by emulating the reset button on a physical machine

CLI Example:

```
salt '*' virt.reset <vm name>
```

**salt.modules.virt.resume**(*vm\_*)  
Resume the named vm

CLI Example:

```
salt '*' virt.resume <vm name>
```

**salt.modules.virt.seed\_non\_shared\_migrate**(*disks, force=False*)

Non shared migration requires that the disks be present on the migration destination, pass the disks information via this function, to the migration destination before executing the migration.

CLI Example:

```
salt '*' virt.seed_non_shared_migrate <disks>
```

**salt.modules.virt.set\_autostart**(*vm\_, state='on'*)

Set the autostart flag on a VM so that the VM will start with the host system on reboot.

CLI Example:

```
salt "*" virt.set_autostart <vm name> <on | off>
```

**salt.modules.virt.setmem**(*vm\_, memory, config=False*)

Changes the amount of memory allocated to VM. The VM must be shutdown for this to work.

memory is to be specified in MB If config is True then we ask libvirt to modify the config as well

CLI Example:

```
salt '*' virt.setmem myvm 768
```

**salt.modules.virt.setvcpus**(*vm\_, vcpus, config=False*)

Changes the amount of vcpus allocated to VM. The VM must be shutdown for this to work.

vcpus is an int representing the number to be assigned If config is True then we ask libvirt to modify the config as well

CLI Example:

```
salt '*' virt.setvcpus myvm 2
```

**salt.modules.virt.shutdown**(*vm\_*)

Send a soft shutdown signal to the named vm

CLI Example:

```
salt '*' virt.shutdown <vm name>
```

**salt.modules.virt.start**(*vm\_*)

Alias for the obscurely named `create` function

CLI Example:

```
salt '*' virt.start <vm name>
```

**salt.modules.virt.stop**(*vm\_*)

Alias for the obscurely named `destroy` function

CLI Example:

```
salt '*' virt.stop <vm name>
```

**salt.modules.virt.undefine**(*vm\_*)

Remove a defined vm, this does not purge the virtual machine image, and this only works if the vm is powered down

CLI Example:

```
salt '*' virt.undefine <vm name>
```

**salt.modules.virt.virt\_type()**

Returns the virtual machine type as a string

CLI Example:

```
salt '*' virt.virt_type
```

**salt.modules.virt.vm\_cputime**(*vm\_=None*)

Return cputime used by the vms on this hyper in a list of dicts:

```
[
  'your-vm': {
    'cputime' <int>
    'cputime_percent' <int>
  },
  ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_cputime
```

**salt.modules.virt.vm\_diskstats**(*vm\_=None*)

Return disk usage counters used by the vms on this hyper in a list of dicts:

```
[
  'your-vm': {
    'rd_req' : 0,
    'rd_bytes' : 0,
    'wr_req' : 0,
    'wr_bytes' : 0,
    'errs' : 0
  },
  ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_blockstats
```

**salt.modules.virt.vm\_info**(*vm\_=None*)

Return detailed information about the vms on this hyper in a list of dicts:

```
[
  'your-vm': {
    'cpu': <int>,
    'maxMem': <int>,
    'mem': <int>,
    'state': '<state>',
    'cputime' <int>
  },
  ...
]
```

```
...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_info
```

`salt.modules.virt.vm_netstats` (*vm\_=None*)

Return combined network counters used by the vms on this hyper in a list of dicts:

```
[
  'your-vm': {
    'rx_bytes' : 0,
    'rx_packets' : 0,
    'rx_errs' : 0,
    'rx_drop' : 0,
    'tx_bytes' : 0,
    'tx_packets' : 0,
    'tx_errs' : 0,
    'tx_drop' : 0
  },
  ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_netstats
```

`salt.modules.virt.vm_state` (*vm\_=None*)

Return list of all the vms and their state.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_state <vm name>
```

### 30.16.257 salt.modules.virtualenv

Create virtualenv environments.

New in version 0.17.0.

`salt.modules.virtualenv_mod.create` (*path*, *venv\_bin=None*, *system\_site\_packages=False*, *distribute=False*, *clear=False*, *python=None*, *extra\_search\_dir=None*, *never\_download=None*, *prompt=None*, *pip=False*, *symlinks=None*, *upgrade=None*, *user=None*, *use\_vt=False*, *saltenv='base'*)

Create a virtualenv

**path** The path to create the virtualenv

**venv\_bin** [None (default `virtualenv`)] The name (and optionally path) of the virtualenv command. This can also be set globally in the minion config file as `virtualenv.venv_bin`.

**system\_site\_packages** [False] Passthrough argument given to virtualenv or pyvenv

**distribute** [False] Passthrough argument given to virtualenv

**pip** [False] Install pip after creating a virtual environment, implies `distribute=True`

**clear** [False] Passthrough argument given to virtualenv or pyvenv

**python** [None (default)] Passthrough argument given to virtualenv

**extra\_search\_dir** [None (default)] Passthrough argument given to virtualenv

**never\_download** [None (default)] Passthrough argument given to virtualenv if True

**prompt** [None (default)] Passthrough argument given to virtualenv if not None

**symlinks** [None] Passthrough argument given to pyvenv if True

**upgrade** [None] Passthrough argument given to pyvenv if True

**user** [None] Set ownership for the virtualenv

**runas** [None] Set ownership for the virtualenv

**use\_vt** [False] Use VT terminal emulation (see output while installing)

New in version 2015.5.0.

**saltenv** [`'base'`] Specify a different environment. The default environment is `base`.

New in version 2014.1.0.

---

**Note:** The `runas` argument is deprecated as of 2014.1.0. `user` should be used instead.

---

CLI Example:

```
salt '*' virtualenv.create /path/to/new/virtualenv
```

`salt.modules.virtualenv_mod.get_resource_content`(*venv*, *package\_or\_requirement*, *resource\_name*)

Returns the content of a resource of a package or a distribution inside a virtualenv

New in version 2015.5.0.

CLI Example:

```
salt '*' virtualenv.get_resource_content /path/to/my/venv my_package my/resource.xml
```

`salt.modules.virtualenv_mod.get_resource_path`(*venv*, *package\_or\_requirement*, *resource\_name*)

Returns the path to a resource of a package or a distribution inside a virtualenv

New in version 2015.5.0.

CLI Example:

```
salt '*' virtualenv.get_resource_path /path/to/my/venv my_package my/resource.xml
```

`salt.modules.virtualenv_mod.get_site_packages`(*venv*)

Returns the path to the site-packages directory inside a virtualenv

CLI Example:

```
salt '*' virtualenv.get_site_packages /path/to/my/venv
```

### 30.16.258 salt.modules.win\_autoruns

Module for listing programs that automatically run on startup (very alpha...not tested on anything but my Win 7x64)

`salt.modules.win_autoruns.list_()`  
Get a list of automatically running programs

CLI Example:

```
salt '*' autoruns.list
```

### 30.16.259 salt.modules.win\_disk

Module for gathering disk information on Windows

**depends**

- win32api Python module

`salt.modules.win_disk.usage()`  
Return usage information for volumes mounted on this minion

CLI Example:

```
salt '*' disk.usage
```

### 30.16.260 salt.modules.win\_dns\_client

Module for configuring DNS Client on Windows systems

`salt.modules.win_dns_client.add_dns(ip, interface='Local Area Connection', index=1)`  
Add the DNS server to the network interface (index starts from 1)

Note: if the interface DNS is configured by DHCP, all the DNS servers will be removed from the interface and the requested DNS will be the only one

CLI Example:

```
salt '*' win_dns_client.add_dns <ip> <interface> <index>
```

`salt.modules.win_dns_client.dns_dhcp(interface='Local Area Connection')`  
Configure the interface to get its DNS servers from the DHCP server

CLI Example:

```
salt '*' win_dns_client.dns_dhcp <interface>
```

`salt.modules.win_dns_client.get_dns_config(interface='Local Area Connection')`  
Get the type of DNS configuration (dhcp / static)

CLI Example:

```
salt '*' win_dns_client.get_dns_config 'Local Area Connection'
```

`salt.modules.win_dns_client.get_dns_servers(interface='Local Area Connection')`

Return a list of the configured DNS servers of the specified interface

CLI Example:

```
salt '*' win_dns_client.get_dns_servers 'Local Area Connection'
```

`salt.modules.win_dns_client.rm_dns(ip, interface='Local Area Connection')`

Remove the DNS server from the network interface

CLI Example:

```
salt '*' win_dns_client.rm_dns <ip> <interface>
```

### 30.16.261 salt.modules.win\_file

Manage information about files on the minion, set/read user, group data

**depends**

- win32api
- win32file
- win32security

`salt.modules.win_file.chgrp(path, group)`

Change the group of a file

Under Windows, this will do nothing.

While a file in Windows does have a `primary group`, this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to do nothing while still being compatible with Unix behavior. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to set the `primary group` of a file, use `file.chpgrp`.

CLI Example:

```
salt '*' file.chpgrp c:\temp\test.txt administrators
```

`salt.modules.win_file.chown(path, user, group=None, pgroup=None, follow_symlinks=True)`

Chown a file, pass the file the desired user and group

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a `primary group` property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

If you do want to change the `primary group` property and understand the implications, pass the Windows only parameter, `pgroup`, instead.

To set the primary group to `None`, it must be specified in quotes. Otherwise Salt will interpret it as the Python value of `None` and no primary group changes will occur. See the example below.

CLI Example:

```
salt '*' file.chown c:\temp\test.txt myusername
salt '*' file.chown c:\temp\test.txt myusername pgroup=Administrators
salt '*' file.chown c:\temp\test.txt myusername "pgroup='None'"
```

### `salt.modules.win_file.chpgrp(path, group)`

Change the group of a file

Under Windows, this will set the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

To set the primary group to `None`, it must be specified in quotes. Otherwise Salt will interpret it as the Python value of None and no primary group changes will occur. See the example below.

CLI Example:

```
salt '*' file.chpgrp c:\temp\test.txt Administrators
salt '*' file.chpgrp c:\temp\test.txt "'None'"
```

### `salt.modules.win_file.get_attributes(path)`

Return a dictionary object with the Windows file attributes for a file.

CLI Example:

```
salt '*' file.get_attributes c:\temp\a.txt
```

### `salt.modules.win_file.get_gid(path, follow_symlinks=True)`

Return the id of the group that owns a given file

Under Windows, this will return the uid of the file.

While a file in Windows does have a `primary group`, this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to access the `primary group` of a file, use `file.get_pgid`.

CLI Example:

```
salt '*' file.get_gid c:\temp\test.txt
```

### `salt.modules.win_file.get_group(path, follow_symlinks=True)`

Return the group that owns a given file

Under Windows, this will return the user (owner) of the file.

While a file in Windows does have a `primary group`, this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to access the `primary group` of a file, use `file.get_pgroup`.

CLI Example:

```
salt '*' file.get_group c:\temp\test.txt
```

`salt.modules.win_file.get_mode(path)`

Return the mode of a file

Right now we're just returning None because Windows' doesn't have a mode like Linux

CLI Example:

```
salt '*' file.get_mode /etc/passwd
```

`salt.modules.win_file.get_pgid(path, follow_symlinks=True)`

Return the id of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

CLI Example:

```
salt '*' file.get_pgid c:\temp\test.txt
```

`salt.modules.win_file.get_pgroup(path, follow_symlinks=True)`

Return the name of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

The return value may be `None`, e.g. if the user is not on a domain. This is a valid group - do not confuse this with the Salt/Python value of None which means no value was returned. To be certain, use the `get_pgid` function which will return the SID, including for the system `None` group.

CLI Example:

```
salt '*' file.get_pgroup c:\temp\test.txt
```

`salt.modules.win_file.get_uid(path, follow_symlinks=True)`

Return the id of the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify `follow_symlinks=False` to turn off this behavior.

CLI Example:

```
salt '*' file.get_uid c:\temp\test.txt
salt '*' file.get_uid c:\temp\test.txt follow_symlinks=False
```

`salt.modules.win_file.get_user(path, follow_symlinks=True)`

Return the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify `follow_symlinks=False` to turn off this behavior.

CLI Example:

```
salt '*' file.get_user c:\temp\test.txt
salt '*' file.get_user c:\temp\test.txt follow_symlinks=False
```

`salt.modules.win_file.gid_to_group(gid)`

Convert the group id to the group name on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as `uid_to_user`.

For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the `uid_to_user` function instead; an info level log entry will be generated if this function is used directly.

CLI Example:

```
salt '*' file.gid_to_group S-1-5-21-626487655-2533044672-482107328-1010
```

`salt.modules.win_file.group_to_gid(group)`

Convert the group to the gid on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as `user_to_uid`, except if None is given, '' is returned.

For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the `user_to_uid` function instead; an info level log entry will be generated if this function is used directly.

CLI Example:

```
salt '*' file.group_to_gid administrators
```

`salt.modules.win_file.is_link(path)`

Return the path that a symlink points to

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a `SaltInvocationError`, not an `OSError`.

CLI Example:

```
salt '*' file.is_link /path/to/link
```

`salt.modules.win_file.lchown(path, user, group=None, pgroup=None)`

Chown a file, pass the file the desired user and group without following any symlinks.

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a 'primary group' property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

If you do want to change the 'primary group' property and understand the implications, pass the Windows only parameter, `pgroup`, instead.

To set the primary group to 'None', it must be specified in quotes. Otherwise Salt will interpret it as the Python value of None and no primary group changes will occur. See the example below.

CLI Example:

```
salt '*' file.lchown c:\temp\test.txt myusername
salt '*' file.lchown c:\temp\test.txt myusername pgroup=Administrators
salt '*' file.lchown c:\temp\test.txt myusername "pgroup='None'"
```

`salt.modules.win_file.readlink(path)`

Return the path that a symlink points to

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a `SaltInvocationError`, not an `OSError`.

CLI Example:

```
salt '*' file.readlink /path/to/link
```

`salt.modules.win_file.remove`(*path*, *force=False*)

Remove the named file or directory

#### Parameters

- **path** (*str*) -- The path to the file or directory to remove.
- **force** (*bool*) -- Remove even if marked Read-Only

**Returns** True if successful, False if unsuccessful

**Return type** `bool`

CLI Example:

```
salt '*' file.remove C:\Temp
```

`salt.modules.win_file.set_attributes`(*path*, *archive=None*, *hidden=None*, *normal=None*, *notIndexed=None*, *readonly=None*, *system=None*, *temporary=None*)

Set file attributes for a file. Note that the normal attribute means that all others are false. So setting it will clear all others.

CLI Example:

```
salt '*' file.set_attributes c:\temp\a.txt normal=True
salt '*' file.set_attributes c:\temp\a.txt readonly=True hidden=True
```

`salt.modules.win_file.set_mode`(*path*, *mode*)

Set the mode of a file

This just calls `get_mode`, which returns `None` because we don't use mode on Windows

CLI Example:

```
salt '*' file.set_mode /etc/passwd 0644
```

`salt.modules.win_file.stats`(*path*, *hash\_type='md5'*, *follow\_symlinks=True*)

Return a dict containing the stats for a given file

Under Windows, *gid* will equal *uid* and *group* will equal *user*.

While a file in Windows does have a 'primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps these properties to keep some kind of compatibility with Unix behavior. If the 'primary group' is required, it can be accessed in the *pgroup* and *pgid* properties.

CLI Example:

```
salt '*' file.stats /etc/passwd
```

`salt.modules.win_file.symlink`(*src*, *link*)

Create a symbolic link to a file

This is only supported with Windows Vista or later and must be executed by a user with the SeCreateSymbolicLink privilege.

The behavior of this function matches the Unix equivalent, with one exception - invalid symlinks cannot be created. The source path must exist. If it doesn't, an error will be raised.

CLI Example:

```
salt '*' file.symlink /path/to/file /path/to/link
```

**salt.modules.win\_file.uid\_to\_user**(*uid*)

Convert a uid to a user name

CLI Example:

```
salt '*' file.uid_to_user S-1-5-21-626487655-2533044672-482107328-1010
```

**salt.modules.win\_file.user\_to\_uid**(*user*)

Convert user name to a uid

CLI Example:

```
salt '*' file.user_to_uid myusername
```

### 30.16.262 salt.modules.win\_firewall

Module for configuring Windows Firewall

**salt.modules.win\_firewall.add\_rule**(*name*, *localport*, *protocol='tcp'*, *action='allow'*, *dir='in'*)

New in version 2015.5.0.

Add a new firewall rule

CLI Example:

```
salt '*' firewall.add_rule "test" "tcp" "8080"
```

**salt.modules.win\_firewall.disable**(*profile='allprofiles'*)

Disable all the firewall profiles

CLI Example:

```
salt '*' firewall.disable
```

**salt.modules.win\_firewall.enable**(*profile='allprofiles'*)

Enable firewall profile :param profile: (default: allprofiles)

New in version 2015.5.0.

CLI Example:

```
salt '*' firewall.enable
```

**salt.modules.win\_firewall.get\_config**()

Get the status of all the firewall profiles

CLI Example:

```
salt '*' firewall.get_config
```

`salt.modules.win_firewall.get_rule(name='all')`

New in version 2015.5.0.

Get firewall rule(s) info

CLI Example:

```
salt '*' firewall.get_rule "MyAppPort"
```

### 30.16.263 salt.modules.win\_groupadd

Manage groups on Windows

**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `group.info` is not available), see [here](#).

`salt.modules.win_groupadd.add(name, gid=None, system=False)`

Add the specified group

CLI Example:

```
salt '*' group.add foo
```

`salt.modules.win_groupadd.adduser(name, username)`

add a user to a group

CLI Example:

```
salt '*' group.adduser foo username
```

`salt.modules.win_groupadd.delete(name)`

Remove the named group

CLI Example:

```
salt '*' group.delete foo
```

`salt.modules.win_groupadd.deluser(name, username)`

remove a user from a group

CLI Example:

```
salt '*' group.deluser foo username
```

`salt.modules.win_groupadd.getent(refresh=False)`

Return info on all groups

CLI Example:

```
salt '*' group.getent
```

`salt.modules.win_groupadd.info(name)`

Return information about a group

CLI Example:

```
salt '*' group.info foo
```

`salt.modules.win_groupadd.members`(*name*, *members\_list*)  
remove a user from a group

CLI Example:

```
salt '*' group.members foo 'user1,user2,user3'
```

### 30.16.264 salt.modules.win\_ip

The networking module for Windows based systems

`salt.modules.win_ip.disable`(*iface*)  
Disable an interface

CLI Example:

```
salt -G 'os_family:Windows' ip.disable 'Local Area Connection #2'
```

`salt.modules.win_ip.enable`(*iface*)  
Enable an interface

CLI Example:

```
salt -G 'os_family:Windows' ip.enable 'Local Area Connection #2'
```

`salt.modules.win_ip.get_all_interfaces`()  
Return configs for all interfaces

CLI Example:

```
salt -G 'os_family:Windows' ip.get_all_interfaces
```

`salt.modules.win_ip.get_default_gateway`()  
Set DNS source to DHCP on Windows

CLI Example:

```
salt -G 'os_family:Windows' ip.get_default_gateway
```

`salt.modules.win_ip.get_interface`(*iface*)  
Return the configuration of a network interface

CLI Example:

```
salt -G 'os_family:Windows' ip.get_interface 'Local Area Connection'
```

`salt.modules.win_ip.get_subnet_length`(*mask*)  
Convenience function to convert the netmask to the CIDR subnet length

CLI Example:

```
salt -G 'os_family:Windows' ip.get_subnet_length 255.255.255.0
```

`salt.modules.win_ip.is_disabled`(*iface*)  
Returns True if interface is disabled, otherwise False

CLI Example:

```
salt -G 'os_family:Windows' ip.is_disabled 'Local Area Connection #2'
```

`salt.modules.win_ip.is_enabled(iface)`  
Returns True if interface is enabled, otherwise False

CLI Example:

```
salt -G 'os_family:Windows' ip.is_enabled 'Local Area Connection #2'
```

`salt.modules.win_ip.raw_interface_configs()`  
Return raw configs for all interfaces

CLI Example:

```
salt -G 'os_family:Windows' ip.raw_interface_configs
```

`salt.modules.win_ip.set_dhcp_all(iface)`  
Set both IP Address and DNS to DHCP

CLI Example:

```
salt -G 'os_family:Windows' ip.set_dhcp_all 'Local Area Connection'
```

`salt.modules.win_ip.set_dhcp_dns(iface)`  
Set DNS source to DHCP on Windows

CLI Example:

```
salt -G 'os_family:Windows' ip.set_dhcp_dns 'Local Area Connection'
```

`salt.modules.win_ip.set_dhcp_ip(iface)`  
Set Windows NIC to get IP from DHCP

CLI Example:

```
salt -G 'os_family:Windows' ip.set_dhcp_ip 'Local Area Connection'
```

`salt.modules.win_ip.set_static_dns(iface, *addrs)`  
Set static DNS configuration on a Windows NIC

CLI Example:

```
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.1'
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.252' '192.168.1.1'
```

`salt.modules.win_ip.set_static_ip(iface, addr, gateway=None, append=False)`  
Set static IP configuration on a Windows NIC

**iface** The name of the interface to manage

**addr** IP address with subnet length (ex. 10.1.2.3/24). The `ip.get_subnet_length` function can be used to calculate the subnet length from a netmask.

**gateway** [None] If specified, the default gateway will be set to this value.

**append** [False] If True, this IP address will be added to the interface. Default is False, which overrides any existing configuration for the interface and sets `addr` as the only address on the interface.

CLI Example:

```
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.3/24 gateway=10.1.2.
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.4/24 append=True
```

### 30.16.265 salt.modules.win\_network

Module for gathering and managing network information

`salt.modules.win_network.dig(host)`

Performs a DNS lookup with dig

Note: dig must be installed on the Windows minion

CLI Example:

```
salt '*' network.dig archlinux.org
```

`salt.modules.win_network.hw_addr(iface)`

Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:

```
salt '*' network.hw_addr 'Wireless Connection #1'
```

`salt.modules.win_network.hwaddr(iface)`

Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:

```
salt '*' network.hw_addr 'Wireless Connection #1'
```

`salt.modules.win_network.in_subnet(cidr)`

Returns True if host is within specified subnet, otherwise False

CLI Example:

```
salt '*' network.in_subnet 10.0.0.0/16
```

`salt.modules.win_network.interfaces()`

Return a dictionary of information about all the interfaces on the minion

CLI Example:

```
salt '*' network.interfaces
```

`salt.modules.win_network.interfaces_names()`

Return a list of all the interfaces names

CLI Example:

```
salt '*' network.interfaces_names
```

`salt.modules.win_network.ip_addrs(interface=None, include_loopback=False)`

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:

```
salt '*' network.ip_addrs
```

`salt.modules.win_network.ip_addrs6(interface=None, include_loopback=False)`

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:

```
salt '*' network.ip_addrs6
```

`salt.modules.win_network.ipaddrs` (*interface=None, include\_loopback=False*)

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:

```
salt '*' network.ip_addrs
```

`salt.modules.win_network.ipaddrs6` (*interface=None, include\_loopback=False*)

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:

```
salt '*' network.ip_addrs6
```

`salt.modules.win_network.netstat` ()

Return information on open ports and states

CLI Example:

```
salt '*' network.netstat
```

`salt.modules.win_network.nslookup` (*host*)

Query DNS for information about a domain or ip address

CLI Example:

```
salt '*' network.nslookup archlinux.org
```

`salt.modules.win_network.ping` (*host*)

Performs a ping to a host

CLI Example:

```
salt '*' network.ping archlinux.org
```

`salt.modules.win_network.subnets` ()

Returns a list of subnets to which the host belongs

CLI Example:

```
salt '*' network.subnets
```

`salt.modules.win_network.traceroute` (*host*)

Performs a traceroute to a 3rd party host

CLI Example:

```
salt '*' network.traceroute archlinux.org
```

### 30.16.266 salt.modules.win\_ntp

Management of NTP servers on Windows

New in version 2014.1.0.

`salt.modules.win_ntp.get_servers()`

Get list of configured NTP servers

CLI Example:

```
salt '*' ntp.get_servers
```

`salt.modules.win_ntp.set_servers(*servers)`

Set Windows to use a list of NTP servers

CLI Example:

```
salt '*' ntp.set_servers 'pool.ntp.org' 'us.pool.ntp.org'
```

### 30.16.267 salt.modules.win\_path

Manage the Windows System PATH

Note that not all Windows applications will rehash the PATH environment variable, Only the ones that listen to the WM\_SETTINGCHANGE message <http://support.microsoft.com/kb/104011>

`salt.modules.win_path.add(path, index=0)`

Add the directory to the SYSTEM path in the index location

**Returns:** boolean True if successful, False if unsuccessful

CLI Example:

```
# Will add to the beginning of the path
salt '*' win_path.add 'c:\python27' 0

# Will add to the end of the path
salt '*' win_path.add 'c:\python27' index='-1'
```

`salt.modules.win_path.exists(path)`

Check if the directory is configured in the SYSTEM path Case-insensitive and ignores trailing backslash

**Returns:** boolean True if path exists, False if not

CLI Example:

```
salt '*' win_path.exists 'c:\python27'
salt '*' win_path.exists 'c:\python27\'
salt '*' win_path.exists 'C:\pyThon27'
```

`salt.modules.win_path.get_path()`

Returns a list of items in the SYSTEM path

CLI Example:

```
salt '*' win_path.get_path
```

`salt.modules.win_path.rehash()`

Send a WM\_SETTINGCHANGE Broadcast to Windows to refresh the Environment variables

CLI Example:

... code-block:: bash

```
salt '*' win_path.rehash
```

`salt.modules.win_path.remove(path)`

Remove the directory from the SYSTEM path

**Returns:** boolean True if successful, False if unsuccessful

CLI Example:

```
# Will remove C:\Python27 from the path
salt '*' win_path.remove 'c:\\python27'
```

### 30.16.268 salt.modules.win\_pkg

A module to manage software on Windows

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

#### depends

- win32com
- win32con
- win32api
- pywintypes

`salt.modules.win_pkg.get_repo_data(saltenv='base')`

Returns the cached winrepo data

CLI Example:

```
salt '*' pkg.get_repo_data
```

`salt.modules.win_pkg.install(name=None, refresh=False, pkgs=None, saltenv='base', **kwargs)`

Install the passed package from the winrepo

#### Parameters

- **name** (*str* or *None*) -- The name of the package to install
- **refresh** (*bool*) -- Boolean value representing whether or not to refresh the winrepo db
- **pkgs** (*list* or *None*) -- A list of packages to install from a software repository. All packages listed under `pkgs` will be installed via a single command.
- **saltenv** (*str*) -- The salt environment to use. Default is base.
- **kwargs** (*dict*) -- Any additional argument that may be passed from the state module. If they don't apply, they are ignored.

#### Returns

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               `new': `<new-version>'}}
```

CLI Example:

```
salt '*' pkg.install <package name>
```

`salt.modules.win_pkg.latest_version(*names, **kwargs)`

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

`salt.modules.win_pkg.list_available(*names)`

Return a list of available versions of the specified package.

CLI Example:

```
salt '*' pkg.list_available <package name>
salt '*' pkg.list_available <package name01> <package name02>
```

`salt.modules.win_pkg.list_pkgs(versions_as_list=False, **kwargs)`

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

`salt.modules.win_pkg.list_upgrades(refresh=True)`

List all available package upgrades on this system

CLI Example:

```
salt '*' pkg.list_upgrades
```

`salt.modules.win_pkg.purge(name=None, pkgs=None, version=None, **kwargs)`

Package purges are not supported, this function is identical to `remove()`.

**name** The name of the package to be deleted.

**version** The version of the package to be deleted. If this option is used in combination with the `pkgs` option below, then this version will be applied to all targeted packages.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>, <package2>, <package3>
salt '*' pkg.purge pkgs=['foo', 'bar']
```

`salt.modules.win_pkg.refresh_db` (*saltenv='base'*)

Just recheck the repository and return a dict:

```
{'<database name>': Bool}
```

CLI Example:

```
salt '*' pkg.refresh_db
```

`salt.modules.win_pkg.remove` (*name=None, pkgs=None, version=None, extra\_uninstall\_flags=None, \*\*kwargs*)

Remove packages.

**name** The name of the package to be deleted.

**version** The version of the package to be deleted. If this option is used in combination with the `pkgs` option below, then this version will be applied to all targeted packages.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>, <package2>, <package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

`salt.modules.win_pkg.upgrade` (*refresh=True*)

Run a full system upgrade

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

`salt.modules.win_pkg.upgrade_available` (*name*)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

`salt.modules.win_pkg.version` (*\*names, \*\*kwargs*)

Returns a version if the package is installed, else returns an empty string

CLI Example:

```
salt '*' pkg.version <package name>
```

### 30.16.269 salt.modules.win\_repo

Module to manage Windows software repo on a Standalone Minion

The following options must be set in the Minion config: file\_client: local win\_repo\_cache: c:saltfile\_rootswinrepo win\_repo: c:saltfile\_rootswinrepo

Place all Windows package files in the `win\_repo` directory.

**salt.modules.win\_repo.genrepo()**  
Generate win\_repo\_cache based on sls files in the win\_repo

CLI Example:

```
salt-call winrepo.genrepo -c c:\salt\conf
```

**salt.modules.win\_repo.update\_git\_repos()**  
Checkout git repos containing Windows Software Package Definitions

---

**Note:** This function will not work unless git is installed and the git module is further updated to work on Windows. In the meantime just place all Windows package files in the win\_repo directory.

---

### 30.16.270 salt.modules.win\_servermanager

Manage Windows features via the ServerManager powershell module

**salt.modules.win\_servermanager.install**(*feature, recurse=False*)  
Install a feature

**Note:** Some features requires reboot after un/installation, if so until the server is restarted Other features can not be installed !

**Note:** Some features takes a long time to complete un/installation, set -t with a long timeout

CLI Example:

```
salt '*' win_servermanager.install Telnet-Client
salt '*' win_servermanager.install SNMP-Service True
```

**salt.modules.win\_servermanager.list\_available()**  
List available features to install

CLI Example:

```
salt '*' win_servermanager.list_available
```

**salt.modules.win\_servermanager.list\_installed()**  
List installed features. Supported on Windows Server 2008 and Windows 8 and newer.

CLI Example:

```
salt '*' win_servermanager.list_installed
```

**salt.modules.win\_servermanager.remove**(*feature*)  
Remove an installed feature

---

**Note:** Some features require a reboot after installation/uninstallation. If one of these features are modified, then other features cannot be installed until the server is restarted. Additionally, some features take a while to complete installation/uninstallation, so it is a good idea to use the -t option to set a longer timeout.

---

CLI Example:

```
salt -t 600 '*' win_servermanager.remove Telnet-Client
```

### 30.16.271 salt.modules.win\_service

Windows Service module.

**salt.modules.win\_service.available**(*name*)  
Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available <service name>
```

**salt.modules.win\_service.create\_win\_salt\_restart\_task**()  
Create a task in Windows task scheduler to enable restarting the salt-minion

CLI Example:

```
salt '*' service.create_win_salt_restart_task()
```

**salt.modules.win\_service.disable**(*name*, *\*\*kwargs*)  
Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

**salt.modules.win\_service.disabled**(*name*)  
Check to see if the named service is disabled to start on boot

CLI Example:

```
salt '*' service.disabled <service name>
```

**salt.modules.win\_service.enable**(*name*, *\*\*kwargs*)  
Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

**salt.modules.win\_service.enabled**(*name*, *\*\*kwargs*)  
Check to see if the named service is enabled to start on boot

CLI Example:

```
salt '*' service.enabled <service name>
```

**salt.modules.win\_service.execute\_salt\_restart\_task**()  
Run the Windows Salt restart task

CLI Example:

```
salt '*' service.execute_salt_restart_task()
```

**salt.modules.win\_service.get\_all**()  
Return all installed services

CLI Example:

```
salt '*' service.get_all
```

**salt.modules.win\_service.get\_disabled()**

Return the disabled services

CLI Example:

```
salt '*' service.get_disabled
```

**salt.modules.win\_service.get\_enabled()**

Return the enabled services

CLI Example:

```
salt '*' service.get_enabled
```

**salt.modules.win\_service.get\_service\_name(\*args)**

The Display Name is what is displayed in Windows when services.msc is executed. Each Display Name has an associated Service Name which is the actual name of the service. This function allows you to discover the Service Name by returning a dictionary of Display Names and Service Names, or filter by adding arguments of Display Names.

If no args are passed, return a dict of all services where the keys are the service Display Names and the values are the Service Names.

If arguments are passed, create a dict of Display Names and Service Names

CLI Example:

```
salt '*' service.get_service_name
salt '*' service.get_service_name 'Google Update Service (gupdate)' 'DHCP Client'
```

**salt.modules.win\_service.getsid(name)**

Return the sid for this windows service

CLI Example:

```
salt '*' service.getsid <service name>
```

**salt.modules.win\_service.has\_powershell()**

Confirm if Powershell is available

CLI Example:

```
salt '*' service.has_powershell
```

**salt.modules.win\_service.missing(name)**

The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing <service name>
```

**salt.modules.win\_service.restart(name)**

Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

`salt.modules.win_service.start(name)`

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

`salt.modules.win_service.status(name, sig=None)`

Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps

CLI Example:

```
salt '*' service.status <service name> [service signature]
```

`salt.modules.win_service.stop(name)`

Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 30.16.272 salt.modules.win\_shadow

Manage the shadow file

---

**Important:** If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `'shadow.info' is not available`), see [here](#).

---

`salt.modules.win_shadow.info(name)`

Return information for the specified user This is just returns dummy data so that salt states can work.

CLI Example:

```
salt '*' shadow.info root
```

`salt.modules.win_shadow.set_password(name, password)`

Set the password for a named user.

CLI Example:

```
salt '*' shadow.set_password root mysecretpassword
```

### 30.16.273 salt.modules.win\_status

Module for returning various status data about a minion. These data can be useful for compiling into stats later.

**depends**

- pythoncom
- wmi

`salt.modules.win_status.master(master=None, connected=True)`

New in version 2015.5.0.

Fire an event if the minion gets disconnected from its master. This function is meant to be run via a scheduled job from the minion. If `master_ip` is an FQDN/Hostname, it must be resolvable to a valid IPv4 address.

CLI Example:

```
salt '*' status.master
```

`salt.modules.win_status.procs()`

Return the process data

CLI Example:

```
salt '*' status.procs
```

### 30.16.274 salt.modules.win\_system

Module for managing windows systems.

**depends**

- win32net

Support for reboot, shutdown, etc

`salt.modules.win_system.get_computer_desc()`

Get the Windows computer description

**Returns** Returns the computer description if found. Otherwise returns False

CLI Example:

```
salt 'minion-id' system.get_computer_desc
```

`salt.modules.win_system.get_computer_name()`

Get the Windows computer name

**Returns** Returns the computer name if found. Otherwise returns False

CLI Example:

```
salt 'minion-id' system.get_computer_name
```

`salt.modules.win_system.get_domain_workgroup()`

Get the domain or workgroup the computer belongs to.

New in version 2015.5.7.

New in version 2015.8.2.

**Returns** The name of the domain or workgroup

**Return type** str

`salt.modules.win_system.get_pending_computer_name()`

Get a pending computer name. If the computer name has been changed, and the change is pending a system reboot, this function will return the pending computer name. Otherwise, None will be returned. If there was an error retrieving the pending computer name, False will be returned, and an error message will be logged to the minion log.

**Returns** Returns the pending name if pending restart. Returns none if not pending restart.

CLI Example:

```
salt 'minion-id' system.get_pending_computer_name
```

`salt.modules.win_system.get_system_date()`

Get the Windows system date

**Returns** Returns the system date.

**Return type** `str`

CLI Example:

```
salt '*' system.get_system_date
```

`salt.modules.win_system.get_system_info()`

Get system information.

**Returns** Returns a Dictionary containing information about the system to include name, description, version, etc...

**Return type** `dict`

`salt.modules.win_system.get_system_time()`

Get the system time.

**Returns** Returns the system time in HH:MM AM/PM format.

**Return type** `str`

`salt.modules.win_system.halt(timeout=5)`

Halt a running system.

**Parameters** **timeout** (*int*) -- Number of seconds before halting the system. Default is 5 seconds.

**Returns** True is successful.

**Return type** `bool`

CLI Example:

```
salt '*' system.halt
```

`salt.modules.win_system.init(runlevel)`

Change the system runlevel on sysV compatible systems

CLI Example:

```
salt '*' system.init 3
```

`salt.modules.win_system.join_domain(domain, username=None, password=None, account_ou=None, account_exists=False, restart=False)`

Join a computer to an Active Directory domain. Requires reboot.

**Parameters**

- **domain** (*str*) -- The domain to which the computer should be joined, e.g. my-company.com
- **username** (*str*) -- Username of an account which is authorized to join computers to the specified domain. Need to be either fully qualified like user@domain.tld or simply user
- **password** (*str*) -- Password of the specified user
- **account\_ou** (*str*) -- The DN of the OU below which the account for this computer should be created when joining the domain, e.g. ou=computers,ou=departm\_432,dc=my-company,dc=com

- **account\_exists** (*bool*) -- Needs to be set to True to allow re-using an existing account
- **restart** (*bool*) -- Restarts the computer after a successful join

New in version 2015.5.7.

New in version 2015.8.2.

**Returns** Returns a dictionary if successful. False if unsuccessful.

**Return type** dict, bool

CLI Example:

```
salt 'minion-id' system.join_domain domain='domain.tld' \  
    username='joinuser' password='joinpassword' \  
    account_ou='ou=clients,ou=org,dc=domain,dc=tld' \  
    account_exists=False, restart=True
```

**salt.modules.win\_system.lock()**

Lock the workstation.

**Returns** True if successful

**Return type** bool

**salt.modules.win\_system.poweroff(timeout=5)**

Power off a running system.

**Parameters** **timeout** (*int*) -- Number of seconds before powering off the system. Default is 5 seconds.

**Returns** True if successful

**Return type** bool

CLI Example:

```
salt '*' system.poweroff
```

**salt.modules.win\_system.reboot(timeout=5)**

Reboot a running system.

**Parameters** **timeout** (*int*) -- Number of seconds before rebooting the system. Default is 5 seconds.

**Returns** True if successful

**Return type** bool

CLI Example:

```
salt '*' system.reboot
```

**salt.modules.win\_system.set\_computer\_desc(desc=None)**

Set the Windows computer description

**Parameters** **desc** (*str*) -- The computer description

**Returns** False if it fails. Description if successful.

CLI Example:

```
salt 'minion-id' system.set_computer_desc 'This computer belongs to Dave!'
```

`salt.modules.win_system.set_computer_name(name)`

Set the Windows computer name

**Parameters** `name` (*str*) -- The new name to give the computer. Requires a reboot to take effect.

**Returns** Returns a dictionary containing the old and new names if successful. False if not.

CLI Example:

```
salt 'minion-id' system.set_computer_name 'DavesComputer'
```

`salt.modules.win_system.set_system_date(newdate)`

Set the Windows system date. Use <mm-dd-yy> format for the date.

**Parameters** `newdate` (*str*) -- The date to set. Can be any of the following formats - YYYY-MM-DD - MM-DD-YYYY - MM-DD-YY - MM/DD/YYYY - MM/DD/YY - YYYY/MM/DD

CLI Example:

```
salt '*' system.set_system_date '03-28-13'
```

`salt.modules.win_system.set_system_date_time(years=None, months=None, days=None, hours=None, minutes=None, seconds=None)`

Set the system date and time. Each argument is an element of the date, but not required. If an element is not passed, the current system value for that element will be used. For example, if you don't pass the year, the current system year will be used. (Used by `set_system_date` and `set_system_time`)

**Parameters**

- **years** (*int*) -- Years digit, ie: 2015
- **months** (*int*) -- Months digit: 1 - 12
- **days** (*int*) -- Days digit: 1 - 31
- **hours** (*int*) -- Hours digit: 0 - 23
- **minutes** (*int*) -- Minutes digit: 0 - 59
- **seconds** (*int*) -- Seconds digit: 0 - 59

**Returns** True if successful. Otherwise False.

**Return type** `bool`

CLI Example:

```
salt '*' system.set_system_date_ time 2015 5 12 11 37 53
```

`salt.modules.win_system.set_system_time(newtime)`

Set the system time.

**Parameters** `newtime` (*str*) -- The time to set. Can be any of the following formats. - HH:MM:SS AM/PM - HH:MM AM/PM - HH:MM:SS (24 hour) - HH:MM (24 hour)

**Returns** Returns True if successful. Otherwise False.

**Return type** `bool`

`salt.modules.win_system.shutdown(message=None, timeout=5, force_close=True, reboot=False)`

Shutdown a running system.

**Parameters**

- **message** (*str*) -- A message to display to the user before shutting down.

- **timeout** (*int*) -- The length of time that the shutdown dialog box should be displayed, in seconds. While this dialog box is displayed, the shutdown can be stopped by the `shutdown_abort` function.

If `dwTimeout` is not zero, `InitiateSystemShutdown` displays a dialog box on the specified computer. The dialog box displays the name of the user who called the function, displays the message specified by the `lpMessage` parameter, and prompts the user to log off. The dialog box beeps when it is created and remains on top of other windows in the system. The dialog box can be moved but not closed. A timer counts down the remaining time before a forced shutdown.

If `dwTimeout` is zero, the computer shuts down without displaying the dialog box, and the shutdown cannot be stopped by `shutdown_abort`.

Default is 5

- **force\_close** (*bool*) -- True to force close all open applications. False displays a dialog box instructing the user to close the applications.
- **reboot** (*bool*) -- True restarts the computer immediately after shutdown. False caches to disk and safely powers down the system.

**Returns** True if successful

**Return type** `bool`

`salt.modules.win_system.shutdown_abort()`

Abort a shutdown. Only available while the dialog box is being displayed to the user. Once the shutdown has initiated, it cannot be aborted

**Returns** True if successful

**Return type** `bool`

`salt.modules.win_system.shutdown_hard()`

Shutdown a running system with no timeout or warning.

**Parameters** **timeout** (*int*) -- Number of seconds before shutting down the system. Default is 5 seconds.

**Returns** True if successful

**Return type** `bool`

CLI Example:

```
salt '*' system.shutdown_hard
```

`salt.modules.win_system.start_time_service()`

Start the Windows time service

**Returns** True if successful. Otherwise False

**Return type** `bool`

CLI Example:

```
salt '*' system.start_time_service
```

`salt.modules.win_system.stop_time_service()`

Stop the Windows time service

**Returns** True if successful. Otherwise False

**Return type** `bool`

CLI Example:

```
salt '*' system.stop_time_service
```

`salt.modules.win_system.unjoin_domain` (*username=None, password=None, domain=None, workgroup='WORKGROUP', disable=False, restart=False*)

Unjoin a computer from an Active Directory Domain. Requires restart.

#### Parameters

- **username** -- Username of an account which is authorized to manage computer accounts on the domain. Need to be fully qualified like `user@domain.tld` or `domain.tld\user`. If domain not specified, the passed domain will be used. If computer account doesn't need to be disabled, can be None.
- **password** (*str*) -- Password of the specified user
- **domain** (*str*) -- The domain from which to unjoin the computer. Can be None
- **workgroup** (*str*) -- The workgroup to join the computer to. Default is

WORKGROUP

New in version 2015.5.7.

New in version 2015.8.2.

#### Parameters

- **disable** (*bool*) -- Disable the user account in Active Directory. True to disable.
- **restart** (*bool*) -- Restart the computer after successful unjoin

New in version 2015.5.7.

New in version 2015.8.2.

**Returns** Returns a dictionary if successful. False if unsuccessful.

**Return type** dict, bool

CLI Example:

```
salt 'minion-id' system.unjoin_domain restart=True

salt 'minion-id' system.unjoin_domain username='unjoinuser' \\  
password='unjoinpassword' disable=True \\  
restart=True
```

### 30.16.275 salt.modules.win\_timezone

Module for managing timezone on Windows systems.

`salt.modules.win_timezone.get_hwclock()`  
Get current hardware clock setting (UTC or localtime)

CLI Example:

```
salt '*' timezone.get_hwclock
```

`salt.modules.win_timezone.get_offset()`  
Get current numeric timezone offset from UCT (i.e. -0700)

CLI Example:

```
salt '*' timezone.get_offset
```

`salt.modules.win_timezone.get_zone()`  
Get current timezone (i.e. America/Denver)

CLI Example:

```
salt '*' timezone.get_zone
```

`salt.modules.win_timezone.get_zonecode()`  
Get current timezone (i.e. PST, MDT, etc)

CLI Example:

```
salt '*' timezone.get_zonecode
```

`salt.modules.win_timezone.set_hwclock(clock)`  
Sets the hardware clock to be either UTC or localtime

CLI Example:

```
salt '*' timezone.set_hwclock UTC
```

`salt.modules.win_timezone.set_zone(timezone)`  
Unlinks, then symlinks /etc/localtime to the set timezone.

The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever your system uses as its cron and syslog daemons). This will not be magically done for you!

CLI Example:

```
salt '*' timezone.set_zone 'America/Denver'
```

`salt.modules.win_timezone.zone_compare(timezone)`  
Checks the md5sum between the given timezone, and the one set in /etc/localtime. Returns True if they match, and False if not. Mostly useful for running state checks.

Example:

```
salt '*' timezone.zone_compare 'America/Denver'
```

### 30.16.276 salt.modules.win\_update

Module for running windows updates.

**depends**

- win32com
- win32con
- win32api
- pywintypes

New in version 2014.7.0.

Set windows updates to run by category. Default behavior is to install all updates that do not require user interaction to complete. Optionally set `categories` to a category of your choice to only install certain updates. Default is to set to install all available but driver updates. The following example will install all Security and Critical Updates, and download but not install standard updates.

```
salt '*' win_update.install_updates categories="['Critical Updates', 'Security Updates']"
```

You can also specify a number of features about the update to have a fine grain approach to specific types of updates. These are the following features/states of updates available for configuring: .. code-block:: text

```
`UI` - User interaction required, skipped by default
`downloaded` - Already downloaded, included by default
`present` - Present on computer, included by default
`installed` - Already installed, skipped by default
`reboot` - Reboot required, included by default
`hidden` - Skip hidden updates, skipped by default
`software` - Software updates, included by default
`driver` - Driver updates, included by default
```

The following example installs all updates that don't require a reboot: .. code-block:: bash

```
salt '*' win_update.install_updates skips="{reboot:True}"
```

Once installed Salt will return a similar output:

```
2 : Windows Server 2012 Update (KB123456)
4 : Internet Explorer Security Update (KB098765)
2 : Malware Definition Update (KB321456)
...
```

The number at the beginning of the line is an `OperationResultCode` from the Windows Update Agent, it's enumeration is described here: [https://msdn.microsoft.com/en-us/library/windows/desktop/aa387095\(v=vs.85\).aspx](https://msdn.microsoft.com/en-us/library/windows/desktop/aa387095(v=vs.85).aspx). The result code is then followed by the update name and its KB identifier.

```
class salt.modules.win_update.PyWinUpdater (categories=None, skipUI=True, skip-
Downloaded=False, skipInstalled=True,
skipReboot=False, skipPresent=False, skipSoft-
wareUpdates=False, skipDriverUpdates=False,
skipHidden=True)
```

#### **AutoSearch()**

this function generates a search string. simplifying the search function while still providing as many features as possible.

#### **Download()**

#### **GetAvailableCategories()**

#### **GetCategories()**

#### **GetDownloadResults()**

#### **GetInstallationResults()**

this gets results of installation process.

#### **GetInstallationResultsPretty()**

converts the installation results into a pretty print.

#### **GetSearchResults()**

#### **GetSearchResultsPretty()**

#### **Install()**

#### **Search(searchString)**

#### **SetCategories(categories)**

#### **SetSkip(skip, state)**

#### **SetSkips(skips)**

`salt.modules.win_update.download_updates` (*skips=None, retries=5, categories=None*)

Downloads all available updates, skipping those that require user interaction.

Various aspects of the updates can be included or excluded. this feature is still in development.

**retries** Number of retries to make before giving up. This is total, not per step.

**categories** Specify the categories to update. Must be passed as a list.

```
salt '*' win_update.download_updates categories="['Updates']"
```

Categories include the following:

- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:

```
# Normal Usage
salt '*' win_update.download_updates

# Download critical updates only
salt '*' win_update.download_updates categories="['Critical Updates']"
```

`salt.modules.win_update.install_updates` (*skips=None, retries=5, categories=None*)

Downloads and installs all available updates, skipping those that require user interaction.

Add `cached` to only install those updates which have already been downloaded.

you can set the maximum number of retries to `n` in the search process by adding: `retries=n`

various aspects of the updates can be included or excluded. This function is still under development.

**retries** Number of retries to make before giving up. This is total, not per step.

**categories** Specify the categories to install. Must be passed as a list.

```
salt '*' win_update.install_updates categories="['Updates']"
```

Categories include the following:

- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:

```
# Normal Usage
salt '*' win_update.install_updates

# Install all critical updates
salt '*' win_update.install_updates categories="['Critical Updates']"
```

`salt.modules.win_update.list_updates` (*verbose=False, skips=None, retries=5, categories=None*)

Returns a summary of available updates, grouped into their non-mutually exclusive categories.

**verbose** Print results in greater detail

**retries** Number of retries to make before giving up. This is total, not per step.

**categories** Specify the categories to list. Must be passed as a list.

```
salt '*' win_update.list_updates categories=["Updates"]
```

Categories include the following:

- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:

```
# Normal Usage
salt '*' win_update.list_updates

# List all critical updates list in verbose detail
salt '*' win_update.list_updates categories=['Critical Updates'] verbose=True
```

### 30.16.277 salt.modules.win\_useradd

Module for managing Windows Users

**Important:** If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `'user.info' is not available`), see [here](#).

#### depends

- pywintypes
- win32api
- win32net
- win32netcon
- win32profile
- win32security
- win32ts

**Note:** This currently only works with local user accounts, not domain accounts

`salt.modules.win_useradd.add`(*name, password=None, fullname=False, description=None, groups=None, home=None, homedrive=None, profile=None, logonscript=None*)

Add a user to the minion.

#### Parameters

- **name** (*str*) -- User name
- **password** (*str*) -- User's password in plain text.
- **fullname** (*str*) -- The user's full name.
- **description** (*str*) -- A brief description of the user account.
- **groups** (*list*) -- A list of groups to add the user to.
- **home** (*str*) -- The path to the user's home directory.
- **homedrive** (*str*) -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
- **profile** (*str*) -- An explicit path to a profile. Can be a UNC or a folder on the system. If left blank, windows uses it's default profile directory.
- **logonscript** (*str*) -- Path to a login script to run when the user logs on.

**Returns** True if successful. False is unsuccessful.

**Return type** `bool`

CLI Example:

```
salt '*' user.add name password
```

`salt.modules.win_useradd.addgroup` (*name*, *group*)

Add user to a group

**Parameters**

- **name** (*str*) -- user name to add to the group
- **group** (*str*) -- name of the group to which to add the user

**Returns** True if successful. False is unsuccessful.

**Return type** `bool`

CLI Example:

```
salt '*' user.addgroup jsnuffy 'Power Users'
```

`salt.modules.win_useradd.chfullname` (*name*, *fullname*)

Change the full name of the user

**Parameters**

- **name** (*str*) -- user name for which to change the full name
- **fullname** (*str*) -- the new value for the full name

**Returns** True if successful. False is unsuccessful.

**Return type** `bool`

CLI Example:

```
salt '*' user.chfullname user 'First Last'
```

`salt.modules.win_useradd.chgroups` (*name*, *groups*, *append=True*)

Change the groups this user belongs to, add `append=False` to make the user a member of only the specified groups

**Parameters**

- **name** (*str*) -- user name for which to change groups
- **groups** (*list*, *str*) -- a single group or a list of groups to assign to the user
- **append** (*bool*) -- True adds the passed groups to the user's current groups False sets the user's groups to the passed groups only

**Returns** True if successful. False is unsuccessful.

**Return type** `bool`

CLI Example:

```
salt '*' user.chgroups jsnuffy Administrators,Users True
```

`salt.modules.win_useradd.chhome` (*name*, *home*, *persist=False*)

Change the home directory of the user, pass True for persist to move files to the new home directory if the old home directory exist.

**Parameters**

- **name** (*str*) -- name of the user whose home directory you wish to change
- **home** (*str*) -- new location of the home directory
- **persist** (*bool*) -- True to move the contents of the existing home directory to the new location

**Returns** True if successful. False is unsuccessful.

**Return type** `bool`

CLI Example:

```
salt '*' user.chhome foo \\filesERVER\home\foo True
```

`salt.modules.win_useradd.chprofile` (*name*, *profile*)

Change the profile directory of the user

**Parameters**

- **name** (*str*) -- name of the user whose profile you wish to change
- **profile** (*str*) -- new location of the profile

**Returns**

True if successful. False is unsuccessful. :rtype: bool

CLI Example:

```
salt '*' user.chprofile foo \\filesERVER\profiles\foo
```

`salt.modules.win_useradd.current` (*sam=False*)

Get the username that salt-minion is running under. If salt-minion is running as a service it should return the Local System account. If salt is running from a command prompt it should return the username that started the command prompt.

New in version 2015.5.6.

**Parameters** **sam** (*bool*) -- False returns just the username without any domain notation. True returns the domain with the username in the SAM format. Ie:

domain\username

**Returns** Returns False if the username cannot be returned. Otherwise returns the username.

**Return type** bool str

CLI Example:

```
salt '*' user.current
```

`salt.modules.win_useradd.delete`(*name*, *purge=False*, *force=False*)

Remove a user from the minion

**Parameters**

- **name** (*str*) -- The name of the user to delete
- **purge** (*bool*) -- Boolean value indicating that the user profile should also be removed when the user account is deleted. If set to True the profile will be removed.
- **force** (*bool*) -- Boolean value indicating that the user account should be deleted even if the user is logged in. True will log the user out and delete user.

**Returns** True if successful

**Return type** bool

CLI Example:

```
salt '*' user.delete name
```

`salt.modules.win_useradd.getUserSid`(*username*)

Get the Security ID for the user

**Parameters** **username** (*str*) -- user name for which to look up the SID

**Returns** Returns the user SID

**Return type** str

CLI Example:

```
salt '*' user.getUserSid jsnuffy
```

`salt.modules.win_useradd.getent`(*refresh=False*)

Return the list of all info for all users

**Parameters** **refresh** (*bool*) -- Refresh the cached user information. Default is False. Useful when used from within a state function.

**Returns** A dictionary containing information about all users on the system

**Return type** dict

CLI Example:

```
salt '*' user.getent
```

`salt.modules.win_useradd.info`(*name*)

Return user information

**Parameters** **name** (*str*) -- Username for which to display information

**Returns**

A dictionary containing user information

- fullname
- username

- SID
- passwd (will always return None)
- comment (same as description, left here for backwards compatibility)
- description
- active
- logonscript
- profile
- home
- homedrive
- groups
- password\_changed
- successful\_logon\_attempts
- failed\_logon\_attempts
- last\_logon
- account\_disabled
- account\_locked
- password\_never\_expires
- disallow\_change\_password
- gid

**Return type** *dict*

CLI Example:

```
salt '*' user.info jsnuffy
```

`salt.modules.win_useradd.list_groups(name)`

Return a list of groups the named user belongs to

**Parameters** *name* (*str*) -- user name for which to list groups

**Returns** list of groups to which the user belongs

**Return type** *list*

CLI Example:

```
salt '*' user.list_groups foo
```

`salt.modules.win_useradd.list_users()`

Return a list of users on Windows

**Returns** list of users on the system

**Return type** *list*

CLI Example:

```
salt '*' user.list_users
```

`salt.modules.win_useradd.removegroup(name, group)`

Remove user from a group

**Parameters**

- **name** (*str*) -- user name to remove from the group
- **group** (*str*) -- name of the group from which to remove the user

**Returns** True if successful. False is unsuccessful.

**Return type** `bool`

CLI Example:

```
salt '*' user.removegroup jsnuffy 'Power Users'
```

`salt.modules.win_useradd.rename(name, new_name)`

Change the username for a named user

**Parameters**

- **name** (*str*) -- user name to change
- **new\_name** (*str*) -- the new name for the current user

**Returns** True if successful. False is unsuccessful.

**Return type** `bool`

CLI Example:

```
salt '*' user.rename jsnuffy jshmoie
```

`salt.modules.win_useradd.setpassword(name, password)`

Set the user's password

**Parameters**

- **name** (*str*) -- user name for which to set the password
- **password** (*str*) -- the new password

**Returns** True if successful. False is unsuccessful.

**Return type** `bool`

CLI Example:

```
salt '*' user.setpassword jsnuffy sup3rs3cr3t
```

`salt.modules.win_useradd.update(name, password=None, fullname=None, description=None, home=None, homedrive=None, logonscript=None, profile=None, expiration_date=None, expired=None, account_disabled=None, unlock_account=None, password_never_expires=None, disallow_change_password=None)`

Updates settings for the windows user. Name is the only required parameter. Settings will only be changed if the parameter is passed a value.

New in version 2015.8.0.

**Parameters**

- **name** (*str*) -- The user name to update.
- **password** (*str*) -- New user password in plain text.

- **fullname** (*str*) -- The user's full name.
- **description** (*str*) -- A brief description of the user account.
- **home** (*str*) -- The path to the user's home directory.
- **homedrive** (*str*) -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
- **logonscript** (*str*) -- The path to the logon script.
- **profile** (*str*) -- The path to the user's profile directory.
- **expiration\_date** (*date*) -- The date and time when the account expires. Can

be a valid date/time string. To set to never expire pass the string `Never`.

Parameters **expired** (*bool*) -- Pass *True* to expire the account. The user will be

prompted to change their password at the next logon. Pass *False* to mark the account as `not expired`. You can't use this to negate the expiration if the expiration was caused by the account expiring. You'll have to change the *expiration\_date* as well.

Parameters **account\_disabled** (*bool*) -- True disables the account. False enables the account.

Parameters **unlock\_account** (*bool*) -- True unlocks a locked user account. False is ignored.

Parameters **password\_never\_expires** (*bool*) -- True sets the password to never expire. False allows the password to expire.

Parameters **disallow\_change\_password** (*bool*) -- True blocks the user from changing the password. False allows the user to change the password.

Returns True if successful. False is unsuccessful.

Return type *bool*

CLI Example:

```
salt '*' user.update bob password=secret profile=C:\Users\Bob
home=\\server\homesare\bob homedrive=U:
```

### 30.16.278 salt.modules.xapi

This module (mostly) uses the XenAPI to manage Xen virtual machines.

Big fat warning: the XenAPI used in this file is the one bundled with Xen Source, NOT XenServer nor Xen Cloud Platform. As a matter of fact it *will* fail under those platforms. From what I've read, little work is needed to adapt this code to XS/XCP, mostly playing with XenAPI version, but as XCP is not taking precedence on Xen Source on many platforms, please keep compatibility in mind.

Useful documentation:

. <http://downloads.xen.org/Wiki/XenAPI/xenapi-1.0.6.pdf>. [http://docs.vmd.citrix.com/XenServer/6.0.0/1.0/en\\_gb/api/](http://docs.vmd.citrix.com/XenServer/6.0.0/1.0/en_gb/api/)  
. <https://github.com/xapi-project/xen-api/tree/master/scripts/examples/python>  
<http://xenbits.xen.org/gitweb/?p=xen.git;a=tree;f=tools/python/xen/xm;hb=HEAD>

`salt.modules.xapi.create(config_)`

Start a defined domain

CLI Example:

```
salt '*' virt.create <path to Xen cfg file>
```

`salt.modules.xapi.destroy(vm_)`

Hard power down the virtual machine, this is equivalent to pulling the power

CLI Example:

```
salt '*' virt.destroy <vm name>
```

`salt.modules.xapi.freecpu()`

Return an int representing the number of unallocated cpus on this hypervisor

CLI Example:

```
salt '*' virt.freecpu
```

`salt.modules.xapi.freemem()`

Return an int representing the amount of memory that has not been given to virtual machines on this node

CLI Example:

```
salt '*' virt.freemem
```

`salt.modules.xapi.full_info()`

Return the node\_info, vm\_info and freemem

CLI Example:

```
salt '*' virt.full_info
```

`salt.modules.xapi.get_disks(vm_)`

Return the disks of a named vm

CLI Example:

```
salt '*' virt.get_disks <vm name>
```

`salt.modules.xapi.get_macs(vm_)`

Return a list off MAC addresses from the named vm

CLI Example:

```
salt '*' virt.get_macs <vm name>
```

`salt.modules.xapi.get_nics(vm_)`

Return info about the network interfaces of a named vm

CLI Example:

```
salt '*' virt.get_nics <vm name>
```

`salt.modules.xapi.is_hyper()`

Returns a bool whether or not this node is a hypervisor of any kind

CLI Example:

```
salt '*' virt.is_hyper
```

`salt.modules.xapi.list_vms()`

Return a list of virtual machine names on the minion

CLI Example:

```
salt '*' virt.list_vms
```

`salt.modules.xapi.migrate(vm_, target, live=1, port=0, node=-1, ssl=None, change_home_server=0)`

Migrates the virtual machine to another hypervisor

CLI Example:

```
salt '*' virt.migrate <vm name> <target hypervisor> [live] [port] [node] [ssl] [change_home_serv
```

Optional values:

**live** Use live migration

**port** Use a specified port

**node** Use specified NUMA node on target

**ssl** use ssl connection for migration

**change\_home\_server** change home server for managed domains

`salt.modules.xapi.node_info()`

Return a dict with information about this node

CLI Example:

```
salt '*' virt.node_info
```

`salt.modules.xapi.pause(vm_)`

Pause the named vm

CLI Example:

```
salt '*' virt.pause <vm name>
```

`salt.modules.xapi.reboot(vm_)`

Reboot a domain via ACPI request

CLI Example:

```
salt '*' virt.reboot <vm name>
```

`salt.modules.xapi.reset(vm_)`

Reset a VM by emulating the reset button on a physical machine

CLI Example:

```
salt '*' virt.reset <vm name>
```

`salt.modules.xapi.resume(vm_)`

Resume the named vm

CLI Example:

```
salt '*' virt.resume <vm name>
```

`salt.modules.xapi.setmem(vm_, memory)`

Changes the amount of memory allocated to VM.

Memory is to be specified in MB

CLI Example:

```
salt '*' virt.setmem myvm 768
```

`salt.modules.xapi.setvcpus`(*vm\_*, *vcpus*)

Changes the amount of vcpus allocated to VM.

vcpus is an int representing the number to be assigned

CLI Example:

```
salt '*' virt.setvcpus myvm 2
```

`salt.modules.xapi.shutdown`(*vm\_*)

Send a soft shutdown signal to the named vm

CLI Example:

```
salt '*' virt.shutdown <vm name>
```

`salt.modules.xapi.start`(*config\_*)

Alias for the obscurely named `create` function

CLI Example:

```
salt '*' virt.start <path to Xen cfg file>
```

`salt.modules.xapi.vcpu_pin`(*vm\_*, *vcpu*, *cpus*)

Set which CPUs a VCPU can use.

CLI Example:

```
salt 'foo' virt.vcpu_pin domU-id 2 1
salt 'foo' virt.vcpu_pin domU-id 2 2-6
```

`salt.modules.xapi.vm_cputime`(*vm\_=None*)

Return cputime used by the vms on this hyper in a list of dicts:

```
[
  'your-vm': {
    'cputime' <int>
    'cputime_percent' <int>
  },
  ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_cputime
```

`salt.modules.xapi.vm_diskstats`(*vm\_=None*)

Return disk usage counters used by the vms on this hyper in a list of dicts:

```
[
  'your-vm': {
    'io_read_kbs' : 0,
    'io_write_kbs' : 0
  },
  ...
]
```

```
...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_diskstats
```

**salt.modules.xapi.vm\_info**(*vm\_=None*)

Return detailed information about the vms.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_info
```

**salt.modules.xapi.vm\_netstats**(*vm\_=None*)

Return combined network counters used by the vms on this hyper in a list of dicts:

```
[
  'your-vm': {
    'io_read_kbs'           : 0,
    'io_total_read_kbs'    : 0,
    'io_total_write_kbs'   : 0,
    'io_write_kbs'        : 0
  },
  ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_netstats
```

**salt.modules.xapi.vm\_state**(*vm\_=None*)

Return list of all the vms and their state.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_state <vm name>
```

### 30.16.279 salt.modules.xfs

Module for managing XFS file systems.

**salt.modules.xfs.defragment**(*device*)

Defragment mounted XFS filesystem. In order to mount a filesystem, device should be properly mounted and writable.

CLI Example:

```
salt '*' xfs.defragment /dev/sda1
```

**salt.modules.xfs.devices()**

Get known XFS formatted devices on the system.

CLI Example:

```
salt '*' xfs.devices
```

**salt.modules.xfs.dump** (*device, destination, level=0, label=None, noerase=None*)

Dump filesystem device to the media (file, tape etc).

Required parameters:

- device**: XFS device, content of which to be dumped.
- destination**: Specifies a dump destination.

Valid options are:

- label**: Label of the dump. Otherwise automatically generated label is used.
- level**: Specifies a dump level of 0 to 9.
- noerase**: Pre-erase media.

Other options are not used in order to let `xfsdump` use its default values, as they are most optimal. See the `xfsdump(8)` manpage for a more complete description of these options.

CLI Example:

```
salt '*' xfs.dump /dev/sda1 /detination/on/the/client
salt '*' xfs.dump /dev/sda1 /detination/on/the/client label='Company accountancy'
salt '*' xfs.dump /dev/sda1 /detination/on/the/client noerase=True
```

**salt.modules.xfs.estimate** (*path*)

Estimate the space that an XFS filesystem will take. For each directory estimate the space that directory would take if it were copied to an XFS filesystem. Estimation does not cross mount points.

CLI Example:

```
salt '*' xfs.estimate /path/to/file
salt '*' xfs.estimate /path/to/dir/*
```

**salt.modules.xfs.info** (*device*)

Get filesystem geometry information.

CLI Example:

```
salt '*' xfs.info /dev/sda1
```

**salt.modules.xfs.inventory** ()

Display XFS dump inventory without restoration.

CLI Example:

```
salt '*' xfs.inventory
```

**salt.modules.xfs.mkfs** (*device, label=None, ssize=None, noforce=None, bso=None, gmo=None, ino=None, lso=None, rso=None, nmo=None, dso=None*)

Create a file system on the specified device. By default wipes out with force.

General options:

- label**: Specify volume label.
- ssize**: Specify the fundamental sector size of the filesystem.
- noforce**: Do not force create filesystem, if disk is already formatted.

Filesystem geometry options:

- bso**: Block size options.
- gmo**: Global metadata options.
- dso**: **Data section options**. These options specify the location, size, and other parameters of the data section of the filesystem.
- ino**: Inode options to specify the inode size of the filesystem, and other inode allocation parameters.
- lso**: Log section options.
- nmo**: Naming options.
- rso**: Realtime section options.

See the `mkfs.xfs(8)` manpage for a more complete description of corresponding options description.

CLI Example:

```
salt '*' xfs.mkfs /dev/sda1
salt '*' xfs.mkfs /dev/sda1 dso='su=32k,sw=6' noforce=True
salt '*' xfs.mkfs /dev/sda1 dso='su=32k,sw=6' lso='logdev=/dev/sda2,size=10000b'
```

`salt.modules.xfs.modify`(*device*, *label=None*, *lazy\_counting=None*, *uuid=None*)

Modify parameters of an XFS filesystem.

CLI Example:

```
salt '*' xfs.modify /dev/sda1 label='My backup' lazy_counting=False
salt '*' xfs.modify /dev/sda1 uuid=False
salt '*' xfs.modify /dev/sda1 uuid=True
```

`salt.modules.xfs.prune_dump`(*sessionid*)

Prunes the dump session identified by the given session id.

CLI Example:

```
salt '*' xfs.prune_dump b74a3586-e52e-4a4a-8775-c3334fa8ea2c
```

### 30.16.280 salt.modules.xmpp

Module for Sending Messages via XMPP (a.k.a. Jabber)

New in version 2014.1.0.

**depends**

- `sleekxmpp` python module

**configuration** This module can be used by either passing a jid and password directly to `send_message`, or by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```
my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org/resourceName
  xmpp.password: verybadpass
```

The resourceName refers to the resource that is using this account. It is user-definable, and optional. The following configurations are both valid:

```
my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org/salt
  xmpp.password: verybadpass

my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org
  xmpp.password: verybadpass
```

class salt.modules.xmpp.**SendMsgBot**(jid, password, recipient, msg)

**start**(event)

salt.modules.xmpp.**send\_msg**(recipient, message, jid=None, password=None, profile=None)

Send a message to an XMPP recipient. Designed for use in states.

CLI Examples:

```
xmpp.send_msg 'admins@xmpp.example.com' 'This is a salt module test' profile='my-xmpp
xmpp.send_msg 'admins@xmpp.example.com' 'This is a salt module test' jid='myuser@xmpp
```

### 30.16.281 salt.modules.yumpkg

Support for YUM/DNF

---

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

---

**Note:** This module makes use of the **repoquery** utility, from the **yum-utils** package. This package will be installed as a dependency if salt is installed via EPEL. However, if salt has been installed using pip, or a host is being managed using salt-ssh, then as of version 2014.7.0 **yum-utils** will be installed automatically to satisfy this dependency.

DNF is fully supported as of version 2015.5.10 and 2015.8.4 (partial support for DNF was initially added in 2015.8.0), and DNF is used automatically in place of YUM in Fedora 22 and newer. For these versions, repoquery is available from the **dnf-plugins-core** package.

---

salt.modules.yumpkg.**check\_db**(\*names, \*\*kwargs)

New in version 0.17.0.

Returns a dict containing the following information for each specified package:

1. A key `found`, which will be a boolean value denoting if a match was found in the package database.
2. If `found` is `False`, then a second key called `suggestions` will be present, which will contain a list of possible matches.

The `fromrepo`, `enablerepo` and `disablerepo` arguments are supported, as used in pkg states, and the `disableexcludes` option is also supported. However, in Fedora 22 and newer all of these but `fromrepo` is ignored.

New in version 2014.7.0: Support for the `disableexcludes` option

CLI Examples:

```
salt '*' pkg.check_db <package1> <package2> <package3>
salt '*' pkg.check_db <package1> <package2> <package3> fromrepo=epel-testing
salt '*' pkg.check_db <package1> <package2> <package3> disableexcludes=main
```

`salt.modules.yumpkg.clean_metadata(**kwargs)`

New in version 2014.1.0.

Cleans local yum metadata. Functionally identical to `refresh_db()`.

CLI Example:

```
salt '*' pkg.clean_metadata
```

`salt.modules.yumpkg.del_repo(repo, basedir=None, **kwargs)`

Delete a repo from <basedir> (default basedir: all dirs in `reposdir` yum option).

If the `.repo` file in which the repo exists does not contain any other repo configuration, the file itself will be deleted.

CLI Examples:

```
salt '*' pkg.del_repo myrepo
salt '*' pkg.del_repo myrepo basedir=/path/to/dir
salt '*' pkg.del_repo myrepo basedir=/path/to/dir,/path/to/another/dir
```

`salt.modules.yumpkg.diff(*paths)`

Return a formatted diff between current files and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

**Parameters** `path` -- Full path to the installed file

**Returns** Difference string or raises an exception if examined file is binary.

CLI example:

```
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

`salt.modules.yumpkg.download(*packages)`

New in version 2015.5.0.

Download packages to the local disk. Requires `yumdownloader` from `yum-utils` package.

**Note:** `yum-utils` will already be installed on the minion if the package was installed from the Fedora / EPEL repositories.

CLI example:

```
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```

`salt.modules.yumpkg.file_dict(*packages)`

New in version 2014.1.0.

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.yumpkg.file_list(*packages)`

New in version 2014.1.0.

List the files that belong to a package. Not specifying any packages will return a list of *every* file on the system's rpm database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.yumpkg.get_repo(name, basedir=None, **kwargs)`

Display a repo from <basedir> (default basedir: all dirs in `reposdir` yum option).

CLI Examples:

```
salt '*' pkg.get_repo myrepo
salt '*' pkg.get_repo myrepo basedir=/path/to/dir
salt '*' pkg.get_repo myrepo basedir=/path/to/dir,/path/to/another/dir
```

`salt.modules.yumpkg.group_diff(name)`

New in version 2014.1.0.

Changed in version Boron,2015.8.4,2015.5.10: Environment groups are now supported. The key names have been renamed, similar to the changes made in `pkg.group_info`.

Lists packages belonging to a certain group, and which are installed

CLI Example:

```
salt '*' pkg.group_diff 'Perl Support'
```

`salt.modules.yumpkg.group_info(name, expand=False)`

New in version 2014.1.0.

Changed in version Boron,2015.8.4,2015.5.10: The return data has changed. A new key `type` has been added to distinguish environment groups from package groups. Also, keys for the group name and group ID have been added. The mandatory `packages`, `optional packages`, and `default packages` keys have been renamed to `mandatory`, `optional`, and `default` for accuracy, as environment groups include other groups, and not packages. Finally, this function now properly identifies conditional packages.

Lists packages belonging to a certain group

CLI Example:

```
salt '*' pkg.group_info 'Perl Support'
```

`salt.modules.yumpkg.group_install(name, skip=(), include=(), **kwargs)`

New in version 2014.1.0.

Install the passed package group(s). This is basically a wrapper around `pkg.install`, which performs package group resolution for the user. This function is currently considered experimental, and should be expected to undergo changes.

**name** Package group to install. To install more than one group, either use a comma-separated list or pass the value as a python list.

CLI Examples:

```
salt '*' pkg.group_install 'Group 1'
salt '*' pkg.group_install 'Group 1,Group 2'
salt '*' pkg.group_install '["Group 1", "Group 2"]'
```

**skip** Packages that would normally be installed by the package group (``default" packages), which should not be installed. Can be passed either as a comma-separated list or a python list.

CLI Examples:

```
salt '*' pkg.group_install 'My Group' skip='foo,bar'
salt '*' pkg.group_install 'My Group' skip='["foo", "bar"]'
```

**include** Packages which are included in a group, which would not normally be installed by a yum `groupinstall` (``optional" packages). Note that this will not enforce group membership; if you include packages which are not members of the specified groups, they will still be installed. Can be passed either as a comma-separated list or a python list.

CLI Examples:

```
salt '*' pkg.group_install 'My Group' include='foo,bar'
salt '*' pkg.group_install 'My Group' include='["foo", "bar"]'
```

**Note:** Because this is essentially a wrapper around `pkg.install`, any argument which can be passed to `pkg.install` may also be included here, and it will be passed along wholesale.

`salt.modules.yumpkg.group_list()`

New in version 2014.1.0.

Lists all groups known by yum on this system

CLI Example:

```
salt '*' pkg.group_list
```

`salt.modules.yumpkg.hold(name=None, pkgs=None, sources=None, **kwargs)`

New in version 2014.7.0.

Version-lock packages

**Note:** Requires the appropriate `versionlock` plugin package to be installed:

- On RHEL 5: `yum-versionlock`
- On RHEL 6 & 7: `yum-plugin-versionlock`
- On Fedora: `python-dnf-plugins-extras-versionlock`

**name** The name of the package to be held.

Multiple Package Options:

**pkgs** A list of packages to hold. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.hold <package name>
salt '*' pkg.hold pkgs='["foo", "bar"]'
```

`salt.modules.yumpkg.install` (*name=None, refresh=False, skip\_verify=False, pkgs=None, sources=None, reinstall=False, normalize=True, \*\*kwargs*)

Install the passed package(s), add `refresh=True` to clean the yum database before package is installed.

**name** The name of the package to be installed. Note that this parameter is ignored if either `pkgs` or `sources` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `sources` option.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (`.i686`, `.i586`, etc.) to the end of the package name.

CLI Example:

```
salt '*' pkg.install <package name>
```

**refresh** Whether or not to update the yum database before executing.

**reinstall** Specifying `reinstall=True` will use `yum reinstall` rather than `yum install` for requested packages that are already installed.

If a version is specified with the requested package, then `yum reinstall` will only be used if the installed version matches the requested version.

Works with `sources` when the package header of the source can be matched to the name and version of an installed package.

New in version 2014.7.0.

**skip\_verify** Skip the GPG verification check (e.g., `--nogpgcheck`)

**version** Install a specific version of the package, e.g. `1.2.3-4.el5`. Ignored if `pkgs` or `sources` is passed.

Repository Options:

**fromrepo** Specify a package repository (or repositories) from which to install. (e.g., `yum --disablerepo='*' --enablerepo='somerepo'`)

**enablerepo** (ignored if **fromrepo** is specified) Specify a disabled package repository (or repositories) to enable. (e.g., `yum --enablerepo='somerepo'`)

**disablerepo** (ignored if **fromrepo** is specified) Specify an enabled package repository (or repositories) to disable. (e.g., `yum --disablerepo='somerepo'`)

**disableexcludes** Disable exclude from main, for a repo or for everything. (e.g., `yum --disableexcludes='main'`)

New in version 2014.7.0.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version.

CLI Examples:

```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-4.el5"}]'
```

**sources** A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources='[{"foo": "salt://foo.rpm"}, {"bar": "salt://bar.rpm"}]'
```

**normalize** [True] Normalize the package name by removing the architecture. This is useful for poorly created packages which might include the architecture as an actual part of the name such as kernel modules which match a specific kernel version.

```
salt -G role:nsd pkg.install gpbs.gplbin-2.6.32-279.31.1.el6.x86_64 normalize=False
```

New in version 2014.7.0.

Returns a dict containing the new package names and versions:

```
{'package': {'old': '<old-version>',
              'new': '<new-version>'}}
```

`salt.modules.yumpkg.latest_version(*names, **kwargs)`

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

A specific repo can be requested using the `fromrepo` keyword argument, and the `disableexcludes` option is also supported.

New in version 2014.7.0: Support for the `disableexcludes` option

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> fromrepo=epel-testing
salt '*' pkg.latest_version <package name> disableexcludes=main
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

`salt.modules.yumpkg.list_holds(pattern='\\w+(?:[-][^-]+)*', full=True)`

Changed in version Boron,2015.8.4,2015.5.10: Function renamed from `pkg.get_locked_pkgs` to `pkg.list_holds`.

List information on locked packages

**Note:** Requires the appropriate `versionlock` plugin package to be installed:

- On RHEL 5: `yum-versionlock`
- On RHEL 6 & 7: `yum-plugin-versionlock`
- On Fedora: `python-dnf-plugins-extras-versionlock`

**pattern** [`w+(?:[-][^-]+)*`] Regular expression used to match the package name

**full** [True] Show the full hold definition including version and epoch. Set to `False` to return just the name of the package(s) being held.

CLI Example:

```
salt '*' pkg.list_holds
salt '*' pkg.list_holds full=False
```

`salt.modules.yumpkg.list_pkgs(versions_as_list=False, **kwargs)`

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

`salt.modules.yumpkg.list_repo_pkgs(*args, **kwargs)`

New in version 2014.1.0.

Changed in version 2014.7.0: All available versions of each package are now returned. This required a slight modification to the structure of the return dict. The return data shown below reflects the updated return dict structure.

Returns all available packages. Optionally, package names (and name globs) can be passed and the results will be filtered to packages matching those names. This is recommended as it speeds up the function considerably.

**Warning:** Running this function on RHEL/CentOS 6 and earlier will be more resource-intensive, as the version of yum that ships with older RHEL/CentOS has no yum subcommand for listing packages from a repository. Thus, a `yum list installed` and `yum list available` are run, which generates a lot of output, which must then be analyzed to determine which package information to include in the return data.

This function can be helpful in discovering the version or repo to specify in a `pkg.installed` state.

The return data is a dictionary of repo names, with each repo containing a dictionary in which the keys are package names, and the values are a list of version numbers. Here is an example of the return data:

```
{
  'base': {
    'bash': ['4.1.2-15.el6_4'],
    'kernel': ['2.6.32-431.el6']
  },
  'updates': {
    'bash': ['4.1.2-15.el6_5.2', '4.1.2-15.el6_5.1'],
    'kernel': ['2.6.32-431.29.2.el6',
               '2.6.32-431.23.3.el6',
               '2.6.32-431.20.5.el6',
               '2.6.32-431.20.3.el6',
               '2.6.32-431.17.1.el6',
               '2.6.32-431.11.2.el6',
               '2.6.32-431.5.1.el6',
               '2.6.32-431.3.1.el6',
               '2.6.32-431.1.2.0.1.el6']
  }
}
```

**fromrepo** [None] Only include results from the specified repo(s). Multiple repos can be specified, comma-separated.

CLI Example:

```
salt '*' pkg.list_repo_pkgs
salt '*' pkg.list_repo_pkgs foo bar baz
salt '*' pkg.list_repo_pkgs 'samba4*' fromrepo=base,updates
```

`salt.modules.yumpkg.list_repos(basedir=None)`

Lists all repos in `<basedir>` (default: all dirs in `reposdir` yum option).

CLI Example:

```
salt '*' pkg.list_repos
salt '*' pkg.list_repos basedir=/path/to/dir
salt '*' pkg.list_repos basedir=/path/to/dir,/path/to/another/dir
```

`salt.modules.yumpkg.list_upgrades` (*refresh=True, \*\*kwargs*)

Check whether or not an upgrade is available for all packages

The `fromrepo`, `enablerepo`, and `disablerepo` arguments are supported, as used in `pkg` states, and the `disableexcludes` option is also supported. However, in Fedora 22 and newer all of these but `fromrepo` is ignored.

New in version 2014.7.0: Support for the `disableexcludes` option

CLI Example:

```
salt '*' pkg.list_upgrades
```

`salt.modules.yumpkg.mod_repo` (*repo, basedir=None, \*\*kwargs*)

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following values are specified:

**repo** name by which the yum refers to the repo

**name** a human-readable name for the repo

**baseurl** the URL for yum to reference

**mirrorlist** the URL for yum to reference

Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in mind that a name cannot be deleted, and a `baseurl` can only be deleted if a `mirrorlist` is specified (or vice versa).

CLI Examples:

```
salt '*' pkg.mod_repo reponame enabled=1 gpgcheck=1
salt '*' pkg.mod_repo reponame basedir=/path/to/dir enabled=1
salt '*' pkg.mod_repo reponame baseurl= mirrorlist=http://host.com/
```

`salt.modules.yumpkg.modified` (*\*packages, \*\*flags*)

List the modified files that belong to a package. Not specifying any packages will return a list of `_all_` modified files on the system's RPM database.

New in version 2015.5.0.

Filtering by flags (True or False):

**size** Include only files where size changed.

**mode** Include only files which file's mode has been changed.

**checksum** Include only files which MD5 checksum has been changed.

**device** Include only files which major and minor numbers has been changed.

**symlink** Include only files which are symbolic link contents.

**owner** Include only files where owner has been changed.

**group** Include only files where group has been changed.

**time** Include only files where modification time of the file has been changed.

**capabilities** Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

CLI Examples:

```
salt '*' pkg.modified
salt '*' pkg.modified httpd
salt '*' pkg.modified httpd postfix
salt '*' pkg.modified httpd owner=True group=False
```

`salt.modules.yumpkg.normalize_name(name)`

Strips the architecture from the specified package name, if necessary. Circumstances where this would be done include:

- If the arch is 32 bit and the package name ends in a 32-bit arch.
- If the arch matches the OS arch, or is noarch.

CLI Example:

```
salt '*' pkg.normalize_name zsh.x86_64
```

`salt.modules.yumpkg.owner(*paths)`

New in version 2014.7.0.

Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version` <`salt.modules.yumpkg.version`, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:

```
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```

`salt.modules.yumpkg.purge(name=None, pkgs=None, **kwargs)`

Package purges are not supported by yum, this function is identical to `pkg.remove`.

**name** The name of the package to be purged

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>, <package2>, <package3>
salt '*' pkg.purge pkgs=['foo', 'bar']
```

`salt.modules.yumpkg.refresh_db(**kwargs)`

Check the yum repos for updated packages

Returns:

- True: Updates are available
- False: An error occurred
- None: No updates are available

**repo** Refresh just the specified repo

**disablerepo** Do not refresh the specified repo

**enablerepo** Refresh a disabled repo using this option

**branch** Add the specified branch when refreshing

**disableexcludes** Disable the excludes defined in your config files. Takes one of three options: - **all** - disable all excludes - **main** - disable excludes defined in [main] in yum.conf - **repo id** - disable excludes defined for that repo

CLI Example:

```
salt '*' pkg.refresh_db
```

`salt.modules.yumpkg.remove` (*name=None, pkgs=None, \*\*kwargs*)

Remove packages

**name** The name of the package to be removed

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The **name** parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

`salt.modules.yumpkg.unhold` (*name=None, pkgs=None, sources=None, \*\*kwargs*)

New in version 2014.7.0.

Remove version locks

---

**Note:** Requires the appropriate `versionlock` plugin package to be installed:

- On RHEL 5: `yum-versionlock`
  - On RHEL 6 & 7: `yum-plugin-versionlock`
  - On Fedora: `python-dnf-plugins-extras-versionlock`
- 

**name** The name of the package to be unheld

Multiple Package Options:

**pkgs** A list of packages to unhold. Must be passed as a python list. The **name** parameter will be ignored if this option is passed.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.unhold <package name>
salt '*' pkg.unhold pkgs=['foo', 'bar']
```

`salt.modules.yumpkg.upgrade` (*refresh=True, skip\_verify=False, \*\*kwargs*)

Run a full system upgrade, a yum upgrade

Changed in version 2014.7.0.

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

Repository Options:

**fromrepo** Specify a package repository (or repositories) from which to install. (e.g., `yum --disablerepo='*' --enablerepo='somerepo'`)

**enablerepo** (ignored if **fromrepo** is specified) Specify a disabled package repository (or repositories) to enable. (e.g., `yum --enablerepo='somerepo'`)

**disablerepo** (ignored if **fromrepo** is specified) Specify an enabled package repository (or repositories) to disable. (e.g., `yum --disablerepo='somerepo'`)

**disableexcludes** Disable exclude from main, for a repo or for everything. (e.g., `yum --disableexcludes='main'`)

New in version 2014.7.0.

`salt.modules.yumpkg.upgrade_available` (*name*)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

`salt.modules.yumpkg.verify` (*\*names, \*\*kwargs*)

New in version 2014.1.0.

Runs an `rpm -Va` on a system, and returns the results in a dict

Files with an attribute of `config`, `doc`, `ghost`, `license` or `readme` in the package header can be ignored using the `ignore_types` keyword argument

CLI Example:

```
salt '*' pkg.verify
salt '*' pkg.verify httpd
salt '*' pkg.verify 'httpd postfix'
salt '*' pkg.verify 'httpd postfix' ignore_types=['config','doc']
```

`salt.modules.yumpkg.version` (*\*names, \*\*kwargs*)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

`salt.modules.yumpkg.version_cmp` (*pkg1, pkg2*)

New in version 2015.5.4.

Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

CLI Example:

```
salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'
```

### 30.16.282 salt.modules.zcbuildout

Management of zc.buildout

New in version 2014.1.0.

This module is inspired by [minitage's buildout maker](#)

---

**Note:** The zc.buildout integration is still in beta; the API is subject to change

---

#### General notes

You have those following methods:

- upgrade\_bootstrap
- bootstrap
- run\_buildout
- buildout

`salt.modules.zcbuildout.bootstrap(*a, **kw)`  
Run the buildout bootstrap dance (python bootstrap.py).

**directory** directory to execute in

**config** alternative buildout configuration file to use

**runas** User used to run buildout as

**env** environment variables to set when running

**buildout\_ver** force a specific buildout version (1 | 2)

**test\_release** buildout accept test release

**offline** are we executing buildout in offline mode

**distribute** Forcing use of distribute

**new\_st** Forcing use of setuptools >= 0.7

**python** path to a python executable to use in place of default (salt one)

**onlyif** Only execute cmd if statement on the host return 0

**unless** Do not execute cmd if statement on the host return 0

**use\_vt** Use the new salt VT to stream output [experimental]

CLI Example:

```
salt '*' buildout.bootstrap /srv/mybuildout
```

`salt.modules.zcbuildout.buildout(*a, **kw)`

Run buildout in a directory.

**directory** directory to execute in

**config** buildout config to use

**parts** specific buildout parts to run

**runas** user used to run buildout as

**env** environment variables to set when running

**buildout\_ver** force a specific buildout version (1 | 2)

**test\_release** buildout accept test release

**new\_st** Forcing use of setuptools >= 0.7

**distribute** use distribute over setuptools if possible

**offline** does buildout run offline

**python** python to use

**debug** run buildout with -D debug flag

**onlyif** Only execute cmd if statement on the host return 0

**unless** Do not execute cmd if statement on the host return 0

**newest** run buildout in newest mode

**verbose** run buildout in verbose mode (-vvvvv)

**use\_vt** Use the new salt VT to stream output [experimental]

CLI Example:

```
salt '*' buildout.buildout /srv/mybuildout
```

`salt.modules.zcbuildout.run_buildout(*a, **kw)`

Run a buildout in a directory.

**directory** directory to execute in

**config** alternative buildout configuration file to use

**offline** are we executing buildout in offline mode

**runas** user used to run buildout as

**env** environment variables to set when running

**onlyif** Only execute cmd if statement on the host return 0

**unless** Do not execute cmd if statement on the host return 0

**newest** run buildout in newest mode

**force** run buildout unconditionally

**verbose** run buildout in verbose mode (-vvvvv)

**use\_vt** Use the new salt VT to stream output [experimental]

CLI Example:

```
salt '*' buildout.run_buildout /srv/mybuildout
```

`salt.modules.zcbuildout.upgrade_bootstrap(*a, **kw)`

Upgrade current bootstrap.py with the last released one.

Indeed, when we first run a buildout, a common source of problem is to have a locally stale bootstrap, we just try to grab a new copy

**directory** directory to execute in

**offline** are we executing buildout in offline mode

**buildout\_ver** forcing to use a specific buildout version (1 | 2)

**onlyif** Only execute cmd if statement on the host return 0

**unless** Do not execute cmd if statement on the host return 0

CLI Example:

```
salt '*' buildout.upgrade_bootstrap /srv/mybuildout
```

### 30.16.283 salt.modules.zfs

Salt interface to ZFS commands

**codeauthor** Nitin Madhok <nmadhok@clemson.edu>

`salt.modules.zfs.create(name, **kwargs)`

New in version 2015.5.0.

Create a ZFS File System.

CLI Example:

```
salt '*' zfs.create myzpool/mydataset [create_parent=True|False]
```

**Note:** ZFS properties can be specified at the time of creation of the filesystem by passing an additional argument called `properties` and specifying the properties with their respective values in the form of a python dictionary:

```
properties="{ 'property1': 'value1', 'property2': 'value2' }"
```

Example:

```
salt '*' zfs.create myzpool/mydataset properties="{ 'mountpoint': '/export/zfs', 'sharefs': 'on' }
```

`salt.modules.zfs.destroy(name, **kwargs)`

New in version 2015.5.0.

Destroy a ZFS File System.

CLI Example:

```
salt '*' zfs.destroy myzpool/mydataset [force=True|False]
```

`salt.modules.zfs.exists(name)`

New in version 2015.5.0.

Check if a ZFS filesystem or volume or snapshot exists.

CLI Example:

```
salt '*' zfs.exists myzpool/mydataset
```

`salt.modules.zfs.list_(name='', **kwargs)`

New in version 2015.5.0.

Return a list of all datasets or a specified dataset on the system and the values of their used, available, referenced, and mountpoint properties.

---

**Note:** Information about the dataset and all of its descendent datasets can be displayed by passing `recursive=True` on the CLI.

---

CLI Example:

```
salt '*' zfs.list [recursive=True|False]
salt '*' zfs.list /myzpool/mydataset [recursive=True|False]
```

---

**Note:** Dataset property value output can be customized by passing an additional argument called `properties` in the form of a python list:

```
properties="[property1, property2, property3]"
```

Example:

```
salt '*' zfs.list /myzpool/mydataset properties="[name, sharenfs, mountpoint]"
```

---

`salt.modules.zfs.rename(name, new_name)`

New in version 2015.5.0.

Rename or Relocate a ZFS File System.

CLI Example:

```
salt '*' zfs.rename myzpool/mydataset myzpool/renameddataset
```

### 30.16.284 salt.modules.zk\_concurrency

#### Concurrency controls in zookeeper

This module allows you to acquire and release a slot. This is primarily useful for ensuring that no more than N hosts take a specific action at once. This can also be used to coordinate between masters.

`salt.modules.zk_concurrency.lock(path, zk_hosts, identifier=None, max_concurrency=1, timeout=None, ephemeral_lease=False, force=False)`

Get lock (with optional timeout)

**path** The path in zookeeper where the lock is

**zk\_hosts** zookeeper connect string

**identifier** Name to identify this minion

**max\_concurrency** Maximum number of lock holders

**timeout** timeout to wait for the lock. A None timeout will block forever

**ephemeral\_lease** Whether the locks in zookeeper should be ephemeral

**force** Forcibly acquire the lock regardless of available slots

Example:

```
... code-block: bash
```

```
    salt minion zk_concurrency.lock /lock/path host1:1234,host2:1234
```

```
salt.modules.zk_concurrency.lock_holders(path, zk_hosts, identifier=None,
                                          max_concurrency=1, timeout=None,
                                          ephemeral_lease=False)
```

Return an un-ordered list of lock holders

**path** The path in zookeeper where the lock is

**zk\_hosts** zookeeper connect string

**identifier** Name to identify this minion

**max\_concurrency** Maximum number of lock holders

**timeout** timeout to wait for the lock. A None timeout will block forever

**ephemeral\_lease** Whether the locks in zookeeper should be ephemeral

Example:

```
... code-block: bash
```

```
    salt minion zk_concurrency.lock_holders /lock/path host1:1234,host2:1234
```

```
salt.modules.zk_concurrency.unlock(path, zk_hosts=None, identifier=None, max_concurrency=1,
                                     ephemeral_lease=False)
```

Remove lease from semaphore

**path** The path in zookeeper where the lock is

**zk\_hosts** zookeeper connect string

**identifier** Name to identify this minion

**max\_concurrency** Maximum number of lock holders

**timeout** timeout to wait for the lock. A None timeout will block forever

**ephemeral\_lease** Whether the locks in zookeeper should be ephemeral

Example:

```
... code-block: bash
```

```
    salt minion zk_concurrency.unlock /lock/path host1:1234,host2:1234
```

### 30.16.285 salt.modules.znc

znc - An advanced IRC bouncer

New in version 2014.7.0.

Provides an interface to basic ZNC functionality

```
salt.modules.znc.buildmod(*modules)
    Build module using znc-buildmod
```

CLI Example:

```
salt '*' znc.buildmod module.cpp [...]
```

`salt.modules.znc.dumpconf()`

Write the active configuration state to config file

CLI Example:

```
salt '*' znc.dumpconf
```

`salt.modules.znc.rehashconf()`

Rehash the active configuration state from config file

CLI Example:

```
salt '*' znc.rehashconf
```

`salt.modules.znc.version()`

Return server version from `znc --version`

CLI Example:

```
salt '*' znc.version
```

### 30.16.286 salt.modules.zpool

Module for running ZFS `zpool` command

**codeauthor** Nitin Madhok <nmadhok@clemson.edu>

`salt.modules.zpool.add(pool_name, *vdevs)`

Add the specified vdev's to the given pool

CLI Example:

```
salt '*' zpool.add myzpool /path/to/vdev1 /path/to/vdev2 [...]
```

`salt.modules.zpool.create(pool_name, *vdevs, **kwargs)`

New in version 2015.5.0.

Create a simple `zpool`, a mirrored `zpool`, a `zpool` having nested VDEVs, a hybrid `zpool` with cache, spare and log drives or a `zpool` with RAIDZ-1, RAIDZ-2 or RAIDZ-3

CLI Example:

```
salt '*' zpool.create myzpool /path/to/vdev1 [...] [force=True|False]
salt '*' zpool.create myzpool mirror /path/to/vdev1 /path/to/vdev2 [...] [force=True|False]
salt '*' zpool.create myzpool raidz1 /path/to/vdev1 /path/to/vdev2 raidz2 /path/to/vdev3 /path/to/vdev4 [...]
salt '*' zpool.create myzpool mirror /path/to/vdev1 [...] mirror /path/to/vdev2 /path/to/vdev3 [...]
salt '*' zpool.create myhybridzpool mirror /tmp/file1 [...] log mirror /path/to/vdev1 [...] cach
```

---

**Note:** `Zpool` properties can be specified at the time of creation of the pool by passing an additional argument called `properties` and specifying the properties with their respective values in the form of a python dictionary:

```
properties="{ 'property1': 'value1', 'property2': 'value2' }"
```

Example:

```
salt '*' zpool.create myzpool /path/to/vdev1 [...] properties="{ 'property1': 'value1', 'property
```

`salt.modules.zpool.create_file_vdev` (*size*, *\*vdevs*)

Creates file based virtual devices for a zpool

*\*vdevs* is a list of full paths for mkfile to create

CLI Example:

```
salt '*' zpool.create_file_vdev 7g /path/to/vdev1 [/path/to/vdev2] [...]
```

**Note:** Depending on file size, the above command may take a while to return.

`salt.modules.zpool.destroy` (*pool\_name*)

Destroys a storage pool

CLI Example:

```
salt '*' zpool.destroy myzpool
```

`salt.modules.zpool.exists` (*pool\_name*)

Check if a ZFS storage pool is active

CLI Example:

```
salt '*' zpool.exists myzpool
```

`salt.modules.zpool.export` (*\*pools*, *\*\*kwargs*)

New in version 2015.5.0.

Export storage pools

CLI Example:

```
salt '*' zpool.export myzpool ... [force=True|False]
salt '*' zpool.export myzpool2 myzpool2 ... [force=True|False]
```

`salt.modules.zpool.import_` (*pool\_name=''*, *new\_name=''*, *\*\*kwargs*)

New in version 2015.5.0.

Import storage pools or list pools available for import

CLI Example:

```
salt '*' zpool.import [all=True|False]
salt '*' zpool.import myzpool [mynewzpool] [force=True|False]
```

`salt.modules.zpool.iostat` (*name=''*)

Display I/O statistics for the given pools

CLI Example:

```
salt '*' zpool.iostat myzpool
```

`salt.modules.zpool.list_` ()

New in version 2015.5.0.

Return a list of all pools in the system with health status and space usage

CLI Example:

```
salt '*' zpool.list
```

`salt.modules.zpool.offline`(*pool\_name*, \**vdevs*, \*\**kwargs*)

New in version 2015.5.0.

Ensure that the specified devices are offline

**Warning:** By default, the OFFLINE state is persistent. The device remains offline when the system is rebooted. To temporarily take a device offline, use `temporary=True`.

CLI Example:

```
salt '*' zpool.offline myzpool /path/to/vdev1 [...] [temporary=True|False]
```

`salt.modules.zpool.online`(*pool\_name*, \**vdevs*, \*\**kwargs*)

New in version 2015.5.0.

Ensure that the specified devices are online

CLI Example:

```
salt '*' zpool.online myzpool /path/to/vdev1 [...]
```

`salt.modules.zpool.replace`(*pool\_name*, *old*, *new*)

Replaces old device with new device.

CLI Example:

```
salt '*' zpool.replace myzpool /path/to/vdev1 /path/to/vdev2
```

`salt.modules.zpool.scrub`(*pool\_name=None*)

Begin a scrub

CLI Example:

```
salt '*' zpool.scrub myzpool
```

`salt.modules.zpool.status`(*name=""*)

Return the status of the named zpool

CLI Example:

```
salt '*' zpool.status myzpool
```

`salt.modules.zpool.zpool_list`()

Deprecated since version 2014.7.0: Use `list_()` instead.

Return a list of all pools in the system with health status and space usage

CLI Example:

```
salt '*' zpool.zpool_list
```

### 30.16.287 salt.modules.zypper

Package support for openSUSE via the zypper package manager

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `'pkg.install' is not available`), see [here](#).

depends

- zypp Python module. Install with `zypper install python-zypp`

`salt.modules.zypper.add_lock`(*name=None, pkgs=None, \*\*kwargs*)

Add a package lock. Specify packages to lock by exact name.

CLI Example:

```
salt '*' pkg.add_lock <package name>
salt '*' pkg.add_lock <package1>,<package2>,<package3>
salt '*' pkg.add_lock pkgs='["foo", "bar"]'
```

`salt.modules.zypper.clean_locks`()

Remove unused locks that do not currently (with regard to repositories used) lock any package.

CLI Example:

```
salt '*' pkg.clean_locks
```

`salt.modules.zypper.del_repo`(*repo*)

Delete a repo.

CLI Examples:

```
salt '*' pkg.del_repo alias
```

`salt.modules.zypper.diff`(\**paths*)

Return a formatted diff between current files and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

**Parameters** `path` -- Full path to the installed file

**Returns** Difference string or raises an exception if examined file is binary.

CLI example:

```
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

`salt.modules.zypper.download`(\**packages*)

Download packages to the local disk.

CLI example:

```
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```

`salt.modules.zypper.file_dict`(\**packages*)

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of *every* file on the system's rpm database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.zypper.file_list`(\**packages*)

List the files that belong to a package. Not specifying any packages will return a list of *every* file on the system's rpm database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

`salt.modules.zypper.get_repo(repo, **kwargs)`

Display a repo.

CLI Example:

```
salt '*' pkg.get_repo alias
```

`salt.modules.zypper.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, **kwargs)`

Install the passed package(s), add refresh=True to run 'zypper refresh' before package is installed.

**name** The name of the package to be installed. Note that this parameter is ignored if either 'pkgs' or 'sources' is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the 'sources' option.

CLI Example:

```
salt '*' pkg.install <package name>
```

**refresh** Whether or not to refresh the package database before installing.

**fromrepo** Specify a package repository to install from.

**version** Can be either a version number, or the combination of a comparison operator (<, >, <=, >=, =) and a version number (ex. '>1.2.3-4'). This parameter is ignored if 'pkgs' or 'sources' is passed.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. As with the version parameter above, comparison operators can be used to target a specific version of a package.

CLI Examples:

```
salt '*' pkg.install pkgs=['foo', 'bar']
salt '*' pkg.install pkgs=['foo', {'bar': '1.2.3-4'}]
salt '*' pkg.install pkgs=['foo', {'bar': '<1.2.3-4'}]
```

**sources** A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources=[{"foo": "salt://foo.rpm"}, {"bar": "salt://bar.rpm"}]
```

Returns a dict containing the new package names and versions:

```
{'package': {'old': '<old-version>',
              'new': '<new-version>'}}
```

`salt.modules.zypper.latest_version(*names, **kwargs)`

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

**salt.modules.zypper.list\_installed\_patterns()**

List installed patterns on the system.

CLI Examples:

```
salt '*' pkg.list_installed_patterns
```

**salt.modules.zypper.list\_locks()**

List current package locks.

Return a dict containing the locked package with attributes:

```
{'<package>': {'case_sensitive': '<case_sensitive>',
               'match_type': '<match_type>'
               'type': '<type>'}}
```

CLI Example:

```
salt '*' pkg.list_locks
```

**salt.modules.zypper.list\_patterns()**

List all known patterns from available repos.

CLI Examples:

```
salt '*' pkg.list_patterns
```

**salt.modules.zypper.list\_pkgs(*versions\_as\_list=False, \*\*kwargs*)**

List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

**salt.modules.zypper.list\_products()**

List all installed SUSE products.

CLI Examples:

```
salt '*' pkg.list_products
```

**salt.modules.zypper.list\_repos()**

Lists all repos.

CLI Example:

```
salt '*' pkg.list_repos
```

**salt.modules.zypper.list\_upgrades(*refresh=True*)**

List all available package upgrades on this system

CLI Example:

```
salt '*' pkg.list_upgrades
```

`salt.modules.zypper.mod_repo(repo, **kwargs)`

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following values are specified:

**repo or alias** alias by which the zypper refers to the repo

**url, mirrorlist or baseurl** the URL for zypper to reference

**enabled** enable or disable (True or False) repository, but do not remove if disabled.

**refresh** enable or disable (True or False) auto-refresh of the repository.

**cache** Enable or disable (True or False) RPM files caching.

**gpgcheck** Enable or disable (True or False) GPG check for this repository.

Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in mind that a name cannot be deleted, and a url can only be deleted if a mirrorlist is specified (or vice versa).

CLI Examples:

```
salt '*' pkg.mod_repo alias alias=new_alias
salt '*' pkg.mod_repo alias url=mirrorlist=http://host.com/
```

`salt.modules.zypper.modified(*packages, **flags)`

List the modified files that belong to a package. Not specifying any packages will return a list of `_all_` modified files on the system's RPM database.

New in version 2015.5.0.

Filtering by flags (True or False):

**size** Include only files where size changed.

**mode** Include only files which file's mode has been changed.

**checksum** Include only files which MD5 checksum has been changed.

**device** Include only files which major and minor numbers has been changed.

**symlink** Include only files which are symbolic link contents.

**owner** Include only files where owner has been changed.

**group** Include only files where group has been changed.

**time** Include only files where modification time of the file has been changed.

**capabilities** Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

CLI Examples:

```
salt '*' pkg.modified
salt '*' pkg.modified httpd
salt '*' pkg.modified httpd postfix
salt '*' pkg.modified httpd owner=True group=False
```

`salt.modules.zypper.owner(*paths)`

Return the name of the package that owns the file. Multiple file paths can be passed. If a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:

```
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```

`salt.modules.zypper.purge` (*name=None, pkgs=None, \*\*kwargs*)

Recursively remove a package and all dependencies which were installed with it, this will call a `zypper -n remove -u`

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

`salt.modules.zypper.refresh_db` ()

Just run a `zypper refresh`, return a dict:

```
{'<database name>': Bool}
```

CLI Example:

```
salt '*' pkg.refresh_db
```

`salt.modules.zypper.remove` (*name=None, pkgs=None, \*\*kwargs*)

Remove packages with `zypper -n remove`

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

`salt.modules.zypper.remove_lock` (*name=None, pkgs=None, \*\*kwargs*)

Remove specified package lock.

CLI Example:

```
salt '*' pkg.remove_lock <package name>
salt '*' pkg.remove_lock <package1>,<package2>,<package3>
salt '*' pkg.remove_lock pkgs='["foo", "bar"]'
```

`salt.modules.zypper.search(criteria)`  
List known packages, available to the system.

CLI Examples:

```
salt '*' pkg.search <criteria>
```

`salt.modules.zypper.upgrade(refresh=True)`  
Run a full system upgrade, a zypper upgrade  
Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',  
              'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

`salt.modules.zypper.upgrade_available(name)`  
Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

`salt.modules.zypper.verify(*names, **kwargs)`  
Runs an rpm -Va on a system, and returns the results in a dict  
Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the `ignore_types` keyword argument

CLI Example:

```
salt '*' pkg.verify  
salt '*' pkg.verify httpd  
salt '*' pkg.verify 'httpd postfix'  
salt '*' pkg.verify 'httpd postfix' ignore_types=['config','doc']
```

`salt.modules.zypper.version(*names, **kwargs)`  
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>  
salt '*' pkg.version <package1> <package2> <package3> ...
```

## 30.17 Full list of netapi modules

### 30.17.1 rest\_cherry.py

#### A REST API for Salt

New in version 2014.7.0.

**depends**

- CherryPy Python module. Version 3.2.3 is currently recommended when SSL is enabled, since this version worked the best with SSL in internal testing. Versions 3.2.3 - 4.x can be used if SSL is not enabled. Be aware that there is a known [SSL error](#) introduced in version 3.2.5. The issue was reportedly resolved with CherryPy milestone 3.3, but the patch was committed for version 3.6.1.

#### optdepends

- ws4py Python module for websockets support.

#### client\_libraries

- Java: <https://github.com/SUSE/saltstack-netapi-client-java>
- Python: <https://github.com/saltstack/pepper>

**configuration** All authentication is done through Salt's *external\_auth* system which requires additional configuration not described here.

Example production-ready configuration; add to the Salt master config file and restart the `salt-master` and `salt-api` daemons:

```
rest_cherrypy:
  port: 8000
  ssl_cert: /etc/pki/tls/certs/localhost.crt
  ssl_key: /etc/pki/tls/certs/localhost.key
```

Using only a secure HTTPS connection is strongly recommended since Salt authentication credentials will be sent over the wire.

A self-signed certificate can be generated using the `create_self_signed_cert()` execution function. Running this function requires pyOpenSSL and the `salt-call` script is available in the `salt-minion` package.

```
salt-call --local tls.create_self_signed_cert
```

All available configuration options are detailed below. These settings configure the CherryPy HTTP server and do not apply when using an external server such as Apache or Nginx.

#### port Required

The port for the webservice to listen on.

**host** [0.0.0.0] The socket interface for the HTTP server to listen on.

**debug** [False] Starts the web server in development mode. It will reload itself when the underlying code is changed and will output more debugging info.

**ssl\_cert** The path to a SSL certificate. (See below)

**ssl\_key** The path to the private key for your SSL certificate. (See below)

**disable\_ssl** A flag to disable SSL. Warning: your Salt authentication credentials will be sent in the clear!

**webhook\_disable\_auth** [False] The *Webhook* URL requires authentication by default but external services cannot always be configured to send authentication. See the Webhook documentation for suggestions on securing this interface.

**webhook\_url** [/hook] Configure the URL endpoint for the *Webhook* entry point.

**thread\_pool** [100] The number of worker threads to start up in the pool.

**socket\_queue\_size** [30] Specify the maximum number of HTTP connections to queue.

**expire\_responses** [True] Whether to check for and kill HTTP responses that have exceeded the default timeout.

**max\_request\_body\_size** [1048576] Maximum size for the HTTP request body.

**collect\_stats** [False] Collect and report statistics about the CherryPy server

Reports are available via the [Stats](#) URL.

**static** A filesystem path to static HTML/JavaScript/CSS/image assets.

**static\_path** [/static] The URL prefix to use when serving static assets out of the directory specified in the `static` setting.

**app** A filesystem path to an HTML file that will be served as a static file. This is useful for bootstrapping a single-page JavaScript app.

**app\_path** [/app] The URL prefix to use for serving the HTML file specified in the `app` setting. This should be a simple name containing no slashes.

Any path information after the specified path is ignored; this is useful for apps that utilize the HTML5 history API.

**root\_prefix** [/] A URL path to the main entry point for the application. This is useful for serving multiple applications from the same URL.

## Authentication

Authentication is performed by passing a session token with each request. Tokens are generated via the [Login](#) URL.

The token may be sent in one of two ways:

- Include a custom header named `X-Auth-Token`.

For example, using curl:

```
curl -sSk https://localhost:8000/login \  
  -H 'Accept: application/x-yaml' \  
  -d username=saltdev \  
  -d password=saltdev \  
  -d eauth=auto
```

Copy the token value from the output and include it in subsequent requests:

```
curl -sSk https://localhost:8000 \  
  -H 'Accept: application/x-yaml' \  
  -H 'X-Auth-Token: 697adbdc8fe971d09ae4c2a3add7248859c87079' \  
  -d client=local \  
  -d tgt='*' \  
  -d fun=test.ping
```

- Sent via a cookie. This option is a convenience for HTTP clients that automatically handle cookie support (such as browsers).

For example, using curl:

```
# Write the cookie file:  
curl -sSk https://localhost:8000/login \  
  -c ~/cookies.txt \  
  -H 'Accept: application/x-yaml' \  
  -d username=saltdev \  
  -d password=saltdev
```

```

-d password=saltdev \
-d eauth=auto

# Read the cookie file:
curl -sSk https://localhost:8000 \
  -b ~/cookies.txt \
  -H 'Accept: application/x-yaml' \
  -d client=local \
  -d tgt='*' \
  -d fun=test.ping

```

**See also:**

You can bypass the session handling via the *Run* URL.

**Usage**

Commands are sent to a running Salt master via this module by sending HTTP requests to the URLs detailed below.

**Content negotiation**

This REST interface is flexible in what data formats it will accept as well as what formats it will return (e.g., JSON, YAML, x-www-form-urlencoded).

- Specify the format of data in the request body by including the *Content-Type* header.
- Specify the desired data format for the response body with the *Accept* header.

Data sent in *POST* and *PUT* requests must be in the format of a list of lowstate dictionaries. This allows multiple commands to be executed in a single HTTP request. The order of commands in the request corresponds to the return for each command in the response.

Lowstate, broadly, is a dictionary of values that are mapped to a function call. This pattern is used pervasively throughout Salt. The functions called from netapi modules are described in Client Interfaces.

The following example (in JSON format) causes Salt to execute two commands, a command sent to minions as well as a runner function on the master:

```

[
  {
    "client": "local",
    "tgt": "*",
    "fun": "test.fib",
    "arg": ["10"]
  },
  {
    "client": "runner",
    "fun": "jobs.lookup_jid",
    "jid": "20130603122505459265"
  }
]

```

**x-www-form-urlencoded**

Sending JSON or YAML in the request body is simple and most flexible, however sending data in urlencoded format is also supported with the caveats below. It is the default format for HTML forms, many JavaScript libraries, and the **curl** command.

For example, the equivalent to running `salt '*' test.ping` is sending `fun=test.ping&arg&client=local&tgt=*` in the HTTP request body.

Caveats:

- Only a single command may be sent per HTTP request.
- Repeating the `arg` parameter multiple times will cause those parameters to be combined into a single list.

Note, some popular frameworks and languages (notably jQuery, PHP, and Ruby on Rails) will automatically append empty brackets onto repeated parameters. E.g., `arg=one`, `arg=two` will be sent as `arg[]=one`, `arg[]=two`. This is not supported; send JSON or YAML instead.

---

## Deployment

The `rest_cherry.py` netapi module is a standard Python WSGI app. It can be deployed one of two ways.

### `salt-api` using the CherryPy server

The default configuration is to run this module using `salt-api` to start the Python-based CherryPy server. This server is lightweight, multi-threaded, encrypted with SSL, and should be considered production-ready.

### Using a WSGI-compliant web server

This module may be deployed on any WSGI-compliant server such as Apache with `mod_wsgi` or Nginx with `FastCGI`, to name just two (there are many).

Note, external WSGI servers handle URLs, paths, and SSL certs directly. The `rest_cherry.py` configuration options are ignored and the `salt-api` daemon does not need to be running at all. Remember Salt authentication credentials are sent in the clear unless SSL is being enforced!

An example Apache virtual host configuration:

```
<VirtualHost *:80>
    ServerName example.com
    ServerAlias *.example.com

    ServerAdmin webmaster@example.com

    LogLevel warn
    ErrorLog /var/www/example.com/logs/error.log
    CustomLog /var/www/example.com/logs/access.log combined

    DocumentRoot /var/www/example.com/htdocs

    WSGIScriptAlias / /path/to/salt/netapi/rest_cherry.py
</VirtualHost>
```

## REST URI Reference

- /
- /login
- /logout
- /minions
- /jobs
- /run
- /events
- /hook
- /keys
- /ws
- /stats

/

class salt.netapi.rest\_cherry.py.app.**LowDataAdapter**

The primary entry point to Salt's REST API

**GET()**

An explanation of the API with links of where to go next

**GET /**

Request Headers

- **Accept** -- the desired response format.

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:

```
curl -i localhost:8000
```

```
GET / HTTP/1.1
Host: localhost:8000
Accept: application/json
```

Example response:

```
HTTP/1.1 200 OK
Content-Type: application/json
```

**POST**

Mock out specified imports

This allows autodoc to do its thing without having oodles of req'd installed libs. This doesn't work with `import *` imports.

<http://read-the-docs.readthedocs.org/en/latest/faq.html#i-get-import-errors-on-libraries-that-depend-on-c-modules>

**/login**

class salt.netapi.rest\_cherry.py.app.**Login**(\*args, \*\*kwargs)

Log in to receive a session token

*Authentication information.*

**GET()**

Present the login interface

**GET /login**

An explanation of how to log in.

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

**Example request:**

```
curl -i localhost:8000/login
```

```
GET /login HTTP/1.1
Host: localhost:8000
Accept: text/html
```

**Example response:**

```
HTTP/1.1 200 OK
Content-Type: text/html
```

**POST (\*\*kwargs)**

*Authenticate* against Salt's eauth system

**POST /login****Request Headers**

- **X-Auth-Token** -- a session token from *Login*.
- **Accept** -- the desired response format.
- **Content-Type** -- the format of the request body.

**Form Parameters**

- **eauth** -- the eauth backend configured for the user
- **username** -- username
- **password** -- password

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

**Example request:**

```
curl -si localhost:8000/login \
  -H "Accept: application/json" \
  -d username='saltuser' \
  -d password='saltpass' \
  -d eauth='pam'
```

```
POST / HTTP/1.1
Host: localhost:8000
Content-Length: 42
Content-Type: application/x-www-form-urlencoded
Accept: application/json
```

```
username=saltuser&password=saltpass&eauth=pam
```

**Example response:**

```

HTTP/1.1 200 OK
Content-Type: application/json
Content-Length: 206
X-Auth-Token: 6d1b722e
Set-Cookie: session_id=6d1b722e; expires=Sat, 17 Nov 2012 03:23:52 GMT; Path=/

{"return": {
  "token": "6d1b722e",
  "start": 1363805943.776223,
  "expire": 1363849143.776224,
  "user": "saltuser",
  "eauth": "pam",
  "perms": [
    "grains.*",
    "status.*",
    "sys.*",
    "test.*"
  ]
}}
```

### /logout

class salt.netapi.rest\_cherrypy.app.**Logout**

Class to remove or invalidate sessions

#### POST()

Destroy the currently active session and expire the session cookie

### /minions

class salt.netapi.rest\_cherrypy.app.**Minions**

Convenience URLs for working with minions

#### GET (*mid=None*)

A convenience URL for getting lists of minions or getting minion details

#### GET /minions/*(mid)*

Request Headers

- **X-Auth-Token** -- a session token from *Login*.
- **Accept** -- the desired response format.

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:

```
curl -i localhost:8000/minions/ms-3
```

```
GET /minions/ms-3 HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
```

Example response:

```

HTTP/1.1 200 OK
Content-Length: 129005
Content-Type: application/x-yaml

return:
- ms-3:
  grains.items:
  ...

```

**POST** (*\*\*kwargs*)

Start an execution command and immediately return the job id

**POST** /minions

## Request Headers

- **X-Auth-Token** -- a session token from *Login*.
- **Accept** -- the desired response format.
- **Content-Type** -- the format of the request body.

## Response Headers

- **Content-Type** -- the format of the response body; depends on the *Accept* request header.

## Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

*lowstate* data describing Salt commands must be sent in the request body. The `client` option will be set to `local_async()`.

## Example request:

```

curl -sSi localhost:8000/minions \
  -H "Accept: application/x-yaml" \
  -d tgt='*' \
  -d fun='status.diskusage'

```

```

POST /minions HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 26
Content-Type: application/x-www-form-urlencoded

tgt=*&fun=status.diskusage

```

## Example response:

```

HTTP/1.1 202 Accepted
Content-Length: 86
Content-Type: application/x-yaml

return:
- jid: '20130603122505459265'
  minions: [ms-4, ms-3, ms-2, ms-1, ms-0]
  _links:
    jobs:
      - href: /jobs/20130603122505459265

```

**/jobs**

```
class salt.netapi.rest_cherry.py.app.Jobs
```

**GET** (*jid=None*)

A convenience URL for getting lists of previously run jobs or getting the return from a single job

**GET** **/jobs/**(*jid*)

List jobs or show a single job from the job cache.

**Request Headers**

- **X-Auth-Token** -- a session token from *Login*.
- **Accept** -- the desired response format.

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

**Example request:**

```
curl -i localhost:8000/jobs
```

```
GET /jobs HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
```

**Example response:**

```
HTTP/1.1 200 OK
Content-Length: 165
Content-Type: application/x-yaml
```

```
return:
- '20121130104633606931':
  Arguments:
  - '3'
  Function: test.fib
  Start Time: 2012, Nov 30 10:46:33.606931
  Target: jerry
  Target-type: glob
```

**Example request:**

```
curl -i localhost:8000/jobs/20121130104633606931
```

```
GET /jobs/20121130104633606931 HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
```

**Example response:**

```
HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml
```

```
info:
- Arguments:
  - '3'
  Function: test.fib
```

```

Minions:
- jerry
Start Time: 2012, Nov 30 10:46:33.606931
Target: '*'
Target-type: glob
User: saltdev
jid: '20121130104633606931'
return:
- jerry:
  - - 0
  - 1
  - 1
  - 2
  - 6.9141387939453125e-06

```

## /run

### class salt.netapi.rest\_cherrypy.app.Run

Class to run commands without normal session handling

#### POST (\*\*kwargs)

Run commands bypassing the *normal session handling*

#### POST /run

This entry point is primarily for ``one-off'' commands. Each request must pass full Salt authentication credentials. Otherwise this URL is identical to the *root URL (/)*.

*lowstate* data describing Salt commands must be sent in the request body.

#### Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

#### Example request:

```

curl -sS localhost:8000/run \
-H 'Accept: application/x-yaml' \
-d client='local' \
-d tgt='*' \
-d fun='test.ping' \
-d username='saltdev' \
-d password='saltdev' \
-d eauth='pam'

```

#### POST /run HTTP/1.1

```

Host: localhost:8000
Accept: application/x-yaml
Content-Length: 75
Content-Type: application/x-www-form-urlencoded

```

```
client=local&tgt=*&fun=test.ping&username=saltdev&password=saltdev&eauth=pam
```

#### Example response:

```

HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

```

```

return:
- ms-0: true
  ms-1: true
  ms-2: true
  ms-3: true
  ms-4: true

```

The /run endpoint can also be used to issue commands using the salt-ssh subsystem.

When using salt-ssh, eauth credentials should not be supplied. Instead, authentication should be handled by the SSH layer itself. The use of the salt-ssh client does not require a salt master to be running. Instead, only a roster file must be present in the salt configuration directory.

All SSH client requests are synchronous.

**\*\* Example SSH client request:\*\***

```

curl -sS localhost:8000/run \
  -H 'Accept: application/x-yaml' \
  -d client='ssh' \
  -d tgt='*' \
  -d fun='test.ping'

```

```

POST /run HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 75
Content-Type: application/x-www-form-urlencoded

client=ssh&tgt=*&fun=test.ping

```

**Example SSH response:**

```

return:
- silver:
  fun: test.ping
  fun_args: []
  id: silver
  jid: '20141203103525666185'
  retcode: 0
  return: true
  success: true

```

## /events

### class salt.netapi.rest\_cherry.py.app.Events

Expose the Salt event bus

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure.

**See also:**

events

**GET** (*token=None, salt\_token=None*)

An HTTP stream of the Salt master event bus

This stream is formatted per the Server Sent Events (SSE) spec. Each event is formatted as JSON.

**GET /events**

## Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

## Query Parameters

- **token** -- optional parameter containing the token ordinarily supplied via the X-Auth-Token header in order to allow cross-domain requests in browsers that do not include CORS support in the EventSource API. E.g., `curl -NsS localhost:8000/events?token=308650d`
- **salt\_token** -- optional parameter containing a raw Salt *eaauth token* (not to be confused with the token returned from the /login URL). E.g., `curl -NsS localhost:8000/events?salt_token=30742765`

## Example request:

```
curl -NsS localhost:8000/events
```

```
GET /events HTTP/1.1
Host: localhost:8000
```

## Example response:

Note, the `tag` field is not part of the spec. SSE compliant clients should ignore unknown fields. This addition allows non-compliant clients to only watch for certain tags without having to deserialize the JSON object each time.

```
HTTP/1.1 200 OK
Connection: keep-alive
Cache-Control: no-cache
Content-Type: text/event-stream;charset=utf-8

retry: 400

tag: salt/job/20130802115730568475/new
data: {'tag': 'salt/job/20130802115730568475/new', 'data': {'minions': ['ms-4', 'ms-3', 'ms-2', 'ms-1']}}

tag: salt/job/20130802115730568475/ret/jerry
data: {'tag': 'salt/job/20130802115730568475/ret/jerry', 'data': {'jid': '20130802115730568475', 'ret': {'minions': ['ms-4', 'ms-3', 'ms-2', 'ms-1']}}}
```

The event stream can be easily consumed via JavaScript:

```
var source = new EventSource('/events');
source.onopen = function() { console.debug('opening') };
source.onerror = function(e) { console.debug('error!', e) };
source.onmessage = function(e) {
    console.debug('Tag: ', e.data.tag)
    console.debug('Data: ', e.data.data)
};
```

Or using CORS:

```
var source = new EventSource('/events?token=ecd589e4e01912cf3c4035afad73426dbb8dbba75', {withCredentials: true});
```

It is also possible to consume the stream via the shell.

Records are separated by blank lines; the `data:` and `tag:` prefixes will need to be removed manually before attempting to unserialize the JSON.

`curl`'s `-N` flag turns off input buffering which is required to process the stream incrementally.

Here is a basic example of printing each event as it comes in:

```
curl -NsS localhost:8000/events | \
  while IFS= read -r line ; do
    echo $line
  done
```

Here is an example of using awk to filter events based on tag:

```
curl -NsS localhost:8000/events | \
  awk '
    BEGIN { RS=""; FS="\n" }
    $1 ~ /^tag: salt\/job\/[0-9]+\\/new$/ { print $0 }
  '
tag: salt/job/20140112010149808995/new
data: {"tag": "salt/job/20140112010149808995/new", "data": {"tgt_type": "glob", "jid": "20140112010149808995"}, "fun_args": []}
tag: 20140112010149808995
data: {"tag": "20140112010149808995", "data": {"fun_args": [], "jid": "20140112010149808995"}, "fun_args": []}
```

## /hook

### class salt.netapi.rest\_cherrypy.app.Webhook

A generic web hook entry point that fires an event on Salt's event bus

External services can POST data to this URL to trigger an event in Salt. For example, Amazon SNS, Jenkins-CI or Travis-CI, or GitHub web hooks.

---

**Note:** Be mindful of security

Salt's Reactor can run any code. A Reactor SLS that responds to a hook event is responsible for validating that the event came from a trusted source and contains valid data.

**This is a generic interface and securing it is up to you!**

This URL requires authentication however not all external services can be configured to authenticate. For this reason authentication can be selectively disabled for this URL. Follow best practices -- always use SSL, pass a secret key, configure the firewall to only allow traffic from a known source, etc.

---

The event data is taken from the request body. The *Content-Type* header is respected for the payload.

The event tag is prefixed with `salt/netapi/hook` and the URL path is appended to the end. For example, a POST request sent to `/hook/mycompany/myapp/mydata` will produce a Salt event with the tag `salt/netapi/hook/mycompany/myapp/mydata`.

The following is an example `.travis.yml` file to send notifications to Salt of successful test runs:

```
language: python
script: python -m unittest tests
after_success:
  - |
    curl -sSk https://saltapi-url.example.com:8000/hook/travis/build/success
```

See also:

events, reactor

**POST** (*\*args*, *\*\*kwargs*)

Fire an event in Salt with a custom event tag and data

**POST** /hook

## Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available
- **413** -- request body is too large

## Example request:

```
curl -sS localhost:8000/hook -d foo='Foo!' -d bar='Bar!'
```

```
POST /hook HTTP/1.1
Host: localhost:8000
Content-Length: 16
Content-Type: application/x-www-form-urlencoded

foo=Foo&bar=Bar!
```

## Example response:

```
HTTP/1.1 200 OK
Content-Length: 14
Content-Type: application/json

{"success": true}
```

As a practical example, an internal continuous-integration build server could send an HTTP POST request to the URL `https://localhost:8000/hook/mycompany/build/success` which contains the result of a build and the SHA of the version that was built as JSON. That would then produce the following event in Salt that could be used to kick off a deployment via Salt's Reactor:

```
Event fired at Fri Feb 14 17:40:11 2014
*****
Tag: salt/netapi/hook/mycompany/build/success
Data:
{'_stamp': '2014-02-14_17:40:11.440996',
 'headers': {
   'X-My-Secret-Key': 'F0fAgoQjIT@W',
   'Content-Length': '37',
   'Content-Type': 'application/json',
   'Host': 'localhost:8000',
   'Remote-Addr': '127.0.0.1'},
 'post': {'revision': 'aa22a3c4b2e7', 'result': True}}
```

Salt's Reactor could listen for the event:

```
reactor:
- 'salt/netapi/hook/mycompany/build/*':
- /srv/reactor/react_ci_builds.sls
```

And finally deploy the new build:

```
{% set secret_key = data.get('headers', {}).get('X-My-Secret-Key') %}
{% set build = data.get('post', {}) %}

{% if secret_key == 'F0fAgoQjIT@W' and build.result == True %}
deploy_my_app:
  cmd.state.sls:
    - tgt: 'application*'
    - arg:
```

```

    - myapp.deploy
    - kwarg:
      pillar:
        revision: {{ revision }}
{% endif %}

```

## /keys

### class salt.netapi.rest\_cherry.py.app.Keys

Convenience URLs for working with minion keys

New in version 2014.7.0.

These URLs wrap the functionality provided by the *key wheel module* functions.

#### GET

Mock out specified imports

This allows autodoc to do its thing without having oodles of req'd installed libs. This doesn't work with `import * imports`.

<http://read-the-docs.readthedocs.org/en/latest/faq.html#i-get-import-errors-on-libraries-that-depend-on-c-modules>

#### POST

Mock out specified imports

This allows autodoc to do its thing without having oodles of req'd installed libs. This doesn't work with `import * imports`.

<http://read-the-docs.readthedocs.org/en/latest/faq.html#i-get-import-errors-on-libraries-that-depend-on-c-modules>

## /ws

### class salt.netapi.rest\_cherry.py.app.WebsocketEndpoint

Open a WebSocket connection to Salt's event bus

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

See also:

events

#### GET (*token=None, \*\*kwargs*)

Return a websocket connection of Salt's event stream

#### GET /ws/ (*token*)

##### Query Parameters

- **format\_events** -- The event stream will undergo server-side formatting if the `format_events` URL parameter is included in the request. This can be useful to avoid formatting on the client-side:

```
curl -NsS <...snip...> localhost:8000/ws?format_events
```

##### Request Headers

- **X-Auth-Token** -- an authentication token from *Login*.

## Status Codes

- **101** -- switching to the websockets protocol
- **401** -- authentication required
- **406** -- requested Content-Type not available

## Example request:

```
curl -NsSk -H `X-Auth-Token: ffedf49d` -H `Host: localhost:8000` -H `Connection: Upgrade`
-H `Upgrade: websocket` -H `Origin: https://localhost:8000` -H `Sec-WebSocket-Version:
13` -H `Sec-WebSocket-Key: `$(echo -n $RANDOM | base64)` localhost:8000/ws
```

```
GET /ws HTTP/1.1
Connection: Upgrade
Upgrade: websocket
Host: localhost:8000
Origin: https://localhost:8000
Sec-WebSocket-Version: 13
Sec-WebSocket-Key: s65VsgHigh7v/Jcf4nXHnA==
X-Auth-Token: ffedf49d
```

## Example response:

```
HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: mWZjBV9FCglzn1rIKJAxrTFlnJE=
Sec-WebSocket-Version: 13
```

An authentication token **may optionally** be passed as part of the URL for browsers that cannot be configured to send the authentication header or cookie:

```
curl -NsS <...snip...> localhost:8000/ws/ffedf49d
```

The event stream can be easily consumed via JavaScript:

```
// Note, you must be authenticated!
var source = new WebSocket('ws://localhost:8000/ws/d0ce6c1a');
source.onerror = function(e) { console.debug('error!', e); };
source.onmessage = function(e) { console.debug(e.data); };

source.send('websocket client ready')

source.close();
```

Or via Python, using the Python module `websocket-client` for example.

```
# Note, you must be authenticated!

from websocket import create_connection

ws = create_connection('ws://localhost:8000/ws/d0ce6c1a')
ws.send('websocket client ready')

# Look at https://pypi.python.org/pypi/websocket-client/ for more
# examples.
while listening_to_events:
    print ws.recv()

ws.close()
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling `websocket client ready`.

### `/stats`

```
class salt.netapi.rest_cherrypy.app.Stats
```

Expose statistics on the running CherryPy server

#### **GET()**

Return a dump of statistics collected from the CherryPy server

#### **GET /stats**

##### Request Headers

- **X-Auth-Token** -- a session token from *Login*.
- **Accept** -- the desired response format.

##### Response Headers

- **Content-Type** -- the format of the response body; depends on the *Accept* request header.

##### Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

## 30.17.2 rest\_tornado

### A non-blocking REST API for Salt

#### depends

- tornado Python module

**configuration** All authentication is done through Salt's *external auth* system which requires additional configuration not described here.

In order to run `rest_tornado` with the salt-master add the following to the Salt master config file.

```
rest_tornado:
  # can be any port
  port: 8000
  # address to bind to (defaults to 0.0.0.0)
  address: 0.0.0.0
  # socket backlog
  backlog: 128
  ssl_cert: /etc/pki/api/certs/server.crt
  # no need to specify ssl_key if cert and key
  # are in one single file
  ssl_key: /etc/pki/api/certs/server.key
  debug: False
  disable_ssl: False
```

## Authentication

Authentication is performed by passing a session token with each request. Tokens are generated via the *SaltAuthHandler* URL.

The token may be sent in one of two ways:

- Include a custom header named *X-Auth-Token*.
- Sent via a cookie. This option is a convenience for HTTP clients that automatically handle cookie support (such as browsers).

See also:

You can bypass the session handling via the *RunSaltAPIHandler* URL.

## Usage

Commands are sent to a running Salt master via this module by sending HTTP requests to the URLs detailed below.

---

### Content negotiation

This REST interface is flexible in what data formats it will accept as well as what formats it will return (e.g., JSON, YAML, x-www-form-urlencoded).

- Specify the format of data in the request body by including the *Content-Type* header.
  - Specify the desired data format for the response body with the *Accept* header.
- 

Data sent in **POST** and **PUT** requests must be in the format of a list of lowstate dictionaries. This allows multiple commands to be executed in a single HTTP request.

**lowstate** A dictionary containing various keys that instruct Salt which command to run, where that command lives, any parameters for that command, any authentication credentials, what returner to use, etc.

Salt uses the lowstate data format internally in many places to pass command data between functions. Salt also uses lowstate for the *LocalClient()* Python API interface.

The following example (in JSON format) causes Salt to execute two commands:

```
[{
  "client": "local",
  "tgt": "*",
  "fun": "test.fib",
  "arg": ["10"]
},
{
  "client": "runner",
  "fun": "jobs.lookup_jid",
  "jid": "20130603122505459265"
}]
```

Multiple commands in a Salt API request will be executed in serial and makes no gaurantees that all commands will run. Meaning that if test.fib (from the example above) had an exception, the API would still execute ``jobs.lookup\_jid``.

Responses to these lowstates are an in-order list of dicts containing the return data, a yaml response could look like:

```
- ms-1: true
  ms-2: true
- ms-1: foo
  ms-2: bar
```

In the event of an exception while executing a command the return for that lowstate will be a string, for example if no minions matched the first lowstate we would get a return like:

```
- No minions matched the target. No command was sent, no jid was assigned.
- ms-1: true
  ms-2: true
```

---

### x-www-form-urlencoded

Sending JSON or YAML in the request body is simple and most flexible, however sending data in urlencoded format is also supported with the caveats below. It is the default format for HTML forms, many JavaScript libraries, and the **curl** command.

For example, the equivalent to running `salt '*' test.ping` is sending `fun=test.ping&arg&client=local&tgt=*` in the HTTP request body.

Caveats:

- Only a single command may be sent per HTTP request.
- Repeating the `arg` parameter multiple times will cause those parameters to be combined into a single list.

Note, some popular frameworks and languages (notably jQuery, PHP, and Ruby on Rails) will automatically append empty brackets onto repeated parameters. E.g., `arg=one`, `arg=two` will be sent as `arg[]=one`, `arg[]=two`. This is not supported; send JSON or YAML instead.

---

## A Websockets add-on to saltnado

### depends

- tornado Python module

In order to enable `saltnado_websockets` you must add `websockets: True` to your saltnado config block.

```
rest_tornado:
  # can be any port
  port: 8000
  ssl_cert: /etc/pki/api/certs/server.crt
  # no need to specify ssl_key if cert and key
  # are in one single file
  ssl_key: /etc/pki/api/certs/server.key
  debug: False
  disable_ssl: False
  websockets: True
```

## All Events

Exposes all "real-time" events from Salt's event bus on a websocket connection. It should be noted that "Real-time" here means these events are made available to the server as soon as any salt related action (changes to minions,

new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies. Functionality provided by this endpoint is similar to the `/events` endpoint.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain authentication tokens is shown below.

```
% curl -s localhost:8000/login \  
-H "Accept: application/json" \  
-d username='salt' \  
-d password='salt' \  
-d eauth='pam'
```

Which results in the response

```
{  
  "return": [{  
    "perms": [".*", "@runner", "@wheel"],  
    "start": 1400556492.277421,  
    "token": "d0ce6c1a37e99dcc0374392f272fe19c0090cca7",  
    "expire": 1400599692.277422,  
    "user": "salt",  
    "eauth": "pam"  
  }]  
}
```

In this example the token returned is `d0ce6c1a37e99dcc0374392f272fe19c0090cca7` and can be included in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```
// Note, you must be authenticated!  
  
// Get the Websocket connection to Salt  
var source = new WebSocket('wss://localhost:8000/all_events/d0ce6c1a37e99dcc0374392f272fe19c0090cca7');  
  
// Get Salt's "real time" event stream.  
source.onopen = function() { source.send('websocket client ready'); };  
  
// Other handlers  
source.onerror = function(e) { console.debug('error!', e); };  
  
// e.data represents Salt's "real time" event data as serialized JSON.  
source.onmessage = function(e) { console.debug(e.data); };  
  
// Terminates websocket connection and Salt's "real time" event stream on the server.  
source.close();
```

Or via Python, using the Python module `websocket-client` for example. Or the `tornado` client.

```
# Note, you must be authenticated!  
  
from websocket import create_connection
```

```

# Get the Websocket connection to Salt
ws = create_connection('wss://localhost:8000/all_events/d0ce6c1a37e99dcc0374392f272fe19c0090cca7')

# Get Salt's "real time" event stream.
ws.send('websocket client ready')

# Simple listener to print results of Salt's "real time" event stream.
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv()          # Salt's "real time" event data as serialized JSON.

# Terminates websocket connection and Salt's "real time" event stream on the server.
ws.close()

# Please refer to https://github.com/liris/websocket-client/issues/81 when using a self signed cert

```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling `websocket client ready`.

### Formatted Events

Exposes formatted ``real-time'' events from Salt's event bus on a websocket connection. It should be noted that ``Real-time'' here means these events are made available to the server as soon as any salt related action (changes to minions, new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies. Functionality provided by this endpoint is similar to the `/events` end point.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

Formatted events parses the raw ``real time'' event stream and maintains a current view of the following:

- minions
- jobs

A change to the minions (such as addition, removal of keys or connection drops) or jobs is processed and clients are updated. Since we use salt's presence events to track minions, please enable `presence_events` and set a small value for the `loop_interval` in the salt master config file.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain authentication tokens is shown below.

```

% curl -si localhost:8000/login \
  -H "Accept: application/json" \
  -d username='salt' \
  -d password='salt' \
  -d eauth='pam'

```

Which results in the response

```

{
  "return": [{
    "perms": [".*", "@runner", "@wheel"],
    "start": 1400556492.277421,
    "token": "d0ce6c1a37e99dcc0374392f272fe19c0090cca7",

```

```
    "expire": 1400599692.277422,  
    "user": "salt",  
    "eauth": "pam"  
  }  
}
```

In this example the token returned is `d0ce6c1a37e99dcc0374392f272fe19c0090cca7` and can be included in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```
// Note, you must be authenticated!  
  
// Get the Websocket connection to Salt  
var source = new WebSocket('wss://localhost:8000/formatted_events/d0ce6c1a37e99dcc0374392f272fe19c0090cca7');  
  
// Get Salt's "real time" event stream.  
source.onopen = function() { source.send('websocket client ready'); };  
  
// Other handlers  
source.onerror = function(e) { console.debug('error!', e); };  
  
// e.data represents Salt's "real time" event data as serialized JSON.  
source.onmessage = function(e) { console.debug(e.data); };  
  
// Terminates websocket connection and Salt's "real time" event stream on the server.  
source.close();
```

Or via Python, using the Python module `websocket-client` for example. Or the `tornado` client.

```
# Note, you must be authenticated!  
  
from websocket import create_connection  
  
# Get the Websocket connection to Salt  
ws = create_connection('wss://localhost:8000/formatted_events/d0ce6c1a37e99dcc0374392f272fe19c0090cca7');  
  
# Get Salt's "real time" event stream.  
ws.send('websocket client ready')  
  
# Simple listener to print results of Salt's "real time" event stream.  
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.  
while listening_to_events:  
    print ws.recv()      # Salt's "real time" event data as serialized JSON.  
  
# Terminates websocket connection and Salt's "real time" event stream on the server.  
ws.close()  
  
# Please refer to https://github.com/liris/websocket-client/issues/81 when using a self signed cert
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling `websocket client ready`.

## Example responses

Minion information is a dictionary keyed by each connected minion's `id` (`mid`), grains information for each minion is also included.

Minion information is sent in response to the following minion events:

- **connection drops**
  - requires running `manage.present` periodically every `loop_interval` seconds
- minion addition
- minion removal

```
# Not all grains are shown
data: {
  "minions": {
    "minion1": {
      "id": "minion1",
      "grains": {
        "kernel": "Darwin",
        "domain": "local",
        "zmqversion": "4.0.3",
        "kernelrelease": "13.2.0"
      }
    }
  }
}
```

Job information is also tracked and delivered.

Job information is also a dictionary in which each job's information is keyed by salt's `jid`.

```
data: {
  "jobs": {
    "20140609153646699137": {
      "tgt_type": "glob",
      "jid": "20140609153646699137",
      "tgt": "*",
      "start_time": "2014-06-09T15:36:46.700315",
      "state": "complete",
      "fun": "test.ping",
      "minions": {
        "minion1": {
          "return": true,
          "retcode": 0,
          "success": true
        }
      }
    }
  }
}
```

## Setup

### 30.17.3 rest\_wsgi

#### A minimalist REST API for Salt

This `rest_wsgi` module provides a no-frills REST interface for sending commands to the Salt master. There are no dependencies.

Extra care must be taken when deploying this module into production. Please read this documentation in entirety.

All authentication is done through Salt's *external auth* system.

#### Usage

- All requests must be sent to the root URL (/).
- All requests must be sent as a POST request with JSON content in the request body.
- All responses are in JSON.

See also:

[\*rest\\_cherry.py\*](#)

The [\*rest\\_cherry.py\*](#) module is more full-featured, production-ready, and has builtin security features.

#### Deployment

The `rest_wsgi` netapi module is a standard Python WSGI app. It can be deployed one of two ways.

##### Using a WSGI-compliant web server

This module may be run via any WSGI-compliant production server such as Apache with `mod_wsgi` or Nginx with `FastCGI`.

It is strongly recommended that this app be used with a server that supports HTTPS encryption since raw Salt authentication credentials must be sent with every request. Any apps that access Salt through this interface will need to manually manage authentication credentials (either username and password or a Salt token). Tread carefully.

##### **salt-api** using a development-only server

If run directly via the `salt-api` daemon it uses the `wsgiref.simple_server()` that ships in the Python standard library. This is a single-threaded server that is intended for testing and development. **This server does not use encryption**; please note that raw Salt authentication credentials must be sent with every HTTP request.

##### **Running this module via salt-api is not recommended!**

In order to start this module via the `salt-api` daemon the following must be put into the Salt master config:

```
rest_wsgi:
  port: 8001
```

## Usage examples

**POST /**

Example request for a basic test.ping:

```
% curl -sS -i \
  -H 'Content-Type: application/json' \
  -d '[{"eauth":"pam","username":"saltdev","password":"saltdev","client":"local","tgt":"*"}]
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": [{"ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0": true}]}
```

Example request for an asynchronous test.ping:

```
% curl -sS -i \
  -H 'Content-Type: application/json' \
  -d '[{"eauth":"pam","username":"saltdev","password":"saltdev","client":"local_async","tgt":"*"}]
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 103
Content-Type: application/json

{"return": [{"jid": "20130412192112593739", "minions": ["ms--4", "ms--3", "ms--2", "ms--1", "ms--0"]}]}
```

Example request for looking up a job ID:

```
% curl -sS -i \
  -H 'Content-Type: application/json' \
  -d '[{"eauth":"pam","username":"saltdev","password":"saltdev","client":"runner","fun":"job.lookup"}]
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": [{"ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0": true}]}
```

**form lowstate** A list of *lowstate* data appropriate for the *client* interface you are calling.

**status 200** success

**status 401** authentication required

## 30.18 Full list of builtin output modules

Follow one of the below links for further information and examples

[compact](#)

Display compact output data structure

Continued on next page

Table 30.7 -- continued from previous page

<i>highstate</i>	Outputter for displaying results of state runs
<i>json_out</i>	Display return data in JSON format
<i>key</i>	Display salt-key output
<i>nested</i>	Recursively display nested data
<i>newline_values_only</i>	Display values only, separated by newlines
<i>no_out</i>	Display no output
<i>no_return</i>	Display output for minions that did not return
<i>overstatestage</i>	Display clean output of an overstate stage
<i>pprint_out</i>	Python pretty-print (pprint)
<i>progress</i>	Display return data as a progress bar
<i>raw</i>	Display raw output data structure
<i>txt</i>	Simple text outputter
<i>virt_query</i>	virt.query outputter
<i>yaml_out</i>	Display return data in YAML format

### 30.18.1 salt.output.compact

#### Display compact output data structure

Example output:: ``saltdev': {`test_|-always-passes_|-foo_|-succeed_without_changes': {`comment': `Success!', `name': `foo', `start_time': `05:16:26.111814', `result': True, `duration': 1, `__run_num__': 0, `changes': {}}, `test_|-my-custom-combo_|-foo_|-configurable_test_state': {`comment': `bar.baz', `name': `foo', `start_time': `05:16:26.117177', `result': False, `duration': 1, `__run_num__': 4, `changes': {`testing': {`new': `Something pretended to change', `old': `Unchanged'}}}, `test_|-always-fails_|-foo_|-fail_without_changes': {`comment': `Failure!', `name': `foo', `start_time': `05:16:26.113124', `result': False, `duration': 1, `__run_num__': 1, `changes': {}}, `test_|-always-changes-and-succeeds_|-foo_|-succeed_with_changes': {`comment': `Success!', `name': `foo', `start_time': `05:16:26.114570', `result': True, `duration': 0, `__run_num__': 2, `changes': {`testing': {`new': `Something pretended to change', `old': `Unchanged'}}}, `test_|-always-changes-and-fails_|-foo_|-fail_with_changes': {`comment': `Failure!', `name': `foo', `start_time': `05:16:26.115561', `result': False, `duration': 1, `__run_num__': 3, `changes': {`testing': {`new': `Something pretended to change', `old': `Unchanged'}}}}}`myminion': {`foo': {`list': [Hello, `World'], `bar': `baz, `dictionary': {`abc': 123, `def': 456}}}}`

`salt.output.compact.output(data)`

Rather basic....

### 30.18.2 salt.output.highstate

#### Outputter for displaying results of state runs

The return data from the Highstate command is a standard data structure which is parsed by the highstate outputter to deliver a clean and readable set of information about the HighState run on minions.

Two configurations can be set to modify the highstate outputter. These values can be set in the master config to change the output of the `salt` command or set in the minion config to change the output of the `salt-call` command.

**state\_verbose:** By default `state_verbose` is set to `True`, setting this to `False` will instruct the highstate outputter to omit displaying anything in green, this means that nothing with a result of `True` and no changes will not be printed

**state\_output:** The highstate outputter has five output modes, `full`, `terse`, `mixed`, `changes` and `filter`.

- The default is set to `full`, which will display many lines of detailed information for each executed chunk.
- If `terse` is used, then the output is greatly simplified and shown in only one line.
- If `mixed` is used, then terse output will be used unless a state failed, in which case full output will be used.
- If `changes` is used, then terse output will be used if there was no error and no changes, otherwise full output will be used.
- If `filter` is used, then either or both of two different filters can be used: `exclude` or `terse`. These can be set as such from the command line, or in the Salt config as `state_output_exclude` or `state_output_terse`, respectively. The values to exclude must be a comma-separated list of `True`, `False` and/or `None`. Because of parsing nuances, if only one of these is used, it must still contain a comma. For instance: `exclude=True,`.

**state\_tabular:** If `state_output` uses the terse output, set this to `True` for an aligned output format. If you wish to use a custom format, this can be set to a string.

Example output:

```
myminion:
-----
      ID: test.ping
Function: module.run
  Result: True
Comment: Module function test.ping executed
Changes:
         -----
         ret:
           True

Summary
-----
Succeeded: 1
Failed:    0
-----
Total:    0
```

`salt.output.highstate.output(data)`

The HighState Outputter is only meant to be used with the `state.highstate` function, or a function that returns highstate return data.

### 30.18.3 salt.output.json\_out

#### Display return data in JSON format

**configuration** The output format can be configured in two ways: Using the `--out-indent` CLI flag and specifying a positive integer or a negative integer to group JSON from each minion to a single line.

Or setting the `output_indent` setting in the Master or Minion configuration file with one of the following values:

- `Null`: put each minion return on a single line.
- `pretty`: use four-space indents and sort the keys.

- An integer: specify the indentation level.

Salt's outputters operate on a per-minion basis. Each minion return will be output as a single JSON object once it comes in to the master.

Some JSON parsers can guess when an object ends and a new one begins but many can not. A good way to differentiate between each minion return is to use the single-line output format and to parse each line individually. Example output (truncated):

```
{ "dave": { "en0": { "hwaddr": "02:b0:26:32:4c:69", ... } } }
{ "jerry": { "en0": { "hwaddr": "02:26:ab:0d:b9:0d", ... } } }
{ "kevin": { "en0": { "hwaddr": "02:6d:7f:ce:9f:ee", ... } } }
{ "mike": { "en0": { "hwaddr": "02:48:a2:4b:70:a0", ... } } }
{ "phill": { "en0": { "hwaddr": "02:1d:cc:a2:33:55", ... } } }
{ "stuart": { "en0": { "hwaddr": "02:9a:e0:ea:9e:3c", ... } } }
```

```
salt.output.json_out.output(data)
    Print the output data in JSON
```

### 30.18.4 salt.output.key

#### Display salt-key output

The salt-key command makes use of this outputter to format its output.

```
salt.output.key.output(data)
    Read in the dict structure generated by the salt key API methods and print the structure.
```

### 30.18.5 salt.output.nested

#### Recursively display nested data

This is the default outputter for most execution functions.

Example output:

```
myminion:
-----
  foo:
    -----
    bar:
      baz
    dictionary:
      -----
      abc:
        123
      def:
        456
    list:
      - Hello
      - World
```

```
class salt.output.nested.NestDisplay
    Manage the nested display contents
```

**display**(*ret, indent, prefix, out*)

Recursively iterate down through data structures to determine output

**ustring**(*indent, color, msg, prefix='`, suffix='`, endc=None*)

`salt.output.nested.output`(*ret*)

Display ret data

### 30.18.6 salt.output.newline\_values\_only

#### Display values only, separated by newlines

New in version 2015.5.0.

This outputter is designed for Salt CLI return data. It will do the following to the return dict:

1. Get just the values (ignoring the minion IDs).
2. Each value, if it is iterable, is split a separate line.
3. Each minion's values are separated by newlines.

This results in a single string of return data containing all the values from the various minions.

**Warning:** As noted above, this outputter will discard the minion ID. If the minion ID is important, then an outputter that returns the full return dictionary in a parsable format (such as `json`, `pprint`, or `yaml`) may be more suitable.

#### Example 1

##### Input

```
{
  'myminion': ['127.0.0.1', '10.0.0.1'],
  'second-minion': ['127.0.0.1', '10.0.0.2']
}
```

##### Output

```
127.0.0.1
10.0.0.1
127.0.0.1
10.0.0.2
```

#### Example 2

##### Input

```
{
  'myminion': 8,
  'second-minion': 10
}
```

## Output

```
8
10
```

`salt.output.newline_values_only.output(data)`  
Display modified ret data

### 30.18.7 salt.output.no\_out

#### Display no output

No output is produced when this outputter is selected

`salt.output.no_out.output(ret)`  
Don't display data. Used when you only are interested in the return.

### 30.18.8 salt.output.no\_return

#### Display output for minions that did not return

This outputter is used to display notices about which minions failed to return when a salt function is run with `-v` or `--verbose`. It should not be called directly from the CLI.

Example output:

```
virtucentos:
  Minion did not return
```

`class salt.output.no_return.NestDisplay`  
Create generator for nested output

`display(ret, indent, prefix, out)`  
Recursively iterate down through data structures to determine output

`salt.output.no_return.output(ret)`  
Display ret data

### 30.18.9 salt.output.overstatestage

#### Display clean output of an overstate stage

This outputter is used to display *OverState* stages, and should not be called directly.

`salt.output.overstatestage.output(data)`  
Format the data for printing stage information from the overstate system

### 30.18.10 salt.output.pprint\_out

#### Python pretty-print (pprint)

The python pretty-print system was once the default outputter. It simply passes the return data through to `pprint.pformat` and prints the results.

Example output:

```
{'saltmine': {'foo': {'bar': 'baz',  
                    'dictionary': {'abc': 123, 'def': 456},  
                    'list': ['Hello', 'World']}}}}
```

`salt.output.pprint_out.output(data)`  
Print out via pretty print

### 30.18.11 salt.output.progress

Display return data as a progress bar

`salt.output.progress.output(ret, bar)`  
Update the progress bar

`salt.output.progress.progress_iter(progress)`  
Initialize and return a progress bar iter

### 30.18.12 salt.output.raw

#### Display raw output data structure

This outputter simply displays the output as a python data structure, by printing a string representation of it. It is similar to the `pprint` outputter, only the data is not nicely formatted/indented.

This was the original outputter used by Salt before the outputter system was developed.

Example output:

```
{'myminion': {'foo': {'list': ['Hello', 'World'], 'bar': 'baz', 'dictionary': {'abc': 123, 'def': 456}}}}
```

`salt.output.raw.output(data)`  
Rather basic...

### 30.18.13 salt.output.txt

#### Simple text outputter

The txt outputter has been developed to make the output from shell commands on minions appear as they do when the command is executed on the minion.

`salt.output.txt.output(data)`  
Output the data in lines, very nice for running commands

### 30.18.14 salt.output.virt\_query

#### virt.query outputter

Used to display the output from the *virt.query* runner.

`salt.output.virt_query.output(data)`  
 Display output for the salt-run virt.query function

### 30.18.15 salt.output.yaml\_out

#### Display return data in YAML format

This outputter defaults to printing in YAML block mode for better readability.

Example output:

```
saltmine:
  foo:
    bar: baz
    dictionary:
      abc: 123
      def: 456
    list:
      - Hello
      - World
```

`salt.output.yaml_out.output(data)`  
 Print out YAML using the block mode

## 30.19 Peer Communication

Salt 0.9.0 introduced the capability for Salt minions to publish commands. The intent of this feature is not for Salt minions to act as independent brokers one with another, but to allow Salt minions to pass commands to each other.

In Salt 0.10.0 the ability to execute runners from the master was added. This allows for the master to return collective data from runners back to the minions via the peer interface.

The peer interface is configured through two options in the master configuration file. For minions to send commands from the master the `peer` configuration is used. To allow for minions to execute runners from the master the `peer_run` configuration is used.

Since this presents a viable security risk by allowing minions access to the master publisher the capability is turned off by default. The minions can be allowed access to the master publisher on a per minion basis based on regular expressions. Minions with specific ids can be allowed access to certain Salt modules and functions.

### 30.19.1 Peer Configuration

The configuration is done under the `peer` setting in the Salt master configuration file, here are a number of configuration possibilities.

The simplest approach is to enable all communication for all minions, this is only recommended for very secure environments.

```
peer:
  .*:
    - .*
```

This configuration will allow minions with IDs ending in example.com access to the test, ps, and pkg module functions.

```
peer:
  .*example.com:
    - test.*
    - ps.*
    - pkg.*
```

The configuration logic is simple, a regular expression is passed for matching minion ids, and then a list of expressions matching minion functions is associated with the named minion. For instance, this configuration will also allow minions ending with foo.org access to the publisher.

```
peer:
  .*example.com:
    - test.*
    - ps.*
    - pkg.*
  .*foo.org:
    - test.*
    - ps.*
    - pkg.*
```

### 30.19.2 Peer Runner Communication

Configuration to allow minions to execute runners from the master is done via the `peer_run` option on the master. The `peer_run` configuration follows the same logic as the `peer` option. The only difference is that access is granted to runner modules.

To open up access to all minions to all runners:

```
peer_run:
  .*:
    - .*
```

This configuration will allow minions with IDs ending in example.com access to the manage and jobs runner functions.

```
peer_run:
  .*example.com:
    - manage.*
    - jobs.*
```

### 30.19.3 Using Peer Communication

The publish module was created to manage peer communication. The publish module comes with a number of functions to execute peer communication in different ways. Currently there are three functions in the publish module. These examples will show how to test the peer system via the salt-call command.

To execute test.ping on all minions:

```
# salt-call publish.publish '*' test.ping
```

To execute the manage.up runner:

```
# salt-call publish.runner manage.up
```

To match minions using other matchers, use `expr_form`:

```
# salt-call publish.publish 'webserv* and not G@os:Ubuntu' test.ping expr_form='compound'
```

## 30.20 Pillars

Salt includes a number of built-in external pillars, listed at *Full list of builtin pillar modules*.

You may also wish to look at the standard pillar documentation, at *Pillar Configuration*

The source for the built-in Salt pillars can be found here: <https://github.com/saltstack/salt/blob/develop/salt/pillar>

## 30.21 Full list of builtin pillar modules

<code>cmd_json</code>	Execute a command and read the output as JSON.
<code>cmd_yaml</code>	Execute a command and read the output as YAML.
<code>cmd_yamllex</code>	Execute a command and read the output as YAMLEX.
<code>cobbler</code>	A module to pull data from Cobbler via its API into the Pillar dictionary
<code>django_orm</code>	Generate Pillar data from Django models through the Django ORM
<code>ec2_pillar</code>	Retrieve EC2 instance data for minions.
<code>etcd_pillar</code>	Use etcd data as a Pillar source
<code>file_tree</code>	Recursively iterate over directories and add all files as Pillar data.
<code>foreman</code>	A module to pull data from Foreman via its API into the Pillar dictionary
<code>git_pillar</code>	Clone a remote git repository and use the filesystem as a Pillar source
<code>hiera</code>	Use hiera data as a Pillar source
<code>libvirt</code>	Load up the libvirt keys into Pillar for a given minion if said keys have been generated using the libvirt key
<code>mongo</code>	Read Pillar data from a mongodb collection
<code>mysql</code>	Retrieve Pillar data by doing a MySQL query
<code>pepa</code>	Pepa
<code>pillar_ldap</code>	Use LDAP data as a Pillar source
<code>puppet</code>	Execute an unmodified puppet_node_classifier and read the output as YAML.
<code>reclass_adapter</code>	Use the ``reclass`` database as a Pillar source
<code>redismod</code>	Read pillar data from a Redis backend
<code>s3</code>	Copy pillar data from a bucket in Amazon S3
<code>svn_pillar</code>	Clone a remote SVN repository and use the filesystem as a Pillar source
<code>varstack_pillar</code>	Use Varstack data as a Pillar source
<code>virtkey</code>	Accept a key from a hypervisor if the virt runner has already submitted an authorization request

### 30.21.1 salt.pillar.cmd\_json

Execute a command and read the output as JSON. The JSON data is then directly overlaid onto the minion's Pillar data.

```
salt.pillar.cmd_json.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as JSON

### 30.21.2 salt.pillar.cmd\_yaml

Execute a command and read the output as YAML. The YAML data is then directly overlaid onto the minion's Pillar data

```
salt.pillar.cmd_yaml.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as YAML

### 30.21.3 salt.pillar.cmd\_yamllex

Execute a command and read the output as YAMLEX. The YAMLEX data is then directly overlaid onto the minion's Pillar data

```
salt.pillar.cmd_yamllex.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as YAMLEX

### 30.21.4 salt.pillar.cobbler

A module to pull data from Cobbler via its API into the Pillar dictionary

#### Configuring the Cobbler ext\_pillar

The same cobbler.\* parameters are used for both the Cobbler tops and Cobbler pillar modules.

```
ext_pillar:
- cobbler:
    key: cobbler # Nest results within this key. By default, values are not nested.
    only: [parameters] # Add only these keys to pillar.

cobbler.url: https://example.com/cobbler_api #default is http://localhost/cobbler_api
cobbler.user: username # default is no username
cobbler.password: password # default is no password
```

#### Module Documentation

```
salt.pillar.cobbler.ext_pillar(minion_id, pillar, key=None, only=())
```

Read pillar data from Cobbler via its API.

### 30.21.5 salt.pillar.django\_orm

Generate Pillar data from Django models through the Django ORM

**maintainer** Micah Hausler <micah.hausler@gmail.com>

**maturity** new

#### Configuring the django\_orm ext\_pillar

To use this module, your Django project must be on the salt master server with database access. This assumes you are using virtualenv with all the project's requirements installed.

```

ext_pillar:
- django_orm:
  pillar_name: my_application
  project_path: /path/to/project/
  settings_module: my_application.settings
  env_file: /path/to/env/file.sh
  # Optional: If your project is not using the system python,
  # add your virtualenv path below.
  env: /path/to/virtualenv/

  django_app:

    # Required: the app that is included in INSTALLED_APPS
    my_application.clients:

      # Required: the model name
      Client:

        # Required: model field to use as the key in the rendered
        # Pillar. Must be unique; must also be included in the
        # ``fields`` list below.
        name: shortname

        # Optional:
        # See Django's QuerySet documentation for how to use .filter()
        filter: {'kw': 'args'}

        # Required: a list of field names
        # List items will be used as arguments to the .values() method.
        # See Django's QuerySet documentation for how to use .values()
        fields:
        - field_1
        - field_2

```

This would return pillar data that would look like

```

my_application:
  my_application.clients:
    Client:
      client_1:
        field_1: data_from_field_1
        field_2: data_from_field_2
      client_2:

```

```
field_1: data_from_field_1
field_2: data_from_field_2
```

As another example, data from multiple database tables can be fetched using Django's regular lookup syntax. Note, using `ManyToManyFields` will not currently work since the return from `values()` changes if a `ManyToMany` is present.

```
ext_pillar:
- django_orm:
  pillar_name: djangotutorial
  project_path: /path/to/mysite
  settings_module: mysite.settings

  django_app:
    mysite.polls:
      Choices:
        name: poll__question
        fields:
          - poll__question
          - poll__id
          - choice_text
          - votes
```

## Module Documentation

`salt.pillar.django_orm.ext_pillar`(*minion\_id*, *pillar*, *pillar\_name*, *project\_path*, *settings\_module*, *django\_app*, *env=None*, *env\_file=None*, *\*args*, *\*\*kwargs*)

Connect to a Django database through the ORM and retrieve model fields

### Parameters

- **pillar\_name** (*str*) -- The name of the pillar to be returned
- **project\_path** (*str*) -- The full path to your Django project (the directory `manage.py` is in)
- **settings\_module** (*str*) -- The settings module for your project. This can be found in your `manage.py` file
- **django\_app** (*str*) -- A dictionary containing your apps, models, and fields
- **env** (*str*) -- The full path to the `virtualenv` for your Django project
- **env\_file** (*str*) -- An optional bash file that sets up your environment. The file is run in a subprocess and the changed variables are then added

### 30.21.6 salt.pillar.ec2\_pillar

Retrieve EC2 instance data for minions.

The minion id must be the instance-id retrieved from AWS. As an option, `use_grain` can be set to `True`. This allows the use of an instance-id grain instead of the minion-id. Since this is a potential security risk, the configuration can be further expanded to include a list of minions that are trusted to only allow the alternate id of the instances to specific hosts. There is no glob matching at this time.

```

ext_pillar:
  - ec2_pillar:
      use_grain: True
      minion_ids:
        - trusted-minion-1
        - trusted-minion-2
        - trusted-minion-3

```

This is a very simple pillar that simply retrieves the instance data from AWS. Currently the only portion implemented are EC2 tags, which returns a list of key/value pairs for all of the EC2 tags assigned to the instance.

`salt.pillar.ec2_pillar.ext_pillar` (*minion\_id*, *pillar*, *use\_grain=False*, *minion\_ids=None*)  
Execute a command and read the output as YAML

### 30.21.7 salt.pillar.etcd\_pillar

Use etcd data as a Pillar source

New in version 2014.7.0.

#### depends

- python-etcd

In order to use an etcd server, a profile must be created in the master configuration file:

```

my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001

```

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified.

```

ext_pillar:
  - etcd: my_etcd_config

ext_pillar:
  - etcd: my_etcd_config root=/salt

```

Using these configuration profiles, multiple etcd sources may also be used:

```

ext_pillar:
  - etcd: my_etcd_config
  - etcd: my_other_etcd_config

```

The `minion_id` may be used in the `root` path to expose minion-specific information stored in etcd.

```

ext_pillar:
  - etcd: my_etcd_config root=/salt/%(minion_id)s

```

Minion-specific values may override shared values when the minion-specific root appears after the shared root:

```

ext_pillar:
  - etcd: my_etcd_config root=/salt-shared
  - etcd: my_other_etcd_config root=/salt-private/%(minion_id)s

```

Using the configuration above, the following commands could be used to share a key with all minions but override its value for a specific minion:

```
etcdctl set /salt-shared/mykey my_value
etcdctl set /salt-private/special_minion_id/mykey my_other_value
```

```
salt.pillar.etcd_pillar.ext_pillar(minion_id, pillar, conf)
    Check etcd for all data
```

### 30.21.8 salt.pillar.file\_tree

Recursively iterate over directories and add all files as Pillar data.

Example configuration:

```
ext_pillar:
  - file_tree:
      root_dir: /path/to/root/directory
      follow_dir_links: False
      raw_data: False
```

The `root_dir` parameter is required and points to the directory where files for each host are stored. The `follow_dir_links` parameter is optional and defaults to `False`. If `follow_dir_links` is set to `True`, `file_tree` will follow symbolic links to other directories. Be careful when using `follow_dir_links`, the current implementation is dumb and will run into infinite recursion if a recursive symlink chain exists in the `root_dir`!

If `raw_data` is set to `True`, it will revert the behavior of the python `open()` function, which adds a line break character at the end of the file, in this case, the pillar data.

To fill pillar data for each host, `file_tree` recursively iterates over `root_dir/hosts/id` (where `id` is a minion ID), and constructs the same directory tree with contents of all the files inside the pillar tree.

For example, the following `root_dir` tree:

```
./hosts/
./hosts/test-host/
./hosts/test-host/files/
./hosts/test-host/files/testdir/
./hosts/test-host/files/testdir/file1.txt
./hosts/test-host/files/testdir/file2.txt
./hosts/test-host/files/another-testdir/
./hosts/test-host/files/another-testdir/symlink-to-file1.txt
```

will result in the following pillar tree for minion with ID `test-host`:

```
test-host:
  -----
  files:
    -----
    another-testdir:
      -----
      symlink-to-file1.txt:
        Contents of file #1.

    testdir:
      -----
```

```

file1.txt:
    Contents of file #1.

file2.txt:
    Contents of file #2.

```

To fill pillar data for minion in a node group, `file_tree` recursively iterates over `root_dir/nodegroups/nodegroup` (where `nodegroup` is a minion node group), and constructs the same directory tree with contents of all the files inside the pillar tree. **IMPORTANT:** The host data take precedence over the node group data

For example, the following `root_dir` tree:

```

./nodegroups/
./nodegroups/test-group/
./nodegroups/test-group/files/
./nodegroups/test-group/files/testdir/
./nodegroups/test-group/files/testdir/file1.txt
./nodegroups/test-group/files/testdir/file2.txt
./nodegroups/test-group/files/another-testdir/
./nodegroups/test-group/files/another-testdir/symlink-to-file1.txt

```

will result in the following pillar tree for minion in the node group `test-group`:

```

test-host:
  -----
  files:
    -----
    another-testdir:
      -----
      symlink-to-file1.txt:
        Contents of file #1.

    testdir:
      -----
      file1.txt:
        Contents of file #1.

      file2.txt:
        Contents of file #2.

```

`salt.pillar.file_tree.ext_pillar` (*minion\_id, pillar, root\_dir=None, follow\_dir\_links=False, debug=False, raw\_data=False*)

Find pillar data for specified ID.

### 30.21.9 salt.pillar.foreman

A module to pull data from Foreman via its API into the Pillar dictionary

#### Configuring the Foreman `ext_pillar`

Set the following Salt config to setup Foreman as external pillar source:

```
ext_pillar:
  - foreman:
      key: foreman # Nest results within this key
      only: ['hostgroup_name', 'parameters'] # Add only these keys to pillar

foreman.url: https://example.com/foreman_api
foreman.user: username # default is admin
foreman.password: password # default is changeme
```

The following options are optional:

```
foreman.api: apiversion # default is 2 (1 is not supported yet)
foreman.verifyssl: False # default is True
foreman.certfile: /etc/ssl/certs/mycert.pem # default is None
foreman.keyfile: /etc/ssl/private/mykey.pem # default is None
foreman.cacertfile: /etc/ssl/certs/mycert.ca.pem # default is None
foreman.lookup_parameters: True # default is True
```

An alternative would be to use the Foreman modules integrating Salt features in the Smart Proxy and the webinterface.

Further information can be found on [Github](#).

## Module Documentation

`salt.pillar.foreman.ext_pillar` (*minion\_id*, *pillar*, *key=None*, *only=()*)  
Read pillar data from Foreman via its API.

### 30.21.10 salt.pillar.git\_pillar

Clone a remote git repository and use the filesystem as a Pillar source

Currently GitPython is the only supported provider for git Pillars

This external Pillar source can be configured in the master config file like so:

```
ext_pillar:
  - git: master git://gitserver/git-pillar.git root=subdirectory
```

The `root=` parameter is optional and used to set the subdirectory from where to look for Pillar files (such as `top.sls`).

Changed in version 2014.7.0: The optional `root` parameter will be added.

Changed in version 2015.5.0: The special branch name `__env__` will be replaced by the environment (`{{env}}`)

Note that this is not the same thing as configuring pillar data using the `pillar_roots` parameter. The branch referenced in the `ext_pillar` entry above (`master`), would evaluate to the `base` environment, so this branch needs to contain a `top.sls` with a `base` section in it, like this:

```
base:
  '*':
    - foo
```

To use other environments from the same git repo as `git_pillar` sources, just add additional lines, like so:

```

ext_pillar:
  - git: master git://gitserver/git-pillar.git
  - git: dev git://gitserver/git-pillar.git

```

To remap a specific branch to a specific environment separate the branch name and the environment name with a colon:

```

ext_pillar:
  - git: develop:dev git://gitserver/git-pillar.git
  - git: master:prod git://gitserver/git-pillar.git

```

In this case, the dev branch would need its own `top.sls` with a dev section in it, like this:

```

dev:
  '*':
    - bar

```

In a gitfs base setup with pillars from the same repository as the states, the `ext_pillar:` configuration would be like:

```

ext_pillar:
  - git: __env__ git://gitserver/git-pillar.git root=pillar

```

The (optional) `root=pillar` defines the directory that contains the pillar data. The corresponding `top.sls` would be like:

```

{{env}}:
  '*':
    - bar

```

`class salt.pillar.git_pillar.GitPillar(branch, repo_location, opts)`

Deal with the remote git repository for Pillar

**envs**()

Return a list of refs that can be used as environments

**map\_branch**(branch, opts=None)

**update**()

Ensure you are following the latest changes on the remote

Return boolean whether it worked

`salt.pillar.git_pillar.envs(branch, repo_location)`

Return a list of refs that can be used as environments

`salt.pillar.git_pillar.ext_pillar(minion_id, repo_string, pillar_dirs)`

Execute a command and read the output as YAML

`salt.pillar.git_pillar.update(branch, repo_location)`

Ensure you are following the latest changes on the remote

return boolean whether it worked

### 30.21.11 salt.pillar.hiera

Use hiera data as a Pillar source

```
salt.pillar.hiera.ext_pillar(minion_id, pillar, conf)
```

Execute hiera and return the data

### 30.21.12 salt.pillar.libvirt

Load up the libvirt keys into Pillar for a given minion if said keys have been generated using the libvirt key runner

```
salt.pillar.libvirt.ext_pillar(minion_id, pillar, command)
```

Read in the generated libvirt keys

```
salt.pillar.libvirt.gen_hyper_keys(minion_id, country='US', state='Utah', locality='Salt Lake City', organization='Salted')
```

Generate the keys to be used by libvirt hypervisors, this routine gens the keys and applies them to the pillar for the hypervisor minions

### 30.21.13 salt.pillar.mongo

Read Pillar data from a mongodb collection

**depends** pymongo (for salt-master)

This module will load a node-specific pillar dictionary from a mongo collection. It uses the node's id for lookups and can load either the whole document, or just a specific field from that document as the pillar dictionary.

#### Salt Master Mongo Configuration

The module shares the same base mongo connection variables as `salt.returners.mongo_return`. These variables go in your master config file.

- `mongo.db` - The mongo database to connect to. Defaults to 'salt'.
- `mongo.host` - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaults to 'salt'.
- `mongo.port` - The port that the mongo database is running on. Defaults to 27017.
- `mongo.user` - The username for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''.
- `mongo.password` - The password for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''.

#### Configuring the Mongo ext\_pillar

The Mongo `ext_pillar` takes advantage of the fact that the Salt Master configuration file is yaml. It uses a sub-dictionary of values to adjust specific features of the pillar. This is the explicit single-line dictionary notation for yaml. One may be able to get the easier-to-read multi-line dict to work correctly with some experimentation.

```
ext_pillar:
  - mongo: {collection: vm, id_field: name, re_pattern: \.example\.com, fields: [customer_id, software]}
```

In the example above, we've decided to use the `vm` collection in the database to store the data. Minion ids are stored in the `name` field on documents in that collection. And, since minion ids are FQDNs in most cases, we'll need to trim the domain name in order to find the minion by hostname in the collection. When we find a minion, return only the `customer_id`, `software`, and `apache_vhosts` fields, as that will contain the data we want for a given node. They will be available directly inside the `pillar` dict in your SLS templates.

## Module Documentation

`salt.pillar.mongo.ext_pillar` (*minion\_id*, *pillar*, *collection='pillar'*, *id\_field='\_id'*, *re\_pattern=None*, *re\_replace=''*, *fields=None*)

Connect to a mongo database and read per-node pillar information.

Parameters:

- *collection*: The mongodb collection to read data from. Defaults to `'pillar'`.
- *id\_field*: The field in the collection that represents an individual minion id. Defaults to `'_id'`.
- *re\_pattern*: If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. *re\_pattern* will be used to match the name, and *re\_replace* will be used to replace it. Backrefs are supported as they are in the Python standard library. If `None`, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to `None`.
- *re\_replace*: Use as the replacement value in node ids matched with *re\_pattern*. Defaults to `''`. Feel free to use backreferences here.
- *fields*: The specific fields in the document to use for the pillar data. If `None`, will use the entire document. If using the entire document, the `_id` field will be converted to string. Be careful with other fields in the document as they must be string serializable. Defaults to `None`.

### 30.21.14 salt.pillar.mysql

Retrieve Pillar data by doing a MySQL query

MariaDB provides Python support through the MySQL Python package. Therefore, you may use this module with both MySQL or MariaDB.

**maturity** new

**depends** python-mysqldb

**platform** all

#### Theory of mysql ext\_pillar

Ok, here's the theory for how this works...

- If there's a keyword arg of `mysql_query`, that'll go first.
- Then any non-keyword args are processed in order.
- Finally, remaining keywords are processed.

We do this so that it's backward compatible with older configs. Keyword arguments are sorted before being appended, so that they're predictable, but they will always be applied last so overall it's moot.

For each of those items we process, it depends on the object type:

- Strings are executed as is and the pillar depth is determined by the number of fields returned.

- A list has the first entry used as the query, the second as the pillar depth.
- A mapping uses the keys ``query" and ``depth" as the tuple

You can retrieve as many fields as you like, how they get used depends on the exact settings.

### Configuring the mysql ext\_pillar

First an example of how legacy queries were specified.

```
ext_pillar:
  - mysql:
      mysql_query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
```

Alternatively, a list of queries can be passed in

```
ext_pillar:
  - mysql:
      - "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      - "SELECT pillar,value FROM more_pillars WHERE minion_id = %s"
```

Or you can pass in a mapping

```
ext_pillar:
  - mysql:
      main: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      extras: "SELECT pillar,value FROM more_pillars WHERE minion_id = %s"
```

The query can be provided as a string as we have just shown, but they can be provided as lists

```
ext_pillar:
  - mysql:
      - "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      2
```

Or as a mapping

```
ext_pillar:
  - mysql:
      - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      depth: 2
```

The depth defines how the dicts are constructed. Essentially if you query for fields a,b,c,d for each row you'll get:

- With depth 1: {a: {`b": b, `c": c, `d": d}}
- With depth 2: {a: {b: {`c": c, `d": d}}}
- With depth 3: {a: {b: {c: d}}}

Depth greater than 3 wouldn't be different from 3 itself. Depth of 0 translates to the largest depth needed, so 3 in this case. (max depth == key count - 1)

The legacy compatibility translates to depth 1.

Then they are merged in a similar way to plain pillar data, in the order returned by MySQL.

Thus subsequent results overwrite previous ones when they collide.

The `ignore_null` option can be used to change the overwrite behavior so that only non-NULL values in subsequent results will overwrite. This can be used to selectively overwrite default values.

```
ext_pillar:
  - mysql:
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = 'default' and minion_id != %s"
      depth: 2
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
      depth: 2
      ignore_null: True
```

If you specify `as_list: True` in the mapping expression it will convert collisions to lists.

If you specify `with_lists: `...`` in the mapping expression it will convert the specified depths to list. The string provided is a sequence numbers that are comma separated. The string ``1,3`` will result in:

```
a,b,c,d,e,1 # field 1 same, field 3 differs
a,b,c,f,g,2 # ^^^^
a,z,h,y,j,3 # field 1 same, field 3 same
a,z,h,y,k,4 # ^^^^
  ^      ^
```

These columns define list grouping

```
{a: [
  {c: [
    {e: 1},
    {g: 2}
  ]},
  {h: [
    {j: 3, k: 4 }
  ]}
]}
```

The range for `with_lists` is 1 to `number_of_fields`, inclusive. Numbers outside this range are ignored.

Finally, if you pass the queries in via a mapping, the key will be the first level name where as passing them in as a list will place them in the root. This isolates the query results into their own subtrees. This may be a help or hindrance to your aims and can be used as such.

You can basically use any SELECT query that gets you the information, you could even do joins or subqueries in case your `minion_id` is stored elsewhere. It is capable of handling single rows or multiple rows per minion.

MySQL configuration of the MySQL returner is being used (`mysql.db`, `mysql.user`, `mysql.pass`, `mysql.port`, `mysql.host`)

Required python modules: MySQLdb

### More complete example

```
mysql:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'

ext_pillar:
  - mysql:
      fromdb:
        query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                FROM some_random_table
                WHERE minion_pattern LIKE %s'
      depth: 5
      as_list: True
      with_lists: [1,3]
```

`salt.pillar.mysql.ext_pillar`(*minion\_id*, *pillar*, *\*args*, *\*\*kwargs*)

Execute queries, merge and return as a dict

class `salt.pillar.mysql.merger`

This class receives and processes the database rows in a database agnostic way.

**as\_list** = False

**depth** = 0

**enter\_root**(*root*)

Set self.focus for kwarg queries

**extract\_queries**(*args*, *kwargs*)

This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.

**field\_names** = None

**focus** = None

**ignore\_null** = False

**num\_fields** = 0

**process\_fields**(*field\_names*, *depth*)

The primary purpose of this function is to store the sql field list and the depth to which we process.

**process\_results**(*rows*)

This function takes a list of database results and iterates over, merging them into a dict form.

**result** = None

**with\_lists** = None

### 30.21.15 salt.pillar.pepa

#### Pepa

Configuration templating for SaltStack using Hierarchical substitution and Jinja.

## Configuring Pepa

```

extension_modules: /srv/salt/ext

ext_pillar:
- pepa:
    resource: host                # Name of resource directory and sub-key in pillars
    sequence:                    # Sequence used for hierarchical substitution
    - hostname:                 # Name of key
      name: input                # Alias used for template directory
      base_only: True           # Only use templates from Base environment, i.e. no staging
    - default:
    - environment:
    - location..region:
      name: region
    - location..country:
      name: country
    - location..datacenter:
      name: datacenter
    - roles:
    - osfinger:
      name: os
    - hostname:
      name: override
      base_only: True
    subkey: True                # Create a sub-key in pillars, named after the resource in this o
    subkey_only: True           # Only create a sub-key, and leave the top level untouched

pepa_roots:                    # Base directory for each environment
  base: /srv/pepa/base         # Path for base environment
  dev: /srv/pepa/base          # Associate dev with base
  qa: /srv/pepa/qa
  prod: /srv/pepa/prod

# Use a different delimiter for nested dictionaries, defaults to '..' since some keys may use '.' in
#pepa_delimiter: ..

# Supply Grains for Pepa, this should **ONLY** be used for testing or validation
#pepa_grains:
#  environment: dev

# Supply Pillar for Pepa, this should **ONLY** be used for testing or validation
#pepa_pillars:
#  saltversion: 0.17.4

# Enable debug for Pepa, and keep Salt on warning
#log_level: debug

#log_granular_levels:
#  salt: warning
#  salt.loaded.ext.pillar.pepa: debug

```

Pepa can also be used in Master-less SaltStack setup.

## Command line

```
usage: pepa.py [-h] [-c CONFIG] [-d] [-g GRAINS] [-p PILLAR] [-n] [-v]
              hostname

positional arguments:
  hostname              Hostname

optional arguments:
  -h, --help            show this help message and exit
  -c CONFIG, --config CONFIG
                        Configuration file
  -d, --debug           Print debug info
  -g GRAINS, --grains GRAINS
                        Input Grains as YAML
  -p PILLAR, --pillar PILLAR
                        Input Pillar as YAML
  -n, --no-color        No color output
  -v, --validate        Validate output
```

## Templates

Templates is configuration for a host or software, that can use information from Grains or Pillars. These can then be used for hierarchically substitution.

**Example File:** host/input/test\_example\_com.yaml

```
location..region: emea
location..country: nl
location..datacenter: foobar
environment: dev
roles:
  - salt.master
network..gateway: 10.0.0.254
network..interfaces..eth0..hwaddr: 00:20:26:a1:12:12
network..interfaces..eth0..dhcp: False
network..interfaces..eth0..ipv4: 10.0.0.3
network..interfaces..eth0..netmask: 255.255.255.0
network..interfaces..eth0..fqdn: {{ hostname }}
cobbler..profile: fedora-19-x86_64
```

As you see in this example you can use Jinja directly inside the template.

**Example File:** host/region/amer.yaml

```
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
time..ntp..servers:
  - ntp1.amer.example.com
  - ntp2.amer.example.com
  - ntp3.amer.example.com
time..timezone: America/Chihuahua
yum..mirror: yum.amer.example.com
```

Each template is named after the value of the key using lowercase and all extended characters are replaced with underscore.

**Example:**

osfinger: Fedora-19

**Would become:**

fedora\_19.yaml

**Nested dictionaries**

In order to create nested dictionaries as output you can use double dot "." as a delimiter. You can change this using ``pepa\_delimiter`` we choose double dot since single dot is already used by key names in some modules, and using ":" requires quoting in the YAML.

**Example:**

```
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
network..dns..options:
  - timeout:2
  - attempts:1
  - ndots:1
network..dns..search:
  - example.com
```

**Would become:**

```
network:
  dns:
    servers:
      - 10.0.0.1
      - 10.0.0.2
    options:
      - timeout:2
      - attempts:1
      - ndots:1
    search:
      - example.com
```

**Operators**

Operators can be used to merge/unset a list/hash or set the key as immutable, so it can't be changed.

Operator	Description
merge()	Merge list or hash
unset()	Unset key
immutable()	Set the key as immutable, so it can't be changed
imerge()	Set immutable and merge
iunset()	Set immutable and unset

**Example:**

```
network..dns..search..merge():
  - foobar.com
  - dummy.nl
owner..immutable(): Operations
host..printers..unset():
```

## Validation

Since it's very hard to test Jinja as is, the best approach is to run all the permutations of input and validate the output, i.e. Unit Testing.

To facilitate this in Pepa we use YAML, Jinja and Cerberus <<https://github.com/nicolaiarocci/cerberus>>.

## Schema

So this is a validation schema for network configuration, as you see it can be customized with Jinja just as Pepa templates.

This was designed to be run as a build job in Jenkins or similar tool. You can provide Grains/Pillar input using either the config file or command line arguments.

### File Example: host/validation/network.yaml

```
network..dns..search:
  type: list
  allowed:
    - example.com

network..dns..options:
  type: list
  allowed: ['timeout:2', 'attempts:1', 'ndots:1']

network..dns..servers:
  type: list
  schema:
    regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

network..gateway:
  type: string
  regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

{% if network.interfaces is defined %}
{% for interface in network.interfaces %}

network..interfaces..{{ interface }}..dhcp:
  type: boolean

network..interfaces..{{ interface }}..fqdn:
  type: string
  regex: ^([a-z0-9]([a-z0-9-]{0,61}[a-z0-9])?\.)+[a-zA-Z]{2,6}$

network..interfaces..{{ interface }}..hwaddr:
  type: string
  regex: ^([0-9a-f]{1,2}\:){5}[0-9a-f]{1,2}$
```

```

network..interfaces..{{ interface }}..ipv4:
  type: string
  regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

network..interfaces..{{ interface }}..netmask:
  type: string
  regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

{% endfor %}
{% endif %}

```

## Links

For more examples and information see <<https://github.com/mickey76/pepa>>.

`salt.pillar.pepa.ext_pillar`(*minion\_id*, *pillar*, *resource*, *sequence*, *subkey=False*, *subkey\_only=False*)

Evaluate Pepa templates

`salt.pillar.pepa.key_value_to_tree`(*data*)

Convert key/value to tree

`salt.pillar.pepa.validate`(*output*, *resource*)

Validate Pepa templates

### 30.21.16 salt.pillar.pillar\_ldap

Use LDAP data as a Pillar source

This pillar module parses a config file (specified in the salt master config), and executes a series of LDAP searches based on that config. Data returned by these searches is aggregated, with data items found later in the LDAP search order overriding data found earlier on.

The final result set is merged with the pillar data.

`salt.pillar.pillar_ldap.ext_pillar`(*minion\_id*, *pillar*, *config\_file*)

Execute LDAP searches and return the aggregated data

### 30.21.17 salt.pillar.puppet

Execute an unmodified `puppet_node_classifier` and read the output as YAML. The YAML data is then directly overlaid onto the minion's Pillar data.

`salt.pillar.puppet.ext_pillar`(*minion\_id*, *pillar*, *command*)

Execute an unmodified `puppet_node_classifier` and read the output as YAML

### 30.21.18 salt.pillar.reclass\_adapter

Use the ``reclass`` database as a Pillar source

This `ext_pillar` plugin provides access to the `reclass` database, such that Pillar data for a specific minion are fetched using `reclass`.

You can find more information about `reclass` at <http://reclass.pantsfullofunix.net>.

To use the plugin, add it to the `ext_pillar` list in the Salt master config and tell `reclass` by way of a few options how and where to find the inventory:

```
ext_pillar:
  - reclass:
      storage_type: yaml_fs
      inventory_base_uri: /srv/salt
```

This would cause `reclass` to read the inventory from YAML files in `/srv/salt/nodes` and `/srv/salt/classes`.

If you are also using `reclass` as `master_tops` plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for `ext_pillar` and `master_tops`):

```
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
  reclass_source_path: ~/code/reclass

ext_pillar:
  - reclass: *reclass

master_tops:
  reclass: *reclass
```

If you want to run `reclass` from source, rather than installing it, you can either let the master know via the `PYTHONPATH` environment variable, or by setting the configuration option, like in the example above.

`salt.pillar.reclass_adapter.ext_pillar(minion_id, pillar, **kwargs)`  
Obtain the Pillar data from `reclass` for the given `minion_id`.

### 30.21.19 salt.pillar.redismod

#### Read pillar data from a Redis backend

New in version 2014.7.0.

##### depends

- redis Python module (on master)

#### Salt Master Redis Configuration

The module shares the same base Redis connection variables as `salt.returners.redis_return`. These variables go in your master config file.

- `redis.db` - The Redis database to use. Defaults to 0.
- `redis.host` - The Redis host to connect to. Defaults to 'salt'.
- `redis.port` - The port that the Redis database is listening on. Defaults to 6379.
- `redis.password` - The password for authenticating with Redis. Only required if you are using master auth. Defaults to None.

## Configuring the Redis ext\_pillar

```
ext_pillar:
  - redis: {function: key_value}
```

`salt.pillar.redismod.ext_pillar` (*minion\_id, pillar, function, \*\*kwargs*)

Grabs external pillar data based on configured function

`salt.pillar.redismod.key_json` (*minion\_id, pillar, pillar\_key=None*)

Pulls a string from redis and deserializes it from json. Deserialized dictionary data loaded directly into top level if `pillar_key` is not set.

`pillar_key` Pillar key to return data into

`salt.pillar.redismod.key_value` (*minion\_id, pillar, pillar\_key='redis\_pillar'*)

Looks for key in redis matching `minion_id`, returns a structure based on the data type of the redis key. String for string type, dict for hash type and lists for lists, sets and sorted sets.

`pillar_key` Pillar key to return data into

### 30.21.20 salt.pillar.s3

Copy pillar data from a bucket in Amazon S3

The S3 pillar can be configured in the master config file with the following options

```
ext_pillar:
  - s3:
      bucket: my.fancy.pillar.bucket
      keyid: KASKFJWAKJASJKDAJKSD
      key: ksladfdLKDALSFKSD93q032sdDasdfasdfsadkf
      multiple_env: False
      environment: base
      prefix: somewhere/overthere
      verify_ssl: True
      service_url: s3.amazonaws.com
      s3_cache_expire: 30
      s3_sync_on_update: True
```

The `bucket` parameter specifies the target S3 bucket. It is required.

The `keyid` parameter specifies the key id to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `key` parameter specifies the key to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `multiple_env` defaults to `False`. It specifies whether the pillar should interpret top level folders as pillar environments (see mode section below).

The `environment` defaults to `'base'`. It specifies which environment the bucket represents when in single environments mode (see mode section below). It is ignored if `multiple_env` is `True`.

The `prefix` defaults to `''`. It specifies a key prefix to use when searching for data in the bucket for the pillar. It works when `multiple_env` is `True` or `False`. Essentially it tells `ext_pillar` to look for your pillar data in a `'subdirectory'` of your S3 bucket

The `verify_ssl` parameter defaults to `True`. It specifies whether to check for valid S3 SSL certificates. *NOTE* If you use bucket names with periods, this must be set to `False` else an invalid certificate error will be thrown (issue #12200).

The `service_url` parameter defaults to `'s3.amazonaws.com'`. It specifies the base url to use for accessing S3.

The `s3_cache_expire` parameter defaults to `30s`. It specifies expiration time of S3 metadata cache file.

The `s3_sync_on_update` parameter defaults to `True`. It specifies if cache is synced on update rather than `jit`.

This pillar can operate in two modes, single environment per bucket or multiple environments per bucket.

Single environment mode must have this bucket structure:

```
s3://<bucket name>/<prefix>/<files>
```

Multiple environment mode must have this bucket structure:

```
s3://<bucket name>/<prefix>/<environment>/<files>
```

If you wish to define your pillar data entirely within S3 it's recommended that you use the `prefix=` parameter and specify one entry in `ext_pillar` for each environment rather than specifying `multiple_env`. This is due to issue #22471 (<https://github.com/saltstack/salt/issues/22471>)

```
class salt.pillar.s3.S3Credentials(key, keyid, bucket, service_url, verify_ssl, location)
```

```
salt.pillar.s3.ext_pillar(minion_id, pillar, bucket, key=None, keyid=None, verify_ssl=True, location=None, multiple_env=False, environment='base', prefix='', service_url=None, s3_cache_expire=30, s3_sync_on_update=True)
```

Execute a command and read the output as YAML

### 30.21.21 salt.pillar.svn\_pillar

Clone a remote SVN repository and use the filesystem as a Pillar source

This external Pillar source can be configured in the master config file like so:

```
ext_pillar:
  - svn: trunk svn://svnsrvr/repo root=subdirectory
```

The `root=` parameter is optional and used to set the subdirectory from where to look for Pillar files (such as `top.sls`).

Changed in version 2014.7.0: The optional `root` parameter will be added.

Note that this is not the same thing as configuring pillar data using the `pillar_roots` parameter. The branch referenced in the `ext_pillar` entry above (`master`), would evaluate to the `base` environment, so this branch needs to contain a `top.sls` with a `base` section in it, like this:

```
base:
  '*':
    - foo
```

To use other environments from the same SVN repo as `svn_pillar` sources, just add additional lines, like so:

```
ext_pillar:
  - svn: trunk svn://svnsrvr/repo
  - svn: dev svn://svnsrvr/repo
```

In this case, the dev branch would need its own `top.sls` with a dev section in it, like this:

```
dev:
  '*':
    - bar
```

`class salt.pillar.svn_pillar.SvnPillar(branch, repo_location, root, opts)`  
Deal with the remote SVN repository for Pillar

**pillar\_dir()**

Returns the directory of the pillars (repo cache + branch + root)

**update()**

`salt.pillar.svn_pillar.ext_pillar(minion_id, pillar, repo_string)`  
Execute a command and read the output as YAML

### 30.21.22 salt.pillar.varstack\_pillar

Use [Varstack](#) data as a Pillar source

#### Configuring Varstack

Using varstack in Salt is fairly simple. Just put the following into the config file of your master:

```
ext_pillar:
  - varstack: /etc/varstack.yaml
```

Varstack will then use `/etc/varstack.yaml` to determine which configuration data to return as pillar information. From there you can take a look at the [README](#) of varstack on how this file is evaluated.

`salt.pillar.varstack_pillar.ext_pillar(minion_id, pillar, conf)`  
Parse varstack data and return the result

### 30.21.23 salt.pillar.virtkey

Accept a key from a hypervisor if the virt runner has already submitted an authorization request

`salt.pillar.virtkey.ext_pillar(hyper_id, pillar, name, key)`  
Accept the key for the VM on the hyper, if authorized.

## 30.22 Renderers

The Salt state system operates by gathering information from common data types such as lists, dictionaries, and strings that would be familiar to any developer.

SLS files are translated from whatever data templating format they are written in back into Python data types to be consumed by Salt.

By default SLS files are rendered as Jinja templates and then parsed as YAML documents. But since the only thing the state system cares about is raw data, the SLS files can be any structured format that can be dreamed up.

Currently there is support for Jinja + YAML, Mako + YAML, Wempy + YAML, Jinja + json, Mako + json and Wempy + json.

Renderers can be written to support any template type. This means that the Salt states could be managed by XML files, HTML files, Puppet files, or any format that can be translated into the Pythonic data structure used by the state system.

### 30.22.1 Multiple Renderers

A default renderer is selected in the master configuration file by providing a value to the `renderer` key.

When evaluating an SLS, more than one renderer can be used.

When rendering SLS files, Salt checks for the presence of a Salt-specific shebang line.

The shebang line directly calls the name of the renderer as it is specified within Salt. One of the most common reasons to use multiple renderers is to use the Python or py renderer.

Below, the first line is a shebang that references the py renderer.

```
#!/py
def run():
    '''
    Install the python-mako package
    '''
    return {'include': ['python'],
            'python-mako': {'pkg': ['installed']}}
```

### 30.22.2 Composing Renderers

A renderer can be composed from other renderers by connecting them in a series of pipes(`|`).

In fact, the default Jinja + YAML renderer is implemented by connecting a YAML renderer to a Jinja renderer. Such renderer configuration is specified as: `jinja | yaml`.

Other renderer combinations are possible:

**yaml** i.e, just YAML, no templating.

**mako | yaml** pass the input to the mako renderer, whose output is then fed into the yaml renderer.

**jinja | mako | yaml** This one allows you to use both jinja and mako templating syntax in the input and then parse the final rendered output as YAML.

The following is a contrived example SLS file using the `jinja | mako | yaml` renderer:

```
#!/jinja|mako|yaml
An_Example:
  cmd.run:
    - name: |
      echo "Using Salt ${grains['saltversion']}" \
        "from path ${grains['saltpath']}."
    - cwd: /
<%doc> ${...} is Mako's notation, and so is this comment. </%doc>
{#      Similarly, {{...}} is Jinja's notation, and so is this comment. #}
```

For backward compatibility, `jinja | yaml` can also be written as `yaml_jinja`, and similarly, the `yaml_mako`, `yaml_wempy`, `json_jinja`, `json_mako`, and `json_wempy` renderers are all supported.

Keep in mind that not all renderers can be used alone or with any other renderers. For example, the template renderers shouldn't be used alone as their outputs are just strings, which still need to be parsed by another renderer to turn them into highstate data structures.

For example, it doesn't make sense to specify `yaml | jinja` because the output of the YAML renderer is a highstate data structure (a dict in Python), which cannot be used as the input to a template renderer. Therefore, when combining renderers, you should know what each renderer accepts as input and what it returns as output.

### 30.22.3 Writing Renderers

A custom renderer must be a Python module placed in the `renderers` directory and the module implement the `render` function.

The `render` function will be passed the path of the SLS file as an argument.

The purpose of of `render` function is to parse the passed file and to return the Python data structure derived from the file.

Custom renderers must be placed in a `_renderers` directory within the `file_roots` specified by the master config file.

Custom renderers are distributed when any of the following are run:

- `state.apply`
- `saltutil.sync_renderers`
- `saltutil.sync_all`

Any custom renderers which have been synced to a minion, that are named the same as one of Salt's default set of renderers, will take the place of the default renderer with the same name.

### 30.22.4 Examples

The best place to find examples of renderers is in the Salt source code.

Documentation for renderers included with Salt can be found here:

<https://github.com/saltstack/salt/blob/develop/salt/renderers>

Here is a simple YAML renderer example:

```
import yaml
def render(yaml_data, env='', sls='', **kws):
    if not isinstance(yaml_data, basestring):
        yaml_data = yaml_data.read()
    data = yaml.load(yaml_data)
    return data if data else {}
```

### 30.22.5 Full List of Renderers

#### Full list of builtin renderer modules

<i>cheetah</i>	Cheetah Renderer for Salt
<i>genshi</i>	Genshi Renderer for Salt
<i>gpg</i>	Renderer that will decrypt GPG ciphers
<i>jinja</i>	Jinja loading utils to enable a more powerful backend for jinja templates
<i>json</i>	JSON Renderer for Salt
<i>mako</i>	Mako Renderer for Salt
<i>msgpack</i>	
<i>py</i>	Pure python state renderer
<i>pydsl</i>	A Python-based DSL
<i>pyobjects</i>	Python renderer that includes a Pythonic Object based interface
<i>stateconf</i>	A flexible renderer that takes a templating engine and a data format
<i>wempy</i>	
<i>yaml</i>	YAML Renderer for Salt
<i>yamlex</i>	

### **salt.renderers.cheetah**

Cheetah Renderer for Salt

`salt.renderers.cheetah.render(cheetah_data, saltenv='base', sls='', method='xml', **kws)`  
Render a Cheetah template.

**Return type** A Python data structure

### **salt.renderers.genshi**

Genshi Renderer for Salt

`salt.renderers.genshi.render(genshi_data, saltenv='base', sls='', method='xml', **kws)`

Render a Genshi template. A method should be passed in as part of the kwargs. If no method is passed in, xml is assumed. Valid methods are:

Note that the `text` method will call `NewTextTemplate`. If `oldtext` is desired, it must be called explicitly

**Return type** A Python data structure

### **salt.renderers.gpg**

Renderer that will decrypt GPG ciphers

Any key in the SLS file can be a GPG cipher, and this renderer will decrypt it before passing it off to Salt. This allows you to safely store secrets in source control, in such a way that only your Salt master can decrypt them and distribute them only to the minions that need them.

The typical use-case would be to use ciphers in your pillar data, and keep a secret key on your master. You can put the public key in source control so that developers can add new secrets quickly and easily.

This renderer requires the `python-gnupg` package. Be careful to install the `python-gnupg` package, not the `gnupg` package, or you will get errors.

To set things up, you will first need to generate a keypair. On your master, run:

```
# gpg --gen-key --homedir /etc/salt/gpgkeys
```

Do not supply a password for your keypair, and use a name that makes sense for your application. Be sure to back up your gpg directory someplace safe!

**Note:** Unfortunately, there are some scenarios - for example, on virtual machines which don't have real hardware - where insufficient entropy causes key generation to be extremely slow. If you come across this problem, you should investigate means of increasing the system entropy. On virtualised Linux systems, this can often be achieved by installing the `rng-tools` package.

To retrieve the public key:

```
# gpg --armor --homedir /etc/salt/gpgkeys --armor --export <KEY-NAME> > exported_pubkey.gpg
```

Now, to encrypt secrets, copy the public key to your local machine and run:

```
$ gpg --import exported_pubkey.gpg
```

To generate a cipher from a secret:

```
$ echo -n "supersecret" | gpg --armor --encrypt -r <KEY-name>
```

Set up the renderer on your master by adding something like this line to your config:

```
renderer: jinja | yaml | gpg
```

Now you can include your ciphers in your pillar data like so:

```
a-secret: |
  -----BEGIN PGP MESSAGE-----
  Version: GnuPG v1

  hQEMAWeRHKaPCfNeAQf9GLTN16hCfXAbPwU6BbBK0un0c7i9/etGuVc5CyU9Q6um

  skqmFTb0iA==
  =Eqsm
  -----END PGP MESSAGE-----
```

`salt.renderers.gpg.decrypt_ciphertext(c, gpg)`

Given a block of ciphertext as a string, and a gpg object, try to decrypt the cipher and return the decrypted string. If the cipher cannot be decrypted, log the error, and return the ciphertext back out.

`salt.renderers.gpg.decrypt_object(o, gpg)`

Recursively try to decrypt any object. If the object is a string, and it contains a valid GPG header, decrypt it, otherwise keep going until a string is found.

`salt.renderers.gpg.render(gpg_data, saltenv='base', sls='', argline='', **kwargs)`

Create a gpg object given a gpg\_keydir, and then use it to try to decrypt the data to be rendered.

## salt.renderers.jinja

Jinja loading utils to enable a more powerful backend for jinja templates

**Jinja in States** The most basic usage of Jinja in state files is using control structures to wrap conditional or redundant state elements:

```
{% if grains['os'] != 'FreeBSD' %}
tcsh:
  pkg:
    - installed
{% endif %}

motd:
  file.managed:
    {% if grains['os'] == 'FreeBSD' %}
    - name: /etc/motd
    {% elif grains['os'] == 'Debian' %}
    - name: /etc/motd.tail
    {% endif %}
    - source: salt://motd
```

In this example, the first if block will only be evaluated on minions that aren't running FreeBSD, and the second block changes the file name based on the *os* grain.

Writing **if-else** blocks can lead to very redundant state files however. In this case, using [pillars](#), or using a previously defined variable might be easier:

```
{% set motd = ['/etc/motd'] %}
{% if grains['os'] == 'Debian' %}
  {% set motd = ['/etc/motd.tail', '/var/run/motd'] %}
{% endif %}

{% for motdfile in motd %}
{{ motdfile }}:
  file.managed:
    - source: salt://motd
{% endfor %}
```

Using a variable set by the template, the **for loop** will iterate over the list of MOTD files to update, adding a state block for each file.

**Include and Import** Includes and [imports](#) can be used to share common, reusable state configuration between state files and between files.

```
{% from 'lib.sls' import test %}
```

This would import the `test` template variable or macro, not the `test` state element, from the file `lib.sls`. In the case that the included file performs checks against grains, or something else that requires context, passing the context into the included file is required:

```
{% from 'lib.sls' import test with context %}
```

**Macros** `Macros` are helpful for eliminating redundant code, however stripping whitespace from the template block, as well as contained blocks, may be necessary to emulate a variable return from the macro.

```
# init.sls
{% from 'lib.sls' import pythonpkg with context %}

python-virtualenv:
  pkg.installed:
    - name: {{ pythonpkg('virtualenv') }}

python-fabric:
  pkg.installed:
    - name: {{ pythonpkg('fabric') }}
```

```
# lib.sls
{% macro pythonpkg(pkg) -%}
  {%- if grains['os'] == 'FreeBSD' -%}
    py27-{{ pkg }}
  {%- elif grains['os'] == 'Debian' -%}
    python-{{ pkg }}
  {%- endif -%}
{%- endmacro %}
```

This would define a `macro` that would return a string of the full package name, depending on the packaging system's naming convention. The whitespace of the macro was eliminated, so that the macro would return a string without line breaks, using `whitespace control`.

**Template Inheritance** `Template inheritance` works fine from state files and files. The search path starts at the root of the state tree or pillar.

**Filters** Saltstack extends `builtin filters` with these custom filters:

**strftime** Converts any time related object into a time based string. It requires a valid `strftime directives`. An [exhaustive list](#) can be found in the official Python documentation.

```
{% set curtime = None | strftime() %}
```

Fuzzy dates require the `timelib` Python module is installed.

```
{{ "2002/12/25"|strftime("%y") }}
{{ "1040814000"|strftime("%Y-%m-%d") }}
{{ datetime|strftime("%u") }}
{{ "tomorrow"|strftime }}
```

**sequence** Ensure that parsed data is a sequence.

**yaml\_encode** Serializes a single object into a YAML scalar with any necessary handling for escaping special characters. This will work for any scalar YAML data type: ints, floats, timestamps, booleans, strings, unicode. It will *not* work for multi-objects such as sequences or maps.

```
{%- set bar = 7 %}
{%- set baz = none %}
{%- set zip = true %}
{%- set zap = 'The word of the day is "salty"' %}

{%- load_yaml as foo %}
```

```

bar: {{ bar|yaml_encode }}
baz: {{ baz|yaml_encode }}
baz: {{ zip|yaml_encode }}
baz: {{ zap|yaml_encode }}
{%- endload %}

```

In the above case ```{{ bar }}``` and ```{{ foo.bar }}``` should be identical and ```{{ baz }}``` and ```{{ foo.baz }}``` should be identical.

**yaml\_dquote** Serializes a string into a properly-escaped YAML double-quoted string. This is useful when the contents of a string are unknown and may contain quotes or unicode that needs to be preserved. The resulting string will be emitted with opening and closing double quotes.

```

{%- set bar = '"The quick brown fox . . ."' %}
{%- set baz = 'The word of the day is "salty".' %}

{%- load_yaml as foo %}
bar: {{ bar|yaml_dquote }}
baz: {{ baz|yaml_dquote }}
{%- endload %}

```

In the above case ```{{ bar }}``` and ```{{ foo.bar }}``` should be identical and ```{{ baz }}``` and ```{{ foo.baz }}``` should be identical. If variable contents are not guaranteed to be a string then it is better to use ```yaml_encode``` which handles all YAML scalar types.

**yaml\_squote** Similar to the `yaml_dquote` filter but with single quotes. Note that YAML only allows special escapes inside double quotes so `yaml_squote` is not nearly as useful (viz. you likely want to use `yaml_encode` or `yaml_dquote`).

**Jinja in Files** Jinja can be used in the same way in managed files:

```

# redis.sls
/etc/redis/redis.conf:
  file.managed:
    - source: salt://redis.conf
    - template: jinja
    - context:
      bind: 127.0.0.1

```

```

# lib.sls
{% set port = 6379 %}

```

```

# redis.conf
{% from 'lib.sls' import port with context %}
port {{ port }}
bind {{ bind }}

```

As an example, configuration was pulled from the file context and from an external template file.

**Note:** Macros and variables can be shared across templates. They should not be starting with one or more underscores, and should be managed by one of the following tags: `macro`, `set`, `load_yaml`, `load_json`, `import_yaml` and `import_json`.

**Calling Salt Functions** The Jinja renderer provides a shorthand lookup syntax for the `salt` dictionary of *execution function*.

New in version 2014.7.0.

```
# The following two function calls are equivalent.
{{ salt['cmd.run']('whoami') }}
{{ salt.cmd.run('whoami') }}
```

**Debugging** The `show_full_context` function can be used to output all variables present in the current Jinja context.

New in version 2014.7.0.

```
Context is: {{ show_full_context() }}
```

```
salt.renderers.jinja.render(template_file, saltenv='base', sls='', argline='', context=None, tm-
                             plpath=None, **kws)
```

Render the `template_file`, passing the functions and grains into the Jinja rendering system.

**Return type** *string*

```
class salt.utils.jinja.SerializerExtension(environment)
```

Yaml and Json manipulation.

**Format filters**

Allows to jsonify or yamlify any data structure. For example, this dataset:

```
data = {
    'foo': True,
    'bar': 42,
    'baz': [1, 2, 3],
    'qux': 2.0
}
```

```
yaml = {{ data|yaml }}
json = {{ data|json }}
python = {{ data|python }}
```

will be rendered as:

```
yaml = {bar: 42, baz: [1, 2, 3], foo: true, qux: 2.0}
json = {"baz": [1, 2, 3], "foo": true, "bar": 42, "qux": 2.0}
python = {'bar': 42, 'baz': [1, 2, 3], 'foo': True, 'qux': 2.0}
```

The `yaml` filter takes an optional `flow_style` parameter to control the default-flow-style parameter of the YAML dumper.

```
{{ data|yaml(False) }}
```

will be rendered as:

```
bar: 42
baz:
  - 1
  - 2
  - 3
foo: true
qux: 2.0
```

### Load filters

Strings and variables can be deserialized with `load_yaml` and `load_json` tags and filters. It allows one to manipulate data directly in templates, easily:

```
{%- set yaml_src = "{foo: it works}"|load_yaml %}
{% set json_src = '{"bar": "for real"}"|load_json %}
Dude, {{ yaml_src.foo }} {{ json_src.bar }}!
```

will be rendered as:

```
Dude, it works for real!
```

### Load tags

Salt implements `import_yaml` and `import_json` tags. They work like the `import` tag, except that the document is also deserialized.

Syntaxes are `{% load_yaml as [VARIABLE] %}[YOUR DATA]{% endload %}` and `{% load_json as [VARIABLE] %}[YOUR DATA]{% endload %}`

For example:

```
{% load_yaml as yaml_src %}
  foo: it works
{% endload %}
{% load_json as json_src %}
  {
    "bar": "for real"
  }
{% endload %}
Dude, {{ yaml_src.foo }} {{ json_src.bar }}!
```

will be rendered as:

```
Dude, it works for real!
```

### Import tags

External files can be imported and made available as a Jinja variable.

```
{% import_yaml "myfile.yml" as myfile %}
{% import_json "defaults.json" as defaults %}
{% import_text "completeworksofshakespeare.txt" as poems %}
```

### Catalog

`import_*` and `load_*` tags will automatically expose their target variable to import. This feature makes catalog of data to handle.

for example:

```
# doc1.sls
{% load_yaml as var1 %}
  foo: it works
{% endload %}
{% load_yaml as var2 %}
  bar: for real
{% endload %}
```

```
# doc2.sls
{% from "doc1.sls" import var1, var2 as local2 %}
{{ var1.foo }} {{ local2.bar }}
```

### salt.renderers.json

JSON Renderer for Salt

`salt.renderers.json.render` (*json\_data*, *saltenv='base'*, *sls=''*, *\*\*kws*)  
Accepts JSON as a string or as a file object and runs it through the JSON parser.

**Return type** A Python data structure

### salt.renderers.mako

Mako Renderer for Salt

`salt.renderers.mako.render` (*template\_file*, *saltenv='base'*, *sls=''*, *context=None*, *tmplpath=None*, *\*\*kws*)  
Render the *template\_file*, passing the functions and grains into the Mako rendering system.

**Return type** *string*

### salt.renderers.msgpack

`salt.renderers.msgpack.render` (*msgpack\_data*, *saltenv='base'*, *sls=''*, *\*\*kws*)  
Accepts a message pack string or a file object, renders said data back to a python dict.

**Return type** A Python data structure

### salt.renderers.py

Pure python state renderer

The SLS file should contain a function called `run` which returns high state data.

In this module, a few objects are defined for you, giving access to Salt's execution functions, grains, pillar, etc. They are:

- `__salt__` - *Execution functions* (i.e. `__salt__['test.echo']('foo')`)
- `__grains__` - *Grains* (i.e. `__grains__['os']`)
- `__pillar__` - *Pillar data* (i.e. `__pillar__['foo']`)
- `__opts__` - Minion configuration options

- `__env__` - The effective salt filesrv environment (i.e. `base`). Also referred to as a ```saltenv```. `__env__` should not be modified in a pure python SLS file. To use a different environment, the environment should be set when executing the state. This can be done in a couple different ways:
  - Using the `saltenv` argument on the salt CLI (i.e. `salt '*' state.sls foo.bar.baz saltenv=env_name`).
  - By adding a `saltenv` argument to an individual state within the SLS file. In other words, adding a line like this to the state's data structure: `{'saltenv': 'env_name'}`
- `__sls__` - The SLS path of the file. For example, if the root of the base environment is `/srv/salt`, and the SLS file is `/srv/salt/foo/bar/baz.sls`, then `__sls__` in that file will be `foo.bar.baz`.

```

1  #!py
2
3  def run():
4      config = {}
5
6      if __grains__['os'] == 'Ubuntu':
7          user = 'ubuntu'
8          group = 'ubuntu'
9          home = '/home/{0}'.format(user)
10     else:
11         user = 'root'
12         group = 'root'
13         home = '/root/'
14
15     config['s3cmd'] = {
16         'pkg': [
17             'installed',
18             {'name': 's3cmd'},
19         ],
20     }
21
22     config[home + '/.s3cfg'] = {
23         'file.managed': [
24             {'source': 'salt://s3cfg/templates/s3cfg'},
25             {'template': 'jinja'},
26             {'user': user},
27             {'group': group},
28             {'mode': 600},
29             {'context': {
30                 'aws_key': __pillar__['AWS_ACCESS_KEY_ID'],
31                 'aws_secret_key': __pillar__['AWS_SECRET_ACCESS_KEY'],
32             }},
33         ],
34     },
35 }
36
37     return config

```

`salt.renderers.py.render` (*template*, *saltenv='base'*, *sls=''*, *tmplpath=None*, *\*\*kws*)

Render the python module's components

Return type *string*

**salt.renderers.pydsl**

A Python-based DSL

**maintainer** Jack Kuan <kjkuan@gmail.com>

**maturity** new

**platform** all

The *pydsl* renderer allows one to author salt formulas (.sls files) in pure Python using a DSL that's easy to write and easy to read. Here's an example:

```

1  #!/pydsl
2
3  apache = state('apache')
4  apache.pkg.installed()
5  apache.service.running()
6  state('/var/www/index.html') \
7      .file('managed',
8           source='salt://webserver/index.html') \
9      .require(pkg='apache')
```

Notice that any Python code is allow in the file as it's really a Python module, so you have the full power of Python at your disposal. In this module, a few objects are defined for you, including the usual (with `__` added) `__salt__` dictionary, `__grains__`, `__pillar__`, `__opts__`, `__env__`, and `__sls__`, plus a few more:

`__file__`

local file system path to the sls module.

`__pydsl__`

Salt PyDSL object, useful for configuring DSL behavior per sls rendering.

`include`

Salt PyDSL function for creating *Include declaration*'s.

`extend`

Salt PyDSL function for creating *Extend declaration*'s.

`state`

Salt PyDSL function for creating *ID declaration*'s.

A state *ID declaration* is created with a `state(id)` function call. Subsequent `state(id)` call with the same `id` returns the same object. This singleton access pattern applies to all declaration objects created with the DSL.

```

state('example')
assert state('example') is state('example')
assert state('example').cmd is state('example').cmd
assert state('example').cmd.running is state('example').cmd.running
```

The *id* argument is optional. If omitted, an UUID will be generated and used as the *id*.

`state(id)` returns an object under which you can create a *State declaration* object by accessing an attribute named after *any* state module available in Salt.

```
state('example').cmd
state('example').file
state('example').pkg
...
```

Then, a *Function declaration* object can be created from a *State declaration* object by one of the following two ways:

1. by calling a method named after the state function on the *State declaration* object.

```
state('example').file.managed(...)
```

2. by directly calling the attribute named for the *State declaration*, and supplying the state function name as the first argument.

```
state('example').file('managed', ...)
```

With either way of creating a *Function declaration* object, any *Function arg declaration*'s can be passed as keyword arguments to the call. Subsequent calls of a *Function declaration* will update the arg declarations.

```
state('example').file('managed', source='salt://webserver/index.html')
state('example').file.managed(source='salt://webserver/index.html')
```

As a shortcut, the special *name* argument can also be passed as the first or second positional argument depending on the first or second way of calling the *State declaration* object. In the following two examples *ls -la* is the *name* argument.

```
state('example').cmd.run('ls -la', cwd='/')
state('example').cmd('run', 'ls -la', cwd='/')
```

Finally, a *Requisite declaration* object with its *Requisite reference*'s can be created by invoking one of the requisite methods (see *State Requisites*) on either a *Function declaration* object or a *State declaration* object. The return value of a requisite call is also a *Function declaration* object, so you can chain several requisite calls together.

Arguments to a requisite call can be a list of *State declaration* objects and/or a set of keyword arguments whose names are state modules and values are IDs of *ID declaration*'s or names of *Name declaration*'s.

```
apache2 = state('apache2')
apache2.pkg.installed()
state('libapache2-mod-wsgi').pkg.installed()

# you can call requisites on function declaration
apache2.service.running() \
    .require(apache2.pkg,
             pkg='libapache2-mod-wsgi') \
    .watch(file='/etc/apache2/httpd.conf')

# or you can call requisites on state declaration.
# this actually creates an anonymous function declaration object
# to add the requisites.
apache2.service.require(state('libapache2-mod-wsgi').pkg,
                        pkg='apache2') \
    .watch(file='/etc/apache2/httpd.conf')

# we still need to set the name of the function declaration.
apache2.service.running()
```

*Include declaration* objects can be created with the `include` function, while *Extend declaration* objects can be created with the `extend` function, whose arguments are just *Function declaration* objects.

```
include('edit.vim', 'http.server')
extend(state('apache2').service.watch(file='/etc/httpd/httpd.conf')
```

The `include` function, by default, causes the included sls file to be rendered as soon as the `include` function is called. It returns a list of rendered module objects; sls files not rendered with the pydsl renderer return `None`'s. This behavior creates no *Include declaration*'s in the resulting high state data structure.

```
import types

# including multiple sls returns a list.
_, mod = include('a-non-pydsl-sls', 'a-pydsl-sls')

assert _ is None
assert isinstance(slsmods[1], types.ModuleType)

# including a single sls returns a single object
mod = include('a-pydsl-sls')

# myfunc is a function that calls state(...) to create more states.
mod.myfunc(1, 2, "three")
```

Notice how you can define a reusable function in your pydsl sls module and then call it via the module returned by `include`.

It's still possible to do late includes by passing the `delayed=True` keyword argument to `include`.

```
include('edit.vim', 'http.server', delayed=True)
```

Above will just create a *Include declaration* in the rendered result, and such call always returns `None`.

**Special integration with the `cmd` state** Taking advantage of rendering a Python module, PyDSL allows you to declare a state that calls a pre-defined Python function when the state is executed.

```
greeting = "hello world"
def helper(something, *args, **kws):
    print greeting          # hello world
    print something, args, kws  # test123 ['a', 'b', 'c'] {'x': 1, 'y': 2}

state().cmd.call(helper, "test123", 'a', 'b', 'c', x=1, y=2)
```

The `cmd.call` state function takes care of calling our `helper` function with the arguments we specified in the states, and translates the return value of our function into a structure expected by the state system. See `salt.states.cmd.call()` for more information.

**Implicit ordering of states** Salt states are explicitly ordered via *Requisite declaration*'s. However, with *pydsl* it's possible to let the renderer track the order of creation for *Function declaration* objects, and implicitly add `require` requisites for your states to enforce the ordering. This feature is enabled by setting the `ordered` option on `__pydsl__`.

**Note:** this feature is only available if your minions are using Python `>= 2.7`.

```
include('some.sls.file')

A = state('A').cmd.run(cwd='/var/tmp')
extend(A)

__pydsl__.set(ordered=True)

for i in range(10):
    i = str(i)
    state(i).cmd.run('echo '+i, cwd='/')
state('1').cmd.run('echo one')
state('2').cmd.run(name='echo two')
```

Notice that the `ordered` option needs to be set after any `extend` calls. This is to prevent *pydsl* from tracking the creation of a state function that's passed to an `extend` call.

Above example should create states from 0 to 9 that will output 0, one, two, 3, ... 9, in that order.

It's important to know that *pydsl* tracks the *creations* of *Function declaration* objects, and automatically adds a `require` requisite to a *Function declaration* object that requires the last *Function declaration* object created before it in the sls file.

This means later calls (perhaps to update the function's *Function arg declaration*) to a previously created function declaration will not change the order.

**Render time state execution** When Salt processes a salt formula file, the file is rendered to salt's high state data representation by a renderer before the states can be executed. In the case of the *pydsl* renderer, the `.sls` file is executed as a python module as it is being rendered which makes it easy to execute a state at render time. In *pydsl*, executing one or more states at render time can be done by calling a configured *ID declaration* object.

```
#!/pydsl

s = state() # save for later invocation

# configure it
s.cmd.run('echo at render time', cwd='/')
s.file.managed('target.txt', source='salt://source.txt')

s() # execute the two states now
```

Once an *ID declaration* is called at render time it is detached from the sls module as if it was never defined.

---

**Note:** If *implicit ordering* is enabled (i.e., via `__pydsl__.set(ordered=True)`) then the *first* invocation of a *ID declaration* object must be done before a new *Function declaration* is created.

---

**Integration with the stateconf renderer** The `salt.renderers.stateconf` renderer offers a few interesting features that can be leveraged by the *pydsl* renderer. In particular, when using with the *pydsl* renderer, we are interested in *stateconf*'s sls namespacing feature (via dot-prefixed id declarations), as well as, the automatic *start* and *goal* states generation.

Now you can use *pydsl* with *stateconf* like this:

```
#!/pydsl|stateconf -ps
```

```
include('xxx', 'yyy')

# ensure that states in xxx run BEFORE states in this file.
extend(state('.start').stateconf.require(stateconf='xxx:goal'))

# ensure that states in yyy run AFTER states in this file.
extend(state('.goal').stateconf.require_in(stateconf='yyy:start'))

__pydsl__.set(ordered=True)

...
```

-s enables the generation of a stateconf *start* state, and -p lets us pipe high state data rendered by *pydsl* to *stateconf*. This example shows that by *require*-ing or *require\_in*-ing the included sls' *start* or *goal* states, it's possible to ensure that the included sls files can be made to execute before or after a state in the including sls file.

**Importing custom Python modules** To use a custom Python module inside a PyDSL state, place the module somewhere that it can be loaded by the Salt loader, such as *\_modules* in the */srv/salt* directory.

Then, copy it to any minions as necessary by using *saltutil.sync\_modules*.

To import into a PyDSL SLS, one must bypass the Python importer and insert it manually by getting a reference from Python's *sys.modules* dictionary.

For example:

```
#!/pydsl|stateconf -ps

def main():
    my_mod = sys.modules['salt.loaded.ext.module.my_mod']
```

`salt.renderers.pydsl.render` (*template*, *saltenv*='base', *sls*='', *tmplpath*=None, *rendered\_sls*=None, *\*\*kws*)

### `salt.renderers.pyobjects`

Python renderer that includes a Pythonic Object based interface

**maintainer** Evan Borgstrom <evan@borgstrom.ca>

Let's take a look at how you use *pyobjects* in a state file. Here's a quick example that ensures the */tmp* directory is in the correct state.

```
1 #!pyobjects
2
3 File.managed("/tmp", user='root', group='root', mode='1777')
```

Nice and Pythonic!

By using the ``shebang'' syntax to switch to the *pyobjects* renderer we can now write our state data using an object based interface that should feel at home to python developers. You can import any module and do anything that you'd like (with caution, importing *sqlalchemy*, *django* or other large frameworks has not been tested yet). Using the *pyobjects* renderer is exactly the same as using the built-in Python renderer with the exception that *pyobjects* provides you with an object based interface for generating state data.

**Creating state data** Pyobjects takes care of creating an object for each of the available states on the minion. Each state is represented by an object that is the CamelCase version of its name (i.e. `File`, `Service`, `User`, etc), and these objects expose all of their available state functions (i.e. `File.managed`, `Service.running`, etc).

The name of the state is split based upon underscores (`_`), then each part is capitalized and finally the parts are joined back together.

Some examples:

- `postgres_user` becomes `PostgresUser`
- `ssh_known_hosts` becomes `SshKnownHosts`

**Context Managers and requisites** How about something a little more complex. Here we're going to get into the core of how to use pyobjects to write states.

```

1  #!/pyobjects
2
3  with Pkg.installed("nginx"):
4      Service.running("nginx", enable=True)
5
6      with Service("nginx", "watch_in"):
7          File.managed("/etc/nginx/conf.d/mysite.conf",
8                      owner='root', group='root', mode='0444',
9                      source='salt://nginx/mysite.conf')
```

The objects that are returned from each of the magic method calls are setup to be used a Python context managers (`with`) and when you use them as such all declarations made within the scope will **automatically** use the enclosing state as a requisite!

The above could have also been written use direct requisite statements as.

```

1  #!/pyobjects
2
3  Pkg.installed("nginx")
4  Service.running("nginx", enable=True, require=Pkg("nginx"))
5  File.managed("/etc/nginx/conf.d/mysite.conf",
6              owner='root', group='root', mode='0444',
7              source='salt://nginx/mysite.conf',
8              watch_in=Service("nginx"))
```

You can use the direct requisite statement for referencing states that are generated outside of the current file.

```

1  #!/pyobjects
2
3  # some-other-package is defined in some other state file
4  Pkg.installed("nginx", require=Pkg("some-other-package"))
```

The last thing that direct requisites provide is the ability to select which of the SaltStack requisites you want to use (`require`, `require_in`, `watch`, `watch_in`, `use` & `use_in`) when using the requisite as a context manager.

```

1  #!/pyobjects
2
3  with Service("my-service", "watch_in"):
4      ...
```

The above example would cause all declarations inside the scope of the context manager to automatically have their `watch_in` set to `Service("my-service")`.

**Including and Extending** To include other states use the `include()` function. It takes one name per state to include.

To extend another state use the `extend()` function on the name when creating a state.

```

1  #!pyobjects
2
3  include('http', 'ssh')
4
5  Service.running(extend('apache'),
6                  watch=[File('/etc/httpd/extra/httpd-vhosts.conf')])

```

**Importing from other state files** Like any Python project that grows you will likely reach a point where you want to create reusability in your state tree and share objects between state files, Map Data (described below) is a perfect example of this.

To facilitate this Python's `import` statement has been augmented to allow for a special case when working with a Salt state tree. If you specify a Salt url (`salt://...`) as the target for importing from then the pyobjects renderer will take care of fetching the file for you, parsing it with all of the pyobjects features available and then place the requested objects in the global scope of the template being rendered.

This works for both types of import statements, `import X` and `from X import Y`.

```

1  #!pyobjects
2
3  import salt://myfile.sls
4  from salt://something/data.sls import Object

```

See the Map Data section for a more practical use.

Caveats:

- Imported objects are ALWAYS put into the global scope of your template, regardless of where your import statement is.

**Salt object** In the spirit of the object interface for creating state data pyobjects also provides a simple object interface to the `__salt__` object.

A function named `salt` exists in scope for your sls files and will dispatch its attributes to the `__salt__` dictionary.

The following lines are functionally equivalent:

```

1  #!pyobjects
2
3  ret = salt.cmd.run(bar)
4  ret = __salt__['cmd.run'](bar)

```

**Pillar, grain, mine & config data** Pyobjects provides shortcut functions for calling `pillar.get`, `grains.get`, `mine.get` & `config.get` on the `__salt__` object. This helps maintain the readability of your state files.

Each type of data can be access by a function of the same name: `pillar()`, `grains()`, `mine()` and `config()`.

The following pairs of lines are functionally equivalent:

```

1  #!pyobjects
2
3  value = pillar('foo:bar:baz', 'qux')
4  value = __salt__['pillar.get']('foo:bar:baz', 'qux')
5
6  value = grains('pkg:apache')
7  value = __salt__['grains.get']('pkg:apache')
8
9  value = mine('os:Fedora', 'network.interfaces', 'grain')
10 value = __salt__['mine.get']('os:Fedora', 'network.interfaces', 'grain')
11
12 value = config('foo:bar:baz', 'qux')
13 value = __salt__['config.get']('foo:bar:baz', 'qux')
```

**Map Data** When building complex states or formulas you often need a way of building up a map of data based on grain data. The most common use of this is tracking the package and service name differences between distributions.

To build map data using pyobjects we provide a class named `Map` that you use to build your own classes with inner classes for each set of values for the different grain matches.

```

1  #!pyobjects
2
3  class Samba(Map):
4      merge = 'samba:lookup'
5
6      class Debian:
7          server = 'samba'
8          client = 'samba-client'
9          service = 'samba'
10
11     class Ubuntu:
12         __grain__ = 'os'
13         service = 'smbd'
14
15     class RedHat:
16         server = 'samba'
17         client = 'samba'
18         service = 'smb'
```

To use this new data you can import it into your state file and then access your attributes. To access the data in the map you simply access the attribute name on the base class that is extending `Map`. Assuming the above `Map` was in the file `samba/map.sls`, you could do the following.

```

1  #!pyobjects
2
3  from salt://samba/map.sls import Samba
4
5  with Pkg.installed("samba", names=[Samba.server, Samba.client]):
6      Service.running("samba", name=Samba.service)
```

## TODO

- Interface for working with reactor files

`class salt.renderers.pyobjects.PyobjectsModule(name, attrs)`

This provides a wrapper for bare imports.

`salt.renderers.pyobjects.load_states()`

This loads our states into the salt `__context__`

`salt.renderers.pyobjects.render(template, saltenv='base', sls=',', salt_data=True, **kwargs)`

### salt.renderers.stateconf

**maintainer** Jack Kuan <kjkuan@gmail.com>

**maturity** new

**platform** all

This module provides a custom renderer that processes a salt file with a specified templating engine (e.g. Jinja) and a chosen data renderer (e.g. YAML), extracts arguments for any `stateconf.set` state, and provides the extracted arguments (including Salt-specific args, such as `require`, etc) as template context. The goal is to make writing reusable/configurable/parameterized salt files easier and cleaner.

To use this renderer, either set it as the default renderer via the `renderer` option in master/minion's config, or use the shebang line in each individual sls file, like so: `#!stateconf`. Note, due to the way this renderer works, it must be specified as the first renderer in a render pipeline. That is, you cannot specify `#!mako|yaml|stateconf`, for example. Instead, you specify them as renderer arguments: `#!stateconf mako . yaml`.

Here's a list of features enabled by this renderer.

- Prefixes any state id (declaration or reference) that starts with a dot (.) to avoid duplicated state ids when the salt file is included by other salt files.

For example, in the `salt://some/file.sls`, a state id such as `.sls_params` will be turned into `some.file::sls_params`. Example:

```
#!stateconf yaml . jinja

.vim:
  pkg.installed
```

Above will be translated into:

```
some.file::vim:
  pkg.installed:
    - name: vim
```

Notice how that if a state under a dot-prefixed state id has no `name` argument then one will be added automatically by using the state id with the leading dot stripped off.

The leading dot trick can be used with extending state ids as well, so you can include relatively and extend relatively. For example, when extending a state in `salt://some/other_file.sls`, e.g.:

```
#!stateconf yaml . jinja

include:
  - .file

extend:
```

```
.file::sls_params:
  stateconf.set:
    - name1: something
```

Above will be pre-processed into:

```
include:
  - some.file

extend:
  some.file::sls_params:
    stateconf.set:
      - name1: something
```

- Adds a `sls_dir` context variable that expands to the directory containing the rendering salt file. So, you can write `salt://{{sls_dir}}/...` to reference templates files used by your salt file.
- Recognizes the special state function, `stateconf.set`, that configures a default list of named arguments usable within the template context of the salt file. Example:

```
#!stateconf yaml . jinja

.sls_params:
  stateconf.set:
    - name1: value1
    - name2: value2
    - name3:
      - value1
      - value2
      - value3
    - require_in:
      - cmd: output

# --- end of state config ---

.output:
  cmd.run:
    - name: |
      echo 'name1={{sls_params.name1}}
          name2={{sls_params.name2}}
          name3[1]={{sls_params.name3[1]}}
      ,
```

This even works with `include + extend` so that you can override the default configured arguments by including the salt file and then extend the `stateconf.set` states that come from the included salt file. (*IMPORTANT: Both the included and the extending sls files must use the `stateconf` renderer for this ``extend`` to work!*)

Notice that the end of configuration marker (`# --- end of state config ---`) is needed to separate the use of `stateconf.set` from the rest of your salt file. The regex that matches such marker can be configured via the `stateconf_end_marker` option in your master or minion config file.

Sometimes, it is desirable to set a default argument value that's based on earlier arguments in the same `stateconf.set`. For example, it may be tempting to do something like this:

```
#!stateconf yaml . jinja

.apache:
  stateconf.set:
```

```

- host: localhost
- port: 1234
- url: 'http://{{host}}:{{port}}/'

# --- end of state config ---

.test:
  cmd.run:
    - name: echo '{{apache.url}}'
    - cwd: /

```

However, this won't work. It can however be worked around like so:

```

#!stateconf yaml . jinja

.apache:
  stateconf.set:
    - host: localhost
    - port: 1234
  {# - url: 'http://{{host}}:{{port}}/' #}

# --- end of state config ---
# {{ apache.setdefault('url', "http://%(host)s:%(port)s/" % apache) }}

.test:
  cmd.run:
    - name: echo '{{apache.url}}'
    - cwd: /

```

- Adds support for relative include and exclude of .sls files. Example:

```

#!stateconf yaml . jinja

include:
  - .apache
  - .db.mysql

exclude:
  - sls: .users

```

If the above is written in a salt file at `salt://some/where.sls` then it will include `salt://some/apache.sls` and `salt://some/db/mysql.sls`, and exclude `salt://some/users.sls`. Actually, it does that by rewriting the above `include` and `exclude` into:

```

include:
  - some.apache
  - some.db.mysql

exclude:
  - sls: some.users

```

- Optionally (enabled by default, *disable* via the `-G` renderer option, e.g. in the shebang line: `#!stateconf -G`), generates a `stateconf.set` goal state (state id named as `.goal` by default, configurable via the master/minion config option, `stateconf_goal_state`) that requires all other states in the salt file. Note, the `.goal` state id is subject to dot-prefix rename rule mentioned earlier.

Such goal state is intended to be required by some state in an including salt file. For example, in your `webapp` salt file, if you include a `sls` file that is supposed to setup Tomcat, you might want to make sure that all states in the Tomcat `sls` file will be executed before some state in the `webapp` `sls` file.

- Optionally (enable via the `-o` renderer option, e.g. in the shebang line: `#!stateconf -o`), orders the states in a sls file by adding a `require` requisite to each state such that every state requires the state defined just before it. The order of the states here is the order they are defined in the sls file. (Note: this feature is only available if your minions are using Python  $\geq$  2.7. For Python 2.6, it should also work if you install the `ordereddict` module from PyPI)

By enabling this feature, you are basically agreeing to author your sls files in a way that gives up the explicit (or implicit?) ordering imposed by the use of `require`, `watch`, `require_in` or `watch_in` requisites, and instead, you rely on the order of states you define in the sls files. This may or may not be a better way for you. However, if there are many states defined in a sls file, then it tends to be easier to see the order they will be executed with this feature.

You are still allowed to use all the requisites, with a few restrictions. You cannot `require` or `watch` a state defined *after* the current state. Similarly, in a state, you cannot `require_in` or `watch_in` a state defined *before* it. Breaking any of the two restrictions above will result in a state loop. The renderer will check for such incorrect uses if this feature is enabled.

Additionally, `names` declarations cannot be used with this feature because the way they are compiled into low states make it impossible to guarantee the order in which they will be executed. This is also checked by the renderer. As a workaround for not being able to use `names`, you can achieve the same effect, by generate your states with the template engine available within your sls file.

Finally, with the use of this feature, it becomes possible to easily make an included sls file execute all its states *after* some state (say, with id X) in the including sls file. All you have to do is to make state, X, `require_in` the first state defined in the included sls file.

When writing sls files with this renderer, one should avoid using what can be defined in a `name` argument of a state as the state's id. That is, avoid writing states like this:

```
/path/to/some/file:
  file.managed:
    - source: salt://some/file

cp /path/to/some/file file2:
  cmd.run:
    - cwd: /
    - require:
      - file: /path/to/some/file
```

Instead, define the state id and the `name` argument separately for each state. Also, the ID should be something meaningful and easy to reference within a requisite (which is a good habit anyway, and such extra indirection would also makes the sls file easier to modify later). Thus, the above states should be written like this:

```
add-some-file:
  file.managed:
    - name: /path/to/some/file
    - source: salt://some/file

copy-files:
  cmd.run:
    - name: cp /path/to/some/file file2
    - cwd: /
    - require:
      - file: add-some-file
```

Moreover, when referencing a state from a requisite, you should reference the state's id plus the state name rather than the state name plus its `name` argument. (Yes, in the above example, you can actually `require` the `file:`

/path/to/some/file, instead of the file: add-some-file). The reason is that this renderer will re-write or rename state id's and their references for state id's prefixed with .. So, if you reference name then there's no way to reliably rewrite such reference.

#### `salt.renderers.wempy`

`salt.renderers.wempy.render` (*template\_file*, *saltenv='base'*, *sls=''*, *argline=''*, *context=None*, *\*\*kws*)  
Render the data passing the functions and grains into the rendering system

Return type *string*

#### `salt.renderers.yaml`

**Understanding YAML** The default renderer for SLS files is the YAML renderer. YAML is a markup language with many powerful features. However, Salt uses a small subset of YAML that maps over very commonly used data structures, like lists and dictionaries. It is the job of the YAML renderer to take the YAML data structure and compile it into a Python data structure for use by Salt.

Though YAML syntax may seem daunting and terse at first, there are only three very simple rules to remember when writing YAML for SLS files.

**Rule One: Indentation** YAML uses a fixed indentation scheme to represent relationships between data layers. Salt requires that the indentation for each level consists of exactly two spaces. Do not use tabs.

**Rule Two: Colons** Python dictionaries are, of course, simply key-value pairs. Users from other languages may recognize this data type as hashes or associative arrays.

Dictionary keys are represented in YAML as strings terminated by a trailing colon. Values are represented by either a string following the colon, separated by a space:

```
my_key: my_value
```

In Python, the above maps to:

```
{'my_key': 'my_value'}
```

Dictionaries can be nested:

```
first_level_dict_key:
  second_level_dict_key: value_in_second_level_dict
```

And in Python:

```
{'first_level_dict_key': {'second_level_dict_key': 'value_in_second_level_dict'}}
```

**Rule Three: Dashes** To represent lists of items, a single dash followed by a space is used. Multiple items are a part of the same list as a function of their having the same level of indentation.

```
- list_value_one
- list_value_two
- list_value_three
```

Lists can be the value of a key-value pair. This is quite common in Salt:

```
my_dictionary:
  - list_value_one
  - list_value_two
  - list_value_three
```

**Reference** `YAML Renderer for Salt`

`salt.renderers.yaml.get_yaml_loader` (*argline*)  
Return the ordered dict yaml loader

`salt.renderers.yaml.render` (*yaml\_data*, *saltenv='base'*, *sls=''*, *argline=''*, *\*\*kws*)  
Accepts YAML as a string or as a file object and runs it through the YAML parser.

**Return type** A Python data structure

`salt.renderers.yamlex`

YAMLEX renderer is a replacement of the YAML renderer. It's 100% YAML with a pinch of Salt magic:

- All mappings are automatically `OrderedDict`
- All strings are automatically `str` obj
- data aggregation with `!aggregation` yaml tag, based on the `salt.utils.aggregation` module.
- data aggregation over documents for pillar

Instructed aggregation within the `!aggregation` and the `!reset` tags:

```
#!yamlex
foo: !aggregate first
foo: !aggregate second
bar: !aggregate {first: foo}
bar: !aggregate {second: bar}
baz: !aggregate 42
qux: !aggregate default
!reset qux: !aggregate my custom data
```

is roughly equivalent to

```
foo: [first, second]
bar: {first: foo, second: bar}
baz: [42]
qux: [my custom data]
```

**Reference**

`salt.renderers.yamlex.render` (*sls\_data*, *saltenv='base'*, *sls=''*, *\*\*kws*)

Accepts `YAML_EX` as a string or as a file object and runs it through the `YAML_EX` parser.

**Return type** A Python data structure

## 30.23 Returners

By default the return values of the commands sent to the Salt minions are returned to the Salt master, however anything at all can be done with the results data.

By using a Salt returner, results data can be redirected to external data-stores for analysis and archival.

Returners pull their configuration values from the Salt minions. Returners are only configured once, which is generally at load time.

The returner interface allows the return data to be sent to any system that can receive data. This means that return data can be sent to a Redis server, a MongoDB server, a MySQL server, or any system.

**See also:**

*Full list of builtin returners*

### 30.23.1 Using Returners

All Salt commands will return the command data back to the master. Specifying returners will ensure that the data is `_also_sent` to the specified returner interfaces.

Specifying what returners to use is done when the command is invoked:

```
salt '*' test.ping --return redis_return
```

This command will ensure that the `redis_return` returner is used.

It is also possible to specify multiple returners:

```
salt '*' test.ping --return mongo_return,redis_return,cassandra_return
```

In this scenario all three returners will be called and the data from the `test.ping` command will be sent out to the three named returners.

### 30.23.2 Writing a Returner

A returner is a Python module containing at minimum a `returner` function. Other optional functions can be included to add support for `master_job_cache`, `external_job_cache`, and *Event Returners*.

**returner** The returner function must accept a single argument. The argument contains return data from the called minion function. If the minion function `test.ping` is called, the value of the argument will be a dictionary. Run the following command from a Salt master to get a sample of the dictionary:

```
salt-call --local --metadata test.ping --out=pprint
```

```

import redis
import json

def returner(ret):
    """
    Return information to a redis server
    """
    # Get a redis connection
    serv = redis.Redis(
        host='redis-serv.example.com',
        port=6379,
        db='0')
    serv.sadd("%(id)s:jobs" % ret, ret['jid'])
    serv.set("%(jid)s:%(id)s" % ret, json.dumps(ret['return']))
    serv.sadd('jobs', ret['jid'])
    serv.sadd(ret['jid'], ret['id'])

```

The above example of a returner set to send the data to a Redis server serializes the data as JSON and sets it in redis.

### Master Job Cache Support

master\_job\_cache, external\_job\_cache, and *Event Returners*. Salt's master\_job\_cache allows returners to be used as a pluggable replacement for the *Default Job Cache*. In order to do so, a returner must implement the following functions:

---

**Note:** The code samples contained in this section were taken from the `cassandra_cql` returner.

---

**prep\_jid** Ensures that job ids (jid) don't collide, unless passed\_jid is provided.

nochache is an optional boolean that indicates if return data should be cached. passed\_jid is a caller provided jid which should be returned unconditionally.

```

def prep_jid(nocache, passed_jid=None): # pylint: disable=unused-argument
    """
    Do any work necessary to prepare a JID, including sending a custom id
    """
    return passed_jid if passed_jid is not None else salt.utils.jid.gen_jid()

```

**save\_load** Save job information. The jid is generated by prep\_jid and should be considered a unique identifier for the job. The jid, for example, could be used as the primary/unique key in a database. The load is what is returned to a Salt master by a minion. The following code example stores the load as a JSON string in the salt.jids table.

```

def save_load(jid, load):
    """
    Save the load to the specified jid id
    """
    query = '''INSERT INTO salt.jids (
        jid, load
    ) VALUES (
        '{0}', '{1}'
    );'''.format(jid, json.dumps(load))

    # cassandra_cql.cql_query may raise a CommandExecutionError
    try:

```

```

    __salt__['cassandra_cql.cql_query'](query)
except CommandExecutionError:
    log.critical('Could not save load in jids table.')
    raise
except Exception as e:
    log.critical('Unexpected error while inserting into
        jids: {0}'.format(str(e)))
    raise

```

**get\_load** must accept a job id (jid) and return the job load stored by `save_load`, or an empty dictionary when not found.

```

def get_load(jid):
    """
    Return the load data that marks a specified jid
    """
    query = '''SELECT load FROM salt.jids WHERE jid = '{0}';'''.format(jid)

    ret = {}

    # cassandra_cql.cql_query may raise a CommandExecutionError
    try:
        data = __salt__['cassandra_cql.cql_query'](query)
        if data:
            load = data[0].get('load')
            if load:
                ret = json.loads(load)
    except CommandExecutionError:
        log.critical('Could not get load from jids table.')
        raise
    except Exception as e:
        log.critical('Unexpected error while getting load from
            jids: {0}'.format(str(e)))
        raise

    return ret

```

### External Job Cache Support

Salt's `external_job_cache` extends the `master_job_cache`. External Job Cache support requires the following functions in addition to what is required for Master Job Cache support:

**get\_jid** Return a dictionary containing the information (load) returned by each minion when the specified job id was executed.

Sample:

```

{
  "local": {
    "master_minion": {
      "fun_args": [],
      "jid": "20150330121011408195",
      "return": true,
      "retcode": 0,
      "success": true,
      "cmd": "_return",

```

```
    "_stamp": "2015-03-30T12:10:12.708663",
    "fun": "test.ping",
    "id": "master_minion"
  }
}
```

**get\_fun** Return a dictionary of minions that called a given Salt function as their last function call.

Sample:

```
{
  "local": {
    "minion1": "test.ping",
    "minion3": "test.ping",
    "minion2": "test.ping"
  }
}
```

**get\_jids** Return a list of all job ids.

Sample:

```
{
  "local": [
    "20150330121011408195",
    "20150330195922139916"
  ]
}
```

**get\_minions** Returns a list of minions

Sample:

```
{
  "local": [
    "minion3",
    "minion2",
    "minion1",
    "master_minion"
  ]
}
```

Please refer to one or more of the existing returners (i.e. `mysql`, `cassandra_cql`) if you need further clarification.

## Event Support

An `event_return` function must be added to the returner module to allow events to be logged from a master via the returner. A list of events are passed to the function by the master.

The following example was taken from the MySQL returner. In this example, each event is inserted into the `salt_events` table keyed on the event tag. The tag contains the jid and therefore is guaranteed to be unique.

```

def event_return(events):
    '''
    Return event to mysql server

    Requires that configuration be enabled via 'event_return'
    option in master config.
    '''
    with _get_serv(events, commit=True) as cur:
        for event in events:
            tag = event.get('tag', '')
            data = event.get('data', '')
            sql = '''INSERT INTO `salt_events` (`tag`, `data`, `master_id` )
                VALUES (%s, %s, %s)'''
            cur.execute(sql, (tag, json.dumps(data), __opts__['id']))

```

### Custom Returners

Place custom returners in a `_returners` directory within the `file_roots` specified by the master config file.

Custom returners are distributed when any of the following are called:

- `state.apply`
- `saltutil.sync_returners`
- `saltutil.sync_all`

Any custom returners which have been synced to a minion that are named the same as one of Salt's default set of returners will take the place of the default returner with the same name.

### Naming the Returner

Note that a returner's default name is its filename (i.e. `foo.py` becomes returner `foo`), but that its name can be overridden by using a `__virtual__` function. A good example of this can be found in the `redis` returner, which is named `redis_return.py` but is loaded as simply `redis`:

```

try:
    import redis
    HAS_REDIS = True
except ImportError:
    HAS_REDIS = False

__virtualname__ = 'redis'

def __virtual__():
    if not HAS_REDIS:
        return False
    return __virtualname__

```

### Testing the Returner

The returner, `prep_jid`, `save_load`, `get_load`, and `event_return` functions can be tested by configuring the `master_job_cache` and `Event Returners` in the master config file and submitting a job to `test.ping` each minion from the master.

Once you have successfully exercised the Master Job Cache functions, test the External Job Cache functions using the `ret` execution module.

```
salt-call ret.get_jids cassandra_cql --output=json
salt-call ret.get_fun cassandra_cql test.ping --output=json
salt-call ret.get_minions cassandra_cql --output=json
salt-call ret.get_jid cassandra_cql 20150330121011408195 --output=json
```

### 30.23.3 Event Returners

For maximum visibility into the history of events across a Salt infrastructure, all events seen by a salt master may be logged to a returner.

To enable event logging, set the `event_return` configuration option in the master config to returner which should be designated as the handler for event returns.

---

**Note:** Not all returners support event returns. Verify a returner has an `event_return()` function before using.

---

**Note:** On larger installations, many hundreds of events may be generated on a busy master every second. Be certain to closely monitor the storage of a given returner as Salt can easily overwhelm an underpowered server with thousands of returns.

---

### 30.23.4 Full List of Returners

#### Full list of builtin returner modules

<i>carbon_return</i>	Take data from salt and ``return" it into a carbon receiver
<i>cassandra_return</i>	Return data to a Cassandra ColumnFamily
<i>couchbase_return</i>	Simple returner for Couchbase.
<i>couchdb_return</i>	Simple returner for CouchDB.
<i>django_return</i>	A returner that will infor a Django system that returns are available using Django's signal system.
<i>elasticsearch_return</i>	Return data to an elasticsearch server for indexing.
<i>etcd_return</i>	Return data to an etcd server or cluster
<i>hipchat_return</i>	Return salt data via hipchat.
<i>kafka_return</i>	Return data to a Kafka topic
<i>local</i>	The local returner is used to test the returner interface, it just prints the
<i>local_cache</i>	Return data to local job cache
<i>memcache_return</i>	Return data to a memcache server
<i>mongo_future_return</i>	Return data to a mongodb server
<i>mongo_return</i>	Return data to a mongodb server
<i>multi_returner</i>	Read/Write multiple returners
<i>mysql</i>	Return data to a mysql server
<i>odbc</i>	Return data to an ODBC compliant server.
<i>postgres</i>	Return data to a postgresql server
<i>postgres_local_cache</i>	Use a postgresql server for the master job cache.
<i>redis_return</i>	Return data to a redis server
<i>sentry_return</i>	Salt returner that report execution results back to sentry.
<i>slack_returner</i>	Return salt data via slack

---

Continued on next page

Table 30.10 -- continued from previous page

<code>sms_return</code>	Return data by SMS.
<code>smtplib_return</code>	Return salt data via email
<code>sqlite3_return</code>	Insert minion return data into a sqlite3 database
<code>syslog_return</code>	Return data to the host operating system's syslog facility
<code>xmpp_return</code>	Return salt data via xmpp

**salt.returners.carbon\_return**

Take data from salt and ``return" it into a carbon receiver

Add the following configuration to the minion configuration file:

```
carbon.host: <server ip address>
carbon.port: 2003
```

Errors when trying to convert data to numbers may be ignored by setting `carbon.skip_on_error` to `True`:

```
carbon.skip_on_error: True
```

By default, data will be sent to carbon using the plaintext protocol. To use the pickle protocol, set `carbon.mode` to `pickle`:

```
carbon.mode: pickle
```

You can also specify the pattern used for the metric base path (except for virt modules metrics):

```
carbon.metric_base_pattern: carbon.[minion_id].[module].[function]
```

**These tokens can be used :** `[module]`: salt module `[function]`: salt function `[minion_id]`: minion id

**Default is :** `carbon.metric_base_pattern: [module].[function].[minion_id]`

Carbon settings may also be configured as:

```
carbon:
  host: <server IP or hostname>
  port: <carbon port>
  skip_on_error: True
  mode: (pickle|text)
  metric_base_pattern: <pattern> | [module].[function].[minion_id]
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.carbon:
  host: <server IP or hostname>
  port: <carbon port>
  skip_on_error: True
  mode: (pickle|text)
```

To use the carbon returner, append `--return carbon` to the salt command.

```
salt '*' test.ping --return carbon
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return carbon --return_config alternative
```

`salt.returners.carbon_return.prep_jid`(*nocache=False, passed\_jid=None*)

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.carbon_return.returner`(*ret*)

Return data to a remote carbon server using the text metric protocol

Each metric will look like:

```
[module].[function].[minion_id].[metric path [...]].[metric name]
```

### `salt.returners.cassandra_return`

Return data to a Cassandra ColumnFamily

Here's an example Keyspace / ColumnFamily setup that works with this returner:

```
create keyspace salt;
use salt;
create column family returns
  with key_validation_class='UTF8Type'
  and comparator='UTF8Type'
  and default_validation_class='UTF8Type';
```

Required python modules: pycassa

To use the cassandra returner, append `--return cassandra` to the salt command. ex:

```
salt '*' test.ping --return cassandra
```

`salt.returners.cassandra_return.prep_jid`(*nocache=False, passed\_jid=None*)

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.cassandra_return.returner`(*ret*)

Return data to a Cassandra ColumnFamily

### `salt.returners.couchbase_return`

Simple returner for Couchbase. Optional configuration settings are listed below, along with sane defaults.

`couchbase.host`: 'salt' `couchbase.port`: 8091 `couchbase.bucket`: 'salt' `couchbase.skip_verify_views`: False

To use the couchbase returner, append `--return couchbase` to the salt command. ex:

```
salt '*' test.ping --return couchbase
```

All of the return data will be stored in documents as follows:

**JID** load: load obj tgt\_minions: list of minions targeted nocache: should we not cache the return data

JID/MINION\_ID return: return\_data out: out\_data

`salt.returners.couchbase_return.get_jid(jid)`

Return the information returned when the specified job id was executed

`salt.returners.couchbase_return.get_jids()`

Return a list of all job ids

`salt.returners.couchbase_return.get_load(jid)`

Return the load data that marks a specified jid

`salt.returners.couchbase_return.prep_jid(nocache=False, passed_jid=None)`

Return a job id and prepare the job id directory This is the function responsible for making sure jids don't collide (unless its passed a jid) So do what you have to do to make sure that stays the case

`salt.returners.couchbase_return.returner(load)`

Return data to the local job cache

`salt.returners.couchbase_return.save_load(jid, clear_load)`

Save the load to the specified jid

#### `salt.returners.couchdb_return`

Simple returner for CouchDB. Optional configuration settings are listed below, along with sane defaults:

```
couchdb.db: 'salt'
couchdb.url: 'http://salt:5984/'
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.couchdb.db: 'salt'
alternative.couchdb.url: 'http://salt:5984/'
```

To use the couchdb returner, append `--return couchdb` to the salt command. Example:

```
salt '*' test.ping --return couchdb
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return couchdb --return_config alternative
```

**On concurrent database access** As this returner creates a couchdb document with the salt job id as document id and as only one document with a given id can exist in a given couchdb database, it is advised for most setups that every minion be configured to write to its own database (the value of `couchdb.db` may be suffixed with the minion id), otherwise multi-minion targetting can lead to losing output:

- the first returning minion is able to create a document in the database
- other minions fail with `{'error': 'HTTP Error 409: Conflict'}`

`salt.returners.couchdb_return.ensure_views()`

This function makes sure that all the views that should exist in the design document do exist.

`salt.returners.couchdb_return.get_fun(fun)`  
Return a dict with key being minion and value being the job details of the last run of function `fun`.

`salt.returners.couchdb_return.get_jid(jid)`  
Get the document with a given JID.

`salt.returners.couchdb_return.get_jids()`  
List all the jobs that we have..

`salt.returners.couchdb_return.get_minions()`  
Return a list of minion identifiers from a request of the view.

`salt.returners.couchdb_return.get_valid_salt_views()`  
Returns a dict object of views that should be part of the salt design document.

`salt.returners.couchdb_return.prep_jid(nocache=False, passed_jid=None)`  
Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.couchdb_return.returner(ret)`  
Take in the return and shove it into the couchdb database.

`salt.returners.couchdb_return.set_salt_view()`  
Helper function that sets the salt design document. Uses `get_valid_salt_views` and some hardcoded values.

#### `salt.returners.django_return`

A returner that will infor a Django system that returns are available using Django's signal system.

<https://docs.djangoproject.com/en/dev/topics/signals/>

It is up to the Django developer to register necessary handlers with the signals provided by this returner and process returns as necessary.

The easiest way to use signals is to import them from this returner directly and then use a decorator to register them.

An example Django module that registers a function called `returner\_callback` with this module's `returner` function:

```
import salt.returners.django_return
from django.dispatch import receiver

@receiver(salt.returners.django_return, sender=returner)
def returner_callback(sender, ret):
    print('I received {0} from {1}'.format(ret, sender))
```

`salt.returners.django_return.prep_jid(nocache=False, passed_jid=None)`  
Do any work necessary to prepare a JID, including sending a custom ID

`salt.returners.django_return.returner(ret)`  
Signal a Django server that a return is available

`salt.returners.django_return.save_load(jid, load)`  
Save the load to the specified jid

#### `salt.returners.elasticsearch_return`

Return data to an elasticsearch server for indexing.

**maintainer** Jurnell Cockhren <jurnell.cockhren@sophicware.com>

**maturity** New

**depends** elasticsearch-py, jsonpickle

**platform** all

To enable this returner the elasticsearch python client must be installed on the desired minions (all or some subset).

The required configuration is as follows:

```
elasticsearch:
  host: 'somehost.example.com:9200'
  index: 'salt'
  number_of_shards: 1 (optional)
  number_of_replicas: 0 (optional)
```

or to specify multiple elasticsearch hosts for resiliency:

```
elasticsearch:
  host:
    - 'somehost.example.com:9200'
    - 'anotherhost.example.com:9200'
    - 'yetanotherhost.example.com:9200'
  index: 'salt'
  number_of_shards: 1 (optional)
  number_of_replicas: 0 (optional)
```

The above configuration can be placed in a targeted pillar, minion or master configurations.

To use the returner per salt call:

```
salt '*' test.ping --return elasticsearch
```

In order to have the returner apply to all minions:

```
ext_job_cache: elasticsearch
```

`salt.returners.elasticsearch_return.prep_jid` (*nocache=False*, *passed\_jid=None*)

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.elasticsearch_return.returner` (*ret*)

Process the return from Salt

### `salt.returners.etcd_return`

Return data to an etcd server or cluster

**depends**

- python-etcd

In order to return to an etcd server, a profile should be created in the master configuration file:

```
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```
etcd.host: 127.0.0.1
etcd.port: 4001
```

Additionally, two more options must be specified in the top-level configuration in order to use the etcd returner:

```
etcd.returner: my_etcd_config
etcd.returner_root: /salt/return
```

The `etcd.returner` option specifies which configuration profile to use. The `etcd.returner_root` option specifies the path inside etcd to use as the root of the returner system.

Once the etcd options are configured, the returner may be used:

CLI Example:

```
salt '*' test.ping --return etcd
```

`salt.returners.etcd_return.get_fun()`

Return a dict of the last function called for all minions

`salt.returners.etcd_return.get_jid(jid)`

Return the information returned when the specified job id was executed

`salt.returners.etcd_return.get_jids()`

Return a list of all job ids

`salt.returners.etcd_return.get_load(jid)`

Return the load data that marks a specified jid

`salt.returners.etcd_return.get_minions()`

Return a list of minions

`salt.returners.etcd_return.prep_jid(nocache=False, passed_jid=None)`

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.etcd_return.returner(ret)`

Return data to an etcd server or cluster

`salt.returners.etcd_return.save_load(jid, load)`

Save the load to the specified jid

#### `salt.returners.hipchat_return`

Return salt data via hipchat.

New in version 2015.5.0.

The following fields can be set in the minion conf file:

```
hipchat.room_id (required)
hipchat.api_key (required)
hipchat.api_version (required)
hipchat.from_name (required)
hipchat.color (optional)
hipchat.notify (optional)
hipchat.profile (optional)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
hipchat.room_id
hipchat.api_key
hipchat.api_version
hipchat.from_name
```

Hipchat settings may also be configured as:

```
hipchat:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

alternative.hipchat:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

hipchat_profile:
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

hipchat:
  profile: hipchat_profile
  room_id: RoomName

alternative.hipchat:
  profile: hipchat_profile
  room_id: RoomName
```

To use the HipChat returner, append '--return hipchat' to the salt command.

```
salt '*' test.ping --return hipchat
```

To use the alternative configuration, append '--return\_config alternative' to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return hipchat --return_config alternative
```

`salt.returners.hipchat_return.returner(ret)`  
Send an hipchat message with the data

#### `salt.returners.kafka_return`

Return data to a Kafka topic

**maintainer** Christer Edwards ([christer.edwards@gmail.com](mailto:christer.edwards@gmail.com))

**maturity** 0.1

**depends** kafka-python

**platform** all

To enable this returner install kafka-python and enable the following settings in the minion config:

**returner.kafka.hostnames:**

- ``server1"
- ``server2"
- ``server3"

returner.kafka.topic: `topic`

To use the kafka returner, append `--return kafka` to the Salt command, eg;

```
salt '*' test.ping --return kafka
```

**salt.returners.kafka\_return.returner** (*ret*)

Return information to a Kafka server

### **salt.returners.local**

The local returner is used to test the returner interface, it just prints the return data to the console to verify that it is being passed properly

To use the local returner, append `--return local` to the salt command. ex:

```
salt '*' test.ping --return local
```

**salt.returners.local.event\_return** (*event*)

Print event return data to the terminal to verify functionality

**salt.returners.local.returner** (*ret*)

Print the return data to the terminal to verify functionality

### **salt.returners.local\_cache**

Return data to local job cache

**salt.returners.local\_cache.clean\_old\_jobs** ()

Clean out the old jobs from the job cache

**salt.returners.local\_cache.get\_jid** (*jid*)

Return the information returned when the specified job id was executed

**salt.returners.local\_cache.get\_jids** ()

Return a list of all job ids

**salt.returners.local\_cache.get\_load** (*jid*)

Return the load data that marks a specified jid

**salt.returners.local\_cache.prep\_jid** (*nocache=False, passed\_jid=None, recurse\_count=0*)

Return a job id and prepare the job id directory.

This is the function responsible for making sure jids don't collide (unless it is passed a jid). So do what you have to do to make sure that stays the case

**salt.returners.local\_cache.returner** (*load*)

Return data to the local job cache

`salt.returners.local_cache.save_load(jid, clear_load, recurse_count=0)`  
 Save the load to the specified jid

#### `salt.returners.memcache_return`

Return data to a memcache server

To enable this returner the minion will need the python client for memcache installed and the following values configured in the minion or master config, these are the defaults.

```
memcache.host: 'localhost'
memcache.port: '11211'
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location.

```
alternative.memcache.host: 'localhost'
alternative.memcache.port: '11211'
```

python2-memcache uses `localhost` and `11211` as syntax on connection.

To use the memcache returner, append `--return memcache` to the salt command.

```
salt '*' test.ping --return memcache
```

To use the alternative configuration, append `--return\_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return memcache --return_config alternative
```

`salt.returners.memcache_return.get_fun(fun)`

Return a dict of the last function called for all minions

`salt.returners.memcache_return.get_jid(jid)`

Return the information returned when the specified job id was executed

`salt.returners.memcache_return.get_jids()`

Return a list of all job ids

`salt.returners.memcache_return.get_load(jid)`

Return the load data that marks a specified jid

`salt.returners.memcache_return.get_minions()`

Return a list of minions

`salt.returners.memcache_return.prep_jid(nocache=False, passed_jid=None)`

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.memcache_return.returner(ret)`

Return data to a memcache data store

`salt.returners.memcache_return.save_load(jid, load)`

Save the load to the specified jid

### `salt.returners.mongo_future_return`

Return data to a mongodb server

Required python modules: pymongo

This returner will send data from the minions to a MongoDB server. To configure the settings for your MongoDB server, add the following lines to the minion config files:

```
mongo.db: <database name>
mongo.host: <server ip address>
mongo.user: <MongoDB username>
mongo.password: <MongoDB user password>
mongo.port: 27017
```

You can also ask for indexes creation on the most common used fields, which should greatly improve performance. Indexes are not created by default.

```
mongo.indexes: true
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.mongo.db: <database name>
alternative.mongo.host: <server ip address>
alternative.mongo.user: <MongoDB username>
alternative.mongo.password: <MongoDB user password>
alternative.mongo.port: 27017
```

This mongo returner is being developed to replace the default mongodb returner in the future and should not be considered API stable yet.

To use the mongo returner, append `--return mongo` to the salt command.

```
salt '*' test.ping --return mongo
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return mongo --return_config alternative
```

`salt.returners.mongo_future_return.get_fun(fun)`  
Return the most recent jobs that have executed the named function

`salt.returners.mongo_future_return.get_jid(jid)`  
Return the return information associated with a jid

`salt.returners.mongo_future_return.get_jids()`  
Return a list of job ids

`salt.returners.mongo_future_return.get_load(jid)`  
Return the load associated with a given job id

`salt.returners.mongo_future_return.get_minions()`  
Return a list of minions

`salt.returners.mongo_future_return.prep_jid`(*nocache=False, passed\_jid=None*)

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.mongo_future_return.returner`(*ret*)

Return data to a mongodb server

`salt.returners.mongo_future_return.save_load`(*jid, load*)

Save the load for a given job id

#### `salt.returners.mongo_return`

Return data to a mongodb server

Required python modules: pymongo

This returner will send data from the minions to a MongoDB server. To configure the settings for your MongoDB server, add the following lines to the minion config files.

```
mongo.db: <database name>
mongo.host: <server ip address>
mongo.user: <MongoDB username>
mongo.password: <MongoDB user password>
mongo.port: 27017
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location.

```
alternative.mongo.db: <database name>
alternative.mongo.host: <server ip address>
alternative.mongo.user: <MongoDB username>
alternative.mongo.password: <MongoDB user password>
alternative.mongo.port: 27017
```

To use the mongo returner, append `--return mongo` to the salt command.

```
salt '*' test.ping --return mongo_return
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return mongo_return --return_config alternative
```

`salt.returners.mongo_return.get_fun`(*fun*)

Return the most recent jobs that have executed the named function

`salt.returners.mongo_return.get_jid`(*jid*)

Return the return information associated with a jid

`salt.returners.mongo_return.prep_jid`(*nocache=False, passed\_jid=None*)

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.mongo_return.returner`(*ret*)

Return data to a mongodb server

### `salt.returners.multi_returner`

Read/Write multiple returners

`salt.returners.multi_returner.clean_old_jobs()`

Clean out the old jobs from all returners (if you have it)

`salt.returners.multi_returner.get_jid(jid)`

Merge the return data from all returners

`salt.returners.multi_returner.get_jids()`

Return all job data from all returners

`salt.returners.multi_returner.get_load(jid)`

Merge the load data from all returners

`salt.returners.multi_returner.prep_jid(nocache=False, passed_jid=None)`

Call both with `prep_jid` on all returners in `multi_returner`

TODO: finish this, what do do when you get different jids from 2 returners... since our jids are time based, this make this problem hard, because they aren't unique, meaning that we have to make sure that no one else got the `jid` and if they did we spin to get a new one, which means ``locking" the `jid` in 2 returners is non-trivial

`salt.returners.multi_returner.returner(load)`

Write return to all returners in `multi_returner`

`salt.returners.multi_returner.save_load(jid, clear_load)`

Write load to all returners in `multi_returner`

### `salt.returners.mysql`

Return data to a mysql server

**maintainer** Dave Boucha <dave@saltstack.com>, Seth House <shouse@saltstack.com>

**maturity** new

**depends** python-mysqldb

**platform** all

To enable this returner, the minion will need the python client for mysql installed and the following values configured in the minion or master config. These are the defaults:

```
mysql.host: 'salt'
mysql.user: 'salt'
mysql.pass: 'salt'
mysql.db: 'salt'
mysql.port: 3306
```

SSL is optional. The defaults are set to None. If you do not want to use SSL, either exclude these options or set them to None.

```
mysql.ssl_ca: None
mysql.ssl_cert: None
mysql.ssl_key: None
```

Alternative configuration values can be used by prefacing the configuration with *alternative.*. Any values not found in the alternative configuration will be pulled from the default location. As stated above, SSL configuration is optional. The following ssl options are simply for illustration purposes:

```
alternative.mysql.host: 'salt'
alternative.mysql.user: 'salt'
alternative.mysql.pass: 'salt'
alternative.mysql.db: 'salt'
alternative.mysql.port: 3306
alternative.mysql.ssl_ca: '/etc/pki/mysql/certs/localhost.pem'
alternative.mysql.ssl_cert: '/etc/pki/mysql/certs/localhost.crt'
alternative.mysql.ssl_key: '/etc/pki/mysql/certs/localhost.key'
```

Use the following mysql database schema:

```
CREATE DATABASE `salt`
DEFAULT CHARACTER SET utf8
DEFAULT COLLATE utf8_general_ci;

USE `salt`;

--
-- Table structure for table `jids`
--

DROP TABLE IF EXISTS `jids`;
CREATE TABLE `jids` (
  `jid` varchar(255) NOT NULL,
  `load` mediumtext NOT NULL,
  UNIQUE KEY `jid` (`jid`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8;

--
-- Table structure for table `salt_returns`
--

DROP TABLE IF EXISTS `salt_returns`;
CREATE TABLE `salt_returns` (
  `fun` varchar(50) NOT NULL,
  `jid` varchar(255) NOT NULL,
  `return` mediumtext NOT NULL,
  `id` varchar(255) NOT NULL,
  `success` varchar(10) NOT NULL,
  `full_ret` mediumtext NOT NULL,
  `alter_time` TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
  KEY `id` (`id`),
  KEY `jid` (`jid`),
  KEY `fun` (`fun`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8;

--
-- Table structure for table `salt_events`
--

DROP TABLE IF EXISTS `salt_events`;
CREATE TABLE `salt_events` (
  `id` BIGINT NOT NULL AUTO_INCREMENT,
```

```
`tag` varchar(255) NOT NULL,  
`data` mediumtext NOT NULL,  
`alter_time` TIMESTAMP DEFAULT CURRENT_TIMESTAMP,  
`master_id` varchar(255) NOT NULL,  
PRIMARY KEY (`id`),  
KEY `tag` (`tag`)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

Required python modules: MySQLdb

To use the mysql returner, append `--return mysql` to the salt command.

```
salt '*' test.ping --return mysql
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return mysql --return_config alternative
```

`salt.returners.mysql.event_return(events)`

Return event to mysql server

Requires that configuration be enabled via `'event_return'` option in master config.

`salt.returners.mysql.get_fun(fun)`

Return a dict of the last function called for all minions

`salt.returners.mysql.get_jid(jid)`

Return the information returned when the specified job id was executed

`salt.returners.mysql.get_jids()`

Return a list of all job ids

`salt.returners.mysql.get_load(jid)`

Return the load data that marks a specified jid

`salt.returners.mysql.get_minions()`

Return a list of minions

`salt.returners.mysql.prep_jid(nocache=False, passed_jid=None)`

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.mysql.returner(ret)`

Return data to a mysql server

`salt.returners.mysql.save_load(jid, load)`

Save the load to the specified jid id

#### `salt.returners.odbc`

Return data to an ODBC compliant server. This driver was developed with Microsoft SQL Server in mind, but theoretically could be used to return data to any compliant ODBC database as long as there is a working ODBC driver for it on your minion platform.

#### **maintainer**

3. (a) Oldham ([cr@saltstack.com](mailto:cr@saltstack.com))

**maturity** New

**depends** unixodbc, pyodbc, freetds (for SQL Server)

**platform** all

To enable this returner the minion will need

On Linux:

unixodbc (<http://www.unixodbc.org>) pyodbc (*pip install pyodbc*) The FreeTDS ODBC driver for SQL Server (<http://www.freetds.org>) or another compatible ODBC driver

On Windows:

TBD

unixODBC and FreeTDS need to be configured via `/etc/odbcinst.ini` and `/etc/odbc.ini`.

`/etc/odbcinst.ini`:

```
[TDS]
Description=TDS
Driver=/usr/lib/x86_64-linux-gnu/odbc/libtdsodbc.so
```

(Note the above Driver line needs to point to the location of the FreeTDS shared library. This example is for Ubuntu 14.04.)

`/etc/odbc.ini`:

```
[TS]
Description = "Salt Returner"
Driver=TDS
Server = <your server ip or fqdn>
Port = 1433
Database = salt
Trace = No
```

Also you need the following values configured in the minion or master config. Configure as you see fit:

```
returner.odbc.dsn: 'TS'
returner.odbc.user: 'salt'
returner.odbc.passwd: 'salt'
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.returner.odbc.dsn: 'TS'
alternative.returner.odbc.user: 'salt'
alternative.returner.odbc.passwd: 'salt'
```

Running the following commands against Microsoft SQL Server in the desired database as the appropriate user should create the database tables correctly. Replace with equivalent SQL for other ODBC-compliant servers

```
--
-- Table structure for table 'jids'
--
if OBJECT_ID('dbo.jids', 'U') is not null
```

```

DROP TABLE dbo.jids

CREATE TABLE dbo.jids (
  jid   varchar(255) PRIMARY KEY,
  load  varchar(MAX) NOT NULL
);

--
-- Table structure for table 'salt_returns'
--
IF OBJECT_ID('dbo.salt_returns', 'U') IS NOT NULL
  DROP TABLE dbo.salt_returns;

CREATE TABLE dbo.salt_returns (
  added    datetime not null default (getdate()),
  fun      varchar(100) NOT NULL,
  jid      varchar(255) NOT NULL,
  retval   varchar(MAX) NOT NULL,
  id       varchar(255) NOT NULL,
  success  bit default(0) NOT NULL,
  full_ret varchar(MAX)
);

CREATE INDEX salt_returns_added on dbo.salt_returns(added);
CREATE INDEX salt_returns_id on dbo.salt_returns(id);
CREATE INDEX salt_returns_jid on dbo.salt_returns(jid);
CREATE INDEX salt_returns_fun on dbo.salt_returns(fun);

```

To use this returner, append `--return odbc` to the salt command.

```

.. code-block:: bash

  salt '*' status.diskusage --return odbc

```

To use the alternative configuration, append `--return_config alternative` to the salt command.

```

.. versionadded:: 2015.5.0

.. code-block:: bash

  salt '*' test.ping --return odbc --return_config alternative

```

`salt.returners.odbc.get_fun(fun)`  
Return a dict of the last function called for all minions

`salt.returners.odbc.get_jid(jid)`  
Return the information returned when the specified job id was executed

`salt.returners.odbc.get_jids()`  
Return a list of all job ids

`salt.returners.odbc.get_load(jid)`  
Return the load data that marks a specified jid

`salt.returners.odbc.get_minions()`  
Return a list of minions

`salt.returners.odbc.prep_jid(nocache=False, passed_jid=None)`  
Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.odbc.returner`(*ret*)

Return data to an odbc server

`salt.returners.odbc.save_load`(*jid, load*)

Save the load to the specified jid id

`salt.returners.postgres`

Return data to a postgresql server

**maintainer** None

**maturity** New

**depends** pycopg2

**platform** all

To enable this returner the minion will need the pycopg2 installed and the following values configured in the minion or master config:

```
returner.postgres.host: 'salt'
returner.postgres.user: 'salt'
returner.postgres.passwd: 'salt'
returner.postgres.db: 'salt'
returner.postgres.port: 5432
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.returner.postgres.host: 'salt'
alternative.returner.postgres.user: 'salt'
alternative.returner.postgres.passwd: 'salt'
alternative.returner.postgres.db: 'salt'
alternative.returner.postgres.port: 5432
```

Running the following commands as the postgres user should create the database correctly:

```
psql << EOF
CREATE ROLE salt WITH PASSWORD 'salt';
CREATE DATABASE salt WITH OWNER salt;
EOF

psql -h localhost -U salt << EOF
--
-- Table structure for table 'jids'
--
DROP TABLE IF EXISTS jids;
CREATE TABLE jids (
  jid varchar(20) PRIMARY KEY,
  load text NOT NULL
);
--
-- Table structure for table 'salt_returns'
--
```

```
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (
  added      TIMESTAMP WITH TIME ZONE DEFAULT now(),
  fun        text NOT NULL,
  jid        varchar(20) NOT NULL,
  return     text NOT NULL,
  id         text NOT NULL,
  success    boolean
);
CREATE INDEX ON salt_returns (added);
CREATE INDEX ON salt_returns (id);
CREATE INDEX ON salt_returns (jid);
CREATE INDEX ON salt_returns (fun);
EOF
```

Required python modules: psycopg2

To use the postgres returner, append '--return postgres' to the salt command.

```
salt '*' test.ping --return postgres
```

To use the alternative configuration, append '--return\_config alternative' to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return postgres --return_config alternative
```

`salt.returners.postgres.get_fun(fun)`

Return a dict of the last function called for all minions

`salt.returners.postgres.get_jid(jid)`

Return the information returned when the specified job id was executed

`salt.returners.postgres.get_jids()`

Return a list of all job ids

`salt.returners.postgres.get_load(jid)`

Return the load data that marks a specified jid

`salt.returners.postgres.get_minions()`

Return a list of minions

`salt.returners.postgres.prep_jid(nocache=False, passed_jid=None)`

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.postgres.returner(ret)`

Return data to a postgres server

`salt.returners.postgres.save_load(jid, load)`

Save the load to the specified jid id

`salt.returners.postgres_local_cache`

Use a postgresql server for the master job cache. This helps the job cache to cope with scale.

**maintainer** [giredelinguys@gmail.com](mailto:giredelinguys@gmail.com)

**maturity** New

**depends** psycpg2

**platform** all

To enable this returner the minion will need the psycpg2 installed and the following values configured in the master config:

```
master_job_cache: postgres_local_cache
master_job_cache.postgres.host: 'salt'
master_job_cache.postgres.user: 'salt'
master_job_cache.postgres.passwd: 'salt'
master_job_cache.postgres.db: 'salt'
master_job_cache.postgres.port: 5432
```

Running the following command as the postgres user should create the database correctly:

```
psql << EOF
CREATE ROLE salt WITH PASSWORD 'salt';
CREATE DATABASE salt WITH OWNER salt;
EOF
```

and then:

```
psql -h localhost -U salt << EOF
--
-- Table structure for table 'jids'
--
DROP TABLE IF EXISTS jids;
CREATE TABLE jids (
  jid  varchar(20) PRIMARY KEY,
  started  TIMESTAMP WITH TIME ZONE DEFAULT now(),
  tgt_type text NOT NULL,
  cmd text NOT NULL,
  tgt text NOT NULL,
  kwargs text NOT NULL,
  ret text NOT NULL,
  username text NOT NULL,
  arg text NOT NULL,
  fun text NOT NULL
);
--
-- Table structure for table 'salt_returns'
--
-- note that 'success' must not have NOT NULL constraint, since
-- some functions don't provide it.
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (
  added  TIMESTAMP WITH TIME ZONE DEFAULT now(),
  fun text NOT NULL,
  jid  varchar(20) NOT NULL,
  return text NOT NULL,
  id text NOT NULL,
  success boolean
);
CREATE INDEX ON salt_returns (added);
```

```
CREATE INDEX ON salt_returns (id);
CREATE INDEX ON salt_returns (jid);
CREATE INDEX ON salt_returns (fun);
EOF
```

Required python modules: psycopg2

`salt.returners.postgres_local_cache.clean_old_jobs()`

Clean out the old jobs from the job cache

`salt.returners.postgres_local_cache.get_jid(jid)`

Return the information returned when the specified job id was executed

`salt.returners.postgres_local_cache.get_jids()`

Return a list of all job ids For master job cache this also formats the output and returns a string

`salt.returners.postgres_local_cache.get_load(jid)`

Return the load data that marks a specified jid

`salt.returners.postgres_local_cache.prep_jid(nocache=False, passed_jid=None)`

Return a job id and prepare the job id directory This is the function responsible for making sure jids don't collide (unless its passed a jid). So do what you have to do to make sure that stays the case

`salt.returners.postgres_local_cache.returner(load)`

Return data to a postgres server

`salt.returners.postgres_local_cache.save_load(jid, clear_load)`

Save the load to the specified jid id

`salt.returners.redis_return`

Return data to a redis server

To enable this returner the minion will need the python client for redis installed and the following values configured in the minion or master config, these are the defaults:

```
redis.db: '0'
redis.host: 'salt'
redis.port: 6379
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.redis.db: '0'
alternative.redis.host: 'salt'
alternative.redis.port: 6379
```

To use the redis returner, append `--return redis` to the salt command.

```
salt '*' test.ping --return redis
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return redis --return_config alternative
```

`salt.returners.redis_return.get_fun(fun)`  
Return a dict of the last function called for all minions

`salt.returners.redis_return.get_jid(jid)`  
Return the information returned when the specified job id was executed

`salt.returners.redis_return.get_jids()`  
Return a list of all job ids

`salt.returners.redis_return.get_load(jid)`  
Return the load data that marks a specified jid

`salt.returners.redis_return.get_minions()`  
Return a list of minions

`salt.returners.redis_return.prep_jid(nocache=False, passed_jid=None)`  
Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.redis_return.returner(ret)`  
Return data to a redis data store

`salt.returners.redis_return.save_load(jid, load)`  
Save the load to the specified jid

#### `salt.returners.sentry_return`

Salt returner that report execution results back to sentry. The returner will inspect the payload to identify errors and flag them as such.

Pillar needs something like:

```
raven:
  servers:
    - http://192.168.1.1
    - https://sentry.example.com
  public_key: deadbeefdeadbeefdeadbeefdeadbeef
  secret_key: beefdeadbeefdeadbeefdeadbeefdead
  project: 1
  tags:
    - os
    - master
    - saltversion
    - cpuarch
```

and <https://pypi.python.org/pypi/raven> installed

The tags list (optional) specifies grains items that will be used as sentry tags, allowing tagging of events in the sentry ui.

`salt.returners.sentry_return.prep_jid(nocache=False, passed_jid=None)`  
Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.sentry_return.returner(ret)`  
Log outcome to sentry. The returner tries to identify errors and report them as such. All other messages will be reported at info level.

### salt.returners.slack\_returner

Return salt data via slack

New in version 2015.5.0.

The following fields can be set in the minion conf file:

```
slack.channel (required)
slack.api_key (required)
slack.from_name (required)
slack.profile (optional)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
slack.channel
slack.api_key
slack.from_name
```

Hipchat settings may also be configured as:

```
slack:
  channel: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  from_name: user@email.com

alternative.slack:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  from_name: user@email.com

slack_profile:
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  from_name: user@email.com

slack:
  profile: slack_profile
  channel: RoomName

alternative.slack:
  profile: slack_profile
  channel: RoomName
```

To use the HipChat returner, append '--return slack' to the salt command.

```
salt '*' test.ping --return slack
```

To use the alternative configuration, append '--return\_config alternative' to the salt command.

```
salt '*' test.ping --return slack --return_config alternative
```

`salt.returners.slack_returner.returner` (*ret*)  
Send an slack message with the data

**salt.returners.sms\_return**

Return data by SMS.

New in version 2015.5.0.

**maintainer** Damian Myerscough

**maturity** new

**depends** twilio

**platform** all

To enable this returner the minion will need the python twilio library installed and the following values configured in the minion or master config:

```
twilio.sid: 'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
twilio.token: 'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
twilio.to: '+1415XXXXXXXX'
twilio.from: '+1650XXXXXXXX'
```

To use the sms returner, append '--return sms' to the salt command.

```
salt '*' test.ping --return sms
```

**salt.returners.sms\_return.returner**(ret)

Return a response in an SMS message

**salt.returners.smtp\_return**

Return salt data via email

The following fields can be set in the minion conf file:

```
smtp.from (required)
smtp.to (required)
smtp.host (required)
smtp.port (optional, defaults to 25)
smtp.username (optional)
smtp.password (optional)
smtp.tls (optional, defaults to False)
smtp.subject (optional, but helpful)
smtp.gpgowner (optional)
smtp.fields (optional)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.smtp.from
alternative.smtp.to
alternative.smtp.host
alternative.smtp.port
alternative.smtp.username
alternative.smtp.password
alternative.smtp.tls
```

```
alternative.smtp.subject
alternative.smtp.gpgowner
alternative.smtp.fields
```

There are a few things to keep in mind:

- If a username is used, a password is also required. It is recommended (but not required) to use the TLS setting when authenticating.
- You should at least declare a subject, but you don't have to.
- The use of encryption, i.e. setting gpgowner in your settings, requires python-gnupg to be installed.
- The field gpgowner specifies a user's ~/.gpg directory. This must contain a gpg public key matching the address the mail is sent to. If left unset, no encryption will be used.
- smtp.fields lets you include the value(s) of various fields in the subject line of the email. These are comma-delimited. For instance:

```
smtp.fields: id,fun
```

...will display the id of the minion and the name of the function in the subject line. You may also use `jid` (the job id), but it is generally recommended not to use `return`, which contains the entire return data structure (which can be very large). Also note that the subject is always unencrypted.

To use the SMTP returner, append `--return smtp` to the salt command.

```
salt '*' test.ping --return smtp
```

To use the alternative configuration, append `--return\_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return smtp --return_config alternative
```

**salt.returners.smtp\_return.prep\_jid**(*nocache=False, passed\_jid=None*)

Do any work necessary to prepare a JID, including sending a custom id

**salt.returners.smtp\_return.returner**(*ret*)

Send an email with the data

### **salt.returners.sqlite3**

Insert minion return data into a sqlite3 database

**maintainer** Mickey Malone <[mickey.malone@gmail.com](mailto:mickey.malone@gmail.com)>

**maturity** New

**depends** None

**platform** All

Sqlite3 is a serverless database that lives in a single file. In order to use this returner the database file must exist, have the appropriate schema defined, and be accessible to the user whom the minion process is running as. This returner requires the following values configured in the master or minion config:

```
returner.sqlite3.database: /usr/lib/salt/salt.db
returner.sqlite3.timeout: 5.0
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.returner.sqlite3.database: /usr/lib/salt/salt.db
alternative.returner.sqlite3.timeout: 5.0
```

Use the commands to create the sqlite3 database and tables:

```
sqlite3 /usr/lib/salt/salt.db << EOF
--
-- Table structure for table 'jids'
--
CREATE TABLE jids (
  jid TEXT PRIMARY KEY,
  load TEXT NOT NULL
);
--
-- Table structure for table 'salt_returns'
--
CREATE TABLE salt_returns (
  fun TEXT KEY,
  jid TEXT KEY,
  id TEXT KEY,
  fun_args TEXT,
  date TEXT NOT NULL,
  full_ret TEXT NOT NULL,
  success TEXT NOT NULL
);
EOF
```

To use the sqlite returner, append '--return sqlite3' to the salt command.

```
salt '*' test.ping --return sqlite3
```

To use the alternative configuration, append '--return\_config alternative' to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return sqlite3 --return_config alternative
```

```
salt.returners.sqlite3_return.get_fun(fun)
    Return a dict of the last function called for all minions
salt.returners.sqlite3_return.get_jid(jid)
    Return the information returned from a specified jid
salt.returners.sqlite3_return.get_jids()
    Return a list of all job ids
```

`salt.returners.sqlite3_return.get_load(jid)`

Return the load from a specified jid

`salt.returners.sqlite3_return.get_minions()`

Return a list of minions

`salt.returners.sqlite3_return.prep_jid(nocache=False, passed_jid=None)`

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.sqlite3_return.returner(ret)`

Insert minion return data into the sqlite3 database

`salt.returners.sqlite3_return.save_load(jid, load)`

Save the load to the specified jid

#### `salt.returners.syslog_return`

Return data to the host operating system's syslog facility

Required python modules: syslog, json

The syslog returner simply reuses the operating system's syslog facility to log return data

To use the syslog returner, append `--return syslog` to the salt command.

```
salt '*' test.ping --return syslog
```

`salt.returners.syslog_return.prep_jid(nocache=False, passed_jid=None)`

Do any work necessary to prepare a JID, including sending a custom id

`salt.returners.syslog_return.returner(ret)`

Return data to the local syslog

#### `salt.returners.xmpp_return`

Return salt data via xmpp

The following fields can be set in the minion conf file:

```
xmpp.jid (required)
xmpp.password (required)
xmpp.recipient (required)
xmpp.profile (optional)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
xmpp.jid
xmpp.password
xmpp.recipient
xmpp.profile
```

XMPP settings may also be configured as:

```

xmpp:
  jid: user@xmpp.domain.com/resource
  password: password
  recipient: user@xmpp.example.com

alternative.xmpp:
  jid: user@xmpp.domain.com/resource
  password: password
  recipient: someone@xmpp.example.com

xmpp_profile:
  jid: user@xmpp.domain.com/resource
  password: password

xmpp:
  profile: xmpp_profile
  recipient: user@xmpp.example.com

alternative.xmpp:
  profile: xmpp_profile
  recipient: someone-else@xmpp.example.com

```

To use the XMPP returner, append `--return xmpp` to the salt command.

```
salt '*' test.ping --return xmpp
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return xmpp --return_config alternative
```

```
class salt.returners.xmpp_return.SendMsgBot(jid, password, recipient, msg)
```

```
    start(event)
```

```
    salt.returners.xmpp_return.returner(ret)
```

```
        Send an xmpp message with the data
```

## 30.24 Full list of builtin roster modules

<i>ansible</i>	Read in an Ansible inventory file or script
<i>cache</i>	Use the minion cache on the master to derive IP addresses based on minion ID.
<i>cloud</i>	Use the cloud cache on the master to derive IPv4 addresses based on minion ID.
<i>clustershell</i>	This roster resolves hostname in a pdsh/clustershell style.
<i>flat</i>	Read in the roster from a flat file using the renderer system
<i>scan</i>	Scan a netmask or ipaddr for open ssh ports

### 30.24.1 salt.roster.ansible

Read in an Ansible inventory file or script

Flat inventory files should be in the regular ansible inventory format.

```
[servers]
salt.gtmanfred.com ansible_ssh_user=gtmanfred ansible_ssh_host=127.0.0.1 ansible_ssh_port=22 ansible_

[desktop]
home ansible_ssh_user=gtmanfred ansible_ssh_host=12.34.56.78 ansible_ssh_port=23 ansible_ssh_pass='pa

[computers:children]
desktop
servers

[names:vars]
http_port=80
```

then salt-ssh can be used to hit any of them

```
[~]# salt-ssh all test.ping
salt.gtmanfred.com:
  True
home:
  True
[~]# salt-ssh desktop test.ping
home:
  True
[~]# salt-ssh computers test.ping
salt.gtmanfred.com:
  True
home:
  True
[~]# salt-ssh salt.gtmanfred.com test.ping
salt.gtmanfred.com:
  True
```

There is also the option of specifying a dynamic inventory, and generating it on the fly

```
#!/bin/bash
echo '{
  "servers": {
    "hosts": [
      "salt.gtmanfred.com"
    ]
  },
  "desktop": {
    "hosts": [
      "home"
    ]
  },
  "computers": {
    "hosts": {},
    "children": [
      "desktop",
      "servers"
    ]
  },
  "_meta": {
    "hostvars": {
```

```

"salt.gtmanfred.com": {
  "ansible_ssh_user": "gtmanfred",
  "ansible_ssh_host": "127.0.0.1",
  "ansible_sudo_pass": "password",
  "ansible_ssh_port": 22
},
"home": {
  "ansible_ssh_user": "gtmanfred",
  "ansible_ssh_host": "12.34.56.78",
  "ansible_sudo_pass": "password",
  "ansible_ssh_port": 23
}
}
}
}'

```

This is the format that an inventory script needs to output to work with ansible, and thus here.

```

[~]# salt-ssh --roster-file /etc/salt/hosts salt.gtmanfred.com test.ping
salt.gtmanfred.com:
    True

```

Any of the [groups] or direct hostnames will return. The `all` is special, and returns everything.

**class salt.roster.ansible.Inventory**(tgt, tgt\_type='glob', inventory\_file='/etc/salt/roster')

Matcher for static inventory files

**class salt.roster.ansible.Script**(tgt, tgt\_type='glob', inventory\_file='/etc/salt/roster')

Matcher for Inventory scripts

**class salt.roster.ansible.Target**

**get\_glob()**  
Return minions that match via glob

**targets()**  
Execute the correct tgt\_type routine and return

**salt.roster.ansible.targets**(tgt, tgt\_type='glob', \*\*kwargs)

Return the targets from the ansible inventory\_file Default: /etc/salt/roster

### 30.24.2 salt.roster.cache

Use the minion cache on the master to derive IP addresses based on minion ID.

Currently only contains logic to return an IPv4 address; does not handle IPv6, or authentication (passwords, keys, etc).

It is possible to configure this roster to prefer a particular type of IP over another. To configure the order, set the roster\_order in the master config file. The default for this is:

```

roster_order:
- public
- private
- local

```

`salt.roster.cache.extract_ipv4(roster_order, ipv4)`

Extract the preferred IP address from the ipv4 grain

`salt.roster.cache.targets(tgt, tgt_type='glob', **kwargs)`

Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

### 30.24.3 salt.roster.cloud

Use the cloud cache on the master to derive IPv4 addresses based on minion ID.

This roster requires that the minion in question was created using at least the 2015.5.0 version of Salt Cloud. Starting with the 2015.5.0 release, Salt Cloud maintains an index of minions that it creates and deletes. This index tracks the provider and profile configuration used to provision the minion, including authentication information. So long as this configuration remains current, it can be used by Salt SSH to log into any minion in the index.

`salt.roster.cloud.extract_ipv4(roster_order, ipv4)`

Extract the preferred IP address from the ipv4 grain

`salt.roster.cloud.targets(tgt, tgt_type='glob', **kwargs)`

Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

### 30.24.4 salt.roster.clustershell

This roster resolves hostname in a pdsh/clustershell style.

**depends** clustershell, <https://github.com/cea-hpc/clustershell>

When you want to use host globs for target matching, use `--roster clustershell`. For example:

```
salt-ssh --roster clustershell 'server_[1-10,21-30],test_server[5,7,9]' test.ping
```

`salt.roster.clustershell.targets(tgt, tgt_type='glob', **kwargs)`

Return the targets

### 30.24.5 salt.roster.flat

Read in the roster from a flat file using the renderer system

`class salt.roster.flat.RosterMatcher(raw, tgt, tgt_type, ipv='ipv4')`

Matcher for the roster data structure

**get\_data**(minion)

Return the configured ip

**ret\_glob\_minions**()

Return minions that match via glob

**ret\_list\_minions**()

Return minions that match via list

**ret\_pcre\_minions**()

Return minions that match via pcre

**targets**()

Execute the correct tgt\_type routine and return

`salt.roster.flat.targets(tgt, tgt_type='glob', **kwargs)`

Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

### 30.24.6 salt.roster.scan

Scan a netmask or ipaddr for open ssh ports

```
class salt.roster.scan.RosterMatcher(tgt, tgt_type)
```

Matcher for the roster data structure

```
targets()
```

Return ip addrs based on netmask, sitting in the ``glob" spot because it is the default

```
salt.roster.scan.targets(tgt, tgt_type='glob', **kwargs)
```

Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

## 30.25 Salt Runners

Salt runners are convenience applications executed with the salt-run command.

Salt runners work similarly to Salt execution modules however they execute on the Salt master itself instead of remote Salt minions.

A Salt runner can be a simple client call or a complex application.

See also:

*The full list of runners*

### 30.25.1 Full list of runner modules

<i>cache</i>	Return cached data from minions
<i>cloud</i>	The Salt Cloud Runner
<i>doc</i>	A runner module to collect and display the inline documentation from the
<i>drac</i>	Manage Dell DRAC from the Master
<i>error</i>	Error generator to enable integration testing of salt runner error handling
<i>f5</i>	Runner to provide F5 Load Balancer functionality
<i>fileservers</i>	Directly manage the Salt fileservers plugins
<i>git_pillar</i>	Directly manage the salt git_pillar plugin
<i>http</i>	Module for making various web calls.
<i>jobs</i>	A convenience system to manage jobs, both active and already run
<i>launchd</i>	Manage launchd plist files
<i>lxc</i>	Control Linux Containers via Salt
<i>manage</i>	General management functions for salt, tools like seeing what hosts are up
<i>mine</i>	A runner to access data from the salt mine
<i>nacl</i>	This runner helps create encrypted passwords that can be included in pillars.
<i>network</i>	Network tools to run from the Master
<i>pagerduty</i>	Runner Module for Firing Events via PagerDuty
<i>pillar</i>	Functions to interact with the pillar compiler on the master
<i>queue</i>	General management and processing of queues.
<i>sdb</i>	Runner for setting and querying data via the sdb API on the master
<i>search</i>	Runner frontend to search system
<i>state</i>	Execute overstate functions
<i>survey</i>	A general map/reduce style salt runner for aggregating results returned by several different minions.
<i>test</i>	This runner is used only for test purposes and servers no production purpose

Continued on next page

Table 30.12 -- continued from previous page

<i>thin</i>	The thin runner is used to manage the salt thin systems.
<i>virt</i>	Control virtual machines via Salt
<i>winrepo</i>	Runner to manage Windows software repo

**salt.runners.cache**

Return cached data from minions

**salt.runners.cache.clear\_all** (*tgt=None, expr\_form='glob'*)  
Clear the cached pillar, grains, and mine data of the targeted minions

CLI Example:

```
salt-run cache.clear_all
```

**salt.runners.cache.clear\_grains** (*tgt=None, expr\_form='glob'*)  
Clear the cached grains data of the targeted minions

CLI Example:

```
salt-run cache.clear_grains
```

**salt.runners.cache.clear\_mine** (*tgt=None, expr\_form='glob'*)  
Clear the cached mine data of the targeted minions

CLI Example:

```
salt-run cache.clear_mine
```

**salt.runners.cache.clear\_mine\_func** (*tgt=None, expr\_form='glob', clear\_mine\_func\_flag=None*)  
Clear the cached mine function data of the targeted minions

CLI Example:

```
salt-run cache.clear_mine_func tgt='*' clear_mine_func='network.interfaces'
```

**salt.runners.cache.clear\_pillar** (*tgt=None, expr\_form='glob'*)  
Clear the cached pillar data of the targeted minions

CLI Example:

```
salt-run cache.clear_pillar
```

**salt.runners.cache.grains** (*tgt=None, expr\_form='glob', outputter=None, \*\*kwargs*)  
Return cached grains of the targeted minions

CLI Example:

```
salt-run cache.grains
```

**salt.runners.cache.mine** (*tgt=None, expr\_form='glob', outputter=None, \*\*kwargs*)  
Return cached mine data of the targeted minions

CLI Example:

```
salt-run cache.mine
```

**salt.runners.cache.pillar** (*tgt=None, expr\_form='glob', outputter=None, \*\*kwargs*)  
Return cached pillars of the targeted minions

CLI Example:

```
salt-run cache.pillar
```

## salt.runners.cloud

### The Salt Cloud Runner

This runner wraps the functionality of salt cloud making salt cloud routines available to all internal apis via the runner system

**salt.runners.cloud.action**(*func=None, cloudmap=None, instances=None, provider=None, instance=None, \*\*kwargs*)

Execute a single action on the given map/provider/instance

**salt.runners.cloud.create**(*provider, instances, \*\*kwargs*)

Create an instance using Salt Cloud

CLI Example:

```
salt-run cloud.create my-ec2-config myinstance image=ami-1624987f size='t1.micro' ss
```

**salt.runners.cloud.destroy**(*instances*)

Destroy the named vm(s)

**salt.runners.cloud.full\_query**(*query\_type='list\_nodes\_full'*)

List all available cloud provider data

**salt.runners.cloud.list\_images**(*provider='all'*)

List cloud provider images for the given providers

**salt.runners.cloud.list\_locations**(*provider='all'*)

List cloud provider sizes for the given providers

**salt.runners.cloud.list\_sizes**(*provider='all'*)

List cloud provider sizes for the given providers

**salt.runners.cloud.map\_run**(*path, \*\*kwargs*)

Execute a salt cloud map file

**salt.runners.cloud.profile**(*prof=None, instances=None, \*\*kwargs*)

Create a cloud vm with the given profile and instances, instances can be a list or comma-delimited string

CLI Example:

```
salt-run cloud.profile prof=my-ec2 instances=node1,node2,node3
```

**salt.runners.cloud.query**(*query\_type='list\_nodes'*)

List cloud provider data for all providers

**salt.runners.cloud.select\_query**(*query\_type='list\_nodes\_select'*)

List selected nodes

## salt.runners.doc

A runner module to collect and display the inline documentation from the various module types

**salt.runners.doc.execution**()

Collect all the sys.doc output from each minion and return the aggregate

CLI Example:

```
salt-run doc.execution
```

`salt.runners.doc.runner()`

Return all inline documentation for runner modules

CLI Example:

```
salt-run doc.runner
```

`salt.runners.doc.wheel()`

Return all inline documentation for wheel modules

CLI Example:

```
salt-run doc.wheel
```

### `salt.runners.drac`

Manage Dell DRAC from the Master

The login credentials need to be configured in the Salt master configuration file.

`salt.runners.drac.poweroff(hostname, timeout=20)`

Power server off

CLI Example:

```
salt-run drac.poweroff example.com
```

`salt.runners.drac.poweron(hostname, timeout=20)`

Power server on

CLI Example:

```
salt-run drac.poweron example.com
```

`salt.runners.drac.pxe(hostname, timeout=20)`

Connect to the Dell DRAC and have the boot order set to PXE and power cycle the system to PXE boot

CLI Example:

```
salt-run drac.pxe example.com
```

`salt.runners.drac.reboot(hostname, timeout=20)`

Reboot a server using the Dell DRAC

CLI Example:

```
salt-run drac.reboot example.com
```

`salt.runners.drac.version(hostname, timeout=20)`

Display the version of DRAC

CLI Example:

```
salt-run drac.version example.com
```

**salt.runners.error**

Error generator to enable integration testing of salt runner error handling

```
salt.runners.error.error(name=None, message='')
```

If name is None Then return empty dict

Otherwise raise an exception with `__name__` from name, message from message

CLI Example:

```
salt-run error
salt-run error.error name="Exception" message="This is an error."
```

**salt.runners.f5**

Runner to provide F5 Load Balancer functionality

**depends**

- pycontrol Python module

**configuration** In order to connect to a F5 Load Balancer, you must specify in the Salt master configuration the currently available load balancers

```
load_balancers:
  bigip1.example.com
    username: admin
    password: secret
  bigip2.example.com:
    username: admin
    password: secret
```

```
class salt.runners.f5.F5Mgmt(lb, username, password)
```

```
add_pool_member(name, port, pool_name)
```

Add a node to a pool

```
check_member_pool(member, pool_name)
```

Check a pool member exists in a specific pool

```
check_pool(name)
```

Check to see if a pool exists

```
check_virtualserver(name)
```

Check to see if a virtual server exists

```
create_pool(name, method='ROUND_ROBIN')
```

Create a pool on the F5 load balancer

```
create_vs(name, ip, port, protocol, profile, pool_name)
```

Create a virtual server

```
lbmethods()
```

List all the load balancer methods

```
salt.runners.f5.add_pool_member(lb, name, port, pool_name)
```

Add a node to a pool

CLI Examples:

```
salt-run f5.add_pool_member load_balancer 10.0.0.1 80 my_pool
```

**salt.runners.f5.check\_member\_pool**(*lb, member, pool\_name*)

Check a pool member exists in a specific pool

CLI Examples:

```
salt-run f5.check_member_pool load_balancer 10.0.0.1 my_pool
```

**salt.runners.f5.check\_pool**(*lb, name*)

Check to see if a pool exists

CLI Examples:

```
salt-run f5.check_pool load_balancer pool_name
```

**salt.runners.f5.check\_virtualserver**(*lb, name*)

Check to see if a virtual server exists

CLI Examples:

```
salt-run f5.check_virtualserver load_balancer virtual_server
```

**salt.runners.f5.create\_pool**(*lb, name, method='ROUND\_ROBIN'*)

Create a pool on the F5 load balancer

CLI Examples:

```
salt-run f5.create_pool load_balancer pool_name loadbalance_method  
salt-run f5.create_pool load_balancer my_pool ROUND_ROBIN
```

**salt.runners.f5.create\_vs**(*lb, name, ip, port, protocol, profile, pool\_name*)

Create a virtual server

CLI Examples:

```
salt-run f5.create_vs lbalancer vs_name 10.0.0.1 80 tcp http poolname
```

## **salt.runners.fileserver**

Directly manage the Salt fileserver plugins

**salt.runners.fileserver.clear\_cache**(*backend=None*)

New in version 2015.5.0.

Clear the fileserver cache from VCS fileserver backends (*git, hg, svn*). Executing this runner with no arguments will clear the cache for all enabled VCS fileserver backends, but this can be narrowed using the **backend** argument.

**backend** Only clear the update lock for the specified backend(s). If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: **backend=-roots,git**) then the ones starting with a minus sign will be disregarded.

CLI Example:

```
salt-run fileserver.clear_cache  
salt-run fileserver.clear_cache backend=git,hg  
salt-run fileserver.clear_cache hg  
salt-run fileserver.clear_cache -roots
```

`salt.runners.fileserver.clear_lock`(*backend=None, remote=None*)

New in version 2015.5.0.

Clear the fileserver update lock from VCS fileserver backends (*git, hg, svn*). This should only need to be done if a fileserver update was interrupted and a remote is not updating (generating a warning in the Master's log file). Executing this runner with no arguments will remove all update locks from all enabled VCS fileserver backends, but this can be narrowed by using the following arguments:

**backend** Only clear the update lock for the specified backend(s).

**remote** If not None, then any remotes which contain the passed string will have their lock cleared. For example, a `remote` value of `github` will remove the lock from all github.com remotes.

CLI Example:

```
salt-run fileserver.clear_lock
salt-run fileserver.clear_lock backend=git,hg
salt-run fileserver.clear_lock backend=git remote=github
salt-run fileserver.clear_lock remote=bitbucket
```

`salt.runners.fileserver.dir_list`(*saltenv='base', backend=None, outputter=None*)

Return a list of directories in the given environment

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:

```
salt-run fileserver.dir_list
salt-run fileserver.dir_list saltenv=prod
salt-run fileserver.dir_list saltenv=dev backend=git
salt-run fileserver.dir_list base hg,roots
salt-run fileserver.dir_list -git
```

`salt.runners.fileserver.empty_dir_list`(*saltenv='base', backend=None, outputter=None*)

New in version 2015.5.0.

Return a list of empty directories in the given environment

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

---

**Note:** Some backends (such as *git* and *hg*) do not support empty directories. So, passing `backend=git` or `backend=hg` will result in an empty list being returned.

---

CLI Example:

```
salt-run fileserver.empty_dir_list
salt-run fileserver.empty_dir_list saltenv=prod
salt-run fileserver.empty_dir_list backend=roots
```

`salt.runners.fileserver.envs` (*backend=None, sources=False, outputter=None*)

Return the available fileserver environments. If no backend is provided, then the environments for all configured backends will be returned.

**backend** Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: `backend=["roots', 'git']"`)

CLI Example:

```
salt-run fileserver.envs
salt-run fileserver.envs backend=roots,git
salt-run fileserver.envs git
```

`salt.runners.fileserver.file_list` (*saltenv='base', backend=None, outputter=None*)

Return a list of files from the salt fileserver

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Examples:

```
salt-run fileserver.file_list
salt-run fileserver.file_list saltenv=prod
salt-run fileserver.file_list saltenv=dev backend=git
salt-run fileserver.file_list base hg,roots
salt-run fileserver.file_list -git
```

`salt.runners.fileserver.lock` (*backend=None, remote=None*)

New in version 2015.5.0.

Set a fileserver update lock for VCS fileserver backends (*git, hg, svn*).

---

**Note:** This will only operate on enabled backends (those configured in *fileserver\_backend*).

---

**backend** Only set the update lock for the specified backend(s).

**remote** If not None, then any remotes which contain the passed string will have their lock cleared. For example, a `remote` value of `*github.com*` will remove the lock from all github.com remotes.

CLI Example:

```
salt-run fileserver.lock
salt-run fileserver.lock backend=git,hg
salt-run fileserver.lock backend=git remote='*github.com*'
salt-run fileserver.lock remote=bitbucket
```

`salt.runners.fileserver.symlink_list` (*saltenv='base', backend=None, outputter=None*)

Return a list of symlinked files and dirs

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:

```
salt-run fileserver.symlink_list
salt-run fileserver.symlink_list saltenv=prod
salt-run fileserver.symlink_list saltenv=dev backend=git
salt-run fileserver.symlink_list base hg,roots
salt-run fileserver.symlink_list -git
```

**salt.runners.fileserver.update** (*backend=None*)

Update the fileserver cache. If no backend is provided, then the cache for all configured backends will be updated.

**backend** Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: `backend=["roots', 'git']"`)

CLI Example:

```
salt-run fileserver.update
salt-run fileserver.update backend=roots,git
```

### **salt.runners.git\_pillar**

Directly manage the salt git\_pillar plugin

**salt.runners.git\_pillar.update** (*branch, repo*)

Execute an update for the configured git fileserver backend for Pillar

CLI Example:

```
salt-run git_pillar.update branch='branch' repo='location'
```

### **salt.runners.http**

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

**salt.runners.http.query** (*url, output=True, \*\*kwargs*)

Query a resource, and decode the return data

New in version 2015.5.0.

CLI Example:

```

salt-run http.query http://somelink.com/
salt-run http.query http://somelink.com/ method=POST          params='key1=val1&key2=val2'
salt-run http.query http://somelink.com/ method=POST          data='<xml>somecontent</xml>'

```

**salt.runners.http.update\_ca\_bundle** (*target=None, source=None, merge\_files=None*)  
Update the local CA bundle file from a URL

New in version 2015.5.0.

CLI Example:

```

salt-run http.update_ca_bundle
salt-run http.update_ca_bundle target=/path/to/cacerts.pem
salt-run http.update_ca_bundle source=https://example.com/cacerts.pem

```

If the `target` is not specified, it will be pulled from the `ca_cert` configuration variable available to the master. If it cannot be found there, it will be placed at `<<FILE_ROOTS>>/cacerts.pem`.

If the `source` is not specified, it will be pulled from the `ca_cert_url` configuration variable available to the master. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

`merge_files` may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:

```

salt-run http.update_ca_bundle merge_files=/path/to/mycert.pem

```

## salt.runners.jobs

A convenience system to manage jobs, both active and already run

**salt.runners.jobs.active** (*outputter=None, display\_progress=False*)  
Return a report on all actively running jobs from a job id centric perspective

CLI Example:

```

salt-run jobs.active

```

**salt.runners.jobs.list\_job** (*jid, ext\_source=None, outputter=None*)  
List a specific job given by its jid

CLI Example:

```

salt-run jobs.list_job 20130916125524463507

```

**salt.runners.jobs.list\_jobs** (*ext\_source=None, outputter=None, search\_metadata=None, search\_function=None, search\_target=None, display\_progress=False*)  
List all detectable jobs and associated functions

CLI Example:

```

salt-run jobs.list_jobs

```

**salt.runners.jobs.lookup\_jid** (*jid, ext\_source=None, missing=False, outputter=None, display\_progress=False*)  
Return the printout from a previously executed job

**jid** The jid to look up.

**ext\_source** The external job cache to use. Default: *None*.

**missing** When set to *True*, adds the minions that did not return from the command. Default: *False*.

**display\_progress** Displays progress events when set to *True*. Default: *False*.

New in version 2015.5.0.

CLI Example:

```
salt-run jobs.lookup_jid 20130916125524463507
salt-run jobs.lookup_jid 20130916125524463507 outputter=highstate
```

**salt.runners.jobs.print\_job**(*jid*, *ext\_source=None*, *outputter=None*)

Print a specific job's detail given by it's jid, including the return data.

CLI Example:

```
salt-run jobs.print_job 20130916125524463507
```

### **salt.runners.launchd**

Manage launchd plist files

**salt.runners.launchd.write\_launchd\_plist**(*program*)

Write a launchd plist for managing salt-master or salt-minion

CLI Example:

```
salt-run launchd.write_launchd_plist salt-master
```

### **salt.runners.lxc**

Control Linux Containers via Salt

**depends** lxc execution module

**salt.runners.lxc.cloud\_init**(*names*, *host=None*, *quiet=False*, *\*\*kwargs*)

Wrapper for using lxc.init in saltcloud compatibility mode

**names** Name of the containers, supports a single name or a comma delimited list of names.

**host** Minion to start the container on. Required.

**saltcloud\_mode** init the container with the saltcloud opts format instead

**salt.runners.lxc.find\_guest**(*name*, *quiet=False*)

Returns the host for a container.

```
salt-run lxc.find_guest name
```

**salt.runners.lxc.find\_guests**(*names*)

Return a dict of hosts and named guests

**salt.runners.lxc.freeze**(*name*, *quiet=False*)

Freeze the named container

```
salt-run lxc.freeze name
```

**salt.runners.lxc.info**(*name*, *quiet=False*)

Returns information about a container.

```
salt-run lxc.info name
```

**salt.runners.lxc.init**(*names, host=None, saltcloud\_mode=False, quiet=False, \*\*kwargs*)  
Initialize a new container

```
salt-run lxc.init name host=minion_id [cpuset=cgroups_cpuset] \
    [cpushare=cgroups_cpushare] [memory=cgroups_memory] \
    [template=lxc_template_name] [clone=original name] \
    [profile=lxc_profile] [network_profile=network_profile] \
    [nic=network_profile] [nic_opts=nic_opts] \
    [start=(true|false)] [seed=(true|false)] \
    [install=(true|false)] [config=minion_config] \
    [snapshot=(true|false)]
```

**names** Name of the containers, supports a single name or a comma delimited list of names.

**host** Minion on which to initialize the container (**required**)

**saltcloud\_mode** init the container with the saltcloud opts format instead See `lxc.init_interface` module documentation

**cpuset** cgroups cpuset.

**cpushare** cgroups cpu shares.

**memory** cgroups memory limit, in MB

Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass `memory=0` to set no limit.

**template** Name of LXC template on which to base this container

**clone** Clone this container from an existing container

**profile** A LXC profile (defined in config or pillar).

**network\_profile** Network profile to use for the container

New in version 2015.5.0.

**nic** Deprecated since version 2015.5.0: Use `network_profile` instead

**nic\_opts** Extra options for network interfaces. E.g.:

```
{"eth0": {"mac": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1", "ipv6":
"2001:db8::ff00:42:8329"}}
```

**start** Start the newly created container.

**seed** Seed the container with the minion config and autosign its key. Default: true

**install** If salt-minion is not already installed, install it. Default: true

**config** Optional config parameters. By default, the id is set to the name of the container.

**salt.runners.lxc.list\_**(*host=None, quiet=False*)

List defined containers (running, stopped, and frozen) for the named (or all) host(s).

```
salt-run lxc.list [host=minion_id]
```

**salt.runners.lxc.purge**(*name, delete\_key=True, quiet=False*)

Purge the named container and delete its minion key if present. WARNING: Destroys all data associated with the container.

```
salt-run lxc.purge name
```

`salt.runners.lxc.start`(*name*, *quiet=False*)  
Start the named container.

```
salt-run lxc.start name
```

`salt.runners.lxc.stop`(*name*, *quiet=False*)  
Stop the named container.

```
salt-run lxc.stop name
```

`salt.runners.lxc.unfreeze`(*name*, *quiet=False*)  
Unfreeze the named container

```
salt-run lxc.unfreeze name
```

### `salt.runners.manage`

General management functions for salt, tools like seeing what hosts are up and what hosts are down

`salt.runners.manage.bootstrap`(*version='develop'*, *script=None*, *hosts=''*, *root\_user=True*)  
Bootstrap minions with salt-bootstrap

**version** [develop] Git tag of version to install

**script** [<https://bootstrap.saltstack.com>] Script to execute

**hosts** Comma-separated hosts [example: `hosts='host1.local,host2.local'`]

**root\_user** [True] Prepend `root@` to each host.

CLI Example:

```
salt-run manage.bootstrap hosts='host1,host2'
salt-run manage.bootstrap hosts='host1,host2' version='v0.17'
salt-run manage.bootstrap hosts='host1,host2' version='v0.17' script='https://bootstrap.saltstack.com'
salt-run manage.bootstrap hosts='ec2-user@host1,ec2-user@host2' root_user=False
```

`salt.runners.manage.bootstrap_psexec`(*hosts=''*, *master=None*, *version=None*, *arch='win32'*, *installer\_url=None*, *username=None*, *password=None*)

Bootstrap Windows minions via PsExec.

**hosts** Comma separated list of hosts to deploy the Windows Salt minion.

**master** Address of the Salt master passed as an argument to the installer.

**version** Point release of installer to download. Defaults to the most recent.

**arch** Architecture of installer to download. Defaults to win32.

**installer\_url** URL of minion installer executable. Defaults to the latest version from <http://docs.saltstack.com/downloads>

**username** Optional user name for login on remote computer.

**password** Password for optional username. If omitted, PsExec will prompt for one to be entered for each host.

CLI Example:

```
salt-run manage.bootstrap_psexec hosts='host1,host2'
salt-run manage.bootstrap_psexec hosts='host1,host2' version='0.17' username='DOMAIN\Administrator'
salt-run manage.bootstrap_psexec hosts='host1,host2' installer_url='http://exampledomain/salt-in'
```

`salt.runners.manage.down` (*removekeys=False*)

Print a list of all the down or unresponsive salt minions Optionally remove keys of down minions

CLI Example:

```
salt-run manage.down
salt-run manage.down removekeys=True
```

`salt.runners.manage.key_regen` ()

This routine is used to regenerate all keys in an environment. This is invasive! ALL KEYS IN THE SALT ENVIRONMENT WILL BE REGENERATED!!

The `key_regen` routine sends a command out to minions to revoke the master key and remove all minion keys, it then removes all keys from the master and prompts the user to restart the master. The minions will all reconnect and keys will be placed in pending.

After the master is restarted and minion keys are in the pending directory execute a `salt-key -A` command to accept the regenerated minion keys.

The master *must* be restarted within 60 seconds of running this command or the minions will think there is something wrong with the keys and abort.

Only Execute this runner after upgrading minions and master to 0.15.1 or higher!

CLI Example:

```
salt-run manage.key_regen
```

`salt.runners.manage.not_present` (*subset=None, show\_ipv4=False*)

Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)

**subset** [None] Pass in a CIDR range to filter minions by IP address.

**show\_ipv4** [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.not_present
```

`salt.runners.manage.present` (*subset=None, show\_ipv4=False*)

Print a list of all minions that are up according to Salt's presence detection (no commands will be sent)

**subset** [None] Pass in a CIDR range to filter minions by IP address.

**show\_ipv4** [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.present
```

`salt.runners.manage.safe_accept` (*target, expr\_form='glob'*)

Accept a minion's public key after checking the fingerprint over salt-ssh

CLI Example:

```
salt-run manage.safe_accept my_minion
salt-run manage.safe_accept minion1,minion2 expr_form=list
```

`salt.runners.manage.status` (*output=True*)

Print the status of all known salt minions

CLI Example:

```
salt-run manage.status
```

`salt.runners.manage.up()`

Print a list of all of the minions that are up

CLI Example:

```
salt-run manage.up
```

`salt.runners.manage.versions()`

Check the version of active minions

CLI Example:

```
salt-run manage.versions
```

### `salt.runners.mine`

A runner to access data from the salt mine

`salt.runners.mine.get(tgt, fun, tgt_type='glob', output=None)`

Gathers the data from the specified minions' mine, pass in the target, function to look up and the target type

CLI Example:

```
salt-run mine.get '*' network.interfaces
```

### `salt.runners.nacl`

This runner helps create encrypted passwords that can be included in pillars.

**depends** `libnacl`, <https://github.com/saltstack/libnacl>

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I dont advise making your pillars public regardless if they are encrypted or not.

The following configurations can be defined in the master config so your users can create encrypted passwords using the runner `nacl`:

```
cat /etc/salt/master.d/nacl.conf
nacl.config:
  key: None
  keyfile: /root/.nacl
```

Now with the config in the master you can use the runner `nacl` like:

```
salt-run nacl.enc 'data'
```

`salt.runners.nacl.dec(data, **kwargs)`

Takes a key generated from `nacl.keygen` and decrypt some data.

CLI Examples:

```
salt-run nacl.dec pEXHQM6cuaF7A=
salt-run nacl.dec data='pEXHQM6cuaF7A=' keyfile=/root/.nacl
salt-run nacl.dec data='pEXHQM6cuaF7A=' key='cKEzd4kXsbeCE7/nLTIqXwnUiD1u1g4NoeeYccFpd9k='
```

`salt.runners.nacl.enc`(*data*, *\*\*kwargs*)

Takes a key generated from `nacl.keygen` and encrypt some data.

CLI Examples:

```
salt-run nacl.enc datatoenc
salt-run nacl.enc datatoenc keyfile=/root/.nacl
salt-run nacl.enc datatoenc key='cKEzd4kXsbeCE7/nLTIqXwnUiD1uIlg4NoeeYcCFpd9k='
```

`salt.runners.nacl.keygen`(*keyfile=None*)

Use libnacl to generate a private key

CLI Examples:

```
salt-run nacl.keygen
salt-run nacl.keygen keyfile=/root/.nacl
salt-run --out=newline_values_only nacl.keygen > /root/.nacl
```

## `salt.runners.network`

Network tools to run from the Master

`salt.runners.network.wol`(*mac*, *bcast='255.255.255.255'*, *destport=9*)

Send a ``Magic Packet'' to wake up a Minion

CLI Example:

```
salt-run network.wol 08-00-27-13-69-77
salt-run network.wol 080027136977 255.255.255.255 7
salt-run network.wol 08:00:27:13:69:77 255.255.255.255 7
```

`salt.runners.network.wolllist`(*maclist*, *bcast='255.255.255.255'*, *destport=9*)

Send a ``Magic Packet'' to wake up a list of Minions. This list must contain one MAC hardware address per line

CLI Example:

```
salt-run network.wolllist '/path/to/maclist'
salt-run network.wolllist '/path/to/maclist' 255.255.255.255 7
salt-run network.wolllist '/path/to/maclist' 255.255.255.255 7
```

## `salt.runners.pagerduty`

Runner Module for Firing Events via PagerDuty

New in version 2014.1.0.

**configuration** This module can be used by specifying the name of a configuration profile in the master config.

For example:

```
my-pagerduty-account:
  pagerduty.api_key: F3Rbyjbve43rFWf2214
  pagerduty.subdomain: mysubdomain
```

`salt.runners.pagerduty.create_event`(*service\_key=None*, *description=None*, *details=None*, *incident\_key=None*, *profile=None*)

Create an event in PagerDuty. Designed for use in states.

CLI Example:

```
salt-run pagerduty.create_event <service_key> <description> <details> profile=my-pagerdu
```

The following parameters are required:

**service\_key** This key can be found by using `pagerduty.list_services`.

**description** This is a short description of the event.

**details** This can be a more detailed description of the event.

**profile** This refers to the configuration profile to use to connect to the PagerDuty service.

`salt.runners.pagerduty.list_escalation_policies` (*profile=None, api\_key=None*)  
List escalation policies belonging to this account

CLI Example:

```
salt-run pagerduty.list_policies my-pagerduty-account salt-run pagerduty.list_escalation_policies my-pagerduty-account
```

`salt.runners.pagerduty.list_incidents` (*profile=None, api\_key=None*)  
List incidents belonging to this account

CLI Example:

```
salt-run pagerduty.list_incidents my-pagerduty-account
```

`salt.runners.pagerduty.list_maintenance_windows` (*profile=None, api\_key=None*)  
List maintenance windows belonging to this account

CLI Example:

```
salt-run pagerduty.list_windows my-pagerduty-account salt-run pagerduty.list_maintenance_windows my-pagerduty-account
```

`salt.runners.pagerduty.list_policies` (*profile=None, api\_key=None*)  
List escalation policies belonging to this account

CLI Example:

```
salt-run pagerduty.list_policies my-pagerduty-account salt-run pagerduty.list_escalation_policies my-pagerduty-account
```

`salt.runners.pagerduty.list_schedules` (*profile=None, api\_key=None*)  
List schedules belonging to this account

CLI Example:

```
salt-run pagerduty.list_schedules my-pagerduty-account
```

`salt.runners.pagerduty.list_services` (*profile=None, api\_key=None*)  
List services belonging to this account

CLI Example:

```
salt-run pagerduty.list_services my-pagerduty-account
```

`salt.runners.pagerduty.list_users` (*profile=None, api\_key=None*)  
List users belonging to this account

CLI Example:

```
salt-run pagerduty.list_users my-pagerduty-account
```

`salt.runners.pagerduty.list_windows` (*profile=None, api\_key=None*)

List maintenance windows belonging to this account

CLI Example:

```
salt-run pagerduty.list_windows my-pagerduty-account salt-run pager-
duty.list_maintenance_windows my-pagerduty-account
```

### `salt.runners.pillar`

Functions to interact with the pillar compiler on the master

`salt.runners.pillar.show_pillar` (*minion='\*', \*\*kwargs*)

Returns the compiled pillar either of a specific minion or just the global available pillars. This function assumes that no minion has the id `*`.

CLI Example:

shows minion specific pillar:

```
salt-run pillar.show_pillar 'www.example.com'
```

shows global pillar:

```
salt-run pillar.show_pillar
```

shows global pillar for `'dev'` pillar environment:

```
salt-run pillar.show_pillar 'saltenv=dev'
```

API Example:

```
import salt.config
import salt.runner
opts = salt.config.master_config('/etc/salt/master')
runner = salt.runner.RunnerClient(opts)
pillar = runner.cmd('pillar.show_pillar', [])
print(pillar)
```

`salt.runners.pillar.show_top` (*minion=None, saltenv='base'*)

Returns the compiled top data for pillar for a specific minion. If no minion is specified, we use the first minion we find.

CLI Example:

```
salt-run pillar.show_top
```

### `salt.runners.queue`

General management and processing of queues.

This runner facilitates interacting with various queue backends such as the included `sqlite3` queue or the planned `AWS SQS` and `Redis` queues

The queue functions such as `insert`, `delete`, and `pop` can be used for typical management of the queue.

The `process_queue` function pops the requested number of items from the queue and creates a Salt Event that can then be processed by a Reactor. The `process_queue` function can be called manually, or can be configured to run on a schedule with the Salt Scheduler or regular system cron. It is also possible to use the peer system to allow a minion to call the runner.

This runner, as well as the Queues system, is not api stable at this time.

There are many things that could potentially be done with queues within Salt. For the time being the focus will be on queueing infrastructure actions on specific minions. The queues generally will be populated with minion IDs. When the `process_queue` runner function is called events are created on the Salt Event bus that indicate the queue and a list of one or more minion IDs. The reactor is set up to match on event tags for a specific queue and then take infrastructure actions on those minion IDs. These actions might be to delete the minion's key from the master, use salt-cloud to destroy the vm, or some other custom action.

`salt.runners.queue.delete` (*queue, items, backend='sqlite'*)  
Delete an item or items from a queue

CLI Example:

```
salt-run queue.delete myqueue myitem
salt-run queue.delete myqueue myitem backend=sqlite
salt-run queue.delete myqueue ["item1', 'item2', 'item3']"
```

`salt.runners.queue.insert` (*queue, items, backend='sqlite'*)  
Add an item or items to a queue

CLI Example:

```
salt-run queue.insert myqueue myitem
salt-run queue.insert myqueue ["item1', 'item2', 'item3']"
salt-run queue.insert myqueue myitem backend=sqlite
salt-run queue.insert myqueue ["item1', 'item2', 'item3']" backend=sqlite
```

`salt.runners.queue.list_items` (*queue, backend='sqlite'*)  
List contents of a queue

CLI Example:

```
salt-run queue.list_items myqueue
salt-run queue.list_items myqueue backend=sqlite
```

`salt.runners.queue.list_length` (*queue, backend='sqlite'*)  
Provide the number of items in a queue

CLI Example:

```
salt-run queue.list_length myqueue
salt-run queue.list_length myqueue backend=sqlite
```

`salt.runners.queue.list_queues` (*backend='sqlite'*)  
Return a list of Salt Queues on the backend

CLI Example:

```
salt-run queue.list_queues
salt-run queue.list_queues backend=sqlite
```

`salt.runners.queue.pop` (*queue, quantity=1, backend='sqlite'*)  
Pop one or more or all items from a queue

CLI Example:

```
salt-run queue.pop myqueue
salt-run queue.pop myqueue 6
salt-run queue.pop myqueue all
salt-run queue.pop myqueue 6 backend=sqlite
salt-run queue.pop myqueue all backend=sqlite
```

`salt.runners.queue.process_queue(queue, quantity=1, backend='sqlite')`

Pop items off a queue and create an event on the Salt event bus to be processed by a Reactor.

CLI Example:

```
salt-run queue.process_queue myqueue
salt-run queue.process_queue myqueue 6
salt-run queue.process_queue myqueue all backend=sqlite
```

### `salt.runners.sdb`

Runner for setting and querying data via the sdb API on the master

`salt.runners.sdb.get(uri)`

Get a value from a db, using a uri in the form of `sdb://<profile>/<key>`. If the uri provided does not start with `sdb://`, then it will be returned as-is.

CLI Example:

```
salt '*' sdb.get sdb://mymemcached/foo
```

`salt.runners.sdb.set_(uri, value)`

Set a value in a db, using a uri in the form of `sdb://<profile>/<key>`. If the uri provided does not start with `sdb://` or the value is not successfully set, return `False`.

CLI Example:

```
salt '*' sdb.set sdb://mymemcached/foo bar
```

### `salt.runners.search`

Runner frontend to search system

`salt.runners.search.query(term)`

Query the search system

CLI Example:

```
salt-run search.query foo
```

### `salt.runners.state`

Execute overstate functions

`salt.runners.state.event(tagmatch='*', count=-1, quiet=False, sock_dir=None, pretty=False)`

Watch Salt's event bus and block until the given tag is matched

New in version 2014.7.0.

This is useful for utilizing Salt's event bus from shell scripts or for taking simple actions directly from the CLI.

Enable debug logging to see ignored events.

#### Parameters

- **tagmatch** -- the event is written to stdout for each tag that matches this pattern; uses the same matching semantics as Salt's Reactor.

- **count** -- this number is decremented for each event that matches the `tagmatch` parameter; pass `-1` to listen forever.
- **quiet** -- do not print to stdout; just block
- **sock\_dir** -- path to the Salt master's event socket file.
- **pretty** -- Output the JSON all on a single line if `False` (useful for shell tools); pretty-print the JSON output if `True`.

CLI Examples:

```
# Reboot a minion and run highstate when it comes back online
salt 'jerry' system.reboot && \\  
    salt-run state.event 'salt/minion/jerry/start' count=1 quiet=True && \\  
    salt 'jerry' state.highstate

# Reboot multiple minions and run highstate when all are back online
salt -L 'kevin,stewart,dave' system.reboot && \\  
    salt-run state.event 'salt/minion/*/start' count=3 quiet=True && \\  
    salt -L 'kevin,stewart,dave' state.highstate

# Watch the event bus forever in a shell while-loop.
salt-run state.event | while read -r tag data; do
    echo $tag
    echo $data | jq -colour-output .
done
```

See also:

See `:glob:'tests/eventlisten.sh'` for an example of usage within a shell script.

`salt.runners.state.orchestrate` (*mods*, *saltenv='base'*, *test=None*, *exclude=None*, *pillar=None*)  
New in version 0.17.0.

Execute a state run from the master, used as a powerful orchestration system.

See also:

More Orchestrate documentation

- *Full Orchestrate Tutorial*
- *Docs for the master-side state module*

CLI Examples:

```
salt-run state.orchestrate webserver
salt-run state.orchestrate webserver saltenv=dev test=True
```

Changed in version 2014.1.1: Runner renamed from `state.sls` to `state.orchestrate`

Changed in version 2014.7.0: Runner uses the pillar variable

`salt.runners.state.orchestrate_high` (*data*, *test=None*, *queue=False*, *pillar=None*, *\*\*kwargs*)  
Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

```
salt-run state.orchestrate_high '{
    stage_one:
        {salt.state: [{tgt: "db*"}, {sls: postgres_setup}]},
    stage_two:
```

```
{salt.state: [{tgt: "web*"}, {sls: apache_setup}, {
    require: [{salt: stage_one}],
  }]},
}
```

`salt.runners.state.orchestrate_single`(*fun*, *name*, *test=None*, *queue=False*, *pillar=None*, *\*\*kwargs*)

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

```
salt-run state.orchestrate_single fun=salt.wheel name=key.list_all
```

`salt.runners.state.over`(*saltenv='base'*, *os\_fn=None*)

New in version 0.11.0.

**Warning:** `state.over` is deprecated in favor of `state.orchestrate`, and will be removed in the Salt feature release codenamed Boron. (Three feature releases after the 2014.7.0 release, which is codenamed Helium)

Execute an overstate sequence to orchestrate the executing of states over a group of systems

CLI Examples:

```
salt-run state.over base /path/to/myoverstate.sls
```

`salt.runners.state.show_stages`(*saltenv='base'*, *os\_fn=None*)

New in version 0.11.0.

Display the OverState's stage data

CLI Examples:

```
salt-run state.show_stages
salt-run state.show_stages saltenv=dev /root/overstate.sls
```

## `salt.runners.survey`

A general map/reduce style salt runner for aggregating results returned by several different minions.

New in version 2014.7.0.

Aggregated results are sorted by the size of the minion pools which returned matching results.

Useful for playing the game: " some of these things are not like the others... " when identifying discrepancies in a large infrastructure managed by salt.

`salt.runners.survey.diff`(\*args, *\*\*kwargs*)

Return the DIFFERENCE of the result sets returned by each matching minion pool

New in version 2014.7.0.

These pools are determined from the aggregated and sorted results of a salt command. This command displays the ``diffs`` as a series of 2-way differences-- namely the difference between the FIRST displayed minion pool (according to sort order) and EACH SUBSEQUENT minion pool result set. Differences are displayed according to the Python ``difflib.unified\_diff()`` as in the case of the salt execution module ``file.get\_diff``.

This command is submitted via a salt runner using the general form:

```
salt-run survey.diff [survey_sort=up/down] <target> <salt-execution-module> <salt-
execution-module parameters>
```

Optionally accept a ``survey\_sort=" parameter. Default: ``survey\_sort=down"

CLI Example #1: ( Example to display the ``differences of files" )

```
salt-run survey.diff survey_sort=up "*" cp.get_file_str file:///etc/hosts
```

```
salt.runners.survey.hash(*args, **kwargs)
```

Return the MATCHING minion pools from the aggregated and sorted results of a salt command

New in version 2014.7.0.

This command is submitted via a salt runner using the general form:

```
salt-run survey.hash [survey_sort=up/down] <target> <salt-execution-module> <salt-
execution-module parameters>
```

Optionally accept a ``survey\_sort=" parameter. Default: ``survey\_sort=down"

CLI Example #1: ( functionally equivalent to ``salt-run manage.up" )

```
salt-run survey.hash "*" test.ping
```

CLI Example #2: ( find an ``outlier" minion config file )

```
salt-run survey.hash "*" file.get_hash /etc/salt/minion survey_sort=up
```

### salt.runners.test

This runner is used only for test purposes and servers no production purpose

```
salt.runners.test.arg(*args, **kwargs)
```

Output the given args and kwargs

Kwargs will be filtered for `private` keynames.

```
salt.runners.test.raw_arg(*args, **kwargs)
```

Output the given args and kwargs

```
salt.runners.test.sleep(s_time=10)
```

Sleep t seconds, then return True

```
salt.runners.test.stdout_print()
```

Print `foo` and return `bar`

```
salt.runners.test.stream()
```

Return True

### salt.runners.thin

The thin runner is used to manage the salt thin systems.

Salt Thin is a transport-less version of Salt that can be used to run routines in a standalone way. This runner has tools which generate the standalone salt system for easy consumption.

```
salt.runners.thin.generate(extra_mods='', overwrite=False, so_mods='')
```

Generate the salt-thin tarball and print the location of the tarball Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.

CLI Example:

```
salt-run thin.generate
salt-run thin.generate mako
salt-run thin.generate mako,wempy 1
salt-run thin.generate overwrite=1
```

### **salt.runners.virt**

Control virtual machines via Salt

**salt.runners.virt.force\_off**(*name*)

Force power down the named virtual machine

**salt.runners.virt.hyper\_info**(*hyper=None*)

Return information about the hypervisors connected to this master

**salt.runners.virt.init**(*name, cpu, mem, image, hyper=None, seed=True, nic='default', install=True*)

This routine is used to create a new virtual machine. This routine takes a number of options to determine what the newly created virtual machine will look like.

**name** The mandatory name of the new virtual machine. The name option is also the minion id, all minions must have an id.

**cpu** The number of cpus to allocate to this new virtual machine.

**mem** The amount of memory to allocate to this virtual machine. The number is interpreted in megabytes.

**image** The network location of the virtual machine image, commonly a location on the salt fileserver, but http, https and ftp can also be used.

**hyper** The hypervisor to use for the new virtual machine, if this is omitted Salt will automatically detect what hypervisor to use.

**seed** Set to False to prevent Salt from seeding the new virtual machine.

**nic** The nic profile to use, defaults to the ``default`` nic profile which assumes a single network interface per vm associated with the ``br0`` bridge on the master.

**install** Set to False to prevent Salt from installing a minion on the new vm before it spins up.

**salt.runners.virt.list**(*hyper=None, quiet=False*)

List the virtual machines on each hyper, this is a simplified query, showing only the virtual machine names belonging to each hypervisor. A single hypervisor can be passed in to specify an individual hypervisor to list.

**salt.runners.virt.migrate**(*name, target=''*)

Migrate a vm from one hypervisor to another. This routine will just start the migration and display information on how to look up the progress.

**salt.runners.virt.next\_hyper**()

Return the hypervisor to use for the next autodeployed vm. This queries the available hypervisors and executes some math to determine the most ``available`` next hypervisor.

**salt.runners.virt.pause**(*name*)

Pause the named vm

**salt.runners.virt.purge**(*name, delete\_key=True*)

Destroy the named vm

**salt.runners.virt.query**(*hyper=None, quiet=False*)

Query the virtual machines. When called without options all hypervisors are detected and a full query is returned. A single hypervisor can be passed in to specify an individual hypervisor to query.

```

salt.runners.virt.reset(name)
    Force power down and restart an existing vm

salt.runners.virt.resume(name)
    Resume a paused vm

salt.runners.virt.start(name)
    Start a named virtual machine

salt.runners.virt.vm_info(name, quiet=False)
    Return the information on the named vm

```

### **salt.runners.winrepo**

Runner to manage Windows software repo

```

salt.runners.winrepo.genrepo()
    Generate win_repo_cache file based on sls files in the win_repo

    CLI Example:

```

```
salt-run winrepo.genrepo
```

```

salt.runners.winrepo.update_git_repos()
    Checkout git repos containing Windows Software Package Definitions

    CLI Example:

```

```
salt-run winrepo.update_git_repos
```

## 30.25.2 Writing Salt Runners

A Salt runner is written in a similar manner to a Salt execution module. Both are Python modules which contain functions and each public function is a runner which may be executed via the *salt-run* command.

For example, if a Python module named `test.py` is created in the `runners` directory and contains a function called `foo`, the `test` runner could be invoked with the following command:

```
# salt-run test.foo
```

To add custom runners, put them in a directory and add it to *runner\_dirs* in the master configuration file.

## 30.25.3 Examples

Examples of runners can be found in the Salt distribution:

<https://github.com/saltstack/salt/blob/develop/salt/runners>

A simple runner that returns a well-formatted list of the minions that are responding to Salt calls could look like this:

```

# Import salt modules
import salt.client

def up():
    '''

```

```
Print a list of all of the minions that are up
'''
client = salt.client.LocalClient(__opts__['conf_file'])
minions = client.cmd('*', 'test.ping', timeout=1)
for minion in sorted(minions):
    print minion
```

## 30.26 State Enforcement

Salt offers an optional interface to manage the configuration or ``state" of the Salt minions. This interface is a fully capable mechanism used to enforce the state of systems from a central manager.

### 30.26.1 Mod Aggregate State Runtime Modifications

New in version 2014.7.0.

The `mod_aggregate` system was added in the 2014.7.0 release of Salt and allows for runtime modification of the executing state data. Simply put, it allows for the data used by Salt's state system to be changed on the fly at runtime, kind of like a configuration management JIT compiler or a runtime import system. All in all, it makes Salt much more dynamic.

#### How it Works

The best example is the `pkg` state. One of the major requests in Salt has long been adding the ability to install all packages defined at the same time. The `mod_aggregate` system makes this a reality. While executing Salt's state system, when a `pkg` state is reached the `mod_aggregate` function in the state module is called. For `pkg` this function scans all of the other states that are slated to run, and picks up the references to `name` and `pkgs`, then adds them to `pkgs` in the first state. The result is a single call to `yum`, `apt-get`, `pacman`, etc as part of the first package install.

#### How to Use it

---

**Note:** Since this option changes the basic behavior of the state runtime, after it is enabled states should be executed using `test=True` to ensure that the desired behavior is preserved.

---

#### In config files

The first way to enable aggregation is with a configuration option in either the master or minion configuration files. Salt will invoke `mod_aggregate` the first time it encounters a state module that has aggregate support.

If this option is set in the master config it will apply to all state runs on all minions, if set in the minion config it will only apply to said minion.

Enable for all states:

```
state_aggregate: True
```

Enable for only specific state modules:

```
state_aggregate:
  - pkg
```

### In states

The second way to enable aggregation is with the state-level `aggregate` keyword. In this configuration, Salt will invoke the `mod_aggregate` function the first time it encounters this keyword. Any additional occurrences of the keyword will be ignored as the aggregation has already taken place.

The following example will trigger `mod_aggregate` when the `lamp_stack` state is processed resulting in a single call to the underlying package manager.

```
lamp_stack:
  pkg.installed:
    - pkgs:
      - php
      - mysql-client
    - aggregate: True

memcached:
  pkg.installed:
    - name: memcached
```

### Adding `mod_aggregate` to a State Module

Adding a `mod_aggregate` routine to an existing state module only requires adding an additional function to the state module called `mod_aggregate`.

The `mod_aggregate` function just needs to accept three parameters and return the low data to use. Since `mod_aggregate` is working on the state runtime level it does need to manipulate *low data*.

The three parameters are *low*, *chunks*, and *running*. The *low* option is the low data for the state execution which is about to be called. The *chunks* is the list of all of the low data dictionaries which are being executed by the runtime and the *running* dictionary is the return data from all of the state executions which have already be executed.

This example, simplified from the `pkg` state, shows how to create `mod_aggregate` functions:

```
def mod_aggregate(low, chunks, running):
    """
    The mod_aggregate function which looks up all packages in the available
    low chunks and merges them into a single pkgs ref in the present low data
    """
    pkgs = []
    # What functions should we aggregate?
    agg_enabled = [
        'installed',
        'latest',
        'removed',
        'purged',
    ]
    # The `low` data is just a dict with the state, function (fun) and
    # arguments passed in from the sls
    if low.get('fun') not in agg_enabled:
        return low
```

```
# Now look into what other things are set to execute
for chunk in chunks:
    # The state runtime uses "tags" to track completed jobs, it may
    # look familiar with the _|-
    tag = salt.utils.gen_state_tag(chunk)
    if tag in running:
        # Already ran the pkg state, skip aggregation
        continue
    if chunk.get('state') == 'pkg':
        if '__agg__' in chunk:
            continue
        # Check for the same function
        if chunk.get('fun') != low.get('fun'):
            continue
        # Pull out the pkg names!
        if 'pkgs' in chunk:
            pkgs.extend(chunk['pkgs'])
            chunk['__agg__'] = True
        elif 'name' in chunk:
            pkgs.append(chunk['name'])
            chunk['__agg__'] = True
    if pkgs:
        if 'pkgs' in low:
            low['pkgs'].extend(pkgs)
        else:
            low['pkgs'] = pkgs
    # The low has been modified and needs to be returned to the state
    # runtime for execution
    return low
```

---

### 30.26.2 Altering States

**Note:** This documentation has been moved [here](#).

---

### 30.26.3 File State Backups

In 0.10.2 a new feature was added for backing up files that are replaced by the `file.managed` and `file.recurse` states. The new feature is called the backup mode. Setting the backup mode is easy, but it can be set in a number of places.

The `backup_mode` can be set in the minion config file:

```
backup_mode: minion
```

Or it can be set for each file:

```
/etc/ssh/sshd_config:
  file.managed:
    - source: salt://ssh/sshd_config
    - backup: minion
```

## Backed-up Files

The files will be saved in the minion cachedir under the directory named `file_backup`. The files will be in the location relative to where they were under the root filesystem and be appended with a timestamp. This should make them easy to browse.

## Interacting with Backups

Starting with version 0.17.0, it will be possible to list, restore, and delete previously-created backups.

### Listing

The backups for a given file can be listed using `file.list_backups`:

```
# salt foo.bar.com file.list_backups /tmp/foo.txt
foo.bar.com:
-----
 0:
    -----
    Backup Time:
      Sat Jul 27 2013 17:48:41.738027
    Location:
      /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:41_738027_2013
    Size:
      13
 1:
    -----
    Backup Time:
      Sat Jul 27 2013 17:48:28.369804
    Location:
      /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:28_369804_2013
    Size:
      35
```

### Restoring

Restoring is easy using `file.restore_backup`, just pass the path and the numeric id found with `file.list_backups`:

```
# salt foo.bar.com file.restore_backup /tmp/foo.txt 1
foo.bar.com:
-----
comment:
  Successfully restored /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:28_369804_2013
result:
  True
```

The existing file will be backed up, just in case, as can be seen if `file.list_backups` is run again:

```
# salt foo.bar.com file.list_backups /tmp/foo.txt
foo.bar.com:
-----
```

```
0:
-----
Backup Time:
  Sat Jul 27 2013 18:00:19.822550
Location:
  /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_18:00:19_822550_2013
Size:
  53
1:
-----
Backup Time:
  Sat Jul 27 2013 17:48:41.738027
Location:
  /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:41_738027_2013
Size:
  13
2:
-----
Backup Time:
  Sat Jul 27 2013 17:48:28.369804
Location:
  /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:28_369804_2013
Size:
  35
```

---

**Note:** Since no state is being run, restoring a file will not trigger any watches for the file. So, if you are restoring a config file for a service, it will likely still be necessary to run a `service.restart`.

---

## Deleting

Deleting backups can be done using `file.delete_backup`:

```
# salt foo.bar.com file.delete_backup /tmp/foo.txt 0
foo.bar.com:
-----
comment:
  Successfully removed /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_18:00:19_822550_2013
result:
  True
```

## 30.26.4 Understanding State Compiler Ordering

---

**Note:** This tutorial is an intermediate level tutorial. Some basic understanding of the state system and writing Salt Formulas is assumed.

---

Salt's state system is built to deliver all of the power of configuration management systems without sacrificing simplicity. This tutorial is made to help users understand in detail just how the order is defined for state executions in Salt.

This tutorial is written to represent the behavior of Salt as of version 0.17.0.

## Compiler Basics

To understand ordering in depth some very basic knowledge about the state compiler is very helpful. No need to worry though, this is very high level!

### High Data and Low Data

When defining Salt Formulas in YAML the data that is being represented is referred to by the compiler as High Data. When the data is initially loaded into the compiler it is a single large python dictionary, this dictionary can be viewed raw by running:

```
salt '*' state.show_highstate
```

This ``High Data" structure is then compiled down to ``Low Data". The Low Data is what is matched up to create individual executions in Salt's configuration management system. The low data is an ordered list of single state calls to execute. Once the low data is compiled the evaluation order can be seen.

The low data can be viewed by running:

```
salt '*' state.show_lowstate
```

**Note:** The state execution module contains MANY functions for evaluating the state system and is well worth a read! These routines can be very useful when debugging states or to help deepen one's understanding of Salt's state system.

As an example, a state written thusly:

```
apache:
  pkg.installed:
    - name: httpd
  service.running:
    - name: httpd
    - watch:
      - file: apache_conf
      - pkg: apache

apache_conf:
  file.managed:
    - name: /etc/httpd/conf.d/httpd.conf
    - source: salt://apache/httpd.conf
```

Will have High Data which looks like this represented in json:

```
{
  "apache": {
    "pkg": [
      {
        "name": "httpd"
      },
      "installed",
      {
        "order": 10000
      }
    ]
  }
}
```

```

    ],
    "service": [
      {
        "name": "httpd"
      },
      {
        "watch": [
          {
            "file": "apache_conf"
          },
          {
            "pkg": "apache"
          }
        ]
      },
      "running",
      {
        "order": 10001
      }
    ],
    "__sls__": "blah",
    "__env__": "base"
  },
  "apache_conf": {
    "file": [
      {
        "name": "/etc/httpd/conf.d/httpd.conf"
      },
      {
        "source": "salt://apache/httpd.conf"
      }
    ],
    "managed",
    {
      "order": 10002
    }
  ],
  "__sls__": "blah",
  "__env__": "base"
}
}

```

The subsequent Low Data will look like this:

```

[
  {
    "name": "httpd",
    "state": "pkg",
    "__id__": "apache",
    "fun": "installed",
    "__env__": "base",
    "__sls__": "blah",
    "order": 10000
  },
  {
    "name": "httpd",
    "watch": [
      {

```

```

        "file": "apache_conf"
    },
    {
        "pkg": "apache"
    }
],
"state": "service",
"__id__": "apache",
"fun": "running",
"__env__": "base",
"__sls__": "blah",
"order": 10001
},
{
    "name": "/etc/httpd/conf.d/httpd.conf",
    "source": "salt://apache/httpd.conf",
    "state": "file",
    "__id__": "apache_conf",
    "fun": "managed",
    "__env__": "base",
    "__sls__": "blah",
    "order": 10002
}
]

```

This tutorial discusses the Low Data evaluation and the state runtime.

## Ordering Layers

Salt defines 2 order interfaces which are evaluated in the state runtime and defines these orders in a number of passes.

### Definition Order

---

**Note:** The Definition Order system can be disabled by turning the option `state_auto_order` to `False` in the master configuration file.

---

The top level of ordering is the *Definition Order*. The *Definition Order* is the order in which states are defined in salt formulas. This is very straightforward on basic states which do not contain `include` statements or a `top` file, as the states are just ordered from the top of the file, but the include system starts to bring in some simple rules for how the *Definition Order* is defined.

Looking back at the ``Low Data" and ``High Data" shown above, the order key has been transparently added to the data to enable the *Definition Order*.

**The Include Statement** Basically, if there is an include statement in a formula, then the formulas which are included will be run BEFORE the contents of the formula which is including them. Also, the include statement is a list, so they will be loaded in the order in which they are included.

In the following case:

```
foo.sls
```

```
include:
- bar
- baz
```

bar.sls

```
include:
- quo
```

baz.sls

```
include:
- qux
```

In the above case if `state.apply foo` were called then the formulas will be loaded in the following order:

1. quo
2. bar
3. qux
4. baz
5. foo

### The *order* Flag

The *Definition Order* happens transparently in the background, but the ordering can be explicitly overridden using the *order* flag in states:

```
apache:
  pkg.installed:
    - name: httpd
    - order: 1
```

This order flag will over ride the definition order, this makes it very simple to create states that are always executed first, last or in specific stages, a great example is defining a number of package repositories that need to be set up before anything else, or final checks that need to be run at the end of a state run by using *order: last* or *order: -1*.

When the order flag is explicitly set the *Definition Order* system will omit setting an order for that state and directly use the order flag defined.

### Lexicographical Fall-back

Salt states were written to ALWAYS execute in the same order. Before the introduction of *Definition Order* in version 0.17.0 everything was ordered lexicographically according to the name of the state, then function then id.

This is the way Salt has always ensured that states always run in the same order regardless of where they are deployed, the addition of the *Definition Order* method mealy makes this finite ordering easier to follow.

The lexicographical ordering is still applied but it only has any effect when two order statements collide. This means that if multiple states are assigned the same order number that they will fall back to lexicographical ordering to ensure that every execution still happens in a finite order.

**Note:** If running with `state_auto_order: False` the `order` key is not set automatically, since the Lexicographical order can be derived from other keys.

---

## Requisite Ordering

Salt states are fully declarative, in that they are written to declare the state in which a system should be. This means that components can require that other components have been set up successfully. Unlike the other ordering systems, the *Requisite* system in Salt is evaluated at runtime.

The requisite system is also built to ensure that the ordering of execution never changes, but is always the same for a given set of states. This is accomplished by using a runtime that processes states in a completely predictable order instead of using an event loop based system like other declarative configuration management systems.

## Runtime Requisite Evaluation

The requisite system is evaluated as the components are found, and the requisites are always evaluated in the same order. This explanation will be followed by an example, as the raw explanation may be a little dizzying at first as it creates a linear dependency evaluation sequence.

The `Low Data` is an ordered list or dictionaries, the state runtime evaluates each dictionary in the order in which they are arranged in the list. When evaluating a single dictionary it is checked for requisites, requisites are evaluated in order, *require* then *watch* then *prereq*.

---

**Note:** If using requisite in statements like `require_in` and `watch_in` these will be compiled down to `require` and `watch` statements before runtime evaluation.

---

Each requisite contains an ordered list of requisites, these requisites are looked up in the list of dictionaries and then executed. Once all requisites have been evaluated and executed then the requiring state can safely be run (or not run if requisites have not been met).

This means that the requisites are always evaluated in the same order, again ensuring one of the core design principals of Salt's State system to ensure that execution is always finite is intact.

## Simple Runtime Evaluation Example

Given the above `Low Data` the states will be evaluated in the following order:

1. The `pkg.installed` is executed ensuring that the apache package is installed, it contains no requisites and is therefore the first defined state to execute.
2. The `service.running` state is evaluated but NOT executed, a watch requisite is found, therefore they are read in order, the runtime first checks for the file, sees that it has not been executed and calls for the file state to be evaluated.
3. The file state is evaluated AND executed, since it, like the `pkg` state does not contain any requisites.
4. The evaluation of the service state continues, it next checks the `pkg` requisite and sees that it is met, with all requisites met the service state is now executed.

## Best Practice

The best practice in Salt is to choose a method and stick with it, official states are written using requisites for all associations since requisites create clean, traceable dependency trails and make for the most portable formulas. To

accomplish something similar to how classical imperative systems function all requisites can be omitted and the `failhard` option then set to `True` in the master configuration, this will stop all state runs at the first instance of a failure.

In the end, using requisites creates very tight and fine grained states, not using requisites makes full sequence runs and while slightly easier to write, and gives much less control over the executions.

### 30.26.5 Extending External SLS Data

Sometimes a state defined in one SLS file will need to be modified from a separate SLS file. A good example of this is when an argument needs to be overwritten or when a service needs to watch an additional state.

#### The Extend Declaration

The standard way to extend is via the extend declaration. The extend declaration is a top level declaration like `include` and encapsulates ID declaration data included from other SLS files. A standard extend looks like this:

```
include:
- http
- ssh

extend:
  apache:
    file:
      - name: /etc/httpd/conf/httpd.conf
      - source: salt://http/httpd2.conf
  ssh-server:
    service:
      - watch:
        - file: /etc/ssh/banner

/etc/ssh/banner:
  file.managed:
    - source: salt://ssh/banner
```

A few critical things happened here, first off the SLS files that are going to be extended are included, then the extend dec is defined. Under the extend dec 2 IDs are extended, the apache ID's file state is overwritten with a new name and source. Than the ssh server is extended to watch the banner file in addition to anything it is already watching.

#### Extend is a Top Level Declaration

This means that `extend` can only be called once in an sls, if it is used twice then only one of the extend blocks will be read. So this is WRONG:

```
include:
- http
- ssh

extend:
  apache:
    file:
      - name: /etc/httpd/conf/httpd.conf
      - source: salt://http/httpd2.conf
# Second extend will overwrite the first!! Only make one
```

```

extend:
  ssh-server:
    service:
      - watch:
        - file: /etc/ssh/banner

```

### The Requisite ``in" Statement

Since one of the most common things to do when extending another SLS is to add states for a service to watch, or anything for a watcher to watch, the requisite in statement was added to 0.9.8 to make extending the watch and require lists easier. The ssh-server extend statement above could be more cleanly defined like so:

```

include:
  - ssh

/etc/ssh/banner:
  file.managed:
    - source: salt://ssh/banner
    - watch_in:
      - service: ssh-server

```

### Rules to Extend By

There are a few rules to remember when extending states:

1. Always include the SLS being extended with an include declaration
2. Requisites (watch and require) are appended to, everything else is overwritten
3. extend is a top level declaration, like an ID declaration, cannot be declared twice in a single SLS
4. Many IDs can be extended under the extend declaration

## 30.26.6 Failhard Global Option

Normally, when a state fails Salt continues to execute the remainder of the defined states and will only refuse to execute states that require the failed state.

But the situation may exist, where you would want all state execution to stop if a single state execution fails. The capability to do this is called `failhard`.

### State Level Failhard

A single state can have a failhard set, this means that if this individual state fails that all state execution will immediately stop. This is a great thing to do if there is a state that sets up a critical config file and setting a require for each state that reads the config would be cumbersome. A good example of this would be setting up a package manager early on:

```

/etc/yum.repos.d/company.repo:
  file.managed:
    - source: salt://company/yumrepo.conf
    - user: root
    - group: root

```

```
- mode: 644
- order: 1
- failhard: True
```

In this situation, the yum repo is going to be configured before other states, and if it fails to lay down the config file, than no other states will be executed.

### Global Failhard

It may be desired to have failhard be applied to every state that is executed, if this is the case, then failhard can be set in the master configuration file. Setting failhard in the master configuration file will result in failing hard when any minion gathering states from the master have a state fail.

This is NOT the default behavior, normally Salt will only fail states that require a failed state.

Using the global failhard is generally not recommended, since it can result in states not being executed or even checked. It can also be confusing to see states failhard if an admin is not actively aware that the failhard has been set.

To use the global failhard set failhard: True in the master configuration file.

### 30.26.7 Global State Arguments

---

**Note:** This documentation has been moved [here](#).

---

### 30.26.8 Highstate data structure definitions

#### The Salt State Tree

A state tree is a collection of SLS files and directories that live under the directory specified in *file\_roots*.

---

**Note:** Directory names or filenames in the state tree cannot contain a period, with the exception of the period in the .sls file suffix.

---

#### Top file

The main state file that instructs minions what environment and modules to use during state execution.

Configurable via *state\_top*.

**See also:**

[A detailed description of the top file](#)

#### Include declaration

Defines a list of *Module reference* strings to include in this SLS.

Occurs only in the top level of the SLS data structure.

Example:

```
include:
  - edit.vim
  - http.server
```

### Module reference

The name of a SLS module defined by a separate SLS file and residing on the Salt Master. A module named `edit.vim` is a reference to the SLS file `salt://edit/vim.sls`.

### ID declaration

Defines an individual *highstate* component. Always references a value of a dictionary containing keys referencing *State declaration* and *Requisite declaration*. Can be overridden by a *Name declaration* or a *Names declaration*.

Occurs on the top level or under the *Extend declaration*.

Must be unique across entire state tree. If the same ID declaration is used twice, only the first one matched will be used. All subsequent ID declarations with the same name will be ignored.

---

**Note:** Naming gotchas

In Salt versions earlier than 0.9.7, ID declarations containing dots would result in unpredictable output.

---

### Extend declaration

Extends a *Name declaration* from an included SLS module. The keys of the extend declaration always refer to an existing *ID declaration* which have been defined in included SLS modules.

Occurs only in the top level and defines a dictionary.

States cannot be extended more than once in a single state run.

Extend declarations are useful for adding-to or overriding parts of a *State declaration* that is defined in another SLS file. In the following contrived example, the shown `mywebsite.sls` file is `include`-ing and `extend`-ing the `apache.sls` module in order to add a `watch` declaration that will restart Apache whenever the Apache configuration file, `mywebsite` changes.

```
include:
  - apache

extend:
  apache:
    service:
      - watch:
        - file: mywebsite

mywebsite:
  file.managed:
    - name: /var/www/mysite
```

**See also:**

`watch_in` and `require_in`

Sometimes it is more convenient to use the *watch\_in* or *require\_in* syntax instead of extending another SLS file.

### State Requisites

#### State declaration

A list which contains one string defining the *Function declaration* and any number of *Function arg declaration* dictionaries.

Can, optionally, contain a number of additional components like the name override components — *name* and *names*. Can also contain *requisite declarations*.

Occurs under an *ID declaration*.

#### Requisite declaration

A list containing *requisite references*.

Used to build the action dependency tree. While Salt states are made to execute in a deterministic order, this order is managed by requiring and watching other Salt states.

Occurs as a list component under a *State declaration* or as a key under an *ID declaration*.

#### Requisite reference

A single key dictionary. The key is the name of the referenced *State declaration* and the value is the ID of the referenced *ID declaration*.

Occurs as a single index in a *Requisite declaration* list.

#### Function declaration

The name of the function to call within the state. A state declaration can contain only a single function declaration.

For example, the following state declaration calls the *installed* function in the *pkg* state module:

```
httpd:
  pkg.installed: []
```

The function can be declared inline with the state as a shortcut. The actual data structure is compiled to this form:

```
httpd:
  pkg:
    - installed
```

Where the function is a string in the body of the state declaration. Technically when the function is declared in dot notation the compiler converts it to be a string in the state declaration list. Note that the use of the first example more than once in an ID declaration is invalid yaml.

INVALID:

```
httpd:
  pkg.installed
  service.running
```

When passing a function without arguments and another state declaration within a single ID declaration, then the long or ``standard`` format needs to be used since otherwise it does not represent a valid data structure.

VALID:

```
httpd:
  pkg.installed: []
  service.running: []
```

Occurs as the only index in the *State declaration* list.

### Function arg declaration

A single key dictionary referencing a Python type which is to be passed to the named *Function declaration* as a parameter. The type must be the data type expected by the function.

Occurs under a *Function declaration*.

For example in the following state declaration `user`, `group`, and `mode` are passed as arguments to the *managed* function in the `file` state module:

```
/etc/http/conf/http.conf:
  file.managed:
    - user: root
    - group: root
    - mode: 644
```

### Name declaration

Overrides the name argument of a *State declaration*. If name is not specified the *ID declaration* satisfies the name argument.

The name is always a single key dictionary referencing a string.

Overriding name is useful for a variety of scenarios.

For example, avoiding clashing ID declarations. The following two state declarations cannot both have `/etc/motd` as the ID declaration:

```
motd_perms:
  file.managed:
    - name: /etc/motd
    - mode: 644

motd_quote:
  file.append:
    - name: /etc/motd
    - text: "Of all smells, bread; of all tastes, salt."
```

Another common reason to override name is if the ID declaration is long and needs to be referenced in multiple places. In the example below it is much easier to specify `mywebsite` than to specify `/etc/apache2/sites-available/mywebsite.com` multiple times:

```
mywebsite:
  file.managed:
    - name: /etc/apache2/sites-available/mywebsite.com
    - source: salt://mywebsite.com

a2ensite mywebsite.com:
  cmd.wait:
    - unless: test -L /etc/apache2/sites-enabled/mywebsite.com
    - watch:
      - file: mywebsite

apache2:
  service.running:
    - watch:
      - file: mywebsite
```

### Names declaration

Expands the contents of the containing *State declaration* into multiple state declarations, each with its own name.

For example, given the following state declaration:

```
python-pkgs:
  pkg.installed:
    - names:
      - python-django
      - python-crypto
      - python-yaml
```

Once converted into the lowstate data structure the above state declaration will be expanded into the following three state declarations:

```
python-django:
  pkg.installed

python-crypto:
  pkg.installed

python-yaml:
  pkg.installed
```

Other values can be overridden during the expansion by providing an additional dictionary level.

New in version 2014.7.0.

```
ius:
  pkgrepo.managed:
    - humanname: IUS Community Packages for Enterprise Linux 6 - $basearch
    - gpgcheck: 1
    - baseurl: http://mirror.rackspace.com/ius/stable/CentOS/6/$basearch
    - gpgkey: http://dl.iuscommunity.org/pub/ius/IUS-COMMUNITY-GPG-KEY
    - names:
      - ius
      - ius-devel:
          - baseurl: http://mirror.rackspace.com/ius/development/CentOS/6/$basearch
```

## Large example

Here is the layout in yaml using the names of the highdata structure components.

```

<Include Declaration>:
  - <Module Reference>
  - <Module Reference>

<Extend Declaration>:
  <ID Declaration>:
    [<overrides>]

# standard declaration

<ID Declaration>:
  <State Module>:
    - <Function>
    - <Function Arg>
    - <Function Arg>
    - <Function Arg>
    - <Name>: <name>
    - <Requisite Declaration>:
      - <Requisite Reference>
      - <Requisite Reference>

# inline function and names

<ID Declaration>:
  <State Module>.<Function>:
    - <Function Arg>
    - <Function Arg>
    - <Function Arg>
    - <Names>:
      - <name>
      - <name>
      - <name>
    - <Requisite Declaration>:
      - <Requisite Reference>
      - <Requisite Reference>

# multiple states for single id

<ID Declaration>:
  <State Module>:
    - <Function>
    - <Function Arg>
    - <Name>: <name>
    - <Requisite Declaration>:
      - <Requisite Reference>
  <State Module>:
    - <Function>
    - <Function Arg>
    - <Names>:
      - <name>
      - <name>

```

- ```
- <Requisite Declaration>:  
  - <Requisite Reference>
```

### 30.26.9 Include and Exclude

Salt sls files can include other sls files and exclude sls files that have been otherwise included. This allows for an sls file to easily extend or manipulate other sls files.

#### Include

When other sls files are included, everything defined in the included sls file will be added to the state run. When including define a list of sls formulas to include:

```
include:  
  - http  
  - libvirt
```

The include statement will include sls formulas from the same environment that the including sls formula is in. But the environment can be explicitly defined in the configuration to override the running environment, therefore if an sls formula needs to be included from an external environment named ``dev" the following syntax is used:

```
include:  
  - dev: http
```

#### Relative Include

In Salt 0.16.0 the capability to include sls formulas which are relative to the running sls formula was added, simply precede the formula name with a .:

```
include:  
  - .virt  
  - .virt.hyper
```

#### Exclude

The exclude statement, added in Salt 0.10.3 allows an sls to hard exclude another sls file or a specific id. The component is excluded after the high data has been compiled, so nothing should be able to override an exclude.

Since the exclude can remove an id or an sls the type of component to exclude needs to be defined. an exclude statement that verifies that the running *highstate* does not contain the http sls and the `/etc/vimrc` id would look like this:

```
exclude:  
  - sls: http  
  - id: /etc/vimrc
```

### 30.26.10 State System Layers

The Salt state system is comprised of multiple layers. While using Salt does not require an understanding of the state layers, a deeper understanding of how Salt compiles and manages states can be very beneficial.

#### Function Call

The lowest layer of functionality in the state system is the direct state function call. State executions are executions of single state functions at the core. These individual functions are defined in state modules and can be called directly via the `state.single` command.

```
salt '*' state.single pkg.installed name='vim'
```

#### Low Chunk

The low chunk is the bottom of the Salt state compiler. This is a data representation of a single function call. The low chunk is sent to the state caller and used to execute a single state function.

A single low chunk can be executed manually via the `state.low` command.

```
salt '*' state.low '{name: vim, state: pkg, fun: installed}'
```

The passed data reflects what the state execution system gets after compiling the data down from sls formulas.

#### Low State

The *Low State* layer is the list of low chunks ``evaluated" in order. To see what the low state looks like for a *highstate*, run:

```
salt '*' state.show_lowstate
```

This will display the raw lowstate in the order which each low chunk will be evaluated. The order of evaluation is not necessarily the order of execution, since requisites are evaluated at runtime. Requisite execution and evaluation is finite; this means that the order of execution can be ascertained with 100% certainty based on the order of the low state.

#### High Data

High data is the data structure represented in YAML via SLS files. The High data structure is created by merging the data components rendered inside sls files (or other render systems). The High data can be easily viewed by executing the `state.show_highstate` or `state.show_sls` functions. Since this data is a somewhat complex data structure, it may be easier to read using the `json`, `yaml`, or `pprint` outputters:

```
salt '*' state.show_highstate --out yaml
salt '*' state.show_sls edit.vim --out pprint
```

## SLS

Above ``High Data'', the logical layers are no longer technically required to be executed, or to be executed in a hierarchy. This means that how the High data is generated is optional and very flexible. The SLS layer allows for many mechanisms to be used to render sls data from files or to use the fileserver backend to generate sls and file data from external systems.

The SLS layer can be called directly to execute individual sls formulas.

---

**Note:** SLS Formulas have historically been called ``SLS files''. This is because a single SLS was only constituted in a single file. Now the term ``SLS Formula'' better expresses how a compartmentalized SLS can be expressed in a much more dynamic way by combining pillar and other sources, and the SLS can be dynamically generated.

---

To call a single SLS formula named `edit.vim`, execute `state.apply` and pass `edit.vim` as an argument:

```
salt '*' state.apply edit.vim
```

## HighState

Calling SLS directly logically assigns what states should be executed from the context of the calling minion. The Highstate layer is used to allow for full contextual assignment of what is executed where to be tied to groups of, or individual, minions entirely from the master. This means that the environment of a minion, and all associated execution data pertinent to said minion, can be assigned from the master without needing to execute or configure anything on the target minion. This also means that the minion can independently retrieve information about its complete configuration from the master.

To execute the *highstate* use `state.apply`:

```
salt '*' state.apply
```

## OverState

The overstate layer expresses the highest functional layer of Salt's automated logic systems. The Overstate allows for stateful and functional orchestration of routines from the master. The overstate defines in data execution stages which minions should execute states, or functions, and in what order using requisite logic.

### 30.26.11 The Orchestrate Runner

---

**Note:** This documentation has been moved [here](#).

---

### 30.26.12 Ordering States

The way in which configuration management systems are executed is a hotly debated topic in the configuration management world. Two major philosophies exist on the subject, to either execute in an imperative fashion where things are executed in the order in which they are defined, or in a declarative fashion where dependencies need to be mapped between objects.

Imperative ordering is finite and generally considered easier to write, but declarative ordering is much more powerful and flexible but generally considered more difficult to create.

Salt has been created to get the best of both worlds. States are evaluated in a finite order, which guarantees that states are always executed in the same order, and the states runtime is declarative, making Salt fully aware of dependencies via the *requisite* system.

### State Auto Ordering

Salt always executes states in a finite manner, meaning that they will always execute in the same order regardless of the system that is executing them. But in Salt 0.17.0, the `state_auto_order` option was added. This option makes states get evaluated in the order in which they are defined in sls files.

The evaluation order makes it easy to know what order the states will be executed in, but it is important to note that the requisite system will override the ordering defined in the files, and the `order` option described below will also override the order in which states are defined in sls files.

If the classic ordering is preferred (lexicographic), then set `state_auto_order` to `False` in the master configuration file. Otherwise, `state_auto_order` defaults to `True`.

### Requisite Statements

---

**Note:** This document represents behavior exhibited by Salt requisites as of version 0.9.7 of Salt.

---

Often when setting up states any single action will require or depend on another action. Salt allows for the building of relationships between states with requisite statements. A requisite statement ensures that the named state is evaluated before the state requiring it. There are three types of requisite statements in Salt, **require**, **watch**, and **prereq**.

These requisite statements are applied to a specific state declaration:

```
httpd:
  pkg.installed: []
  file.managed:
    - name: /etc/httpd/conf/httpd.conf
    - source: salt://httpd/httpd.conf
    - require:
      - pkg: httpd
```

In this example, the **require** requisite is used to declare that the file `/etc/httpd/conf/httpd.conf` should only be set up if the `pkg` state executes successfully.

The requisite system works by finding the states that are required and executing them before the state that requires them. Then the required states can be evaluated to see if they have executed correctly.

Require statements can refer to any state defined in Salt. The basic examples are *pkg*, *service*, and *file*, but any used state can be referenced.

In addition to state declarations such as `pkg`, `file`, etc., `sls` type requisites are also recognized, and essentially allow 'chaining' of states. This provides a mechanism to ensure the proper sequence for complex state formulas, especially when the discrete states are split or groups into separate sls files:

```
include:
  - network

httpd:
  pkg.installed: []
  service.running:
```

```
- require:  
  - pkg: httpd  
  - sls: network
```

In this example, the httpd service running state will not be applied (i.e., the httpd service will not be started) unless both the httpd package is installed AND the network state is satisfied.

**Note:** Requisite matching

Requisites match on both the ID Declaration and the name parameter. Therefore, if using the `pkgs` or `sources` argument to install a list of packages in a `pkg` state, it's important to note that it is impossible to match an individual package in the list, since all packages are installed as a single state.

### Multiple Requisites

The requisite statement is passed as a list, allowing for the easy addition of more requisites. Both requisite types can also be separately declared:

```
httpd:  
  pkg.installed: []  
  service.running:  
    - enable: True  
    - watch:  
      - file: /etc/httpd/conf/httpd.conf  
    - require:  
      - pkg: httpd  
      - user: httpd  
      - group: httpd  
  file.managed:  
    - name: /etc/httpd/conf/httpd.conf  
    - source: salt://httpd/httpd.conf  
    - require:  
      - pkg: httpd  
  user.present: []  
  group.present: []
```

In this example, the httpd service is only going to be started if the package, user, group, and file are executed successfully.

### Requisite Documentation

For detailed information on each of the individual requisites, [please look here](#).

### The Order Option

Before using the `order` option, remember that the majority of state ordering should be done with a *Requisite declaration*, and that a requisite declaration will override an `order` option, so a state with `order` option should not require or be required by other states.

The `order` option is used by adding an order number to a state declaration with the option `order`:

```
vim:
  pkg.installed:
    - order: 1
```

By adding the order option to `1` this ensures that the vim package will be installed in tandem with any other state declaration set to the order `1`.

Any state declared without an order option will be executed after all states with order options are executed.

But this construct can only handle ordering states from the beginning. Certain circumstances will present a situation where it is desirable to send a state to the end of the line. To do this, set the order to `last`:

```
vim:
  pkg.installed:
    - order: last
```

### 30.26.13 OverState System

---

**Note:** This documentation has been moved [here](#).

---

### 30.26.14 State Providers

New in version 0.9.8.

Salt predetermines what modules should be mapped to what uses based on the properties of a system. These determinations are generally made for modules that provide things like package and service management.

Sometimes in states, it may be necessary to use an alternative module to provide the needed functionality. For instance, an very old Arch Linux system may not be running `systemd`, so instead of using the `systemd` service module, you can revert to the default service module:

```
httpd:
  service.running:
    - enable: True
    - provider: service
```

In this instance, the basic `service` module (which manages `sysvinit`-based services) will replace the `systemd` module which is used by default on Arch Linux.

This change only affects this one state though. If it is necessary to make this override for most or every service, it is better to just override the provider in the minion config file, as described [here](#).

Also, keep in mind that this only works for states with an identically-named virtual module (`pkg`, `service`, etc.).

#### Arbitrary Module Redirects

The provider statement can also be used for more powerful means, instead of overwriting or extending the module used for the named service an arbitrary module can be used to provide certain functionality.

```
emacs:
  pkg.installed:
    - provider:
      - cmd: customcmd
```

In this example, the state is being instructed to use a custom module to invoke commands. Arbitrary module redirects can be used to dramatically change the behavior of a given state.

### 30.26.15 Requisites and Other Global State Arguments

#### Requisites

The Salt requisite system is used to create relationships between states. The core idea being that, when one state is dependent somehow on another, that inter-dependency can be easily defined.

Requisites come in two types: Direct requisites (such as `require`), and `requisite_in`s (such as `require_in`). The relationships are directional: a direct requisite requires something from another state. However, a `requisite_in` inserts a requisite into the targeted state pointing to the targeting state. The following example demonstrates a direct requisite:

```
vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
    - require:
      - pkg: vim
```

In the example above, the file `/etc/vimrc` depends on the `vim` package.

`requisite_in` statements are the opposite. Instead of saying "I depend on something", `requisite_in`s say "Someone depends on me":

```
vim:
  pkg.installed:
    - requisite_in:
      - file: /etc/vimrc

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
```

So here, with a `requisite_in`, the same thing is accomplished as in the first example, but the other way around. The `vim` package is saying "I depend on `/etc/vimrc`". This will result in a `require` being inserted into the `/etc/vimrc` state which targets the `vim` state.

In the end, a single dependency map is created and everything is executed in a finite and predictable order.

---

**Note:** Requisite matching

Requisites match on both the ID Declaration and the `name` parameter. This means that, in the example above, the `require_in` requisite would also have been matched if the `/etc/vimrc` state was written as follows:

```
vimrc:
  file.managed:
    - name: /etc/vimrc
    - source: salt://edit/vimrc
```

### Direct Requisite and Requisite\_in types

There are six direct requisite statements that can be used in Salt: `require`, `watch`, `prereq`, `use`, `onchanges`, and `onfail`. Each direct requisite also has a corresponding `requisite_in`: `require_in`, `watch_in`, `prereq_in`, `use_in`, `onchanges_in`, and `onfail_in`. All of the requisites define specific relationships and always work with the dependency logic defined above.

**require** The use of `require` demands that the dependent state executes before the depending state. The state containing the `require` requisite is defined as the depending state. The state specified in the `require` statement is defined as the dependent state. If the dependent state's execution succeeds, the depending state will then execute. If the dependent state's execution fails, the depending state will not execute. In the first example above, the file `/etc/vimrc` will only execute after the `vim` package is installed successfully.

**Require an entire sls file** As of Salt 0.16.0, it is possible to require an entire sls file. Do this first by including the sls file and then setting a state to `require` the included sls file:

```
include:
  - foo

bar:
  pkg.installed:
    - require:
      - sls: foo
```

**watch** `watch` statements are used to add additional behavior when there are changes in other states.

**Note:** If a state should only execute when another state has changes, and otherwise do nothing, the new `onchanges` requisite should be used instead of `watch`. `watch` is designed to add *additional* behavior when there are changes, but otherwise execute normally.

The state containing the `watch` requisite is defined as the watching state. The state specified in the `watch` statement is defined as the watched state. When the watched state executes, it will return a dictionary containing a key named `changes`. Here are two examples of state return dictionaries, shown in json for clarity:

```
"local": {
  "file_|-/tmp/foo_|-/tmp/foo_|-directory": {
    "comment": "Directory /tmp/foo updated",
    "__run_num__": 0,
    "changes": {
      "user": "bar"
    },
    "name": "/tmp/foo",
    "result": true
  }
}

"local": {
  "pkgrepo_|-salt-minion_|-salt-minion_|-managed": {
    "comment": "Package repo 'salt-minion' already configured",
    "__run_num__": 0,
    "changes": {},
    "name": "salt-minion",
```

```
    "result": true
  }
}
```

If the ```result``` of the watched state is `True`, the watching state *will execute normally*. This part of `watch` mirrors the functionality of the `require` requisite. If the ```result``` of the watched state is `False`, the watching state will never run, nor will the watching state's `mod_watch` function execute.

However, if the ```result``` of the watched state is `True`, and the ```changes``` key contains a populated dictionary (changes occurred in the watched state), then the `watch` requisite can add additional behavior. This additional behavior is defined by the `mod_watch` function within the watching state module. If the `mod_watch` function exists in the watching state module, it will be called *in addition to* the normal watching state. The return data from the `mod_watch` function is what will be returned to the master in this case; the return data from the main watching function is discarded.

If the ```changes``` key contains an empty dictionary, the `watch` requisite acts exactly like the `require` requisite (the watching state will execute if ```result``` is `True`, and fail if ```result``` is `False` in the watched state).

---

**Note:** Not all state modules contain `mod_watch`. If `mod_watch` is absent from the watching state module, the `watch` requisite behaves exactly like a `require` requisite.

---

A good example of using `watch` is with a `service.running` state. When a service watches a state, then the service is reloaded/restarted when the watched state changes, in addition to Salt ensuring that the service is running.

```
ntpd:
  service.running:
    - watch:
      - file: /etc/ntp.conf
  file.managed:
    - name: /etc/ntp.conf
    - source: salt://ntp/files/ntp.conf
```

**prereq** New in version 0.16.0.

`prereq` allows for actions to be taken based on the expected results of a state that has not yet been executed. The state containing the `prereq` requisite is defined as the pre-requiring state. The state specified in the `prereq` statement is defined as the pre-required state.

When a `prereq` requisite is evaluated, the pre-required state reports if it expects to have any changes. It does this by running the pre-required single state as a test-run by enabling `test=True`. This test-run will return a dictionary containing a key named ```changes```. (See the `watch` section above for examples of ```changes``` dictionaries.)

If the ```changes``` key contains a populated dictionary, it means that the pre-required state expects changes to occur when the state is actually executed, as opposed to the test-run. The pre-requiring state will now actually run. If the pre-requiring state executes successfully, the pre-required state will then execute. If the pre-requiring state fails, the pre-required state will not execute.

If the ```changes``` key contains an empty dictionary, this means that changes are not expected by the pre-required state. Neither the pre-required state nor the pre-requiring state will run.

The best way to define how `prereq` operates is displayed in the following practical example: When a service should be shut down because underlying code is going to change, the service should be off-line while the update occurs. In this example, `graceful-down` is the pre-requiring state and `site-code` is the pre-required state.

```

graceful-down:
  cmd.run:
    - name: service apache graceful
    - prereq:
      - file: site-code

site-code:
  file.recurse:
    - name: /opt/site_code
    - source: salt://site/code

```

In this case the apache server will only be shutdown if the site-code state expects to deploy fresh code via the file.recurse call. The site-code deployment will only be executed if the graceful-down run completes successfully.

**onfail** New in version 2014.7.0.

The `onfail` requisite allows for reactions to happen strictly as a response to the failure of another state. This can be used in a number of ways, such as executing a second attempt to set up a service or begin to execute a separate thread of states because of a failure.

The `onfail` requisite is applied in the same way as `require` as `watch`:

```

primary_mount:
  mount.mounted:
    - name: /mnt/share
    - device: 10.0.0.45:/share
    - fstype: nfs

backup_mount:
  mount.mounted:
    - name: /mnt/share
    - device: 192.168.40.34:/share
    - fstype: nfs
    - onfail:
      - mount: primary_mount

```

**onchanges** New in version 2014.7.0.

The `onchanges` requisite makes a state only apply if the required states generate changes, and if the watched state's `__result__` is `True`. This can be a useful way to execute a post hook after changing aspects of a system.

**use** The `use` requisite is used to inherit the arguments passed in another id declaration. This is useful when many files need to have the same defaults.

```

/etc/foo.conf:
  file.managed:
    - source: salt://foo.conf
    - template: jinja
    - makedirs: True
    - user: apache
    - group: apache
    - mode: 755

/etc/bar.conf

```

```
file.managed:
  - source: salt://bar.conf
  - use:
    - file: /etc/foo.conf
```

The `use` statement was developed primarily for the networking states but can be used on any states in Salt. This makes sense for the networking state because it can define a long list of options that need to be applied to multiple network interfaces.

The `use` statement does not inherit the `requisites` arguments of the targeted state. This means also a chain of `use` `requisites` would not inherit inherited options.

**The `_in` versions of requisites** All of the requisites also have corresponding `requisite_in` versions, which do the reverse of their normal counterparts. The examples below all use `require_in` as the example, but note that all of the `_in` requisites work the same way: They result in a normal requisite in the targeted state, which targets the state which has defines the `requisite_in`. Thus, a `require_in` causes the target state to `require` the targeting state. Similarly, a `watch_in` causes the target state to `watch` the targeting state. This pattern continues for the rest of the requisites.

If a state declaration needs to be required by another state declaration then `require_in` can accommodate it. Therefore, these two `sls` files would be the same in the end:

Using `require`

```
httpd:
  pkg.installed: []
  service.running:
    - require:
      - pkg: httpd
```

Using `require_in`

```
httpd:
  pkg.installed:
    - require_in:
      - service: httpd
  service.running: []
```

The `require_in` statement is particularly useful when assigning a `require` in a separate `sls` file. For instance it may be common for `httpd` to `require` components used to set up PHP or `mod_python`, but the HTTP state does not need to be aware of the additional components that `require` it when it is set up:

`http.sls`

```
httpd:
  pkg.installed: []
  service.running:
    - require:
      - pkg: httpd
```

`php.sls`

```
include:
  - http
```

```
php:
  pkg.installed:
    - require_in:
      - service: httpd
```

mod\_python.sls

```
include:
  - http

mod_python:
  pkg.installed:
    - require_in:
      - service: httpd
```

Now the httpd server will only start if php or mod\_python are first verified to be installed. Thus allowing for a requisite to be defined ``after the fact''.

## Altering States

The state altering system is used to make sure that states are evaluated exactly as the user expects. It can be used to double check that a state preformed exactly how it was expected to, or to make 100% sure that a state only runs under certain conditions. The use of unless or onlyif options help make states even more stateful. The check\_cmds option helps ensure that the result of a state is evaluated correctly.

### Unless

New in version 2014.7.0.

The unless requisite specifies that a state should only run when any of the specified commands return `False`. The unless requisite operates as NOR and is useful in giving more granular control over when a state should execute.

**NOTE:** Under the hood unless calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by unless will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion.

```
vim:
  pkg.installed:
    - unless:
      - rpm -q vim-enhanced
      - ls /usr/bin/vim
```

In the example above, the state will only run if either the vim-enhanced package is not installed (returns `False`) or if `/usr/bin/vim` does not exist (returns `False`). The state will run if both commands return `False`.

However, the state will not run if both commands return `True`.

Unless checks are resolved for each name to which they are associated.

For example:

```
deploy_app:
  cmd.run:
    - names:
      - first_deploy_cmd
```

```
- second_deploy_cmd
- unless: ls /usr/bin/vim
```

In the above case, `some_check` will be run prior to `_each_name` -- once for `first_deploy_cmd` and a second time for `second_deploy_cmd`.

### Onlyif

New in version 2014.7.0.

`onlyif` is the opposite of `unless`. If all of the commands in `onlyif` return `True`, then the state is run. If any of the specified commands return `False`, the state will not run.

**NOTE:** Under the hood `onlyif` calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by `unless` will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion.

```
stop-volume:
  module.run:
    - name: glusterfs.stop_volume
    - m_name: work
    - onlyif:
      - gluster volume status work
    - order: 1

remove-volume:
  module.run:
    - name: glusterfs.delete
    - m_name: work
    - onlyif:
      - gluster volume info work
    - watch:
      - cmd: stop-volume
```

The above example ensures that the `stop_volume` and `delete` modules only run if the `gluster` commands return a 0 ret value.

### Listen/Listen\_in

New in version 2014.7.0.

`listen` and its counterpart `listen_in` trigger `mod_wait` functions for states, when those states succeed and result in changes, similar to how `watch` its counterpart `watch_in`. Unlike `watch` and `watch_in`, `listen`, and `listen_in` will not modify the order of states and can be used to ensure your states are executed in the order they are defined. All `listen/listen_in` actions will occur at the end of a state run, after all states have completed.

```
restart-apache2:
  service.running:
    - name: apache2
    - listen:
      - file: /etc/apache2/apache2.conf

configure-apache2:
  file.managed:
```

- ```

- name: /etc/apache2/apache2.conf
- source: salt://apache2/apache2.conf

```

This example will cause apache2 to be restarted when the apache2.conf file is changed, but the apache2 restart will happen at the end of the state run.

```

restart-apache2:
  service.running:
    - name: apache2

configure-apache2:
  file.managed:
    - name: /etc/apache2/apache2.conf
    - source: salt://apache2/apache2.conf
    - listen_in:
      - service: apache2

```

This example does the same as the above example, but puts the state argument on the file resource, rather than the service resource.

### check\_cmd

New in version 2014.7.0.

Check Command is used for determining that a state did or did not run as expected.

**NOTE:** Under the hood `check_cmd` calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by `unless` will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion.

```

comment-repo:
  file.replace:
    - name: /etc/yum.repos.d/fedora.repo
    - pattern: ^enabled=0
    - repl: enabled=1
    - check_cmd:
      - grep 'enabled=0' /etc/yum.repos.d/fedora.repo && return 1 || return 0

```

This will attempt to do a replace on all `enabled=0` in the `.repo` file, and replace them with `enabled=1`. The `check_cmd` is just a bash command. It will do a `grep` for `enabled=0` in the file, and if it finds any, it will return a 0, which will prompt the `&&` portion of the command to return a 1, causing `check_cmd` to set the state as failed. If it returns a 1, meaning it didn't find any `'enabled=0'` it will hit the `||` portion of the command, returning a 0, and declaring the function succeeded.

### Overriding Checks

There are two commands used for the above checks.

`mod_run_check` is used to check for `onlyif` and `unless`. If the goal is to override the global check for these to variables, include a `mod_run_check` in the `salt/states/` file.

`mod_run_check_cmd` is used to check for the `check_cmd` options. To override this one, include a `mod_run_check_cmd` in the states file for the state.

### 30.26.16 Startup States

Sometimes it may be desired that the salt minion execute a state run when it is started. This alleviates the need for the master to initiate a state run on a new minion and can make provisioning much easier.

As of Salt 0.10.3 the minion config reads options that allow for states to be executed at startup. The options are *startup\_states*, *sls\_list*, and *top\_file*.

The *startup\_states* option can be passed one of a number of arguments to define how to execute states. The available options are:

*highstate* Execute *state.apply*

*sls* Read in the *sls\_list* option and execute the named sls files

*top* Read in the *top\_file* option and execute states based on that top file on the Salt Master

#### Examples:

Execute *state.apply* to run the *highstate* when starting the minion:

```
startup_states: highstate
```

Execute the sls files *edit.vim* and *hyper*:

```
startup_states: sls
sls_list:
- edit.vim
- hyper
```

### 30.26.17 State Testing

Executing a Salt state run can potentially change many aspects of a system and it may be desirable to first see what a state run is going to change before applying the run.

Salt has a test interface to report on exactly what will be changed, this interface can be invoked on any of the major state run functions:

```
salt '*' state.apply test=True
salt '*' state.apply mysls test=True
salt '*' state.single test=True
```

The test run is mandated by adding the *test=True* option to the states. The return information will show states that will be applied in yellow and the result is reported as *None*.

#### Default Test

If the value *test* is set to *True* in the minion configuration file then states will default to being executed in test mode. If this value is set then states can still be run by calling *test=False*:

```
salt '*' state.apply test=False
salt '*' state.apply mysls test=False
salt '*' state.single test=False
```

### 30.26.18 The Top File

The top file is used to map what SLS modules get loaded onto what minions via the state system. The top file creates a few general abstractions. First it maps what nodes should pull from which environments, next it defines which matches systems should draw from.

#### Environments

Environments allow conceptually organizing state tree directories. Environments can be made to be self-contained or state trees can be made to bleed through environments.

**Note:** Environments in Salt are very flexible. This section defines how the top file can be used to define what states from what environments are to be used for specific minions.

If the intent is to bind minions to specific environments, then the *environment* option can be set in the minion configuration file.

The environments in the top file corresponds with the environments defined in the *file\_roots* variable. In a simple, single environment setup you only have the *base* environment, and therefore only one state tree. Here is a simple example of *file\_roots* in the master configuration:

```
file_roots:
  base:
    - /srv/salt
```

This means that the top file will only have one environment to pull from, here is a simple, single environment top file:

```
base:
  '*':
    - core
    - edit
```

This also means that */srv/salt* has a state tree. But if you want to use multiple environments, or partition the file server to serve more than just the state tree, then the *file\_roots* option can be expanded:

```
file_roots:
  base:
    - /srv/salt/base
  dev:
    - /srv/salt/dev
  qa:
    - /srv/salt/qa
  prod:
    - /srv/salt/prod
```

Then our top file could reference the environments:

```

dev:
  'webserver*dev*':
    - webserver
  'db*dev*':
    - db
qa:
  'webserver*qa*':
    - webserver
  'db*qa*':
    - db
prod:
  'webserver*prod*':
    - webserver
  'db*prod*':
    - db

```

In this setup we have state trees in three of the four environments, and no state tree in the `base` environment. Notice that the targets for the minions specify environment data. In Salt the master determines who is in what environment, and many environments can be crossed together. For instance, a separate global state tree could be added to the base environment if it suits your deployment:

```

base:
  '*':
    - global
dev:
  'webserver*dev*':
    - webserver
  'db*dev*':
    - db
qa:
  'webserver*qa*':
    - webserver
  'db*qa*':
    - db
prod:
  'webserver*prod*':
    - webserver
  'db*prod*':
    - db

```

In this setup all systems will pull the global SLS from the base environment, as well as pull from their respective environments. If you assign only one SLS to a system, as in this example, a shorthand is also available:

```

base:
  '*': global
dev:
  'webserver*dev*': webserver
  'db*dev*':        db
qa:
  'webserver*qa*': webserver
  'db*qa*':        db
prod:
  'webserver*prod*': webserver
  'db*prod*':        db

```

**Note:** The top files from all defined environments will be compiled into a single top file for all states. Top files are

environment agnostic.

Remember, that since everything is a file in Salt, the environments are primarily file server environments, this means that environments that have nothing to do with states can be defined and used to distribute other files. A clean and recommended setup for multiple environments would look like this:

```
# Master file_roots configuration:
file_roots:
  base:
    - /srv/salt/base
  dev:
    - /srv/salt/dev
  qa:
    - /srv/salt/qa
  prod:
    - /srv/salt/prod
```

Then only place state trees in the dev, qa, and prod environments, leaving the base environment open for generic file transfers. Then the top.sls file would look something like this:

```
dev:
  'webserver*dev*':
    - webserver
  'db*dev*':
    - db
qa:
  'webserver*qa*':
    - webserver
  'db*qa*':
    - db
prod:
  'webserver*prod*':
    - webserver
  'db*prod*':
    - db
```

## Other Ways of Targeting Minions

In addition to globs, minions can be specified in top files a few other ways. Some common ones are [compound matches](#) and [node groups](#).

Here is a slightly more complex top file example, showing the different types of matches you can perform:

```
base:
  '*':
    - ldap-client
    - networking
    - salt.minion

  'salt-master*':
    - salt.master

  '^((memcache|web).(qa|prod).loc$)':
    - match: pcre
    - nagios.mon.web
```

```

- apache.server

'os:Ubuntu':
- match: grain
- repos.ubuntu

'os:(RedHat|CentOS)':
- match: grain_pcre
- repos.epel

'foo,bar,baz':
- match: list
- database

'somekey:abc':
- match: pillar
- xyz

'nag1* or G@role:monitoring':
- match: compound
- nagios.server

```

In this example `top.sls`, all minions get the `ldap-client`, `networking`, and `salt.minion` states. Any minion with an id matching the `salt-master*` glob will get the `salt.master` state. Any minion with ids matching the regular expression `^(memcache|web).(qa|prod).loc$` will get the `nagios.mon.web` and `apache.server` states. All Ubuntu minions will receive the `repos.ubuntu` state, while all RHEL and CentOS minions will receive the `repos.epel` state. The minions `foo`, `bar`, and `baz` will receive the `database` state. Any minion with a pillar named `somekey`, having a value of `abc` will receive the `xyz` state. Finally, minions with ids matching the `nag1*` glob or with a grain named `role` equal to `monitoring` will receive the `nagios.server` state.

## How Top Files Are Compiled

**Warning:** There is currently a known issue with the topfile compilation. The below may not be completely valid until <https://github.com/saltstack/salt/issues/12483#issuecomment-64181598> is closed.

As mentioned earlier, the top files in the different environments are compiled into a single set of data. The way in which this is done follows a few rules, which are important to understand when arranging top files in different environments. The examples below all assume that the `file_roots` are set as in the [above multi-environment example](#).

1. The `base` environment's top file is processed first. Any environment which is defined in the `base` `top.sls` as well as another environment's top file, will use the instance of the environment configured in `base` and ignore all other instances. In other words, the `base` top file is authoritative when defining environments. Therefore, in the example below, the `dev` section in `/srv/salt/dev/top.sls` would be completely ignored.

`/srv/salt/base/top.sls:`

```

base:
  '*':
    - common
dev:
  'webserver*dev*':
    - webserver
  'db*dev*':
    - db

```

```
/srv/salt/dev/top.sls:
```

```
dev:
  '10.10.100.0/24':
    - match: ipcidr
    - deployments.dev.site1
  '10.10.101.0/24':
    - match: ipcidr
    - deployments.dev.site2
```

**Note:** The rules below assume that the environments being discussed were not defined in the base top file.

2. If, for some reason, the base environment is not configured in the base environment's top file, then the other environments will be checked in alphabetical order. The first top file found to contain a section for the base environment wins, and the other top files' base sections are ignored. So, provided there is no base section in the base top file, with the below two top files the dev environment would win out, and the common.centos SLS would not be applied to CentOS hosts.

```
/srv/salt/dev/top.sls:
```

```
base:
  'os:Ubuntu':
    - common.ubuntu
dev:
  'webserver*dev*':
    - webserver
  'db*dev*':
    - db
```

```
/srv/salt/qa/top.sls:
```

```
base:
  'os:Ubuntu':
    - common.ubuntu
  'os:CentOS':
    - common.centos
qa:
  'webserver*qa*':
    - webserver
  'db*qa*':
    - db
```

3. For environments other than base, the top file in a given environment will be checked for a section matching the environment's name. If one is found, then it is used. Otherwise, the remaining (non-base) environments will be checked in alphabetical order. In the below example, the qa section in /srv/salt/dev/top.sls will be ignored, but if /srv/salt/qa/top.sls were cleared or removed, then the states configured for the qa environment in /srv/salt/dev/top.sls will be applied.

```
/srv/salt/dev/top.sls:
```

```
dev:
  'webserver*dev*':
    - webserver
  'db*dev*':
```

```
- db
qa:
  '10.10.200.0/24':
    - match: ipcidr
    - deployments.qa.site1
  '10.10.201.0/24':
    - match: ipcidr
    - deployments.qa.site2
```

/srv/salt/qa/top.sls:

```
qa:
  'webserver*qa*':
    - webserver
  'db*qa*':
    - db
```

---

**Note:** When in doubt, the simplest way to configure your states is with a single top.sls in the base environment.

---

### 30.26.19 SLS Template Variable Reference

The template engines available to sls files and file templates come loaded with a number of context variables. These variables contain information and functions to assist in the generation of templates. See each variable below for its availability -- not all variables are available in all templating contexts.

#### Salt

The *salt* variable is available to abstract the salt library functions. This variable is a python dictionary containing all of the functions available to the running salt minion. It is available in all salt templates.

```
{% for file in salt['cmd.run']('ls -1 /opt/to_remove').splitlines() %}
/opt/to_remove/{{ file }}:
  file.absent
{% endfor %}
```

#### Opts

The *opts* variable abstracts the contents of the minion's configuration file directly to the template. The *opts* variable is a dictionary. It is available in all templates.

```
{{ opts['cachedir'] }}
```

The `config.get` function also searches for values in the *opts* dictionary.

#### Pillar

The *pillar* dictionary can be referenced directly, and is available in all templates:

```
{{ pillar['key'] }}
```

Using the `pillar.get` function via the `salt` variable is generally recommended since a default can be safely set in the event that the value is not available in pillar and dictionaries can be traversed directly:

```
{{ salt['pillar.get']('key', 'failover_value') }}  
{{ salt['pillar.get']('stuff:more:deeper') }}
```

## Grains

The `grains` dictionary makes the minion's grains directly available, and is available in all templates:

```
{{ grains['os'] }}
```

The `grains.get` function can be used to traverse deeper grains and set defaults:

```
{{ salt['grains.get']('os') }}
```

## saltenv

The `saltenv` variable is available in only in sls files when gathering the sls from an environment.

```
{{ saltenv }}
```

## sls

The `sls` variable contains the sls reference value, and is only available in the actual SLS file (not in any files referenced in that SLS). The sls reference value is the value used to include the sls in top files or via the include option.

```
{{ sls }}
```

### 30.26.20 State Modules

State Modules are the components that map to actual enforcement and management of Salt states.

#### States are Easy to Write!

State Modules should be easy to write and straightforward. The information passed to the SLS data structures will map directly to the states modules.

Mapping the information from the SLS data is simple, this example should illustrate:

```
/etc/salt/master: # maps to "name"
  file: # maps to State module filename e.g. https://github.com/saltstack/salt/tree/develop/salt/stater
    - managed # maps to the managed function in the file State module
    - user: root # one of many options passed to the manage function
    - group: root
    - mode: 644
    - source: salt://salt/master
```

Therefore this SLS data can be directly linked to a module, function, and arguments passed to that function.

This does issue the burden, that function names, state names and function arguments should be very human readable inside state modules, since they directly define the user interface.

---

### Keyword Arguments

Salt passes a number of keyword arguments to states when rendering them, including the environment, a unique identifier for the state, and more. Additionally, keep in mind that the requisites for a state are part of the keyword arguments. Therefore, if you need to iterate through the keyword arguments in a state, these must be considered and handled appropriately. One such example is in the *pkgrepo.managed* state, which needs to be able to handle arbitrary keyword arguments and pass them to module execution functions. An example of how these keyword arguments can be handled can be found [here](#).

---

### Using Custom State Modules

Place your custom state modules inside a `_states` directory within the `file_roots` specified by the master config file. These custom state modules can then be distributed in a number of ways. Custom state modules are distributed when `state.apply` is run, or by executing the `saltutil.sync_states` or `saltutil.sync_all` functions.

Any custom states which have been synced to a minion, that are named the same as one of Salt's default set of states, will take the place of the default state with the same name. Note that a state's default name is its filename (i.e. `foo.py` becomes state `foo`), but that its name can be overridden by using a `__virtual__` function.

### Cross Calling Modules

As with Execution Modules, State Modules can also make use of the `__salt__` and `__grains__` data.

It is important to note that the real work of state management should not be done in the state module unless it is needed. A good example is the `pkg` state module. This module does not do any package management work, it just calls the `pkg` execution module. This makes the `pkg` state module completely generic, which is why there is only one `pkg` state module and many backend `pkg` execution modules.

On the other hand some modules will require that the logic be placed in the state module, a good example of this is the `file` module. But in the vast majority of cases this is not the best approach, and writing specific execution modules to do the backend work will be the optimal solution.

### Return Data

A State Module must return a dict containing the following keys/values:

- **name:** The same value passed to the state as `name`.
- **changes:** A dict describing the changes made. Each thing changed should be a key, with its value being another dict with keys called `old` and `new` containing the old/new values. For example, the `pkg` state's `changes`

dict has one key for each package changed, with the ``old`` and ``new`` keys in its sub-dict containing the old and new versions of the package.

- **result:** A tristate value. `True` if the action was successful, `False` if it was not, or `None` if the state was run in test mode, `test=True`, and changes would have been made if the state was not run in test mode.

	live mode	test mode
no changes	<code>True</code>	<code>True</code>
successful changes	<code>True</code>	<code>None</code>
failed changes	<code>False</code>	<code>None</code>

**Note:** Test mode does not predict if the changes will be successful or not.

- **comment:** A string containing a summary of the result.

### Test State

All states should check for and support `test` being passed in the options. This will return data about what changes would occur if the state were actually run. An example of such a check could look like this:

```
# Return comment of changes if test.
if __opts__['test']:
    ret['result'] = None
    ret['comment'] = 'State Foo will execute with param {0}'.format(bar)
return ret
```

Make sure to test and return before performing any real actions on the minion.

### Watcher Function

If the state being written should support the watch requisite then a watcher function needs to be declared. The watcher function is called whenever the watch requisite is invoked and should be generic to the behavior of the state itself.

The watcher function should accept all of the options that the normal state functions accept (as they will be passed into the watcher function).

A watcher function typically is used to execute state specific reactive behavior, for instance, the watcher for the service module restarts the named service and makes it useful for the watcher to make the service react to changes in the environment.

The watcher function also needs to return the same data that a normal state function returns.

### Mod\_init Interface

Some states need to execute something only once to ensure that an environment has been set up, or certain conditions global to the state behavior can be predefined. This is the realm of the `mod_init` interface.

A state module can have a function called `mod_init` which executes when the first state of this type is called. This interface was created primarily to improve the `pkg` state. When packages are installed the package metadata needs to be refreshed, but refreshing the package metadata every time a package is installed is wasteful. The `mod_init` function for the `pkg` state sets a flag down so that the first, and only the first, package installation attempt will refresh the package database (the package database can of course be manually called to refresh via the `refresh` option in the `pkg` state).

The `mod_init` function must accept the **Low State Data** for the given executing state as an argument. The low state data is a dict and can be seen by executing the `state.show_lowstate` function. Then the `mod_init` function must return a bool. If the return value is `True`, then the `mod_init` function will not be executed again, meaning that the needed behavior has been set up. Otherwise, if the `mod_init` function returns `False`, then the function will be called the next time.

A good example of the `mod_init` function is found in the `pkg` state module:

```
def mod_init(low):
    """
    Refresh the package database here so that it only needs to happen once
    """
    if low['fun'] == 'installed' or low['fun'] == 'latest':
        rtag = __gen_rtag()
        if not os.path.exists(rtag):
            open(rtag, 'w+').write('')
        return True
    else:
        return False
```

The `mod_init` function in the `pkg` state accepts the low state data as `low` and then checks to see if the function being called is going to install packages, if the function is not going to install packages then there is no need to refresh the package database. Therefore if the package database is prepared to refresh, then return `True` and the `mod_init` will not be called the next time a `pkg` state is evaluated, otherwise return `False` and the `mod_init` will be called next time a `pkg` state is evaluated.

## Log Output

You can call the logger from custom modules to write messages to the minion logs. The following code snippet demonstrates writing log messages:

```
import logging

log = logging.getLogger(__name__)

log.info('Here is Some Information')
log.warning('You Should Not Do That')
log.error('It Is Busted')
```

## Full State Module Example

The following is a simplistic example of a full state module and function. Remember to call out to execution modules to perform all the real work. The state module should only perform ``before" and ``after" checks.

1. Make a custom state module by putting the code into a file at the following path:  
`/srv/salt/_states/my_custom_state.py`.
2. Distribute the custom state module to the minions:

```
salt '*' saltutil.sync_states
```

3. Write a new state to use the custom state by making a new state file, for instance  
`/srv/salt/my_custom_state.sls`.
4. Add the following SLS configuration to the file created in Step 3:

```

human_friendly_state_id:      # An arbitrary state ID declaration.
my_custom_state:             # The custom state module name.
- enforce_custom_thing      # The function in the custom state module.
- name: a_value              # Maps to the ``name`` parameter in the custom function.
- foo: Foo                   # Specify the required ``foo`` parameter.
- bar: False                 # Override the default value for the ``bar`` parameter.

```

### Example state module

```

import salt.exceptions

def enforce_custom_thing(name, foo, bar=True):
    """
    Enforce the state of a custom thing

    This state module does a custom thing. It calls out to the execution module
    ``my_custom_module`` in order to check the current system and perform any
    needed changes.

    name
        The thing to do something to
    foo
        A required argument
    bar : True
        An argument with a default value
    """
    ret = {'name': name, 'changes': {}, 'result': False, 'comment': ''}

    # Start with basic error-checking. Do all the passed parameters make sense
    # and agree with each-other?
    if bar == True and foo.startswith('Foo'):
        raise salt.exceptions.SaltInvocationError(
            'Argument "foo" cannot start with "Foo" if argument "bar" is True.')

    # Check the current state of the system. Does anything need to change?
    current_state = __salt__['my_custom_module.current_state'](name)

    if current_state == foo:
        ret['result'] = True
        ret['comment'] = 'System already in the correct state'
        return ret

    # The state of the system does need to be changed. Check if we're running
    # in ``test=true`` mode.
    if __opts__['test'] == True:
        ret['comment'] = 'The state of "{0}" will be changed.'.format(name)
        ret['changes'] = {
            'old': current_state,
            'new': 'Description, diff, whatever of the new state',
        }

    # Return ``None`` when running with ``test=true``.
    ret['result'] = None

    return ret

```

```
# Finally, make the actual change and return the result.
new_state = __salt__['my_custom_module.change_state'](name, foo)

ret['comment'] = 'The state of "{0}" was changed!'.format(name)

ret['changes'] = {
    'old': current_state,
    'new': new_state,
}

ret['result'] = True

return ret
```

### 30.26.21 State Management

State management, also frequently called Software Configuration Management (SCM), is a program that puts and keeps a system into a predetermined state. It installs software packages, starts or restarts services or puts configuration files in place and watches them for changes.

Having a state management system in place allows one to easily and reliably configure and manage a few servers or a few thousand servers. It allows configurations to be kept under version control.

Salt States is an extension of the Salt Modules that we discussed in the previous [remote execution](#) tutorial. Instead of calling one-off executions the state of a system can be easily defined and then enforced.

### 30.26.22 Understanding the Salt State System Components

The Salt state system is comprised of a number of components. As a user, an understanding of the SLS and renderer systems are needed. But as a developer, an understanding of Salt states and how to write the states is needed as well.

---

**Note:** States are compiled and executed only on minions that have been targeted. To execute functions directly on masters, see [runners](#).

---

#### Salt SLS System

The primary system used by the Salt state system is the SLS system. SLS stands for SaLt State.

The Salt States are files which contain the information about how to configure Salt minions. The states are laid out in a directory tree and can be written in many different formats.

The contents of the files and they way they are laid out is intended to be as simple as possible while allowing for maximum flexibility. The files are laid out in states and contains information about how the minion needs to be configured.

#### SLS File Layout

SLS files are laid out in the Salt file server.

A simple layout can look like this:

```
top.sls
ssh.sls
sshd_config
users/init.sls
users/admin.sls
salt/master.sls
web/init.sls
```

The `top.sls` file is a key component. The `top.sls` files is used to determine which SLS files should be applied to which minions.

The rest of the files with the `.sls` extension in the above example are state files.

Files without a `.sls` extensions are seen by the Salt master as files that can be downloaded to a Salt minion.

States are translated into dot notation. For example, the `ssh.sls` file is seen as the `ssh` state and the `users/admin.sls` file is seen as the `users.admin` state.

Files named `init.sls` are translated to be the state name of the parent directory, so the `web/init.sls` file translates to the `web` state.

In Salt, everything is a file; there is no "magic translation" of files and file types. This means that a state file can be distributed to minions just like a plain text or binary file.

### SLS Files

The Salt state files are simple sets of data. Since SLS files are just data they can be represented in a number of different ways.

The default format is YAML generated from a Jinja template. This allows for the states files to have all the language constructs of Python and the simplicity of YAML.

State files can then be complicated Jinja templates that translate down to YAML, or just plain and simple YAML files.

The State files are simply common data structures such as dictionaries and lists, constructed using a templating language such as YAML.

Here is an example of a Salt State:

```
vim:
  pkg.installed: []

salt:
  pkg.latest:
    - name: salt
  service.running:
    - names:
      - salt-master
      - salt-minion
    - require:
      - pkg: salt
    - watch:
      - file: /etc/salt/minion

/etc/salt/minion:
  file.managed:
    - source: salt://salt/minion
    - user: root
    - group: root
```

```
- mode: 644
- require:
  - pkg: salt
```

This short stanza will ensure that vim is installed, Salt is installed and up to date, the salt-master and salt-minion daemons are running and the Salt minion configuration file is in place. It will also ensure everything is deployed in the right order and that the Salt services are restarted when the watched file updated.

## The Top File

The top file controls the mapping between minions and the states which should be applied to them.

The top file specifies which minions should have which SLS files applied and which environments they should draw those SLS files from.

The top file works by specifying environments on the top-level.

Each environment contains globs to match minions. Finally, each glob contains a list of lists of Salt states to apply to matching minions:

```
base:
  '*':
    - salt
    - users
    - users.admin
  'saltmaster.*':
    - match: pcre
    - salt.master
```

This above example uses the base environment which is built into the default Salt setup.

The base environment has two globs. First, the ```*``` glob contains a list of SLS files to apply to all minions.

The second glob contains a regular expression that will match all minions with an ID matching `saltmaster.*` and specifies that for those minions, the `salt.master` state should be applied.

## Reloading Modules

Some Salt states require that specific packages be installed in order for the module to load. As an example the `pip` state module requires the `pip` package for proper name and version parsing.

In most of the common cases, Salt is clever enough to transparently reload the modules. For example, if you install a package, Salt reloads modules because some other module or state might require just that package which was installed.

On some edge-cases salt might need to be told to reload the modules. Consider the following state file which we'll call `pep8.sls`:

```
python-pip:
  cmd.run:
    - name: |
      easy_install --script-dir=/usr/bin -U pip
    - cwd: /

pep8:
  pip.installed:
```

```
- require:
  - cmd: python-pip
```

The above example installs `pip` using `easy_install` from `setuptools` and installs `pep8` using `pip`, which, as told earlier, requires `pip` to be installed system-wide. Let's execute this state:

```
salt-call state.apply pep8
```

The execution output would be something like:

```
-----
State: - pip
Name:    pep8
Function: installed
Result:  False
Comment: State pip.installed found in sls pep8 is unavailable

Changes:

Summary
-----
Succeeded: 1
Failed:    1
-----
Total:     2
```

If we executed the state again the output would be:

```
-----
State: - pip
Name:    pep8
Function: installed
Result:  True
Comment: Package was successfully installed
Changes: pep8==1.4.6: Installed

Summary
-----
Succeeded: 2
Failed:    0
-----
Total:     2
```

Since we installed `pip` using `cmd`, Salt has no way to know that a system-wide package was installed.

On the second execution, since the required `pip` package was installed, the state executed correctly.

---

**Note:** Salt does not reload modules on every state run because doing so would greatly slow down state execution.

---

So how do we solve this *edge-case*? `reload_modules`!

`reload_modules` is a boolean option recognized by salt on **all** available states which forces salt to reload its modules once a given state finishes.

The modified state file would now be:

```
python-pip:
  cmd.run:
    - name: |
        easy_install --script-dir=/usr/bin -U pip
    - cwd: /
    - reload_modules: true

pep8:
  pip.installed:
    - require:
        - cmd: python-pip
```

Let's run it, once:

```
salt-call state.apply pep8
```

The output is:

```
-----
State: - pip
Name:   pep8
Function: installed
  Result:   True
  Comment:  Package was successfully installed
  Changes:  pep8==1.4.6: Installed

Summary
-----
Succeeded: 2
Failed:    0
-----
Total:     2
```

## 30.27 Full list of builtin state modules

<i>alias</i>	Configuration of email aliases
<i>alternatives</i>	Configuration of the alternatives system
<i>apache</i>	Apache state
<i>apache_module</i>	Manage Apache Modules
<i>apt</i>	High-Level Interface for working with apt.
<i>archive</i>	Extract an archive
<i>artifactory</i>	This state downloads artifacts from artifactory.
<i>at</i>	Configuration disposable regularly scheduled tasks for at.
<i>augeas</i>	Configuration management using Augeas
<i>aws_sqs</i>	Manage SQS Queues
<i>blockdev</i>	Management of Block Devices
<i>boto_asg</i>	Manage Autoscale Groups
<i>boto_cloudwatch_alarm</i>	Manage Cloudwatch alarms
<i>boto_dynamodb</i>	Manage DynamoDB Tables
<i>boto_elasticache</i>	Manage Elasticache

Continued on next page

Table 30.13 -- continued from previous page

<i>boto_elb</i>	Manage ELBs
<i>boto_iam_role</i>	Manage IAM roles
<i>boto_lc</i>	Manage Launch Configurations
<i>boto_route53</i>	Manage Route53 records
<i>boto_secgroup</i>	Manage Security Groups
<i>boto_sns</i>	Manage SNS Topics
<i>boto_sqs</i>	Manage SQS Queues
<i>chef</i>	Execute Chef client runs
<i>cloud</i>	Using states instead of maps to deploy clouds
<i>cmd</i>	Execution of arbitrary commands
<i>composer</i>	Installation of Composer Packages
<i>cron</i>	Management of cron, the Unix command scheduler
<i>cyg</i>	Installation of Cygwin packages.
<i>ddns</i>	Dynamic DNS updates
<i>debconfmod</i>	Management of debconf selections
<i>disk</i>	Disk monitoring state
<i>dockerio</i>	Manage Docker containers
<i>drac</i>	Management of Dell DRAC
<i>environ</i>	Support for getting and setting the environment variables of the current salt process.
<i>eselect</i>	Management of Gentoo configuration using eselect
<i>event</i>	Send events through Salt's event system during state runs
<i>file</i>	Operations on regular files, special files, directories, and symlinks
<i>gem</i>	Installation of Ruby modules packaged as gems
<i>git</i>	Interaction with Git repositories
<i>glusterfs</i>	Manage glusterfs pool.
<i>gnomedesktop</i>	Configuration of the GNOME desktop
<i>grafana</i>	Manage Grafana Dashboards
<i>grains</i>	Manage grains on the minion
<i>group</i>	Management of user groups
<i>hg</i>	Interaction with Mercurial repositories
<i>hipchat</i>	Send a message to Hipchat
<i>host</i>	Management of addresses and names in hosts file
<i>htpasswd</i>	Support for htpasswd module
<i>http</i>	HTTP monitoring states
<i>incron</i>	Management of incron, the inotify cron
<i>influxdb_database</i>	Management of InfluxDB databases
<i>influxdb_user</i>	Management of InfluxDB users
<i>ini_manage</i>	Manage ini files
<i>ipmi</i>	Manage IPMI devices over LAN
<i>ipset</i>	Management of ipsets
<i>iptables</i>	Management of iptables
<i>jboss7</i>	Manage JBoss 7 Application Server via CLI interface
<i>keyboard</i>	Management of keyboard layouts
<i>keystone</i>	Management of Keystone users
<i>kmod</i>	Loading and unloading of kernel modules
<i>layman</i>	Management of Gentoo Overlays using layman
<i>libvirt</i>	Manage libvirt certificates
<i>linux_acl</i>	Linux File Access Control Lists
<i>locale</i>	Management of languages/locales
<i>lvm</i>	Management of Linux logical volumes

Continued on next page

Table 30.13 -- continued from previous page

<i>lvs_server</i>	Management of LVS (Linux Virtual Server) Real Server
<i>lvs_service</i>	Management of LVS (Linux Virtual Server) Service
<i>lxc</i>	Manage Linux Containers
<i>makeconf</i>	Management of Gentoo make.conf
<i>mdadm</i>	Managing software RAID with mdadm
<i>memcached</i>	States for Management of Memcached Keys
<i>modjk</i>	State to control Apache modjk
<i>modjk_worker</i>	Manage modjk workers
<i>module</i>	Execution of Salt modules from within states
<i>mongodb_database</i>	Management of Mongodb databases
<i>mongodb_user</i>	Management of Mongodb users
<i>mount</i>	Mounting of filesystems
<i>mysql_database</i>	Management of MySQL databases (schemas)
<i>mysql_grants</i>	Management of MySQL grants (user permissions)
<i>mysql_query</i>	Execution of MySQL queries
<i>mysql_user</i>	Management of MySQL users
<i>network</i>	Configuration of network interfaces
<i>nftables</i>	Management of nftables
<i>npm</i>	Installation of NPM Packages
<i>ntp</i>	Management of NTP servers
<i>openstack_config</i>	Manage OpenStack configuration file settings.
<i>pagerduty</i>	Create an Event in PagerDuty
<i>pecl</i>	Installation of PHP Extensions Using pecl
<i>pip_state</i>	Installation of Python Packages Using pip
<i>pkg</i>	Installation of packages using OS package managers such as yum or apt-get
<i>pkgng</i>	Manage package remote repo using FreeBSD pkgng
<i>pkgrepo</i>	Management of APT/YUM package repos
<i>portage_config</i>	Management of Portage package configuration on Gentoo
<i>ports</i>	Manage software from FreeBSD ports
<i>postgres_database</i>	Management of PostgreSQL databases
<i>postgres_extension</i>	Management of PostgreSQL extensions (e.g.: postgis)
<i>postgres_group</i>	Management of PostgreSQL groups (roles)
<i>postgres_schema</i>	Management of PostgreSQL schemas
<i>postgres_user</i>	Management of PostgreSQL users (roles)
<i>powerpath</i>	Powerpath configuration support
<i>process</i>	Process Management
<i>pyenv</i>	Managing python installations with pyenv
<i>pyrax_queues</i>	Manage Rackspace Queues
<i>quota</i>	Management of POSIX Quotas
<i>rabbitmq_cluster</i>	Manage RabbitMQ Clusters
<i>rabbitmq_plugin</i>	Manage RabbitMQ Plugins
<i>rabbitmq_policy</i>	Manage RabbitMQ Policies
<i>rabbitmq_user</i>	Manage RabbitMQ Users
<i>rabbitmq_vhost</i>	Manage RabbitMQ Virtual Hosts
<i>rbenv</i>	Managing Ruby installations with rbenv
<i>rdp</i>	Manage RDP Service on Windows servers
<i>redismod</i>	Management of Redis server
<i>reg</i>	
<i>rvm</i>	Managing Ruby installations and gemsets with Ruby Version Manager (RVM)
<i>saltmod</i>	Control the Salt command interface

Continued on next page

Table 30.13 -- continued from previous page

<i>schedule</i>	Management of the Salt scheduler
<i>selinux</i>	Management of SELinux rules
<i>serverdensity_device</i>	Monitor Server with Server Density
<i>service</i>	Starting or restarting of services and daemons
<i>slack</i>	Send a message to Slack
<i>smtplib</i>	Sending Messages via SMTP
<i>splunk_search</i>	Splunk Search State Module
<i>ssh_auth</i>	Control of entries in SSH authorized_key files
<i>ssh_known_hosts</i>	Control of SSH known_hosts entries
<i>stateconf</i>	Stateconf System
<i>status</i>	Minion status monitoring
<i>supervisord</i>	Interaction with the Supervisor daemon
<i>svn</i>	Manage SVN repositories
<i>sysctl</i>	Configuration of the Linux kernel using sysctl
<i>syslog_ng</i>	State module for syslog_ng
<i>sysrc</i>	
<i>test</i>	Test States
<i>timezone</i>	Management of timezones
<i>tls</i>	Enforce state for SSL/TLS
<i>tomcat</i>	This state uses the manager webapp to manage Apache tomcat webapps
<i>user</i>	Management of user accounts
<i>vbox_guest</i>	VirtualBox Guest Additions installer state
<i>virtualenv_mod</i>	Setup of Python virtualenv sandboxes.
<i>win_dns_client</i>	Module for configuring DNS Client on Windows systems
<i>win_firewall</i>	State for configuring Windows Firewall
<i>win_network</i>	Configuration of network interfaces on Windows hosts
<i>win_path</i>	Manage the Windows System PATH
<i>win_servermanager</i>	Manage Windows features via the ServerManager powershell module
<i>win_system</i>	Management of Windows system information
<i>win_update</i>	Management of the windows update agent
<i>winrepo</i>	Manage Windows Package Repository
<i>xmpp</i>	Sending Messages over XMPP
<i>zcbuildout</i>	Management of zc.buildout
<i>zk_concurrency</i>	Control concurrency of steps within state execution using zookeeper

### 30.27.1 salt.states.alias

Configuration of email aliases

The mail aliases file can be managed to contain definitions for specific email aliases:

```
username:
  alias.present:
    - target: user@example.com
```

```
thomas:
  alias.present:
    - target: thomas@example.com
```

**salt.states.alias.absent**(*name*)

Ensure that the named alias is absent

**name** The alias to remove

**salt.states.alias.present**(*name*, *target*)

Ensures that the named alias is present with the given target or list of targets. If the alias exists but the target differs from the previous entry, the target(s) will be overwritten. If the alias does not exist, the alias will be created.

**name** The local user/address to assign an alias to

**target** The forwarding address

### 30.27.2 salt.states.alternatives

Configuration of the alternatives system

Control the alternatives system

```
{% set my_hadoop_conf = '/opt/hadoop/conf' %}

{{ my_hadoop_conf }}:
  file.directory

hadoop-0.20-conf:
  alternatives.install:
    - name: hadoop-0.20-conf
    - link: /etc/hadoop-0.20/conf
    - path: {{ my_hadoop_conf }}
    - priority: 30
    - require:
      - file: {{ my_hadoop_conf }}

hadoop-0.20-conf:
  alternatives.remove:
    - name: hadoop-0.20-conf
    - path: {{ my_hadoop_conf }}
```

**salt.states.alternatives.auto**(*name*)

New in version 0.17.0.

Instruct alternatives to use the highest priority path for <name>

**name** is the master name for this link group (e.g. pager)

**salt.states.alternatives.install**(*name*, *link*, *path*, *priority*)

Install new alternative for defined <name>

**name** is the master name for this link group (e.g. pager)

**link** is the symlink pointing to /etc/alternatives/<name>. (e.g. /usr/bin/pager)

**path** is the location of the new alternative target. NB: This file / directory must already exist. (e.g. /usr/bin/less)

**priority** is an integer; options with higher numbers have higher priority in automatic mode.

**salt.states.alternatives.remove**(*name*, *path*)

Removes installed alternative for defined <name> and <path> or fallback to default alternative, if some defined before.

**name** is the master name for this link group (e.g. pager)

**path** is the location of one of the alternative target files. (e.g. /usr/bin/less)

`salt.states.alternatives.set_(name, path)`

New in version 0.17.0.

Sets alternative for <name> to <path>, if <path> is defined as an alternative for <name>.

**name** is the master name for this link group (e.g. pager)

**path** is the location of one of the alternative target files. (e.g. /usr/bin/less)

### 30.27.3 salt.states.apache

Apache state

New in version 2014.7.0.

Allows for inputting a yaml dictionary into a file for apache configuration files.

The variable `this` is special and signifies what should be included with the above word between angle brackets (<>).

```
/etc/httpd/conf.d/website.com.conf:
apache.configfile:
- config:
  - VirtualHost:
    this: '*:80'
    ServerName:
      - website.com
    ServerAlias:
      - www.website.com
      - dev.website.com
    ErrorLog: logs/website.com-error_log
    CustomLog: logs/website.com-access_log combined
    DocumentRoot: /var/www/vhosts/website.com
    Directory:
      this: /var/www/vhosts/website.com
      Order: Deny,Allow
      Deny from: all
      Allow from:
        - 127.0.0.1
        - 192.168.100.0/24
      Options:
        - +Indexes
        - FollowSymlinks
    AllowOverride: All
```

`salt.states.apache.configfile(name, config)`

### 30.27.4 salt.states.apache\_module

Manage Apache Modules

New in version 2014.7.0.

Enable and disable apache modules.

```
Enable cgi module:
  apache_module.enable:
    - name: cgi
```

```
Disable cgi module:
  apache_module.disable:
    - name: cgi
```

**salt.states.apache\_module.disable**(*name*)

Ensure an Apache module is disabled.

**name** Name of the Apache module

**salt.states.apache\_module.enable**(*name*)

Ensure an Apache module is enabled.

**name** Name of the Apache module

### 30.27.5 salt.states.archive

Extract an archive

New in version 2014.1.0.

```
salt.states.archive.extracted(name, source, archive_format, archive_user=None,
                              tar_options=None, source_hash=None, if_missing=None,
                              keep=False)
```

New in version 2014.1.0.

State that make sure an archive is extracted in a directory. The downloaded archive is erased if successfully extracted. The archive is downloaded only if necessary.

---

**Note:** If *if\_missing* is not defined, this state will check for *name* instead. If *name* exists, it will assume the archive was previously extracted successfully and will not extract it again.

---

```
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.
    - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
    - tar_options: J
    - archive_format: tar
    - if_missing: /opt/graylog2-server-0.9.6p1/
```

```
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.
    - source_hash: md5=499ae16dcae71eeb7c3a30c75ea7a1a6
    - archive_format: tar
    - tar_options: v
    - if_missing: /opt/graylog2-server-0.9.6p1/
```

**name** Directory name where to extract the archive

**source** Archive source, same syntax as `file.managed` source argument.

**source\_hash** Hash of source file, or file with list of hash-to-file mappings. It uses the same syntax as the `file.managed source_hash` argument.

**archive\_format** tar, zip or rar

**archive\_user**: user to extract files as

**if\_missing** Some archives, such as tar, extract themselves in a subfolder. This directive can be used to validate if the archive had been previously extracted.

**tar\_options** Required if used with `archive_format: tar`, otherwise optional. It needs to be the tar argument specific to the archive being extracted, such as ``J'` for LZMA or ``v'` to verbosely list files processed. Using this option means that the tar executable on the target will be used, which is less platform independent. Main operators like `-x`, `--extract`, `--get`, `-c` and `-f/--file` **should not be used** here. If `archive_format` is `zip` or `rar` and this option is not set, then the Python tarfile module is used. The tarfile module supports `gzip` and `bz2` in Python 2.

**keep** Keep the archive in the minion's cache

### 30.27.6 salt.states.artifactory

This state downloads artifacts from artifactory.

`salt.states.artifactory.downloaded`(*name, artifact, target\_dir='/tmp', target\_file=None*)

Ensures that the artifact from artifactory exists at given location. If it doesn't exist, then it will be downloaded. If it already exists then the checksum of existing file is checked against checksum in artifactory. If it is different then the step will fail.

**artifact:**

Details of the artifact to be downloaded from artifactory.

- `artifactory_url`: URL of the artifactory instance
- `repository`: Repository in artifactory
- `artifact_id`: Artifact ID
- `group_id`: Group ID
- `packaging`: Packaging
- `version`: Version

**target\_dir**: Directory where the artifact should be downloaded. By default it is downloaded to `/tmp` directory.

**target\_file**: Target file to download artifact to. By default file name is resolved by artifactory.

Example:: Download artifact to a specific file:

```
jboss_module_downloaded:
  artifactory.downloaded:
    - artifact:
      artifactory_url: http://artifactory.intranet.company.com/artifactory
      repository: 'libs-release-local'
      artifact_id: 'module'
      group_id: 'com.company.module'
      packaging: 'jar'
      version: '1.0'
    - target_file: /opt/jboss7/modules/com/company/lib/module.jar
```

Download artifact to the folder (automatically resolves file name):

```
jboss_module_downloaded:
  artifactory.downloaded:
    - artifact:
        artifactory_url: http://artifactory.intranet.company.com/artifactory
        repository: 'libs-release-local'
        artifact_id: 'module'
        group_id: 'com.company.module'
        packaging: 'jar'
        version: '1.0'
    - target_dir: /opt/jboss7/modules/com/company/lib
```

### 30.27.7 salt.states.at

#### Configuration disposable regularly scheduled tasks for at.

The at state can be add disposable regularly scheduled tasks for your system.

`salt.states.at.absent` (*name*, *jobid=None*, *\*\*kwargs*)

Remove a job from queue The `kwargs` can include hour. minute. day. month. year

**limit** Target range

**tag** Job's tag

**runas** Runs user-specified jobs

```
example1:
  at.absent:
    - limit: all
```

```
example2:
  at.absent:
    - limit: all
    - year: 13
```

```
example3:
  at.absent:
    - limit: all
    - tag: rose
    - runas: jim
```

```
example4:
  at.absent:
    - limit: all
    - tag: rose
    - day: 13
    - hour: 16
```

`salt.states.at.present` (*name*, *timespec*, *tag=None*, *user=None*, *job=None*)

Add a job to queue.

**job** Command to run.

**timespec** The `timespec` follows the format documented in the at(1) manpage.

**tag** Make a tag for the job.

**user** The user to run the at job

New in version 2014.1.4.

```

rose:
  at.present:
    - job: 'echo "I love saltstack" > love'
    - timespec: '9:09 11/09/13'
    - tag: love
    - user: jam

```

### 30.27.8 salt.states.augeas

Configuration management using Augeas

New in version 0.17.0.

This state requires the `augeas` Python module.

`Augeas` can be used to manage configuration files.

**Warning:** Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with `python-augeas`, causing the `augeas` module to fail to import. If the minion has the `augeas` module installed, and the state fails with a comment saying that the state is unavailable, first restart the `salt-minion` service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing `libpython2.7` has been known to resolve the issue.

`salt.states.augeas.change` (*name*, *context=None*, *changes=None*, *lens=None*, *\*\*kwargs*)

New in version 2014.7.0.

This state replaces `setvalue()`.

Issue changes to Augeas, optionally for a specific context, with a specific lens.

**name** State name

**context** A file path, prefixed by `/files`. Should resolve to an actual file (not an arbitrary augeas path). This is used to avoid duplicating the file name for each item in the `changes` list (for example, `set bind 0.0.0.0` in the example below operates on the file specified by `context`). If `context` is not specified, a file path prefixed by `/files` should be included with the `set` command.

The file path is examined to determine if the specified changes are already present.

```

redis-conf:
  augeas.change:
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0
      - set maxmemory 1G

```

**changes** List of changes that are issued to Augeas. Available commands are `set`, `setm`, `mv/move`, `ins/insert`, and `rm/remove`.

**lens** The lens to use, needs to be suffixed with `.lens`, e.g.: `Nginx.lens`. See the [list of stock lenses](#) shipped with Augeas.

Usage examples:

Set the `bind` parameter in `/etc/redis/redis.conf`:

```
redis-conf:
  augeas.change:
    - changes:
      - set /files/etc/redis/redis.conf/bind 0.0.0.0
```

**Note:** Use the `context` parameter to specify the file you want to manipulate. This way you don't have to include this in the changes every time:

```
redis-conf:
  augeas.change:
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0
      - set databases 4
      - set maxmemory 1G
```

Augeas is aware of a lot of common configuration files and their syntax. It knows the difference between for example ini and yaml files, but also files with very specific syntax, like the hosts file. This is done with *lenses*, which provide mappings between the Augeas tree and the file.

There are many [preconfigured lenses](#) that come with Augeas by default, and they specify the common locations for configuration files. So most of the time Augeas will know how to manipulate a file. In the event that you need to manipulate a file that Augeas doesn't know about, you can specify the lens to use like this:

```
redis-conf:
  augeas.change:
    - lens: redis
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0
```

**Note:** Even though Augeas knows that `/etc/redis/redis.conf` is a Redis configuration file and knows how to parse it, it is recommended to specify the lens anyway. This is because by default, Augeas loads all known lenses and their associated file paths. All these files are parsed when Augeas is loaded, which can take some time. When specifying a lens, Augeas is loaded with only that lens, which speeds things up quite a bit.

A more complex example, this adds an entry to the services file for Zabbix, and removes an obsolete service:

```
zabbix-service:
  augeas.change:
    - lens: services
    - context: /files/etc/services
    - changes:
      - ins service-name after service-name[last()]
      - set service-name[last()] zabbix-agent
      - set service-name[. = 'zabbix-agent']/#comment "Zabbix Agent service"
      - set service-name[. = 'zabbix-agent']/port 10050
      - set service-name[. = 'zabbix-agent']/protocol tcp
      - rm service-name[. = 'im-obsolete']
    - unless: grep "zabbix-agent" /etc/services
```

**Warning:** Don't forget the `unless` here, otherwise a new entry will be added every time this state is run.

### 30.27.9 salt.states.aws\_sqs

Manage SQS Queues

Create and destroy SQS queues. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses the awscli tool provided by Amazon. This can be downloaded from pip. Also check the documentation for awscli for configuration information.

```
myqueue:
  aws_sqs.exists:
    - region: eu-west-1
```

**salt.states.aws\_sqs.absent**(*name, region, user=None, opts=False*)

Remove the named SQS queue if it exists.

**name** Name of the SQS queue.

**region** Region to remove the queue from

**user** Name of the user performing the SQS operations

**opts** Include additional arguments and options to the aws command line

**salt.states.aws\_sqs.exists**(*name, region, user=None, opts=False*)

Ensure the SQS queue exists.

**name** Name of the SQS queue.

**region** Region to create the queue

**user** Name of the user performing the SQS operations

**opts** Include additional arguments and options to the aws command line

### 30.27.10 salt.states.blockdev

Management of Block Devices

A state module to manage blockdevices

```
/dev/sda:
  blockdev.tuned:
    - read-only: True

master-data:
  blockdev.tuned::
    - name : /dev/vg/master-data
    - read-only: True
    - read-ahead: 1024
```

New in version 2014.7.0.

**salt.states.blockdev.formatted**(*name, fs\_type='ext4', \*\*kwargs*)

Manage filesystems of partitions.

**name** The name of the block device

**fs\_type** The filesystem it should be formatted as

**salt.states.blockdev.tuned**(*name, \*\*kwargs*)

Manage options of block device

**name** The name of the block device

**opts:**

- **read-ahead** Read-ahead buffer size
- **filesystem-read-ahead** Filesystem Read-ahead buffer size
- **read-only** Set Read-Only
- **read-write** Set Read-Write

### 30.27.11 salt.states.boto\_asg

#### Manage Autoscale Groups

New in version 2014.7.0.

Create and destroy autoscale groups. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
  region: us-east-1
```

```
Ensure myasg exists:
boto_asg.present:
- name: myasg
- launch_config_name: mylc
- availability_zones:
  - us-east-1a
  - us-east-1b
- min_size: 1
- max_size: 1
- desired_capacity: 1
- load_balancers:
  - myelb
- suspended_processes:
  - AddToLoadBalancer
  - AlarmNotification
- scaling_policies
```

```

-----
- adjustment_type: ChangeInCapacity
- as_name: api-production-iad
- cooldown: 1800
- min_adjustment_step: None
- name: ScaleDown
- scaling_adjustment: -1
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdfklkdflkjgsdfjajkghs

# Using a profile from pillars.
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile: myprofile

# Passing in a profile.
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdfklkdflkjgsdfjajkghs
      region: us-east-1

# Deleting an autoscale group with running instances.
Ensure myasg is deleted:
  boto_asg.absent:
    - name: myasg
    # If instances exist, we must force the deletion of the asg.
    - force: True

```

It's possible to specify cloudwatch alarms that will be setup along with the ASG. Note the alarm name will be the name attribute defined, plus the ASG resource name.

```

Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc

```

```

- availability_zones:
  - us-east-1a
  - us-east-1b
- min_size: 1
- max_size: 1
- desired_capacity: 1
- load_balancers:
  - myelb
- profile: myprofile
- alarms:
  CPU:
    name: 'ASG CPU **MANAGED BY SALT**'
    attributes:
      metric: CPUUtilization
      namespace: AWS/EC2
      statistic: Average
      comparison: '>='
      threshold: 65.0
      period: 60
      evaluation_periods: 30
      unit: null
      description: 'ASG CPU'
      alarm_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
      insufficient_data_actions: []
      ok_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]

```

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `boto_asg_alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for an ASG resource.

Setting the alarms in a pillar:

```

my_asg_alarm:
  CPU:
    name: 'ASG CPU **MANAGED BY SALT**'
    attributes:
      metric: CPUUtilization
      namespace: AWS/EC2
      statistic: Average
      comparison: '>='
      threshold: 65.0
      period: 60
      evaluation_periods: 30
      unit: null
      description: 'ASG CPU'
      alarm_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
      insufficient_data_actions: []
      ok_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]

```

Overriding the alarm values on the resource:

```

Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a

```

```

- us-east-1b
- min_size: 1
- max_size: 1
- desired_capacity: 1
- load_balancers:
  - myelb
- profile: myprofile
- alarms_from_pillar: my_asg_alarm
# override CPU:attributes:threshold
- alarms:
  CPU:
    attributes:
      threshold: 50.0

```

`salt.states.boto_asg.absent`(*name*, *force=False*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Ensure the named autoscale group is deleted.

**name** Name of the autoscale group.

**force** Force deletion of autoscale group.

**region** The region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_asg.present`(*name*, *launch\_config\_name*, *availability\_zones*, *min\_size*, *max\_size*, *launch\_config=None*, *desired\_capacity=None*, *load\_balancers=None*, *default\_cooldown=None*, *health\_check\_type=None*, *health\_check\_period=None*, *placement\_group=None*, *vpc\_zone\_identifier=None*, *tags=None*, *termination\_policies=None*, *suspended\_processes=None*, *scaling\_policies=None*, *alarms=None*, *alarms\_from\_pillar='boto\_asg\_alarms'*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Ensure the autoscale group exists.

**name** Name of the autoscale group.

**launch\_config\_name** Name of the launch config to use for the group. Or, if `launch_config` is specified, this will be the launch config name's prefix. (see below)

**launch\_config** A dictionary of launch config attributes. If specified, a launch config will be used or created, matching this set of attributes, and the autoscale group will be set to use that launch config. The launch config name will be the `launch_config_name` followed by a hyphen followed by a hash of the launch config dict contents.

**availability\_zones** List of availability zones for the group.

**min\_size** Minimum size of the group.

**max\_size** Maximum size of the group.

**desired\_capacity** The desired capacity of the group.

**load\_balancers** List of load balancers for the group. Once set this can not be updated (Amazon restriction).

**default\_cooldown** Number of seconds after a Scaling Activity completes before any further scaling activities can start.

**health\_check\_type** The service you want the health status from, Amazon EC2 or Elastic Load Balancer (EC2 or ELB).

**health\_check\_period** Length of time in seconds after a new EC2 instance comes into service that Auto Scaling starts checking its health.

**placement\_group** Physical location of your cluster placement group created in Amazon EC2. Once set this can not be updated (Amazon restriction).

**vpc\_zone\_identifier** A list of the subnet identifiers of the Virtual Private Cloud.

**tags**

A list of tags. Example:

- key: 'key' value: 'value' propagate\_at\_launch: true

**termination\_policies** A list of termination policies. Valid values are: "OldestInstance", "NewestInstance", "OldestLaunchConfiguration", "ClosestToNextInstanceHour", "Default". If no value is specified, the "Default" value is used.

**suspended\_processes** List of processes to be suspended. see <http://docs.aws.amazon.com/AutoScaling/latest/DeveloperGuide/>

**scaling\_policies** List of scaling policies. Each policy is a dict of key-values described by <http://boto.readthedocs.org/en/latest/ref/autoscale.html#boto.ec2.autoscale.policy.ScalingPolicy>

**alarms:** a dictionary of name->boto\_cloudwatch\_alarm sections to be associated with this ASG. All attributes should be specified except for dimension which will be automatically set to this ASG. See the boto\_cloudwatch\_alarm state for information about these attributes.

**alarms\_from\_pillar:** name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

**region** The region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.12 salt.states.boto\_cloudwatch\_alarm

Manage Cloudwatch alarms

New in version 2014.7.0.

Create and destroy cloudwatch alarms. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

<http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html>

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
cloudwatch.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch.key: askdjghsdfjkghWupUjasdfkldfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklkfklgjsdfjajkghs
  region: us-east-1
```

```
my test alarm:
  boto_cloudwatch_alarm.present:
    - name: my test alarm
    - attributes:
        metric: ApproximateNumberOfMessagesVisible
        namespace: AWS/SQS
        statistic: Average
        comparison: ">="
        threshold: 20000.0
        period: 60
        evaluation_periods: 1
        description: test alarm via salt
        dimensions:
          QueueName:
            - the-sqs-queue-name
        alarm_actions:
          - arn:aws:sns:us-east-1:1111111:myalerting-action
```

`salt.states.boto_cloudwatch_alarm.absent` (*name, region=None, key=None, keyid=None, profile=None*)

Ensure the named cloudwatch alarm is deleted.

**name** Name of the alarm.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_cloudwatch_alarm.present` (*name, attributes, region=None, key=None, keyid=None, profile=None*)

Ensure the cloudwatch alarm exists.

**name** Name of the alarm

**attributes** A dict of key/value cloudwatch alarm attributes.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.13 salt.states.boto\_dynamodb

#### Manage DynamoDB Tables

New in version 2015.5.0.

Create and destroy DynamoDB tables. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses `boto`, which can be installed via package, or pip.

This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdfkdkflgjsdfajkgghs
region: us-east-1
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfkdkflgjsdfajkgghs
  region: us-east-1
```

Ensure DynamoDB table does not exist:

**boto\_dynamodb.absent:**

- table\_name: new\_table
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdfkdkflgjsdfajkgghs
- region: us-east-1

Ensure DynamoDB table exists:

**boto\_dynamodb.present:**

- table\_name: new\_table
- read\_capacity\_units: 1
- write\_capacity\_units: 2
- hash\_key: primary\_id
- hash\_key\_data\_type: N
- range\_key: start\_timestamp
- range\_key\_data\_type: N
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdfkdkflgjsdfajkgghs

- region: us-east-1
- local\_indexes:
  - index:
    - \* name: ``primary\_id\_end\_timestamp\_index"
    - \* hash\_key: primary\_id
    - \* hash\_key\_data\_type: N
    - \* range\_key: end\_timestamp
    - \* range\_key\_data\_type: N
- global\_indexes:
  - index:
    - \* name: ``name\_end\_timestamp\_index"
    - \* hash\_key: name
    - \* hash\_key\_data\_type: S
    - \* range\_key: end\_timestamp
    - \* range\_key\_data\_type: N
    - \* read\_capacity\_units: 3
    - \* write\_capacity\_units: 4

`salt.states.boto_dynamodb.absent`(*table\_name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Ensure the DynamoDB table does not exist.

**table\_name** Name of the DynamoDB table.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_dynamodb.present`(*table\_name*, *region=None*, *key=None*, *keyid=None*, *profile=None*, *read\_capacity\_units=None*, *write\_capacity\_units=None*, *hash\_key=None*, *hash\_key\_data\_type=None*, *range\_key=None*, *range\_key\_data\_type=None*, *local\_indexes=None*, *global\_indexes=None*)

Ensure the DynamoDB table exists. Note: all properties of the table can only be set during table creation. Adding or changing indexes or key schema cannot be done after table creation

**table\_name** Name of the DynamoDB table

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`read_capacity_units` The read throughput for this table  
`write_capacity_units` The write throughput for this table  
`hash_key` The name of the attribute that will be used as the hash key for this table  
`hash_key_data_type` The DynamoDB datatype of the hash key  
`range_key` The name of the attribute that will be used as the range key for this table  
`range_key_data_type` The DynamoDB datatype of the range key  
`local_indexes` The local indexes you would like to create  
`global_indexes` The local indexes you would like to create

### 30.27.14 salt.states.boto\_elasticache

Manage Elasticache

New in version 2014.7.0.

Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon's services, and so may incur charges.

Note: This module currently only supports creation and deletion of elasticache resources and will not modify clusters when their configuration changes in your state files.

This module uses `boto`, which can be installed via `package`, or `pip`.

This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
  region: us-east-1
```

```
Ensure myelasticache exists:
boto_elasticache.present:
  - name: myelasticache
  - engine: redis
  - cache_node_type: cache.t1.micro
  - num_cache_nodes: 1
  - notification_topic_arn: arn:aws:sns:us-east-1:879879:my-sns-topic
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
```

```
# Using a profile from pillars
```

```

Ensure myelasticache exists:
boto_elasticache.present:
  - name: myelasticache
  - engine: redis
  - cache_node_type: cache.t1.micro
  - num_cache_nodes: 1
  - notification_topic_arn: arn:aws:sns:us-east-1:879879:my-sns-topic
  - region: us-east-1
  - profile: myprofile

# Passing in a profile
Ensure myelasticache exists:
boto_elasticache.present:
  - name: myelasticache
  - engine: redis
  - cache_node_type: cache.t1.micro
  - num_cache_nodes: 1
  - notification_topic_arn: arn:aws:sns:us-east-1:879879:my-sns-topic
  - region: us-east-1
  - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdfklkdflkgjsdfjajkghs

```

`salt.states.boto_elasticache.absent` (*name*, *wait=True*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Ensure the named elasticache cluster is deleted.

**name** Name of the cache cluster.

**wait** Boolean. Wait for confirmation from boto that the cluster is in the deleting state.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_elasticache.present` (*name*, *engine*, *cache\_node\_type*, *num\_cache\_nodes=1*, *preferred\_availability\_zone=None*, *port=None*, *cache\_parameter\_group\_name=None*, *cache\_security\_group\_names=None*, *replication\_group\_id=None*, *auto\_minor\_version\_upgrade=True*, *security\_group\_ids=None*, *cache\_subnet\_group\_name=None*, *engine\_version=None*, *notification\_topic\_arn=None*, *preferred\_maintenance\_window=None*, *wait=True*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Ensure the cache cluster exists.

**name** Name of the cache cluster (cache cluster id).

**engine** The name of the cache engine to be used for this cache cluster. Valid values are memcached or redis.

**cache\_node\_type** The compute and memory capacity of the nodes in the cache cluster. cache.t1.micro, cache.m1.small, etc. See: [http://boto.readthedocs.org/en/latest/ref/elasticache.html#boto.elasticache.layer1.ElastiCacheConnection.create\\_cache\\_cl](http://boto.readthedocs.org/en/latest/ref/elasticache.html#boto.elasticache.layer1.ElastiCacheConnection.create_cache_cl)

**num\_cache\_nodes** The number of cache nodes that the cache cluster will have.

- preferred\_availability\_zone** The EC2 Availability Zone in which the cache cluster will be created. All cache nodes belonging to a cache cluster are placed in the preferred availability zone.
- port** The port number on which each of the cache nodes will accept connections.
- cache\_parameter\_group\_name** The name of the cache parameter group to associate with this cache cluster. If this argument is omitted, the default cache parameter group for the specified engine will be used.
- cache\_security\_group\_names** A list of cache security group names to associate with this cache cluster. Use this parameter only when you are creating a cluster outside of a VPC.
- replication\_group\_id** The replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster will be added to the specified replication group as a read replica; otherwise, the cache cluster will be a standalone primary that is not part of any replication group.
- auto\_minor\_version\_upgrade** Determines whether minor engine upgrades will be applied automatically to the cache cluster during the maintenance window. A value of True allows these upgrades to occur; False disables automatic upgrades.
- security\_group\_ids** One or more VPC security groups associated with the cache cluster. Use this parameter only when you are creating a cluster in a VPC.
- cache\_subnet\_group\_name** The name of the cache subnet group to be used for the cache cluster. Use this parameter only when you are creating a cluster in a VPC.
- engine\_version** The version number of the cache engine to be used for this cluster.
- notification\_topic\_arn** The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent. The Amazon SNS topic owner must be the same as the cache cluster owner.
- preferred\_maintenance\_window** The weekly time range (in UTC) during which system maintenance can occur. Example: sun:05:00-sun:09:00
- wait** Boolean. Wait for confirmation from boto that the cluster is in the creating state.
- region** Region to connect to.
- key** Secret key to be used.
- keyid** Access key to be used.
- profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.15 salt.states.boto\_elb

Manage ELBs

New in version 2014.7.0.

Create and destroy ELBs. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses `boto`, which can be installed via `package`, or `pip`.

This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
  region: us-east-1
```

```
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - availability_zones:
      - us-east-1a
      - us-east-1c
      - us-east-1d
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
    - listeners:
      - elb_port: 443
        instance_port: 80
        elb_protocol: HTTPS
        instance_protocol: HTTP
        certificate: 'arn:aws:iam::1111111:server-certificate/mycert'
      - elb_port: 8210
        instance_port: 8210
        elb_protocol: TCP
    - health_check:
        target: 'HTTP:80/'
    - attributes:
        cross_zone_load_balancing:
          enabled: true
        access_log:
          enabled: true
          s3_bucket_name: 'mybucket'
          s3_bucket_prefix: 'my-logs'
          emit_interval: 5
    - cnames:
      - name: mycname.example.com.
        zone: example.com.
        ttl: 60
      - name: myothercname.example.com.
        zone: example.com.
```

*# Using a profile from pillars*

```
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
```

*# Passing in a profile*

```
Ensure myelb ELB exists:
```

```
boto_elb.present:
- name: myelb
- region: us-east-1
- profile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
```

It's possible to specify attributes from pillars by specifying a pillar. You can override the values defined in the pillar by setting the attributes on the resource. The module will use the default pillar key ``boto_elb_attributes'`, which allows you to set default attributes for all ELB resources.

Setting the attributes pillar:

```
my_elb_attributes:
cross_zone_load_balancing:
  enabled: true
connection_draining:
  enabled: true
  timeout: 20
access_log:
  enabled: true
  s3_bucket_name: 'mybucket'
  s3_bucket_prefix: 'my-logs'
  emit_interval: 5
```

Overriding the attribute values on the resource:

```
Ensure myelb ELB exists:
boto_elb.present:
- name: myelb
- region: us-east-1
- attributes_from_pillar: my_elb_attributes
# override cross_zone_load_balancing:enabled
- attributes:
  cross_zone_load_balancing:
    enabled: false
- profile: myelbprofile
```

It's possible to specify cloudwatch alarms that will be setup along with the ELB. Note the alarm name will be defined by the name attribute provided, plus the ELB resource name.

```
Ensure myelb ELB exists:
boto_elb.present:
- name: myelb
- region: us-east-1
- profile: myelbprofile
- alarms:
  UnHealthyHostCount:
    name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
    attributes:
      metric: UnHealthyHostCount
      namespace: AWS/ELB
      statistic: Average
      comparison: '>='
      threshold: 1.0
      period: 600
```

```

evaluation_periods: 6
unit: null
description: ELB UnHealthyHostCount
alarm_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
insufficient_data_actions: []
ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']

```

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `'boto_elb_alarms'` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.

Setting the alarms in a pillar:

```

my_elb_alarm:
  UnHealthyHostCount:
    name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
    attributes:
      metric: UnHealthyHostCount
      namespace: AWS/ELB
      statistic: Average
      comparison: '>='
      threshold: 1.0
      period: 600
      evaluation_periods: 6
      unit: null
      description: ELB UnHealthyHostCount
      alarm_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
      insufficient_data_actions: []
      ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']

```

Overriding the alarm values on the resource:

```

Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - alarms_from_pillar: my_elb_alarm
    # override UnHealthyHostCount:attributes:threshold
    - alarms:
      UnHealthyHostCount:
        attributes:
          threshold: 2.0

```

`salt.states.boto_elb.absent` (*name, region=None, key=None, keyid=None, profile=None*)

`salt.states.boto_elb.present` (*name, listeners, availability\_zones=None, subnets=None, security\_groups=None, scheme='internet-facing', health\_check=None, attributes=None, attributes\_from\_pillar='boto\_elb\_attributes', cnames=None, alarms=None, alarms\_from\_pillar='boto\_elb\_alarms', region=None, key=None, keyid=None, profile=None*)

Ensure the IAM role exists.

**name** Name of the IAM role.

**availability\_zones** A list of availability zones for this ELB.

**listeners** A list of listener lists; example: [

```
[ '443', 'HTTPS', 'arn:aws:iam::1111111:server-certificate/mycert'], [ '8443', '80', 'HTTPS', 'HTTP', 'arn:aws:iam::1111111:server-certificate/mycert'] ]
```

**subnets** A list of subnet IDs in your VPC to attach to your LoadBalancer.

**security\_groups** The security groups assigned to your LoadBalancer within your VPC.

**scheme** The type of a LoadBalancer. internet-facing or internal. Once set, can not be modified.

**health\_check** A dict defining the health check for this ELB.

**attributes** A dict defining the attributes to set on this ELB.

**attributes\_from\_pillar** name of pillar dict that contains attributes. Attributes defined for this specific state will override those from pillar.

**cnames** A list of cname dicts with attributes: name, zone, ttl, and identifier. See the `boto_route53` state for information about these attributes.

**alarms:** a dictionary of name->`boto_cloudwatch_alarm` sections to be associated with this ELB. All attributes should be specified except for dimension which will be automatically set to this ELB. See the `boto_cloudwatch_alarm` state for information about these attributes.

**alarms\_from\_pillar:** name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.16 salt.states.boto\_iam\_role

Manage IAM roles

New in version 2014.7.0.

This module uses `boto`, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjkghWupUjasdfkldfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askjghsdfjkghWupUjasdfkldfklgjsdfjajkghs
  region: us-east-1
```

Creating a role will automatically create an instance profile and associate it with the role. This is the default behavior of the AWS console.

```
myrole:
  boto_iam_role.present:
    - region: us-east-1
    - key: GKTADJGHEIQSXMKKRBJ08H
    - keyid: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
    - policies_from_pillars:
      - shared_iam_bootstrap_policy
    - policies:
      MySQLPolicy:
        Statement:
          - Action:
              - sqs:*
            Effect: Allow
            Resource:
              - arn:aws:sqs:*:*:*
            Sid: MyPolicySQS1
      MyS3Policy:
        Statement:
          - Action:
              - s3:GetObject
            Effect: Allow
            Resource:
              - arn:aws:s3:*:*:mybucket/*

# Using a credentials profile from pillars
myrole:
  boto_iam_role.present:
    - region: us-east-1
    - profile: myiamprofile

# Passing in a credentials profile
myrole:
  boto_iam_role.present:
    - region: us-east-1
    - profile:
      key: GKTADJGHEIQSXMKKRBJ08H
      keyid: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
```

`salt.states.boto_iam_role.absent` (*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Ensure the IAM role is deleted.

**name** Name of the IAM role.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_iam_role.present` (*name*, *policy\_document=None*, *path=None*, *policies=None*, *policies\_from\_pillars=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Ensure the IAM role exists.

**name** Name of the IAM role.

**policy\_document** The policy that grants an entity permission to assume the role. (See [http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create\\_role](http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role))

**path** The path to the instance profile. (See [http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create\\_role](http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role))

**policies** A dict of IAM role policies.

**policies\_from\_pillars** A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies\_from\_pillars.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.17 salt.states.boto\_lc

Manage Launch Configurations

New in version 2014.7.0.

Create and destroy Launch Configurations. Be aware that this interacts with Amazon's services, and so may incur charges.

A limitation of this module is that you can not modify launch configurations once they have been created. If a launch configuration with the specified name exists, this module will always report success, even if the specified configuration doesn't match. This is due to a limitation in Amazon's launch configuration API, as it only allows launch configurations to be created and deleted.

Also note that a launch configuration that's in use by an autoscale group can not be deleted until the autoscale group is no longer using it. This may affect the way in which you want to order your states.

This module uses `boto`, which can be installed via `package`, or `pip`.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
  region: us-east-1
```

Credential information is shared with autoscale groups as launch configurations and autoscale groups are completely dependent on each other.

```

Ensure mylc exists:
  boto_lc.present:
    - name: mylc
    - image_id: ami-0b9c9f62
    - key_name: mykey
    - security_groups:
      - mygroup
    - instance_type: m1.small
    - instance_monitoring: true
    - block_device_mappings:
      - '/dev/sda1':
          size: 20
    - cloud_init:
        scripts:
          'run_salt.sh': |
            #!/bin/bash

            add-apt-repository -y ppa:saltstack/salt
            apt-get update
            apt-get install -y salt-minion
            salt-call state.highstate
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgHwupUjasdfldkdfklgjsdfjajkgHs

# Using a profile from pillars.
Ensure mylc exists:
  boto_lc.present:
    - name: mylc
    - image_id: ami-0b9c9f62
    - profile: myprofile

# Passing in a profile.
Ensure mylc exists:
  boto_lc.present:
    - name: mylc
    - image_id: ami-0b9c9f62
    - profile:
        keyid: GKTADJGHEIQSXMKKRBJ08H
        key: askdjghsdfjkgHwupUjasdfldkdfklgjsdfjajkgHs
        region: us-east-1

```

`salt.states.boto_lc.absent` (*name*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Ensure the named launch configuration is deleted.

**name** Name of the launch configuration.

**region** The region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_lc.present(name, image_id, key_name=None, security_groups=None, user_data=None, cloud_init=None, instance_type='m1.small', kernel_id=None, ramdisk_id=None, block_device_mappings=None, instance_monitoring=False, spot_price=None, instance_profile_name=None, ebs_optimized=False, associate_public_ip_address=None, volume_type=None, delete_on_termination=True, iops=None, use_block_device_types=False, region=None, key=None, keyid=None, profile=None)
```

Ensure the launch configuration exists.

**name** Name of the launch configuration.

**image\_id** AMI to use for instances. AMI must exist or creation of the launch configuration will fail.

**key\_name** Name of the EC2 key pair to use for instances. Key must exist or creation of the launch configuration will fail.

**security\_groups** List of Names or security group id's of the security groups with which to associate the EC2 instances or VPC instances, respectively. Security groups must exist, or creation of the launch configuration will fail.

**user\_data** The user data available to launched EC2 instances.

**cloud\_init** A dict of cloud\_init configuration. Currently supported values: scripts, cloud-config. Mutually exclusive with user\_data.

**instance\_type** The instance type. ex: m1.small.

**kernel\_id** The kernel id for the instance.

**ramdisk\_id** The RAM disk ID for the instance.

**block\_device\_mappings** A dict of block device mappings.

**instance\_monitoring** Whether instances in group are launched with detailed monitoring.

**spot\_price** The spot price you are bidding. Only applies if you are building an autoscaling group with spot instances.

**instance\_profile\_name** The name or the Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance. Instance profile must exist or the creation of the launch configuration will fail.

**ebs\_optimized** Specifies whether the instance is optimized for EBS I/O (true) or not (false).

**associate\_public\_ip\_address** Used for Auto Scaling groups that launch instances into an Amazon Virtual Private Cloud. Specifies whether to assign a public IP address to each instance launched in a Amazon VPC.

**volume\_type** Undocumented in boto.

**delete\_on\_termination** Undocumented in boto.

**iops** Undocumented in boto.

**use\_block\_device\_types** Undocumented in boto.

**region** The region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.18 salt.states.boto\_route53

Manage Route53 records

New in version 2014.7.0.

Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses `boto`, which can be installed via package, or pip.

This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdfkdkfkgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfkdkfkgjsdfjajkghs
  region: us-east-1
```

```
mycnamerecord:
  boto_route53.present:
    - name: test.example.com.
    - value: my-elb.us-east-1.elb.amazonaws.com.
    - zone: example.com.
    - ttl: 60
    - record_type: CNAME
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdfkdkfkgjsdfjajkghs
```

*# Using a profile from pillars*

```
myarecord:
  boto_route53.present:
    - name: test.example.com.
    - value: 1.1.1.1
    - zone: example.com.
    - ttl: 60
    - record_type: A
    - region: us-east-1
    - profile: myprofile
```

*# Passing in a profile*

```
myarecord:
  boto_route53.present:
    - name: test.example.com.
    - value: 1.1.1.1
    - zone: example.com.
    - ttl: 60
    - record_type: A
    - region: us-east-1
```

```
- profile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfkldfklgjsdfjajkghs
```

`salt.states.boto_route53.absent` (*name, zone, record\_type, identifier=None, region=None, key=None, keyid=None, profile=None*)

Ensure the Route53 record is deleted.

**name** Name of the record.

**zone** The zone to delete the record from.

**identifier** An identifier to match for deletion.

**region** The region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_route53.present` (*name, value, zone, record\_type, ttl=None, identifier=None, region=None, key=None, keyid=None, profile=None*)

Ensure the Route53 record is present.

**name** Name of the record.

**value** Value of the record.

**zone** The zone to create the record in.

**record\_type** The record type. Currently supported values: A, CNAME, MX

**ttl** The time to live for the record.

**identifier** The unique identifier to use for this record.

**region** The region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.19 salt.states.boto\_secgroup

#### Manage Security Groups

New in version 2014.7.0.

Create and destroy Security Groups. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses `boto`, which can be installed via package, or pip.

This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
secgroup.keyid: GKTADJGHEIQSXMKKRBJ08H
secgroup.key: askdjghsdfjkghWupUjasdfkldfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfkldfklgjsdfjajkghs
  region: us-east-1
```

```
Ensure mysecgroup exists:
  boto_secgroup.present:
    - name: mysecgroup
    - description: My security group
    - rules:
      - ip_protocol: tcp
        from_port: 80
        to_port: 80
        cidr_ip:
          - 10.0.0.0/0
          - 192.168.0.0/0
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdfkldfklgjsdfjajkghs
```

#### *# Using a profile from pillars*

```
Ensure mysecgroup exists:
  boto_secgroup.present:
    - name: mysecgroup
    - description: My security group
    - region: us-east-1
    - profile: myprofile
```

#### *# Passing in a profile*

```
Ensure mysecgroup exists:
  boto_secgroup.present:
    - name: mysecgroup
    - description: My security group
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdfkldfklgjsdfjajkghs
```

`salt.states.boto_secgroup.absent` (*name*, *vpc\_id=None*, *region=None*, *key=None*, *keyid=None*, *profile=None*)

Ensure a security group with the specified name does not exist.

**name** Name of the security group.

**vpc\_id** The ID of the VPC to create the security group in, if any.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

`salt.states.boto_secgroup.present` (*name, description, vpc\_id=None, rules=None, region=None, key=None, keyid=None, profile=None*)

Ensure the security group exists with the specified rules.

**name** Name of the security group.

**description** A description of this security group.

**vpc\_id** The ID of the VPC to create the security group in, if any.

**rules** A list of ingress rule dicts.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.20 salt.states.boto\_sns

Manage SNS Topics

Create and destroy SNS topics. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses `boto`, which can be installed via `package`, or `pip`.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs
  region: us-east-1
```

```
mytopic:
  boto_sns.present:
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdfklkfkgjsdfjajkghs

# Using a profile from pillars
mytopic:
  boto_sns.present:
    - region: us-east-1
```

```

    - profile: mysnsprofile

# Passing in a profile
mytopic:
  boto_sns.present:
    - region: us-east-1
    - profile:
        keyid: GKTADJGHEIQSXMKKRBJ08H
        key: askdjghsdfjkghWupUjasdfkldfklgjsdfjajkghs

```

**salt.states.boto\_sns.absent** (*name, region=None, key=None, keyid=None, profile=None*)

Ensure the named sns topic is deleted.

**name** Name of the SNS topic.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto\_sns.present** (*name, region=None, key=None, keyid=None, profile=None*)

Ensure the SNS topic exists.

**name** Name of the SNS topic.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.21 salt.states.boto\_sqs

Manage SQS Queues

New in version 2014.7.0.

Create and destroy SQS queues. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses `boto`, which can be installed via package, or pip.

This module accepts explicit SQS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```

sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdfkldfklgjsdfjajkghs

```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdfklkdflkjgjsdfjajkghs
  region: us-east-1
```

```
myqueue:
  boto_sqs.present:
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdfklkdflkjgjsdfjajkghs
    - attributes:
      ReceiveMessageWaitTimeSeconds: 20

# Using a profile from pillars
myqueue:
  boto_sqs.present:
    - region: us-east-1
    - profile: mysqsprofile

# Passing in a profile
myqueue:
  boto_sqs.present:
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdfklkdflkjgjsdfjajkghs
```

**salt.states.boto\_sqs.absent** (*name, region=None, key=None, keyid=None, profile=None*)

Ensure the named sqs queue is deleted.

**name** Name of the SQS queue.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto\_sqs.present** (*name, attributes=None, region=None, key=None, keyid=None, profile=None*)

Ensure the SQS queue exists.

**name** Name of the SQS queue.

**attributes** A dict of key/value SQS attributes.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 30.27.22 salt.states.chef

#### Execute Chef client runs

Run chef-client or chef-solo

```
my-chef-run:
  chef.client:
    - override-runlist: 'demo1,demo2'
    - server: 'https://chef.domain.com'

default-chef-run:
  chef.client: []

my-solo-run:
  chef.solo:
    - environment: dev
```

**salt.states.chef.client**(*name*, *\*\*kwargs*)

**name** Unique identifier for the state. Does not affect the Chef run.

**server** The chef server URL

**client\_key** Set the client key file location

**config** The configuration file to use

**config-file-jail** Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside this path will be loaded).

**environment** Set the Chef Environment on the node

**group** Group to set privilege to

**json-attributes** Load attributes from a JSON file or URL

**localmode** Point chef-client at local repository if True

**log\_level** Set the log level (debug, info, warn, error, fatal)

**logfile** Set the log file location

**node-name** The node name for this client

**override-runlist** Replace current run list with specified items for a single run

**pid** Set the PID file location, defaults to /tmp/chef-client.pid

**run-lock-timeout** Set maximum duration to wait for another client run to finish, default is indefinitely.

**runlist** Permanently replace current run list with specified items

**user** User to set privilege to

**validation\_key** Set the validation key file location, used for registering new clients

**salt.states.chef.solo**(*name*, *\*\*kwargs*)

**name** Unique identifier for the state. Does not affect the Chef run.

**config** The configuration file to use

**environment** Set the Chef Environment on the node

**group** Group to set privilege to

**json-attributes** Load attributes from a JSON file or URL

**log\_level** Set the log level (debug, info, warn, error, fatal)

**logfile** Set the log file location

**node-name** The node name for this client

**override-runlist** Replace current run list with specified items for a single run

**recipe-url** Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache

**run-lock-timeout** Set maximum duration to wait for another client run to finish, default is indefinitely.

**user** User to set privilege to

### 30.27.23 salt.states.cloud

#### Using states instead of maps to deploy clouds

New in version 2014.1.0.

Use this minion to spin up a cloud instance:

```
my-ec2-instance:
  cloud.profile:
    my-ec2-config
```

**salt.states.cloud.absent** (*name*, *onlyif=None*, *unless=None*)

Ensure that no instances with the specified names exist.

CAUTION: This is a destructive state, which will search all configured cloud providers for the named instance, and destroy it.

**name** The name of the instance to destroy

**onlyif** Do run the state only if is unless succeed

**unless** Do not run the state at least unless succeed

**salt.states.cloud.present** (*name*, *cloud\_provider*, *onlyif=None*, *unless=None*, *\*\*kwargs*)

Spin up a single instance on a cloud provider, using salt-cloud. This state does not take a profile argument; rather, it takes the arguments that would normally be configured as part of the state.

Note that while this function does take any configuration argument that would normally be used to create an instance, it will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.untagged, etc).

**name** The name of the instance to create

**cloud\_provider** The name of the cloud provider to use

**onlyif** Do run the state only if is unless succeed

**unless** Do not run the state at least unless succeed

**salt.states.cloud.profile** (*name*, *profile*, *onlyif=None*, *unless=None*, *\*\*kwargs*)

Create a single instance on a cloud provider, using a salt-cloud profile.

Note that while profiles used this function do take any configuration argument that would normally be used to create an instance using a profile, this state will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.untagged, etc).

**name** The name of the instance to create

**profile** The name of the cloud profile to use

**onlyif** Do run the state only if is unless succeed

**unless** Do not run the state at least unless succeed

**kwargs** Any profile override or addition

`salt.states.cloud.volume_absent` (*name*, *provider=None*, *\*\*kwargs*)

Check that a block volume exists.

`salt.states.cloud.volume_attached` (*name*, *server\_name*, *provider=None*, *\*\*kwargs*)

Check if a block volume is attached.

`salt.states.cloud.volume_detached` (*name*, *server\_name=None*, *provider=None*, *\*\*kwargs*)

Check if a block volume is attached.

Returns True if server or Volume do not exist.

`salt.states.cloud.volume_present` (*name*, *provider=None*, *\*\*kwargs*)

Check that a block volume exists.

### 30.27.24 salt.states.cmd

#### Execution of arbitrary commands

The cmd state module manages the enforcement of executed commands, this state can tell a command to run under certain circumstances.

A simple example to execute a command:

```
date > /tmp/salt-run:
  cmd.run
```

Only run if another execution failed, in this case truncate syslog if there is no disk space:

```
> /var/log/messages:
  cmd.run:
    - unless: echo 'foo' > /tmp/.test && rm -f /tmp/.test
```

Only run if the file specified by `creates` does not exist, in this case touch `/tmp/foo` if it does not exist.

```
touch /tmp/foo:
  cmd.run:
    - creates: /tmp/foo
```

---

**Note:** The `creates` option was added to version 2014.7.0

---

Salt determines whether the cmd state is successfully enforced based on the exit code returned by the command. If the command returns a zero exit code, then salt determines that the state was successfully enforced. If the script returns a non-zero exit code, then salt determines that it failed to successfully enforce the state. If a command returns a non-zero exit code but you wish to treat this as a success, then you must place the command in a script and explicitly set the exit code of the script to zero.

Please note that the success or failure of the state is not affected by whether a state change occurred nor the stateful argument.

When executing a command or script, the state (i.e., changed or not) of the command is unknown to Salt's state system. Therefore, by default, the `cmd` state assumes that any command execution results in a changed state.

This means that if a `cmd` state is watched by another state then the state that's watching will always be executed due to the *changed* state in the `cmd` state.

Many state functions in this module now also accept a `stateful` argument. If `stateful` is specified to be true then it is assumed that the command or script will determine its own state and communicate it back by following a simple protocol described below:

1. **If there's nothing in the stdout of the command, then assume no changes.** Otherwise, the stdout must be either in JSON or its *last* non-empty line must be a string of key=value pairs delimited by spaces (no spaces on either side of =).
2. **If it's JSON then it must be a JSON object (e.g., {}).** If it's key=value pairs then quoting may be used to include spaces. (Python's `shlex` module is used to parse the key=value string)

Two special keys or attributes are recognized in the output:

```
changed: bool (i.e., 'yes', 'no', 'true', 'false', case-insensitive)
comment: str (i.e., any string)
```

So, only if `changed` is `True` then assume the command execution has changed the state, and any other key values or attributes in the output will be set as part of the changes.

3. **If there's a comment then it will be used as the comment of the state.**

Here's an example of how one might write a shell script for use with a stateful command:

```
#!/bin/bash
#
echo "Working hard..."

# writing the state line
echo # an empty line here so the next line will be the last.
echo "changed=yes comment='something has changed' whatever=123"
```

And an example SLS file using this module:

```
Run myscript:
  cmd.run:
    - name: /path/to/myscript
    - cwd: /
    - stateful: True

Run only if myscript changed something:
  cmd.wait:
    - name: echo hello
    - cwd: /
    - watch:
      - cmd: Run myscript
```

Note that if the `cmd.wait` state also specifies `stateful: True` it can then be watched by some other states as well.

`cmd.wait` is not restricted to watching only `cmd` states. For example it can also watch a `git` state for changes

```
# Watch for changes to a git repo and rebuild the project on updates
my-project:
  git.latest:
    - name: git@github.com/repo/foo
    - target: /opt/foo
    - rev: master
  cmd.wait:
    - name: make install
    - cwd: /opt/foo
    - watch:
      - git: my-project
```

### Should I use `cmd.run` or `cmd.wait`?

These two states are often confused. The important thing to remember about them is that `cmd.run` states are run each time the SLS file that contains them is applied. If it is more desirable to have a command that only runs after some other state changes, then `cmd.wait` does just that. `cmd.wait` is designed to *watch* other states, and is executed when the state it is watching changes. Example:

```
/usr/local/bin/postinstall.sh:
  cmd.wait:
    - watch:
      - pkg: mycustompkg
  file.managed:
    - source: salt://utils/scripts/postinstall.sh

mycustompkg:
  pkg.installed:
    - require:
      - file: /usr/local/bin/postinstall.sh
```

### How do I create an environment from a pillar map?

The map that comes from a pillar cannot be directly consumed by the `env` option. To use it one must convert it to a list. Example:

```
printenv:
  cmd.run:
    - env:
      {% for key, value in pillar['keys'].iteritems() %}
      - '{{ key }}': '{{ value }}'
      {% endfor %}
```

`salt.states.cmd.call`(*name*, *func*, *args=()*, *kws=None*, *onlyif=None*, *unless=None*, *creates=None*, *output\_loglevel='debug'*, *use\_vt=False*, *\*\*kwargs*)

Invoke a pre-defined Python function with arguments specified in the state declaration. This function is mainly used by the `salt.renderers.pydsl` renderer.

The interpretation of `onlyif` and `unless` arguments are identical to those of `cmd.run`, and all other arguments (`cwd`, `runas`, ...) allowed by `cmd.run` are allowed here, except that their effects apply only to the commands specified in `onlyif` and `unless` rather than to the function to be invoked.

In addition, the `stateful` argument has no effects here.

The return value of the invoked function will be interpreted as follows.

If it's a dictionary then it will be passed through to the state system, which expects it to have the usual structure returned by any salt state function.

Otherwise, the return value (denoted as `result` in the code below) is expected to be a JSON serializable object, and this dictionary is returned:

```
{
  'name': name
  'changes': {'retval': result},
  'result': True if result is None else bool(result),
  'comment': result if isinstance(result, string_types) else ''
}
```

`salt.states.cmd.mod_run_check`(*cmd\_kwargs*, *onlyif*, *unless*, *group*, *creates*)

Execute the `onlyif` and `unless` logic. Return a result dict if: \* `group` is not available \* `onlyif` failed (`onlyif != 0`) \* `unless` succeeded (`unless == 0`) else return `True`

`salt.states.cmd.mod_watch`(*name*, *\*\*kwargs*)

Execute a `cmd` function based on a `watch` call

`salt.states.cmd.run`(*name*, *onlyif=None*, *unless=None*, *creates=None*, *cwd=None*, *user=None*, *group=None*, *shell=None*, *env=None*, *stateful=False*, *umask=None*, *output\_loglevel='debug'*, *quiet=False*, *timeout=None*, *use\_vt=False*, *\*\*kwargs*)

Run a command if certain circumstances are met. Use `cmd.wait` if you want to use the `watch` requisite.

**name** The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif** A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true

**unless** A command to run as a check, only run the named command if the command passed to the `unless` option returns false

**cwd** The current working directory to execute the command in, defaults to `/root`

**user** The user name to run the command as

**group** The group context to run the command as

**shell** The shell to use for execution, defaults to the shell `grain`

**env** A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

**stateful** The command being executed is expected to return data about executing a state

**umask** The umask (in octal) to use when running the command.

**output\_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: `DEBUG`) regardless, unless `quiet` is used for this value.

**quiet** The command will be executed quietly, meaning no log entries of the actual command or its return data. This is deprecated as of the 2014.1.0 release, and is being replaced with `output_loglevel: quiet`.

**timeout** If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

**creates** Only run if the file specified by `creates` does not exist.

New in version 2014.7.0.

**use\_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

---

**Note:** `cmd.run` supports the usage of `reload_modules`. This functionality allows you to force Salt to reload all modules. You should only use `reload_modules` if your `cmd.run` does some sort of installation (such as `pip`), if you do not reload the modules future items in your state which rely on the software being installed will fail.

```
getpip:
  cmd.run:
    - name: /usr/bin/python /usr/local/sbin/get-pip.py
    - unless: which pip
    - require:
      - pkg: python
      - file: /usr/local/sbin/get-pip.py
    - reload_modules: True
```

---

**salt.states.cmd.script** (*name, source=None, template=None, onlyif=None, unless=None, creates=None, cwd=None, user=None, group=None, shell=None, env=None, stateful=False, umask=None, timeout=None, use\_vt=False, output\_loglevel='debug', \*\*kwargs*)

Download a script and execute it with specified arguments.

**source** The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

**name** Either ``cmd arg1 arg2 arg3...`` (`cmd` is not used) or a source ``salt://...``.

**onlyif** Run the named command only if the command passed to the `onlyif` option returns true

**unless** Run the named command only if the command passed to the `unless` option returns false

**cwd** The current working directory to execute the command in, defaults to `/root`

**user** The name of the user to run the command as

**group** The group context to run the command as

**shell** The shell to use for execution. The default is set in `grains['shell']`

**env** A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that **yes**, **no**, **on**, **off**, **true**, and **false** are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

**umask** The umask (in octal) to use when running the command.

**stateful** The command being executed is expected to return data about executing a state

**timeout** If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

**args** String of command line args to pass to the script. Only used if no args are specified as part of the *name* argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: ``arg1 `arg two' arg3``

**creates** Only run if the file specified by **creates** does not exist.

New in version 2014.7.0.

**use\_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**output\_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless **quiet** is used for this value.

```
salt.states.cmd.wait(name, onlyif=None, unless=None, creates=None, cwd=None, user=None,
                    group=None, shell=None, env=(), stateful=False, umask=None, out-
                    put_loglevel='debug', use_vt=False, **kwargs)
```

Run the given command only if the watch statement calls it

**name** The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif** A command to run as a check, run the named command only if the command passed to the **onlyif** option returns true

**unless** A command to run as a check, only run the named command if the command passed to the **unless** option returns false

**cwd** The current working directory to execute the command in, defaults to /root

**user** The user name to run the command as

**group** The group context to run the command as

**shell** The shell to use for execution, defaults to /bin/sh

**env** A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that **yes**, **no**, **on**, **off**, **true**, and **false** are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

**umask** The umask (in octal) to use when running the command.

**stateful** The command being executed is expected to return data about executing a state

**creates** Only run if the file specified by `creates` does not exist.

New in version 2014.7.0.

**output\_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless `quiet` is used for this value.

**use\_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

```
salt.states.cmd.wait_call(name, func, args=(), kws=None, onlyif=None, unless=None, creates=None,
                          stateful=False, use_vt=False, output_loglevel='debug', **kwargs)
```

```
salt.states.cmd.wait_script(name, source=None, template=None, onlyif=None, unless=None,
                            cwd=None, user=None, group=None, shell=None, env=None, stateful=False,
                            umask=None, use_vt=False, output_loglevel='debug',
                            **kwargs)
```

Download a script from a remote source and execute it only if a watch statement calls it.

**source** The source script being downloaded to the minion, this source script is hosted on the salt master server. If the file is located on the master in the directory named `spam`, and is called `eggs`, the source string is `salt://spam/eggs`

**template** If this setting is applied then the named templating engine will be used to render the downloaded file, currently `jinja`, `mako`, and `wempy` are supported

**name** The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif** A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true

**unless** A command to run as a check, only run the named command if the command passed to the `unless` option returns false

**cwd** The current working directory to execute the command in, defaults to `/root`

**user** The user name to run the command as

**group** The group context to run the command as

**shell** The shell to use for execution, defaults to the shell grain

**env** A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

**umask** The umask (in octal) to use when running the command.

**stateful** The command being executed is expected to return data about executing a state

**use\_vt**

Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**output\_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless `quiet` is used for this value.

### 30.27.25 salt.states.composer

#### Installation of Composer Packages

These states manage the installed packages for composer for PHP. Note that either composer is installed and accessible via a bin directory or you can pass the location of composer in the state.

```
get-composer:
  cmd.run:
    - name: 'CURL=`which curl`; $CURL -sS https://getcomposer.org/installer | php'
    - unless: test -f /usr/local/bin/composer
    - cwd: /root/

install-composer:
  cmd.wait:
    - name: mv /root/composer.phar /usr/local/bin/composer
    - cwd: /root/
    - watch:
      - cmd: get-composer

/path/to/project:
  composer.installed:
    - no_dev: true
    - require:
      - cmd: install-composer

# Without composer installed in your PATH
# Note: composer.phar must be executable for state to work properly
/path/to/project:
  composer.installed:
    - composer: /path/to/composer.phar
    - php: /usr/local/bin/php
    - no_dev: true
```

```
salt.states.composer.installed(name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root', always_check=True)
```

Verify that the correct versions of composer dependencies are present.

**dir** Directory location of the composer.json file.

**composer** Location of the composer.phar file. If not set composer will just execute ``composer" as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**user** Which system user to run composer as.

New in version 2014.1.4.

**prefer\_source** --prefer-source option of composer.

**prefer\_dist** --prefer-dist option of composer.

**no\_scripts** --no-scripts option of composer.

**no\_plugins** --no-plugins option of composer.

**optimize** --optimize-autoloader option of composer. Recommended for production.

**no\_dev** --no-dev option for composer. Recommended for production.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer\_home** \$COMPOSER\_HOME environment variable

**always\_check** If True, `_always_ run composer install` in the directory. This is the default behavior. If False, only run `composer install` if there is no vendor directory present.

`salt.states.composer.update` (*name, composer=None, php=None, user=None, prefer\_source=None, prefer\_dist=None, no\_scripts=None, no\_plugins=None, optimize=None, no\_dev=None, quiet=False, composer\_home='/root'*)

Composer update the directory to ensure we have the latest versions of all project dependencies.

**dir** Directory location of the composer.json file.

**composer** Location of the composer.phar file. If not set composer will just execute ```composer``` as if it is installed globally. (i.e. `/path/to/composer.phar`)

**php** Location of the php executable to use with composer. (i.e. `/usr/bin/php`)

**user** Which system user to run composer as.

New in version 2014.1.4.

**prefer\_source** --prefer-source option of composer.

**prefer\_dist** --prefer-dist option of composer.

**no\_scripts** --no-scripts option of composer.

**no\_plugins** --no-plugins option of composer.

**optimize** --optimize-autoloader option of composer. Recommended for production.

**no\_dev** --no-dev option for composer. Recommended for production.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer\_home** \$COMPOSER\_HOME environment variable

### 30.27.26 salt.states.cron

#### Management of cron, the Unix command scheduler

Cron declarations require a number of parameters. The following are the parameters used by Salt to define the various timing values for a cron job:

- minute
- hour
- daymonth
- month
- dayweek (0 to 6 are Sunday through Saturday, 7 can also be used for Sunday)

**Warning:** Any timing arguments not specified take a value of `*`. This means that setting `hour` to 5, while not defining the `minute` param, will result in Salt adding a job that will execute every minute between 5 and 6 A.M.! Additionally, the default user for these states is `root`. Therefore, if the cron job is for another user, it is necessary to specify that user with the `user` parameter.

A long time ago (before 2014.2), when making changes to an existing cron job, the name declaration is the parameter used to uniquely identify the job, so if an existing cron that looks like this:

```
date > /tmp/crontest:
cron.present:
  - user: root
  - minute: 5
```

Is changed to this:

```
date > /tmp/crontest:
cron.present:
  - user: root
  - minute: 7
  - hour: 2
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

The current behavior is still relying on that mechanism, but you can also specify an identifier to identify your crontabs:

```
date > /tmp/crontest:
cron.present:
  - identifier: SUPERCRON
  - user: root
  - minute: 7
  - hour: 2
```

New in version 2014.1.2.

And, some months later, you modify it:

```
superscript > /tmp/crontest:
cron.present:
  - identifier: SUPERCRON
  - user: root
  - minute: 3
  - hour: 4
```

New in version 2014.1.2.

The old `date > /tmp/crontest` will be replaced by `superscript > /tmp/crontest`.

Additionally, Salt also supports running a cron every `x` minutes very similarly to the Unix convention of using `*/5` to have a job run every five minutes. In Salt, this looks like:

```
date > /tmp/crontest:
cron.present:
  - user: root
  - minute: '*/5'
```

The job will now run every 5 minutes.

Additionally, the temporal parameters (minute, hour, etc.) can be randomized by using `random` instead of using a specific value. For example, by using the `random` keyword in the `minute` parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.

```
/path/to/cron/script:
  cron.present:
    - user: root
    - minute: random
    - hour: 2
```

New in version 0.16.0.

Since Salt assumes a value of `*` for unspecified temporal parameters, adding a parameter to the state and setting it to `random` will change that value from `*` to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the `random` keyword will not modify it.

`salt.states.cron.absent` (*name*, *user*='root', *identifier*=False, *\*\*kwargs*)

Verifies that the specified cron job is absent for the specified user; only the name is matched when removing a cron job.

**name** The command that should be absent in the user crontab.

**user** The name of the user whose crontab needs to be modified, defaults to the root user

**identifier** Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state id

`salt.states.cron.env_absent` (*name*, *user*='root')

Verifies that the specified environment variable is absent from the crontab for the specified user

**name** The name of the environment variable to remove from the user crontab

**user** The name of the user whose crontab needs to be modified, defaults to the root user

`salt.states.cron.env_present` (*name*, *value*=None, *user*='root')

Verifies that the specified environment variable is present in the crontab for the specified user.

**name** The name of the environment variable to set in the user crontab

**user** The name of the user whose crontab needs to be modified, defaults to the root user

**value** The value to set for the given environment variable

`salt.states.cron.file` (*name*, *source\_hash*='', *user*='root', *template*=None, *context*=None, *replace*=True, *defaults*=None, *env*=None, *backup*='', *\*\*kwargs*)

Provides file.managed-like functionality (templating, etc.) for a pre-made crontab file, to be assigned to a given user.

**name** The source file to be used as the crontab. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

If the file is hosted on a HTTP or FTP server then the `source_hash` argument is also required

**source\_hash** This can be either a file which contains a source hash string for the source, or a source hash string. The source hash string is the hash algorithm followed by the hash of the file: `md5=e138491e9d5b97023cea823fe17bac22`

**user** The user to whom the crontab should be assigned. This defaults to root.

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently, jinja and mako are supported.

**context** Overrides default context variables passed to the template.

**replace** If the crontab should be replaced, if False then this command will be ignored if a crontab exists for the specified user. Default is True.

**defaults** Default context passed to the template.

**backup** Overrides the default backup mode for the user's crontab.

`salt.states.cron.present` (*name*, *user*='root', *minute*='\*', *hour*='\*', *daymonth*='\*', *month*='\*', *day-week*='\*', *comment*=None, *identifier*=False)

Verifies that the specified cron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your cron system's documentation. Most Unix-like systems' cron documentation can be found via the crontab man page: `man 5 crontab`.

**name** The command that should be executed by the cron job.

**user** The name of the user whose crontab needs to be modified, defaults to the root user

**minute** The information to be set into the minute section, this can be any string supported by your cron system's the minute field. Default is \*

**hour** The information to be set in the hour section. Default is \*

**daymonth** The information to be set in the day of month section. Default is \*

**month** The information to be set in the month section. Default is \*

**dayweek** The information to be set in the day of week section. Default is \*

**comment** User comment to be added on line previous the cron job

**identifier** Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state id

### 30.27.27 salt.states.cyg

Installation of Cygwin packages.

A state module to manage cygwin packages. Packages can be installed or removed.

```
dos2unix:
  cyg.installed
```

`class salt.states.cyg.DictDiffer` (*current\_dict*, *past\_dict*)

Calculate the difference between two dictionaries.

1.items added

2.items removed

3.keys same in both but changed values

4.keys same in both and unchanged values

**added** ()

Return a set of additions to *past\_dict*.

**changed** ()

Return a set of the keys with changed values.

**removed()**

Return a set of things removed from `past_dict`.

**same()**

True if the two dicts are the same.

**unchanged()**

Return a set of the keys with unchanged values.

`salt.states.cyg.installed(name, cyg_arch='x86_64', mirrors=None)`

Make sure that a package is installed.

**name** The name of the package to install

**cyg\_arch** [x86\_64] The cygwin architecture to install the package into. Current options are x86 and x86\_64

**mirrors** [None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:

```
rsync:
  cyg.installed:
    - mirrors:
      - http://mirror/without/public/key: ""
      - http://mirror/with/public/key: http://url/of/public/key
```

`salt.states.cyg.removed(name, cyg_arch='x86_64', mirrors=None)`

Make sure that a package is not installed.

**name** The name of the package to uninstall

**cyg\_arch** [x86\_64] The cygwin architecture to remove the package from. Current options are x86 and x86\_64

**mirrors** [None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:

```
rsync:
  cyg.removed:
    - mirrors:
      - http://mirror/without/public/key: ""
      - http://mirror/with/public/key: http://url/of/public/key
```

`salt.states.cyg.updated(name=None, cyg_arch='x86_64', mirrors=None)`

Make sure all packages are up to date.

**name** [None] No affect, salt fails poorly without the arg available

**cyg\_arch** [x86\_64] The cygwin architecture to update. Current options are x86 and x86\_64

**mirrors** [None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:

```
rsync:
  cyg.updated:
    - mirrors:
      - http://mirror/without/public/key: ""
      - http://mirror/with/public/key: http://url/of/public/key
```

### 30.27.28 salt.states.ddns

#### Dynamic DNS updates

Ensure a DNS record is present or absent utilizing RFC 2136 type dynamic updates. Requires dnspython module.

```
webservers:
  ddns.present:
    - zone: example.com
    - ttl: 60
    - data: 111.222.333.444
    - nameserver: 123.234.345.456
    - keyfile: /srv/salt/tsig_key.txt
```

`salt.states.ddns.absent` (*name, zone, data=None, rdtype=None, \*\*kwargs*)

Ensures that the named DNS record is absent.

**name** The host portion of the DNS record, e.g., 'webservers'

**zone** The zone to check

**data** Data for the DNS record. E.g., the IP address for an A record. If omitted, all records matching name (and rdtype, if provided) will be purged.

**rdtype** DNS resource type. If omitted, all types will be purged.

**\*\*kwargs** Additional arguments the `ddns.delete` function may need (e.g. nameserver, keyfile, keyname).

`salt.states.ddns.present` (*name, zone, ttl, data, rdtype='A', \*\*kwargs*)

Ensures that the named DNS record is present with the given ttl.

**name** The host portion of the DNS record, e.g., 'webservers'

**zone** The zone to check/update

**ttl** TTL for the record

**data** Data for the DNS record. E.g., the IP address for an A record.

**rdtype** DNS resource type. Default 'A'.

**\*\*kwargs** Additional arguments the `ddns.update` function may need (e.g. nameserver, keyfile, keyname).

### 30.27.29 salt.states.debconfmod

#### Management of debconf selections

##### depends

- debconf-utils package

The `debconfmod` state module manages the enforcement of debconf selections, this state can set those selections prior to package installation.

#### Available Functions

The `debconfmod` state has two functions, the `set` and `set_file` functions

**set** Set debconf selections from the state itself

**set\_file** Set debconf selections from a file

```

nullmailer-debconf:
  debconf.set:
    - name: nullmailer
    - data:
      'shared/mailname': {'type': 'string', 'value': 'server.domain.tld'}
      'nullmailer/relayhost': {'type': 'string', 'value': 'mail.domain.tld'}
ferm-debconf:
  debconf.set:
    - name: ferm
    - data:
      'ferm/enable': {'type': 'boolean', 'value': True}

```

**Note:** Due to how PyYAML imports nested dicts (see [here](#)), the values in the `data` dict must be indented four spaces instead of two.

**salt.states.debconfmod.set**(*name*, *data*)

Set debconf selections

```

<state_id>:
  debconf.set:
    - name: <name>
    - data:
      <question>: {'type': <type>, 'value': <value>}
      <question>: {'type': <type>, 'value': <value>}

<state_id>:
  debconf.set:
    - name: <name>
    - data:
      <question>: {'type': <type>, 'value': <value>}
      <question>: {'type': <type>, 'value': <value>}

```

**name:** The package name to set answers for.

**data:** A set of questions/answers for debconf. Note that everything under this must be indented twice.

**question:** The question the is being pre-answered

**type:** The type of question that is being asked (string, boolean, select, etc.)

**value:** The answer to the question

**salt.states.debconfmod.set\_file**(*name*, *source*, *template=None*, *context=None*, *defaults=None*, *\*\*kwargs*)

Set debconf selections from a file or a template

```

<state_id>:
  debconf.set_file:
    - source: salt://pathto/pkg.selections

<state_id>:
  debconf.set_file:
    - source: salt://pathto/pkg.selections?saltenv=myenvironment

<state_id>:
  debconf.set_file:

```

```
- source: salt://pathto/pkg.selections.jinja2
- template: jinja
- context:
    some_value: "false"
```

**source:** The location of the file containing the package selections

**template** If this setting is applied then the named templating engine will be used to render the package selections file, currently jinja, mako, and wempy are supported

**context** Overrides default context variables passed to the template.

**defaults** Default context passed to the template.

### 30.27.30 salt.states.disk

Disk monitoring state

Monitor the state of disk resources

`salt.states.disk.status` (*name, maximum=None, minimum=None*)

Return the current disk usage stats for the named mount point

### 30.27.31 salt.states.dockerio

#### Manage Docker containers

Docker is a lightweight, portable, self-sufficient software container wrapper. The base supported wrapper type is LXC, cgroups, and the Linux Kernel.

**Warning:** This state module is beta. The API is subject to change. No promise as to performance or functionality is yet present.

**Note:** This state module requires `docker-py` version `>= 0.6.0` which supports [Docker Remote API version 1.12](#).

---

#### Available Functions

- built

```
corp/mysuperdocker_img:
  docker.built:
    - path: /path/to/dir/container
```

- pulled

```
ubuntu:
  docker.pulled:
    - tag: latest
```

- pushed

```
corp/mysuperdocker_img:
  docker.pushed
```

- installed

```
mysuperdocker-container:
  docker.installed:
    - name: mysuperdocker
    - hostname: superdocker
    - image: corp/mysuperdocker_img
```

- loaded

```
mysuperdocker-file:
  docker.loaded:
    - name: mysuperdocker
    - source: salt://_files/tmp/docker_image.tar
```

- running

```
my_service:
  docker.running:
    - container: mysuperdocker
    - image: corp/mysuperdocker_img
    - port_bindings:
      - "5000/tcp":
          HostIp: ""
          HostPort: "5000"
```

**Note:** The `port_bindings` argument above is a dictionary. The double indentation is required for PyYAML to load the data structure properly as a python dictionary. More information can be found [here](#)

- absent

```
mys_old_uperdocker:
  docker.absent
```

- run

```
/finish-install.sh:
  docker.run:
    - cid: mysuperdocker
    - unless: grep -q something /var/log/foo
    - docker_unless: grep -q done /install_log
```

**Note:** The docker modules are named `dockerio` because the name ``docker'` would conflict with the underlying `docker-py` library.

`salt.states.dockerio.absent` (*name*)

Ensure that the container is absent; if not, it will will be killed and destroyed. (*docker inspect*)

**name:** Either the container name or id

`salt.states.dockerio.built` (*name, path=None, quiet=False, nocache=False, rm=True, force=False, timeout=None, \*args, \*\*kwargs*)

Build a docker image from a path or URL to a dockerfile. (*docker build*)

**name** Name of the image

**path** URL (e.g. *url/branch/docker\_dir/dockerfile*) or filesystem path to the dockerfile

```
salt.states.dockerio.installed(name, image, command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=0, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, cpu_shares=None, cpuset=None, *args, **kwargs)
```

Ensure that a container with the given name exists; if not, build a new container from the specified image. (*docker run*)

**name** Name for the container

**image** Image from which to build this container

**environment**

Environment variables for the container, either

- a mapping of key, values
- a list of mappings of key, values

**ports**

List of ports definitions, either:

- a port to map
- a mapping of mapping portInHost : PortInContainer

**volumes** List of volumes (see notes for the running function)

For other parameters, see absolutely first the salt.modules.dockerio execution module and the docker-py python bindings for docker documentation <<https://github.com/docker/docker-py#api>>`\_ for *docker.create\_container*.

---

**Note:** This command does not verify that the named container is running the specified image.

---

```
salt.states.dockerio.loaded(name, source=None, source_hash='', force=False)
```

Load an image into the local docker registry (*docker load*)

**name** Name of the docker image

**source** The source .tar file to download to the minion, created by docker save this source file can be hosted on either the salt master server, or on an HTTP or FTP server.

If the file is hosted on a HTTP or FTP server then the source\_hash argument is also required

---

**Note:** See first the documentation for salt file.managed <<http://docs.saltstack.com/en/latest/ref/states/all/salt.states.file.html#salt.states.file.managed>>

---

**source\_hash**

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

---

**Note:** See first the documentation for salt file.managed <<http://docs.saltstack.com/en/latest/ref/states/all/salt.states.file.html#salt.states.file.managed>>

---

**force** Load even if the image exists

```
salt.states.dockerio.mod_watch(name, sfun=None, *args, **kw)
```

`salt.states.dockerio.present`(*name*, *image=None*, *is\_latest=False*)

If a container with the given name is not present, this state will fail. Supports optionally checking for specific image/version (*docker inspect*)

**name:** container id

**image:** image the container should be running (defaults to any)

**is\_latest:** also check if the container runs the latest version of the image ( latest defined as the latest pulled onto the local machine)

`salt.states.dockerio.pulled`(*name*, *tag='latest'*, *force=False*, *insecure\_registry=False*, *\*args*, *\*\*kwargs*)

Pull an image from a docker registry. (*docker pull*)

---

**Note:** See first the documentation for *docker login*, *docker pull*, *docker push*, and [docker.import\\_image](#) (*docker import*). NOTE that we added in SaltStack a way to authenticate yourself with the Docker Hub Registry by supplying your credentials (username, email & password) using pillars. For more information, see `salt.modules.dockerio` execution module.

---

**name** Name of the image

**tag** Tag of the image

**force** Pull even if the image is already pulled

**insecure\_registry** Set to `True` to allow connections to non-HTTPS registries. Default `False`.

`salt.states.dockerio.pushed`(*name*, *tag='latest'*, *insecure\_registry=False*)

Push an image from a docker registry. (*docker push*)

---

**Note:** See first the documentation for *docker login*, *docker pull*, *docker push*, and [docker.import\\_image](#) (*docker import*). NOTE that we added in SaltStack a way to authenticate yourself with the Docker Hub Registry by supplying your credentials (username, email & password) using pillars. For more information, see `salt.modules.dockerio` execution module.

---

**name** Name of the image

**tag** Tag of the image [Optional]

**insecure\_registry** Set to `True` to allow connections to non-HTTPS registries. Default `False`.

`salt.states.dockerio.run`(*name*, *cid=None*, *hostname=None*, *onlyif=None*, *unless=None*, *docked\_onlyif=None*, *docked\_unless=None*, *\*args*, *\*\*kwargs*)

Run a command in a specific container

You can match by either name or hostname

**name** command to run in the container

**cid** Container id or name

**state\_id** state\_id

**onlyif** Only execute cmd if statement on the host returns 0

**unless** Do not execute cmd if statement on the host returns 0

**docked\_onlyif** Only execute cmd if statement in the container returns 0

**docked\_unless** Do not execute cmd if statement in the container returns 0

`salt.states.dockerio.running`(*name*, *image*, *container=None*, *command=None*, *hostname=None*, *user=None*, *detach=True*, *stdin\_open=False*, *tty=False*, *mem\_limit=0*, *ports=None*, *environment=None*, *dns=None*, *volumes=None*, *volumes\_from=None*, *start=True*, *cap\_add=None*, *cap\_drop=None*, *privileged=None*, *lxc\_conf=None*, *network\_mode=None*, *check\_is\_running=True*, *publish\_all\_ports=False*, *links=None*, *restart\_policy=None*, *cpu\_shares=None*, *cpuset=None*, *\*args*, *\*\*kwargs*)

Ensure that a container is running. If the container does not exist, it will be created from the specified image. (*docker run*)

**name / container** Name for the container

**image** Image from which to build this container

**environment**

Environment variables for the container, either

- a mapping of key, values
- a list of mappings of key, values

**ports**

List of ports definitions, either:

- a port to map
- a mapping of mapping `portInHost : PortInContainer`

```
- ports:
  - "5000/tcp":
      HostIp: ""
      HostPort: "5000"
```

**publish\_all\_ports** Publish all ports from the port list (default is false, only meaningful if port does not contain `portinhost:portincontainer` mapping)

**volumes** List of volumes to mount or create in the container (like `-v` of `docker run` command), mapping host directory to container directory.

To specify a volume in the container in terse list format:

```
- volumes:
  - "/var/log/service" # container-only volume
  - "/srv/timezone:/etc/timezone" # bound volume
  - "/usr/local/etc/passwd:/etc/passwd:ro" # read-only bound volume
```

You can also use the short dictionary form (note that the notion of source:target from docker is preserved):

```
- volumes:
  - /var/log/service: /var/log/service # mandatory read-write implied
```

Or, alternatively, to specify read-only mounting, use the extended form:

```
- volumes:
  - /home/user1:
      bind: /mnt/vol2
      ro: True
  - /var/www:
```

```
bind: /mnt/vol1
ro: False
```

Or (for backwards compatibility) another dict style:

```
- volumes:
  /home/user1:
    bind: /mnt/vol2
    ro: True
  /var/www:
    bind: /mnt/vol1
    ro: False
```

**volumes\_from** List of containers to share volumes with

**dns** List of DNS servers.

```
- dns:
  - 127.0.0.1
```

**network\_mode**

- `'bridge'`: creates a new network stack for the container on the docker bridge
- `'none'`: no networking for this container
- `'container:[name|id]'`: reuses another container network stack)
- `'host'`: use the host network stack inside the container

```
- network_mode: host
```

**restart\_policy** Restart policy to apply when a container exits (no, on-failure[:max-retry], always)

```
- restart_policy:
  MaximumRetryCount: 5
  Name: on-failure
```

**cap\_add** List of capabilities to add in a container.

**cap\_drop** List of capabilities to drop in a container.

**check\_is\_running** Enable checking if a container should run or not. Useful for data-only containers that must be linked to another one. e.g. nginx <- static-files

**cpu\_shares** CPU shares (relative weight)

```
- cpu_shares: 2
```

**cpuset** CPUs in which to allow execution ('0-3' or '0,1')

```
- cpuset: '0-3'
```

For other parameters, see `salt.modules.dockerio` execution module and the `docker-py` python bindings for docker documentation <<https://github.com/docker/docker-py#api>>`\_ for `docker.create_container`.

**Note:** This command does not verify that the named container is running the specified image.

`salt.states.dockerio.script(*args, **kw)`

Placeholder function for a `cmd.script` alike.

**Note:** Not yet implemented. Its implementation might be very similar from

*salt.states.dockerio.run*

---

### 30.27.32 salt.states.drac

Management of Dell DRAC

The DRAC module is used to create and manage DRAC cards on Dell servers

Ensure the user damian is present

```
damian:
  drac.present:
    - name: damian
    - password: secret
    - permission: login,test_alerts,clear_logs
```

Ensure the user damian does not exist

```
damian:
  drac.absent:
    - name: damian
```

Ensure DRAC network is in a consistent state

```
my_network:
  drac.network:
    - ip: 10.225.108.29
    - netmask: 255.255.255.224
    - gateway: 10.225.108.1
```

**salt.states.drac.absent**(*name*)

Ensure a user does not exist on the Dell DRAC

**name:** The users username

**salt.states.drac.network**(*ip, netmask, gateway*)

Ensure the DRAC network settings are consistent

**salt.states.drac.present**(*name, password, permission*)

Ensure the user exists on the Dell DRAC

**name:** The users username

**password** The password used to authenticate

**permission** The permissions that should be assigned to a user

### 30.27.33 salt.states.environ

Support for getting and setting the environment variables of the current salt process.

**salt.states.environ.setenv**(*name, value, false\_unsets=False, clear\_all=False, update\_minion=False*)

Set the salt process environment variables.

**name** The environment key to set. Must be a string.

**value** Either a string or dict. When string, it will be the value set for the environment key of `name` above. When a dict, each key/value pair represents an environment variable to set.

**false\_unsets** If a key's value is False and false\_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key's value is False and false\_unsets is not True, then the key's value will be set to an empty string. Default: False

**clear\_all** USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear\_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False

**update\_minion** If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False

CLI Example:

```
a_string_env:
  environ.setenv:
    - name: foo
    - value: bar
    - update_minion: True

a_dict_env:
  environ.setenv:
    - name: does_not_matter
    - value:
        foo: bar
        baz: quux
```

### 30.27.34 salt.states.eselect

#### Management of Gentoo configuration using eselect

A state module to manage Gentoo configuration via eselect

```
profile:
  eselect.set:
    target: hardened/linux/amd64
```

**salt.states.eselect.set\_**(*name*, *target*, *module\_parameter=None*, *action\_parameter=None*)

Verify that the given module is set to the given target

**name** The name of the module

**target** The target to be set for this module

**module\_parameter** additional params passed to the defined module

**action\_parameter** additional params passed to the defined action

### 30.27.35 salt.states.event

Send events through Salt's event system during state runs

**salt.states.event.send**(*name*, *data=None*, *preload=None*, *with\_env=False*, *with\_grains=False*, *with\_pillar=False*, *\*\*kwargs*)

Send an event to the Salt Master

New in version 2014.7.0.

Accepts the same arguments as the `event.send` execution module of the same name.

Example:

```
# ...snip bunch of states above

mycompany/mystaterun/status/update:
  event.send:
    - data:
      status: "Half-way through the state run!"

# ...snip bunch of states below
```

`salt.states.event.wait`(*name*, *sfun=None*)

Fire an event on the Salt master event bus if called from a watch statement

New in version 2014.7.0.

Example:

```
# Stand up a new web server.
apache:
  pkg:
    - installed
    - name: httpd
  service:
    - running
    - enable: True
    - name: httpd

# Notify the load balancer to update the pool once Apache is running.
refresh_pool:
  event:
    - wait
    - name: mycompany/loadbalancer/pool/update
    - data:
      new_web_server_ip: {{ grains['ipv4'] | first() }}
    - watch:
      - pkg: apache
```

### 30.27.36 salt.states.file

#### Operations on regular files, special files, directories, and symlinks

Salt States can aggressively manipulate files on a system. There are a number of ways in which files can be managed.

Regular files can be enforced with the *file.managed* state. This state downloads files from the salt master and places them on the target system. Managed files can be rendered as a jinja, mako, or wempy template, adding a dynamic component to file management. An example of *file.managed* which makes use of the jinja templating system would look like this:

```
/etc/http/conf/http.conf:
  file.managed:
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - defaults:
```

```

    custom_var: "default value"
    other_var: 123
{% if grains['os'] == 'Ubuntu' %}
  - context:
    custom_var: "override"
{% endif %}

```

It is also possible to use the *py renderer* as a templating option. The template would be a python script which would need to contain a function called `run()`, which returns a string. The returned string will be the contents of the managed file. For example:

```

def run():
    lines = ('foo', 'bar', 'baz')
    return '\n\n'.join(lines)

```

**Note:** The `defaults` and `context` arguments require extra indentation (four spaces instead of the normal two) in order to create a nested dictionary. [More information.](#)

If using a template, any user-defined template variables in the file defined in `source` must be passed in using the `defaults` and/or `context` arguments. The general best practice is to place default values in `defaults`, with conditional overrides going into `context`, as seen above.

The template will receive a variable `custom_var`, which would be accessed in the template using `{{ custom_var }}`. If the operating system is Ubuntu, the value of the variable `custom_var` would be *override*, otherwise it is the default *default value*

The `source` parameter can be specified as a list. If this is done, then the first file to be matched will be the one that is used. This allows you to have a default file on which to fall back if the desired file does not exist on the salt fileserver. Here's an example:

```

/etc/foo.conf:
  file.managed:
    - source:
      - salt://foo.conf.{{ grains['fqdn'] }}
      - salt://foo.conf.fallback
    - user: foo
    - group: users
    - mode: 644
    - backup: minion

```

**Note:** Salt supports backing up managed files via the `backup` option. For more details on this functionality please review the [backup\\_mode documentation](#).

The `source` parameter can also specify a file in another Salt environment. In this example `foo.conf` in the `dev` environment will be used instead.

```

/etc/foo.conf:
  file.managed:
    - source:
      - salt://foo.conf?saltenv=dev
    - user: foo
    - group: users
    - mode: '0644'

```

**Warning:** When using a mode that includes a leading zero you must wrap the value in single quotes. If the value is not wrapped in quotes it will be read by YAML as an integer and evaluated as an octal.

Special files can be managed via the `mknod` function. This function will create and enforce the permissions on a special file. The function supports the creation of character devices, block devices, and fifo pipes. The function will create the directory structure up to the special file if it is needed on the minion. The function will not overwrite or operate on (change major/minor numbers) existing special files with the exception of user, group, and permissions. In most cases the creation of some special files require root permissions on the minion. This would require that the minion to be run as the root user. Here is an example of a character device:

```
/var/named/chroot/dev/random:
  file.mknod:
    - ntype: c
    - major: 1
    - minor: 8
    - user: named
    - group: named
    - mode: 660
```

Here is an example of a block device:

```
/var/named/chroot/dev/loop0:
  file.mknod:
    - ntype: b
    - major: 7
    - minor: 0
    - user: named
    - group: named
    - mode: 660
```

Here is an example of a fifo pipe:

```
/var/named/chroot/var/log/logfifo:
  file.mknod:
    - ntype: p
    - user: named
    - group: named
    - mode: 660
```

Directories can be managed via the `directory` function. This function can create and enforce the permissions on a directory. A directory statement will look like this:

```
/srv/stuff/substuf:
  file.directory:
    - user: fred
    - group: users
    - mode: 755
    - makedirs: True
```

If you need to enforce user and/or group ownership or permissions recursively on the directory's contents, you can do so by adding a `recurse` directive:

```
/srv/stuff/substuf:
  file.directory:
```

```

- user: fred
- group: users
- mode: 755
- makedirs: True
- recurse:
  - user
  - group
  - mode

```

As a default, mode will resolve to `dir_mode` and `file_mode`, to specify both directory and file permissions, use this form:

```

/srv/stuff/substuf:
  file.directory:
    - user: fred
    - group: users
    - file_mode: 744
    - dir_mode: 755
    - makedirs: True
    - recurse:
      - user
      - group
      - mode

```

Symlinks can be easily created; the `symlink` function is very simple and only takes a few arguments:

```

/etc/grub.conf:
  file.symlink:
    - target: /boot/grub/grub.conf

```

Recursive directory management can also be set via the `recurse` function. Recursive directory management allows for a directory on the salt master to be recursively copied down to the minion. This is a great tool for deploying large code and configuration systems. A state using `recurse` would look something like this:

```

/opt/code/flask:
  file.recurse:
    - source: salt://code/flask
    - include_empty: True

```

A more complex `recurse` example:

```

{% set site_user = 'testuser' %}
{% set site_name = 'test_site' %}
{% set project_name = 'test_proj' %}
{% set sites_dir = 'test_dir' %}

django-project:
  file.recurse:
    - name: {{ sites_dir }}/{{ site_name }}/{{ project_name }}
    - user: {{ site_user }}
    - dir_mode: 2775
    - file_mode: '0644'
    - template: jinja
    - source: salt://project/templates_dir
    - include_empty: True

```

`salt.states.file.absent(name)`

Make sure that the named file or directory is absent. If it exists, it will be deleted. This will work to reverse any of the functions in the file state module.

**name** The path which should be deleted

`salt.states.file.accumulated(name, filename, text, **kwargs)`

Prepare accumulator which can be used in template in file.managed state. Accumulator dictionary becomes available in template. It can also be used in file.blockreplace.

**name** Accumulator name

**filename** Filename which would receive this accumulator (see file.managed state documentation about name)

**text** String or list for adding in accumulator

**require\_in / watch\_in** One of them required for sure we fill up accumulator before we manage the file. Probably the same as filename

Example:

Given the following:

```
animals_doing_things:
  file.accumulated:
    - filename: /tmp/animal_file.txt
    - text: ' jumps over the lazy dog.'
    - require_in:
      - file: animal_file

animal_file:
  file.managed:
    - name: /tmp/animal_file.txt
    - source: salt://animal_file.txt
    - template: jinja
```

One might write a template for `animal_file.txt` like the following:

```
The quick brown fox{% for animal in accumulator['animals_doing_things'] %}{{ animal }}{% endfor
```

Collectively, the above states and template file will produce:

```
The quick brown fox jumps over the lazy dog.
```

Multiple accumulators can be ``chained" together.

---

**Note:** The `accumulator' data structure is a Python dictionary. Do not expect any loop over the keys in a deterministic order!

---

`salt.states.file.append(name, text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None)`

Ensure that some text appears at the end of a file.

The text will not be appended if it already exists in the file. A single string of text or a list of strings may be appended.

**name** The location of the file to append to.

**text** The text to be appended, which can be a single string or a list of strings.

**makedirs** If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to False.

**source** A single source file to append. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials (see `s3.get` state documentation). File retrieval from Openstack Swift object storage is supported via `swift://container/object_path` URLs (see `swift.get` documentation).

For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`.

If the file is hosted on an HTTP or FTP server, the `source_hash` argument is also required.

#### source\_hash

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

Type	Length
=====	=====
sha512	128
sha384	96
sha256	64
sha224	56
sha1	40
md5	32

The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

Debian file type `*.dsc` is supported.

Examples:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f0233be91c151178b30f0dff8ebbdcc8de71b1d5c8bcc06a /etc/resolv.conf
ead48423703509d37c4a90e6a0d53e143b6fc268
```

**Known issues:** If the remote server URL has the hash file as an apparent sub-directory of the source file, the module will discover that it has already cached a directory where a file should be cached. For example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.ta
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7
```

**template** [`jinj`a] The named templating engine will be used to render the appended-to file. Defaults to `jinj`a.

**sources** A list of source files to append. If the files are hosted on an HTTP or FTP server, the `source_hashes` argument is also required.

**source\_hashes** A list of source\_hashes corresponding to the sources list specified in the sources argument.

**defaults** Default context passed to the template.

**context** Overrides default context variables passed to the template.

Multi-line example:

```
/etc/motd:
file.append:
- text: |
    Thou hadst better eat salt with the Philosophers of Greece,
    than sugar with the Courtiers of Italy.
- Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
file.append:
- text:
- Trust no one unless you have eaten much salt with him.
- "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```
/etc/motd:
file:
- append
- template: jinja
- sources:
- salt://motd/devops-messages.tpl
- salt://motd/hr-messages.tpl
- salt://motd/general-messages.tpl
```

New in version 0.9.5.

**salt.states.file.blockreplace**(*name*, *marker\_start*='#-- start managed zone --', *marker\_end*='#-  
- end managed zone --', *content*='', *append\_if\_not\_found*=False,  
*prepend\_if\_not\_found*=False, *backup*='.bak', *show\_changes*=True)

Maintain an edit in a file in a zone delimited by two line markers

New in version 2014.1.0.

A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal. This can help you maintaining an un-managed file containing manual edits. Note: this function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

**name** Filesystem path to the file to be edited

**marker\_start** The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

**marker\_end** The line content identifying a line as the end of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output. Note: you can use `file.accumulated` and target this state. All accumulated data dictionaries content will be added as new lines in the content

**content** The content to be used between the two lines identified by `marker_start` and `marker_end`

**append\_if\_not\_found** If markers are not found and set to True then the markers and content will be appended to the file. Default is False

**prepend\_if\_not\_found** If markers are not found and set to True then the markers and content will be prepended to the file. Default is False

**backup** The file extension to use for a backup of the file if any edit is made. Set this to False to skip making a backup.

**dry\_run** Don't make any edits to the file

**show\_changes** Output a unified diff of the old file and the new file. If False return a boolean if any changes were made

Example of usage with an accumulator and with a variable:

```
{% set myvar = 42 %}
hosts-config-block-{{ myvar }}:
  file.blockreplace:
    - name: /etc/hosts
    - marker_start: "# START managed zone {{ myvar }} -DO-NOT-EDIT-"
    - marker_end: "# END managed zone {{ myvar }} --"
    - content: 'First line of content'
    - append_if_not_found: True
    - backup: '.bak'
    - show_changes: True

hosts-config-block-{{ myvar }}-accumulated1:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: "text 2"
    - require_in:
      - file: hosts-config-block-{{ myvar }}

hosts-config-block-{{ myvar }}-accumulated2:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: |
        text 3
        text 4
    - require_in:
      - file: hosts-config-block-{{ myvar }}
```

will generate and maintain a block of content in /etc/hosts:

```
# START managed zone 42 -DO-NOT-EDIT-
First line of content
text 2
text 3
text 4
# END managed zone 42 --
```

**salt.states.file.comment** (*name, regex, char='#, backup='.bak'*)

Comment out specified lines in a file.

**name** The full path to the file to be edited

**regex** A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing ^ or \$ characters outside the parenthesis (e.g., the pattern ^foo\$ will be rewritten as ^(foo)\$) Note that you need the leading ^, otherwise each time you run highstate, another comment char will be inserted.

**char** [#] The character to be inserted at the beginning of a line in order to comment it out

**backup** [.bak] The file will be backed up before edit with this file extension

**Warning:** This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

Usage:

```
/etc/fstab:
file.comment:
- regex: ^bind 127.0.0.1
```

New in version 0.9.5.

`salt.states.file.copy`(*name*, *source*, *force=False*, *makedirs=False*, *preserve=False*, *user=None*, *group=None*, *mode=None*, *subdir=False*, *\*\*kwargs*)

If the source file exists on the system, copy it to the named file. The named file will not be overwritten if it already exists unless the `force` option is set to `True`.

**name** The location of the file to copy to

**source** The location of the file to copy to the location specified with `name`

**force** If the target location is present then the file will not be moved, specify `force: True` to overwrite the target file

**makedirs** If the target subdirectories don't exist create them

**preserve** New in version 2015.5.0.

Set `preserve: True` to preserve user/group ownership and mode after copying. Default is `False`. If `preserve` is set to `True`, then user/group/mode attributes will be ignored.

**user** New in version 2015.5.0.

The user to own the copied file, this defaults to the user salt is running as on the minion. If `preserve` is set to `True`, then this will be ignored

**group** New in version 2015.5.0.

The group to own the copied file, this defaults to the group salt is running as on the minion. If `preserve` is set to `True` or on Windows this will be ignored

**mode** New in version 2015.5.0.

The permissions to set on the copied file, aka 644, '0775', '4664'. If `preserve` is set to `True`, then this will be ignored. Not supported on Windows

**subdir** New in version 2015.5.0.

If the name is a directory then place the file inside the named directory

`salt.states.file.directory`(*name*, *user=None*, *group=None*, *recurse=None*, *dir\_mode=None*, *file\_mode=None*, *makedirs=False*, *clean=False*, *require=None*, *exclude\_pat=None*, *follow\_symlinks=False*, *force=False*, *backup\_name=None*, *allow\_symlink=True*, *\*\*kwargs*)

Ensure that a named directory is present and has the right perms

**name** The location to create or manage a directory

**user** The user to own the directory; this defaults to the user salt is running as on the minion

**group** The group ownership set for the directory; this defaults to the group salt is running as on the minion. On Windows, this is ignored

**recurse** Enforce user/group ownership and mode of directory recursively. Accepts a list of strings representing what you would like to recurse. If `mode` is defined, will recurse on both `file_mode` and `dir_mode` if they are defined. If `ignore_files` or `ignore_dirs` is included, files or directories will be left unchanged respectively. Example:

```
/var/log/httpd:
  file.directory:
    - user: root
    - group: root
    - dir_mode: 755
    - file_mode: 644
    - recurse:
      - user
      - group
      - mode
```

Leave files or directories unchanged:

```
/var/log/httpd:
  file.directory:
    - user: root
    - group: root
    - dir_mode: 755
    - file_mode: 644
    - recurse:
      - user
      - group
      - mode
      - ignore_files

/var/log/httpd:
  file.directory:
    - user: root
    - group: root
    - dir_mode: 755
    - file_mode: 644
    - recurse:
      - user
      - group
      - mode
      - ignore_dirs
```

New in version 2015.5.0.

**dir\_mode / mode** The permissions mode to set any directories created. Not supported on Windows

**file\_mode** The permissions mode to set any files created if `'mode'` is run in `'recurse'`. This defaults to `dir_mode`. Not supported on Windows

**makedirs** If the directory is located in a path without a parent directory, then the state will fail. If `makedirs` is set to `True`, then the parent directories will be created to facilitate the creation of the named file.

**clean** Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.

**require** Require other resources such as packages or files

**exclude\_pat** When `'clean'` is set to `True`, exclude this pattern from removal list and preserve in the destination.

**follow\_symlinks** [False] If the desired path is a symlink (or `recurse` is defined and a symlink is encountered while recursing), follow it and check the permissions of the directory/file to which the symlink points.

New in version 2014.1.4.

**force** If the name of the directory exists and is not a directory and force is set to False, the state will fail. If force is set to True, the file in the way of the directory will be deleted to make room for the directory, unless backupname is set, then it will be renamed.

New in version 2014.7.0.

**backupname** If the name of the directory exists and is not a directory, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

New in version 2014.7.0.

**allow\_symlink** [True] If allow\_symlink is True and the specified path is a symlink, it will be allowed to remain if it points to a directory. If allow\_symlink is False then the state will fail, unless force is also set to True, in which case it will be removed or renamed, depending on the value of the backupname argument.

New in version 2014.7.0.

`salt.states.file.exists`(*name*)

Verify that the named file or directory is present or exists. Ensures pre-requisites outside of Salt's purview (e.g., keytabs, private keys, etc.) have been previously satisfied before deployment.

**name** Absolute path which must exist

`salt.states.file.managed`(*name*, *source=None*, *source\_hash='`*, *user=None*, *group=None*, *mode=None*, *template=None*, *makedirs=False*, *dir\_mode=None*, *context=None*, *replace=True*, *defaults=None*, *env=None*, *backup='`*, *show\_diff=True*, *create=True*, *contents=None*, *contents\_pillar=None*, *contents\_grains=None*, *contents\_newline=True*, *follow\_symlinks=True*, *check\_cmd=None*, *\*\*kwargs*)

Manage a given file, this function allows for a file to be downloaded from the salt master and potentially run through a templating system.

**name** The location of the file to manage

**source** The source file to download to the minion, this source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see `s3.get` state documentation) File retrieval from Openstack Swift object storage is supported via `swift://container/object_path` URLs, see `swift.get` documentation. For files hosted on the salt file server, if the file is located on the master in the directory named `spam`, and is called `eggs`, the source string is `salt://spam/eggs`. If source is left blank or None (use `~` in YAML), the file will be created as an empty file and the content will not be managed

If the file is hosted on a HTTP or FTP server then the `source_hash` argument is also required

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored.

```
file_override_example:
  file.managed:
    - source:
      - salt://file_that_does_not_exist
      - salt://file_that_exists
```

**source\_hash**

This can be one of the following:

1. a source hash string

## 2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

Type	Length
sha512	128
sha384	96
sha256	64
sha224	56
sha1	40
md5	32

**Using a Source Hash File** The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

When using a source hash file the `source_hash` argument needs to be a url, the standard download urls are supported, ftp, http, salt etc:

Example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.ta
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7
```

The following is an example of the supported `source_hash` format:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f0233be91c151178b30f0dff8ebbdcc8de71b1d5c8bcc06a /etc/resolv.con
ead48423703509d37c4a90e6a0d53e143b6fc268
```

Debian file type `*.dsc` files are also supported.

**Inserting the Source Hash in the sls Data** Examples:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.ta
    - source_hash: md5=79eef25f9b0b2c642c62b7f737d4f53f
```

**Known issues:** If the remote server URL has the hash file as an apparent sub-directory of the source file, the module will discover that it has already cached a directory where a file should be cached. For example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.ta
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7
```

**user** The user to own the file, this defaults to the user salt is running as on the minion

**group** The group ownership set for the file, this defaults to the group salt is running as on the minion On Windows, this is ignored

**mode** The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows

- template** If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported
- makedirs** If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file.
- dir\_mode** If directories are to be created, passing this option specifies the permissions for those directories. If this is not set, directories will be assigned permissions from the `mode` argument.
- replace** If this file should be replaced. If false, this command will not overwrite file contents but will enforce permissions if the file exists already. Default is True.
- context** Overrides default context variables passed to the template.
- defaults** Default context passed to the template.
- backup** Overrides the default backup mode for this specific file.
- show\_diff** If set to False, the diff will not be shown.
- create** Default is True, if create is set to False then the file will only be managed if the file already exists on the system.
- contents** Default is None. If specified, will use the given string as the contents of the file. Should not be used in conjunction with a source file of any kind. Ignores hashes and does not use a templating engine.
- contents\_pillar** New in version 0.17.0.

Operates like `contents`, but draws from a value stored in pillar, using the pillar path syntax used in `pillar.get`. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

For example, the following could be used to deploy an SSH private key:

```
/home/deployer/.ssh/id_rsa:
  file.managed:
    - user: deployer
    - group: deployer
    - mode: 600
    - contents_pillar: userdata:deployer:id_rsa
```

This would populate `/home/deployer/.ssh/id_rsa` with the contents of `pillar['userdata']['deployer']['id_rsa']`. An example of this pillar setup would be like so:

```
userdata:
  deployer:
    id_rsa: |
      -----BEGIN RSA PRIVATE KEY-----
      MIIEowIBAAKCAQEAOQiwO3JhBquPAa1QF9qP11LZXVjYMIswrMe2HcWUVBgh+vY
      U7sCwx/dH6+VvNwmCoqmNnP+8gTPKGL1vgA0bJAnMT623dMXjVKwnEagZPRJIXDy
      B/HaAre9euNiY3LvIzBTRSeMfT+rWvIKVBpvwlgGrfgz70m0pqxu+UyFbAGLin+
      GpxzZAMaFpZw4sSbIlRuissXZj/sHpQb8p9M5Ie04Z3rjkCP1cxI
      -----END RSA PRIVATE KEY-----
```

---

**Note:** The private key above is shortened to keep the example brief, but shows how to do multiline string in YAML. The key is followed by a pipe character, and the multiline string is indented two more spaces.

---

**contents\_grains** New in version 2014.7.0.

Same as `contents_pillar`, but with grains

**contents\_newline** New in version 2014.7.0.

When using `contents`, `contents_pillar`, or `contents_grains`, this option ensures the file will have a newline at the end. When loading some data this newline is better left off. Setting `contents_newline` to `False` will omit this final newline.

**follow\_symlinks** [True] New in version 2014.7.0.

If the desired path is a symlink follow it and make changes to the file to which the symlink points.

**check\_cmd** New in version 2014.7.0.

The specified command will be run with the managed file as an argument. If the command exits with a nonzero exit code, the command will not be run.

`salt.states.file.missing`(*name*)

Verify that the named file or directory is missing, this returns `True` only if the named file is missing but does not remove the file if it is present.

**name** Absolute path which must NOT exist

`salt.states.file.mknod`(*name*, *ntype*, *major=0*, *minor=0*, *user=None*, *group=None*, *mode='0600'*)

Create a special file similar to the ``nix mknod` command. The supported device types are `p` (fifo pipe), `c` (character device), and `b` (block device). Provide the major and minor numbers when specifying a character device or block device. A fifo pipe does not require this information. The command will create the necessary dirs if needed. If a file of the same name not of the same type/major/minor exists, it will not be overwritten or unlinked (deleted). This is logically in place as a safety measure because you can really shoot yourself in the foot here and it is the behavior of ``nix mknod`. It is also important to note that not just anyone can create special devices. Usually this is only done as root. If the state is executed as none other than root on a minion, you may receive a permission error.

**name** name of the file

**ntype** node type ``p'` (fifo pipe), ``c'` (character device), or ``b'` (block device)

**major** major number of the device does not apply to a fifo pipe

**minor** minor number of the device does not apply to a fifo pipe

**user** owning user of the device/pipe

**group** owning group of the device/pipe

**mode** permissions on the device/pipe

Usage:

```
/dev/chr:
  file.mknod:
    - ntype: c
    - major: 180
    - minor: 31
    - user: root
    - group: root
    - mode: 660

/dev/blk:
  file.mknod:
    - ntype: b
    - major: 8
    - minor: 999
    - user: root
```

```

- group: root
- mode: 660

/dev/fifo:
  file.mknod:
    - ntype: p
    - user: root
    - group: root
    - mode: 660

```

New in version 0.17.0.

`salt.states.file.mod_run_check_cmd(cmd, filename, **check_cmd_opts)`  
Execute the `check_cmd` logic.

Return a result dict if `check_cmd` succeeds (`check_cmd == 0`) otherwise return `True`

`salt.states.file.patch(name, source=None, hash=None, options='', dry_run_first=True, env=None, **kwargs)`

Apply a patch to a file.

---

**Note:** A suitable `patch` executable must be available on the minion when using this state function.

---

**name** The file to which the patch will be applied.

**source** The source patch to download to the minion, this source file must be hosted on the salt master server. If the file is located in the directory named `spam`, and is called `eggs`, the source string is `salt://spam/eggs`. A source is required.

**hash** Hash of the patched file. If the hash of the target file matches this value then the patch is assumed to have been applied. The hash string is the hash algorithm followed by the hash of the file:  
`md5=e138491e9d5b97023cea823fe17bac22`

**options** Extra options to pass to patch.

**dry\_run\_first** [True] Run patch with `--dry-run` first to check if it will apply cleanly.

**env** Specify the environment from which to retrieve the patch file indicated by the `source` parameter. If not provided, this defaults to the environment from which the state is being executed.

Usage:

```

# Equivalent to ``patch --forward /opt/file.txt file.patch``
/opt/file.txt:
  file.patch:
    - source: salt://file.patch
    - hash: md5=e138491e9d5b97023cea823fe17bac22

```

`salt.states.file.prepend(name, text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None)`

Ensure that some text appears at the beginning of a file

The text will not be prepended again if it already exists in the file. You may specify a single line of text or a list of lines to append.

Multi-line example:

```

/etc/motd:
  file.prepend:

```

```
- text: |
    Thou hadst better eat salt with the Philosophers of Greece,
    than sugar with the Courtiers of Italy.
    - Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
  file.prepend:
    - text:
      - Trust no one unless you have eaten much salt with him.
      - "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```
/etc/motd:
  file:
    - prepend
    - template: jinja
    - sources:
      - salt://motd/devops-messages.tpl
      - salt://motd/hr-messages.tpl
      - salt://motd/general-messages.tpl
```

New in version 2014.7.0.

**salt.states.file.recurse**(*name*, *source*, *clean*=False, *require*=None, *user*=None, *group*=None, *dir\_mode*=None, *file\_mode*=None, *sym\_mode*=None, *template*=None, *context*=None, *defaults*=None, *env*=None, *include\_empty*=False, *backup*='', *include\_pat*=None, *exclude\_pat*=None, *maxdepth*=None, *keep\_symlinks*=False, *force\_symlinks*=False, *\*\*kwargs*)

Recurse through a subdirectory on the master and copy said subdirectory over to the specified path.

**name** The directory to set the recursion in

**source** The source directory, this directory is located on the salt master file server and is specified with the salt:// protocol. If the directory is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

**clean** Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.

**require** Require other resources such as packages or files

**user** The user to own the directory. This defaults to the user salt is running as on the minion

**group** The group ownership set for the directory. This defaults to the group salt is running as on the minion. On Windows, this is ignored

**dir\_mode** The permissions mode to set on any directories created. Not supported on Windows

**file\_mode** The permissions mode to set on any files created. Not supported on Windows

**sym\_mode** The permissions mode to set on any symlink created. Not supported on Windows

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Supported templates are: *jinja*, *mako* and *wempy*.

---

**Note:** The template option is required when recursively applying templates.

---

**context** Overrides default context variables passed to the template.

**defaults** Default context passed to the template.

**include\_empty** Set this to True if empty directories should also be created (default is False)

**include\_pat** When copying, include only this pattern from the source. Default is glob match; if prefixed with 'E@', then regexp match. Example:

```
- include_pat: hello*      :: glob matches 'hello01', 'hello02'
                          ... but not 'otherhello'
- include_pat: E@hello    :: regexp matches 'otherhello',
                          'hello01' ...
```

**exclude\_pat** Exclude this pattern from the source when copying. If both *include\_pat* and *exclude\_pat* are supplied, then it will apply conditions cumulatively. i.e. first select based on *include\_pat*, and then within that result apply *exclude\_pat*.

Also, when `clean=True`, exclude this pattern from the removal list and preserve in the destination. Example:

```
- exclude_pat: APPDATA*      :: glob matches APPDATA.01,
                              APPDATA.02,.. for exclusion
- exclude_pat: E@(APPDATA) | (TEMPDATA) :: regexp matches APPDATA
                                          or TEMPDATA for exclusion
```

**maxdepth** When copying, only copy paths which are of depth *maxdepth* from the source path. Example:

```
- maxdepth: 0      :: Only include files located in the source
                    directory
- maxdepth: 1      :: Only include files located in the source
                    or immediate subdirectories
```

**keep\_symlinks** Keep symlinks when copying from the source. This option will cause the copy operation to terminate at the symlink. If desire behavior similar to `rsync`, then set this to True.

**force\_symlinks** Force symlink creation. This option will force the symlink creation. If a file or directory is obstructing symlink creation it will be recursively removed so that symlink creation can proceed. This option is usually not needed except in special circumstances.

`salt.states.file.rename`(*name*, *source*, *force=False*, *makedirs=False*)

If the source file exists on the system, rename it to the named file. The named file will not be overwritten if it already exists unless the *force* option is set to True.

**name** The location of the file to rename to

**source** The location of the file to move to the location specified with *name*

**force** If the target location is present then the file will not be moved, specify `force: True` to overwrite the target file

**makedirs** If the target subdirectories don't exist create them

`salt.states.file.replace`(*name*, *pattern*, *repl*, *count=0*, *flags=8*, *bufsize=1*, *append\_if\_not\_found=False*, *prepend\_if\_not\_found=False*, *not\_found\_content=None*, *backup='.bak'*, *show\_changes=True*)

Maintain an edit in a file.

New in version 0.17.0.

**name** Filesystem path to the file to be edited.

**pattern** Python's [regular expression](#) search.

**repl** The replacement text.

**count** Maximum number of pattern occurrences to be replaced. Defaults to 0. If count is a positive integer n, no more than n occurrences will be replaced, otherwise all occurrences will be replaced.

**flags** A list of flags defined in the [re module documentation](#). Each list item should be a string that will correlate to the human-friendly flag name. E.g., [ 'IGNORECASE', 'MULTILINE' ]. Optionally, flags may be an int, with a value corresponding to the XOR (|) of all the desired flags. Defaults to 8 (which supports 'MULTILINE').

**bufsize** How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value `file` may be specified which will read the entire file into memory before processing.

**append\_if\_not\_found** If pattern is not found and set to `True` then, the content will be appended to the file.

New in version 2014.7.0.

**prepend\_if\_not\_found** If pattern is not found and set to `True` then, the content will be prepended to the file.

New in version 2014.7.0.

**not\_found\_content** Content to use for append/prepend if not found. If `None` (default), uses `repl`. Useful when `repl` uses references to group in pattern.

New in version 2014.7.0.

**backup** The file extension to use for a backup of the file before editing. Set to `False` to skip making a backup.

**show\_changes** Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made. Returns a boolean or a string.

For complex regex patterns it can be useful to avoid the need for complex quoting and escape sequences by making use of YAML's multiline string syntax.

```
complex_search_and_replace:
  file.replace:
    # <...snip...>
    - pattern: |
      CentOS \((2.6.32[^\n]+\n\s+root[^\n]+\n\)+
```

**Note:** When using YAML multiline string syntax in `pattern:`, make sure to also use that syntax in the `repl:` part, or you might lose line feeds.

`salt.states.file.serialize`(*name*, *dataset=None*, *dataset\_pillar=None*, *user=None*, *group=None*, *mode=None*, *env=None*, *backup=''*, *makedirs=False*, *show\_diff=True*, *create=True*, *merge\_if\_exists=False*, *\*\*kwargs*)

Serializes dataset and store it into managed file. Useful for sharing simple configuration files.

**name** The location of the file to create

**dataset** The dataset that will be serialized

**dataset\_pillar** Operates like `dataset`, but draws from a value stored in pillar, using the pillar path syntax used in `pillar.get`. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

New in version FIXME.

**formatter** Write the data as this format. Supported output formats:

- JSON
- YAML
- Python (via `pprint.pformat`)

**user** The user to own the directory, this defaults to the user salt is running as on the minion

**group** The group ownership set for the directory, this defaults to the group salt is running as on the minion

**mode** The permissions to set on this file, aka 644, 0775, 4664

**backup** Overrides the default backup mode for this specific file.

**makedirs** Create parent directories for destination file.

New in version 2014.1.3.

**show\_diff** If set to False, the diff will not be shown.

**create** Default is True, if create is set to False then the file will only be managed if the file already exists on the system.

**merge\_if\_exists** Default is False, if merge\_if\_exists is True then the existing file will be parsed and the dataset passed in will be merged with the existing content

New in version 2014.7.0.

For example, this state:

```
/etc/dummy/package.json:
  file.serialize:
    - dataset:
      name: naive
      description: A package using naive versioning
      author: A confused individual <iam@confused.com>
      dependencies:
        express: >= 1.2.0
        optimist: >= 0.1.0
      engine: node 0.4.1
    - formatter: json
```

will manage the file /etc/dummy/package.json:

```
{
  "author": "A confused individual <iam@confused.com>",
  "dependencies": {
    "express": ">= 1.2.0",
    "optimist": ">= 0.1.0"
  },
  "description": "A package using naive versioning",
  "engine": "node 0.4.1",
  "name": "naive"
}
```

`salt.states.file.symlink`(*name, target, force=False, backupname=None, makedirs=False, user=None, group=None, mode=None, \*\*kwargs*)

Create a symlink

If the file already exists and is a symlink pointing to any location other than the specified target, the symlink will be replaced. If the symlink is a regular file or directory then the state will return False. If the regular file or directory is desired to be replaced with a symlink pass force: True, if it is to be renamed, pass a backupname.

**name** The location of the symlink to create

**target** The location that the symlink points to

**force** If the name of the symlink exists and is not a symlink and force is set to False, the state will fail. If force is set to True, the file or directory in the way of the symlink file will be deleted to make room for the symlink, unless backupname is set, when it will be renamed

**backupname** If the name of the symlink exists and is not a symlink, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

**makedirs** If the location of the symlink does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory

**user** The user to own the file, this defaults to the user salt is running as on the minion

**group** The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored

**mode** The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows

`salt.states.file.touch` (*name*, *atime=None*, *mtime=None*, *makedirs=False*)

Replicate the `nix ``touch` command to create a new empty file or update the atime and mtime of an existing file.

Note that if you just want to create a file and don't care about atime or mtime, you should use `file.managed` instead, as it is more feature-complete. (Just leave out the `source/template/contents` arguments, and it will just create the file and/or check its permissions, without messing with contents)

**name** name of the file

**atime** atime of the file

**mtime** mtime of the file

**makedirs** whether we should create the parent directory/directories in order to touch the file

Usage:

```
/var/log/httpd/logrotate.empty:
  file.touch
```

New in version 0.9.5.

`salt.states.file.uncomment` (*name*, *regex*, *char='#'*, *backup='.bak'*)

Uncomment specified commented lines in a file

**name** The full path to the file to be edited

**regex** A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading ^ character will be stripped for convenience (for easily switching between `comment()` and `uncomment()`). The regex will be searched for from the beginning of the line, ignoring leading spaces (we prepend `^[ t]*`)

**char** [#] The character to remove in order to uncomment a line

**backup** [.bak] The file will be backed up before edit with this file extension;

**Warning:** This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

Usage:

```
/etc/adduser.conf:
  file.uncomment:
    - regex: EXTRA_GROUPS
```

New in version 0.9.5.

### 30.27.37 salt.states.gem

#### Installation of Ruby modules packaged as gems

A state module to manage rubygems. Gems can be set up to be installed or removed. This module will use RVM or rbenv if they are installed. In that case, you can specify what ruby version and gemset to target.

```
addressable:
  gem.installed:
    - user: rvm
    - ruby: jruby@jgemset
```

`salt.states.gem.installed` (*name*, *ruby=None*, *gem\_bin=None*, *user=None*, *version=None*, *rdoc=False*, *ri=False*, *pre\_releases=False*, *proxy=None*)

Make sure that a gem is installed.

**name** The name of the gem to install

**ruby:** **None** Only for RVM or rbenv installations: the ruby version and gemset to target.

**gem\_bin:** **None** Custom gem command to run instead of the default. Use this to install gems to a non-default ruby install. If you are using rvm or rbenv use the ruby argument instead.

**user:** **None** The user under which to run the gem command

New in version 0.17.0.

**version** [None] Specify the version to install for the gem. Doesn't play nice with multiple gems at once

**rdoc** [False] Generate RDoc documentation for the gem(s).

**ri** [False] Generate RI documentation for the gem(s).

**pre\_releases** [False] Install pre-release version of gem(s) if available.

**proxy** [None] Use the specified HTTP proxy server for all outgoing traffic. Format: `http://hostname[:port]`

`salt.states.gem.removed` (*name*, *ruby=None*, *user=None*, *gem\_bin=None*)

Make sure that a gem is not installed.

**name** The name of the gem to uninstall

**gem\_bin** [None] Full path to gem binary to use.

**ruby** [None] If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if `gem_bin` is specified.

**user:** **None** The user under which to run the gem command

New in version 0.17.0.

### 30.27.38 salt.states.git

#### Interaction with Git repositories

Important: Before using git over ssh, make sure your remote host fingerprint exists in ``~/.ssh/known\_hosts`` file. To avoid requiring password authentication, it is also possible to pass private keys to use explicitly.

```
https://github.com/saltstack/salt.git:
git.latest:
- rev: develop
- target: /tmp/salt
```

`salt.states.git.config`(*name*, *value*, *repo=None*, *user=None*, *is\_global=False*)

New in version 2014.7.0.

Manage a git config setting for a user or repository

**name** Name of the git config value to set

**value** Value to set

**repo** [None] An optional location of a git repository for local operations

**user** [None] Optional name of a user as whom *git config* will be run

**is\_global** [False] Whether or not to pass the *--global* option to *git config*

Local config example:

```
mylocalrepo:
git.config:
- name: user.email
- value: fester@bestertester.net
- repo: file://my/path/to/repo
```

Global config example:

```
mylocalrepo:
git.config:
- name: user.name
- value: Esther Bestertester
- user: ebestertester
- is_global: True
```

`salt.states.git.latest`(*name*, *rev=None*, *target=None*, *user=None*, *force=None*, *force\_checkout=False*, *force\_reset=False*, *submodules=False*, *mirror=False*, *bare=False*, *remote\_name='origin'*, *always\_fetch=False*, *depth=None*, *identity=None*, *https\_user=None*, *https\_pass=None*, *onlyif=False*, *unless=False*)

Make sure the repository is cloned to the given directory and is up to date

**name** Address of the remote repository as passed to `git clone`

**rev** The remote branch, tag, or revision ID to checkout after clone / before update

**target** Name of the target directory where repository is about to be cloned

**user** Name of the user performing repository management operations

New in version 0.17.0.

**force** Force git to clone into pre-existing directories (deletes contents)

**force\_checkout** Force a checkout even if there might be overwritten changes (Default: False)

**force\_reset** Force the checkout to `--reset hard` to the remote ref (Default: False)

**submodules** Update submodules on clone or branch change (Default: False)

**mirror** True if the repository is to be a mirror of the remote repository. This implies bare, and thus is incompatible with rev.

**bare** True if the repository is to be a bare clone of the remote repository. This is incompatible with `rev`, as nothing will be checked out.

**remote\_name** defines a different remote name. For the first clone the given name is set to the default remote, else it is just a additional remote. (Default: ``origin``)

**always\_fetch** If a tag or branch name is used as the `rev` a fetch will not occur until the tag or branch name changes. Setting this to true will force a fetch to occur. Only applies when `rev` is set. (Default: False)

**depth** Defines depth in history when git a clone is needed in order to ensure latest. E.g. `depth: 1` is usefull when deploying from a repository with a long history. Use `rev` to specify branch. This is not compatible with tags or revision IDs.(Default: None)

**identity** A path on the minion server to a private key to use over SSH

**https\_user** HTTP Basic Auth username for HTTPS (only) clones

New in version 2015.5.0.

**https\_pass** HTTP Basic Auth password for HTTPS (only) clones

New in version 2015.5.0.

**onlyif** A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true

**unless** A command to run as a check, only run the named command if the command passed to the `unless` option returns false

---

**Note:** Clashing ID declarations can be avoided when including different branches from the same git repository in the same `sls` file by using the `name` declaration. The example below checks out the `gh-pages` and `gh-pages-prod` branches from the same repository into separate directories. The example also sets up the `ssh_known_hosts` ssh key required to perform the git checkout.

---

```
gitlab.example.com:
  ssh_known_hosts:
    - present
    - user: root
    - enc: ecdsa
    - fingerprint: 4e:94:b0:54:c1:5b:29:a2:70:0e:e1:a3:51:ee:ee:e3

git-website-staging:
  git.latest:
    - name: git@gitlab.example.com:user/website.git
    - rev: gh-pages
    - target: /usr/share/nginx/staging
    - identity: /root/.ssh/website_id_rsa
    - require:
      - pkg: git
      - ssh_known_hosts: gitlab.example.com

git-website-prod:
  git.latest:
    - name: git@gitlab.example.com:user/website.git
    - rev: gh-pages-prod
    - target: /usr/share/nginx/prod
    - identity: /root/.ssh/website_id_rsa
    - require:
      - pkg: git
      - ssh_known_hosts: gitlab.example.com
```

`salt.states.git.mod_run_check`(*cmd\_kwargs, onlyif, unless*)  
 Execute the onlyif and unless logic. Return a result dict if: \* onlyif failed (onlyif != 0) \* unless succeeded (unless == 0) else return True

`salt.states.git.present`(*name, bare=True, user=None, force=False, shared=None*)  
 Make sure the repository is present in the given directory

**name** Name of the directory where the repository is about to be created

**bare** Create a bare repository (Default: True)

**user** Name of the user performing repository management operations

New in version 0.17.0.

**force** Force-create a new repository into an pre-existing non-git directory (deletes contents)

**shared**

Specify the permission for sharing, see git-init for details (Default: None)

New in version 2015.5.0.

### 30.27.39 salt.states.glusterfs

Manage glusterfs pool.

`salt.states.glusterfs.add_volume_bricks`(*name, bricks*)  
 Add brick(s) to an existing volume

**name** Volume name

**bricks** List of bricks to add to the volume

myvolume:

glusterfs.add\_volume\_bricks:

- bricks:
  - host1:/srv/gluster/drive1
  - host2:/srv/gluster/drive2

Replicated Volume:

glusterfs.add\_volume\_bricks:

- name: volume2
- bricks: - host1:/srv/gluster/drive2 - host2:/srv/gluster/drive3

`salt.states.glusterfs.created`(*name, bricks, stripe=False, replica=False, device\_vg=False, transport='tcp', start=False*)

Check if volume already exists

**name** name of the volume

```
myvolume:
  glusterfs.created:
    - bricks:
      - host1:/srv/gluster/drive1
      - host2:/srv/gluster/drive2
```

```
Replicated Volume:
  glusterfs.created:
    - name: volume2
    - bricks:
      - host1:/srv/gluster/drive2
      - host2:/srv/gluster/drive3
    - replica: 2
    - start: True
```

**salt.states.glusterfs.peered**(*name*)

Check if node is peered.

**name** The remote host with which to peer.

```
peer-cluster:
  glusterfs.peered:
    - name: two

peer-clusters:
  glusterfs.peered:
    - names:
      - one
      - two
      - three
      - four
```

**salt.states.glusterfs.started**(*name*)

Check if volume has been started

**name** name of the volume

```
mycluster:
  glusterfs.started: []
```

### 30.27.40 salt.states.gnomedesktop

#### Configuration of the GNOME desktop

Control the GNOME settings

```
localdesktop_wm_prefs:
  gnomedesktop.wm_preferences:
    - user: username
    - audible_bell: false
    - action_double_click_titlebar: 'toggle-maximize'
    - visual_bell: true
    - num_workspaces: 6
localdesktop_lockdown:
  gnomedesktop.desktop_lockdown:
    - user: username
    - disable_user_switching: true
localdesktop_interface:
  gnomedesktop.desktop_interface:
    - user: username
    - clock_show_date: true
    - clock_format: 12h
```

```

salt.states.gnomedesktop.desktop_interface(name, user=None, auto-
    matic_mnemonics=None,
    buttons_have_icons=None,
    can_change_accels=None,
    clock_format=None, clock_show_date=None,
    clock_show_seconds=None, cursor_
    blink=None, cursor_blink_time=None,
    cursor_blink_timeout=None, cursor_
    size=None, cursor_theme=None,

```

### 30.27.41 salt.states.grafana

Manage Grafana Dashboards

This module uses `elasticsearch`, which can be installed via package, or pip.

You can specify elasticsearch hosts directly to the module, or you can use an elasticsearch profile via pillars:

```

mygrafanaprofile:
  hosts:
    - es1.example.com:9200
    - es2.example.com:9200
  index: grafana-dash

```

```

# Basic usage (uses default pillar profile key 'grafana')
Ensure myservice dashboard is managed:
grafana.dashboard_present:
  - name: myservice
  - dashboard_from_pillar: default
  - rows_from_pillar:
    - systemhealth
    - requests

# Passing hosts in
Ensure myservice dashboard is managed:
grafana.dashboard_present:
  - name: myservice
  - dashboard_from_pillar: default
  - rows:
    - collapse: false
      editable: true
      height: 150px
      title: System Health
      panels:
        - aliasColors: {}
          id: 200000
          annotate:
            enable: false
          bars: false

```

```

datasource: null
editable: true
error: false
fill: 7
grid:
  leftMax: 100
  leftMin: null
  rightMax: null
  rightMin: null
  threshold1: 60
  threshold1Color: rgb(216, 27, 27)
  threshold2: null
  threshold2Color: rgba(234, 112, 112, 0.22)

        to: now
        timezone: browser
  - rows_from_pillars:
    - systemhealth
```

```
- requests
- profile: mygrafanaprofile
```

The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

`salt.states.grafana.dashboard_absent` (*name*, *hosts=None*, *profile='grafana'*)

Ensure the named grafana dashboard is deleted.

**name** Name of the grafana dashboard.

**profile** A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

`salt.states.grafana.dashboard_present` (*name*, *dashboard=None*, *dashboard\_from\_pillar=None*,  
*rows=None*, *rows\_from\_pillar=None*, *profile='grafana'*)

Ensure the grafana dashboard exists and is managed.

**name** Name of the grafana dashboard.

**dashboard** A dict that defines a dashboard that should be managed.

**dashboard\_from\_pillar** A pillar key that contains a grafana dashboard dict. Mutually exclusive with dashboard.

**rows** A list of grafana rows.

**rows\_from\_pillar** A list of pillar keys that contain lists of grafana dashboard rows. Rows defined in the pillars will be appended to the rows defined in the state.

**profile** A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

### 30.27.42 salt.states.grains

#### Manage grains on the minion

This state allows for grains to be set. Grains set or altered this way are stored in the `grains` file on the minions, by default at: `/etc/salt/grains`

Note: This does NOT override any grains set in the minion file.

`salt.states.grains.absent` (*name*, *destructive=False*)

New in version 2014.7.0.

Delete a grain from the grains config file

**name** The grain name

**Parameters destructive** -- If destructive is True, delete the entire grain. If destructive is False, set the grain's value to None. Defaults to False.

```
grain_name:
  grains.absent
```

`salt.states.grains.append` (*name*, *value*, *convert=False*)

New in version 2014.7.0.

Append a value to a list in the grains config file

**name** The grain name

**value** The value to append

**Parameters** **convert** -- If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.

```
grain_name:
  grains.append:
    - value: to_be_appended
```

**salt.states.grains.list\_absent**(*name*, *value*)

Delete a value from a grain formed as a list.

New in version 2014.1.0.

**name** The grain name.

**value** The value to delete from the grain list.

The grain should be [list type](#)

```
roles:
  grains.list_absent:
    - value: db
```

For multiple grains, the syntax looks like:

```
roles:
  grains.list_absent:
    - value:
      - web
      - dev
```

**salt.states.grains.list\_present**(*name*, *value*)

New in version 2014.1.0.

Ensure the value is present in the list type grain.

**name** The grain name.

**value** The value is present in the list type grain.

The grain should be [list type](#)

```
roles:
  grains.list_present:
    - value: web
```

For multiple grains, the syntax looks like:

```
roles:
  grains.list_present:
    - value:
      - web
      - dev
```

**salt.states.grains.present**(*name*, *value*)

Ensure that a grain is set

**name** The grain name

**value** The value to set on the grain

If the grain with the given name exists, its value is updated to the new value. If the grain does not yet exist, a new grain is set to the given value.

```
cheese:
  grains.present:
    - value: edam
```

### 30.27.43 salt.states.group

#### Management of user groups

The group module is used to create and manage unix group settings, groups can be either present or absent:

```
cheese:
  group.present:
    - gid: 7648
    - system: True
    - addusers:
      - user1
      - users2
    - delusers:
      - foo
```

```
cheese:
  group.present:
    - gid: 7648
    - system: True
    - members:
      - foo
      - bar
      - user1
      - user2
```

`salt.states.group.absent`(*name*)

Ensure that the named group is absent

**name** The name of the group to remove

`salt.states.group.present`(*name*, *gid=None*, *system=False*, *addusers=None*, *delusers=None*, *members=None*)

Ensure that a group is present

**name** The name of the group to manage

**gid** The group id to assign to the named group; if left empty, then the next available group id will be assigned

**system** Whether or not the named group is a system group. This is essentially the `-r` option of `groupadd`.

**addusers** List of additional users to be added as a group members.

**delusers** Ensure these user are removed from the group membership.

**members** Replace existing group members with a list of new members.

**Note:** Options `members` and `addusers/delusers` are mutually exclusive and can not be used together.

### 30.27.44 salt.states.hg

#### Interaction with Mercurial repositories

Before using hg over ssh, make sure the remote host fingerprint already exists in ~/.ssh/known\_hosts, and the remote host has this host's public key.

```
https://bitbucket.org/example_user/example_repo:
hg.latest:
  - rev: tip
  - target: /tmp/example_repo
```

`salt.states.hg.latest`(*name*, *rev=None*, *target=None*, *clean=False*, *user=None*, *identity=None*, *force=False*, *opts=False*)

Make sure the repository is cloned to the given directory and is up to date

**name** Address of the remote repository as passed to ``hg clone``

**rev** The remote branch, tag, or revision hash to clone/pull

**target** Target destination directory path on minion to clone into

**clean** Force a clean update with -C (Default: False)

**user** Name of the user performing repository management operations

New in version 0.17.0.

**identity** Private SSH key on the minion server for authentication (ssh://)

New in version 2015.5.0.

**force** Force hg to clone into pre-existing directories (deletes contents)

**opts** Include additional arguments and options to the hg command line

### 30.27.45 salt.states.hipchat

#### Send a message to Hipchat

This state is useful for sending messages to Hipchat during state runs.

New in version 2015.5.0.

```
hipchat-message:
  hipchat.send_message:
    - room_id: 123456
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
    - api_version: v1
```

The api key can be specified in the master or minion configuration like below: .. code-block:: yaml

```
hipchat: api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version: v1
```

`salt.states.hipchat.send_message`(*name*, *room\_id*, *from\_name*, *message*, *api\_key=None*, *api\_version=None*, *message\_color='yellow'*, *notify=False*)

Send a message to a Hipchat room.

```

hipchat-message:
  hipchat.send_message:
    - room_id: 123456
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
    - api_version: v1
    - color: green
    - notify: True

```

The following parameters are required:

**name** The unique name for this event.

**room\_id** The room to send the message to. Can either be the ID or the name.

**from\_name** The name of that is to be shown in the ``from" field. If not specified, defaults to.

**message** The message that is to be sent to the Hipchat room.

The following parameters are optional:

**api\_key** The api key for Hipchat to use for authentication, if not specified in the configuration options of master or minion.

**api\_version** The api version for Hipchat to use, if not specified in the configuration options of master or minion.

**color** The color the Hipchat message should be displayed in. One of the following, default: yellow ``yellow", ``red", ``green", ``purple", ``gray", or ``random".

**notify** Should a notification in the room be raised.

### 30.27.46 salt.states.host

#### Management of addresses and names in hosts file

The `/etc/hosts` file can be managed to contain definitions for specific hosts:

```

salt-master:
  host.present:
    - ip: 192.168.0.42

```

Or using the `names` directive, you can put several names for the same IP. (Do not try one name with space-separated values).

```

server1:
  host.present:
    - ip: 192.168.0.42
    - names:
      - server1
      - florida

```

**Note:** Changing the names in `host.present` does not cause an update to remove the old entry.

```
server1:
  host.present:
    - ip:
      - 192.168.0.42
      - 192.168.0.43
      - 192.168.0.44
    - names:
      - server1
```

`salt.states.host.absent`(*name*, *ip*)

Ensure that the named host is absent

**name** The host to remove

**ip** The ip addr(s) of the host to remove

`salt.states.host.present`(*name*, *ip*)

Ensures that the named host is present with the given ip

**name** The host to assign an ip to

**ip** The ip addr(s) to apply to the host

### 30.27.47 salt.states.htpasswd

Support for htpasswd module

New in version 2014.7.0.

```
username:
  webutil.user_exists:
    - password: secr3t
    - htpasswd_file: /etc/nginx/htpasswd
    - options: d
    - force: true
```

`salt.states.htpasswd.user_exists`(*name*, *password=None*, *htpasswd\_file=None*, *options=''*,  
*force=False*, *runas=None*)

Make sure the user is inside the specified htpasswd file

**name** User name

**password** User password

**htpasswd\_file** Path to the htpasswd file

**options** See `salt.modules.htpasswd.useradd`

**force** Touch the file even if user already created

**runas** The system user to run htpasswd command with

### 30.27.48 salt.states.http

HTTP monitoring states

Perform an HTTP query and statefully return the result

New in version 2015.5.0.

`salt.states.http.query` (*name*, *match=None*, *match\_type='string'*, *status=None*, *\*\*kwargs*)  
 Perform an HTTP query and statefully return the result

New in version 2015.5.0.

### 30.27.49 salt.states.incron

#### Management of incron, the inotify cron

The incron state module allows for user incrontabs to be cleanly managed.

Incron declarations require a number of parameters. The parameters needed to be declared: `path`, `mask`, and `cmd`. The `user` whose incrontab is to be edited also needs to be defined.

When making changes to an existing incron job, the `path` declaration is the unique factor, so if an existing cron that looks like this:

```
Watch for modifications in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask:
      - IN_MODIFY
    - cmd: 'echo "$$ $@"'
```

Is changed to this:

```
Watch for modifications and access in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask:
      - IN_MODIFY
      - IN_ACCESS
    - cmd: 'echo "$$ $@"'
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

New in version 0.17.0.

`salt.states.incron.absent` (*name*, *path*, *mask*, *cmd*, *user='root'*)

Verifies that the specified incron job is absent for the specified user; only the name is matched when removing a incron job.

**name** Unique comment describing the entry

**path** The path that should be watched

**user** The name of the user who's crontab needs to be modified, defaults to the root user

**mask** The mask of events that should be monitored for

**cmd** The cmd that should be executed

`salt.states.incron.present` (*name*, *path*, *mask*, *cmd*, *user='root'*)

Verifies that the specified incron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your incron system's documentation. Most Unix-like systems' incron documentation can be found via the incrontab man page: `man 5 incrontab`.

- name** Unique comment describing the entry
- path** The path that should be watched
- user** The name of the user who's crontab needs to be modified, defaults to the root user
- mask** The mask of events that should be monitored for
- cmd** The cmd that should be executed

### 30.27.50 salt.states.influxdb\_database

#### Management of InfluxDB databases

(compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

**salt.states.influxdb\_database.absent** (*name*, *user=None*, *password=None*, *host=None*,  
*port=None*)

Ensure that the named database is absent

- name** The name of the database to remove
- user** The user to connect as (must be able to remove the database)
- password** The password of the user
- host** The host to connect to
- port** The port to connect to

**salt.states.influxdb\_database.present** (*name*, *user=None*, *password=None*, *host=None*,  
*port=None*)

Ensure that the named database is present

- name** The name of the database to create
- user** The user to connect as (must be able to remove the database)
- password** The password of the user
- host** The host to connect to
- port** The port to connect to

### 30.27.51 salt.states.influxdb\_user

#### Management of InfluxDB users

(compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

**salt.states.influxdb\_user.absent** (*name*, *database=None*, *user=None*, *password=None*, *host=None*,  
*port=None*)

Ensure that the named cluster admin or database user is absent.

- name** The name of the user to remove
- database** The database to remove the user from
- user** The user to connect as (must be able to remove the user)

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

`salt.states.influxdb_user.present` (*name, passwd, database=None, user=None, password=None, host=None, port=None*)

Ensure that the cluster admin or database user is present.

**name** The name of the user to manage

**passwd** The password of the user

**database** The database to create the user in

**user** The user to connect as (must be able to create the user)

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

### 30.27.52 salt.states.ini\_manage

#### Manage ini files

**maintainer** <akilesh1597@gmail.com>

**maturity** new

**depends** re

**platform** all

use section as DEFAULT\_IMPLICIT if your ini file does not have any section for example /etc/sysctl.conf

`salt.states.ini_manage.options_absent` (*name, sections=None*)

```
/home/saltminion/api-paste.ini:
ini.options_present:
- sections:
  test:
    - testkey
    - secondoption
  test1:
    - testkey1
```

options present in file and not specified in sections dict will be untouched

changes dict will contain the list of changes made

`salt.states.ini_manage.options_present` (*name, sections=None*)

```
/home/saltminion/api-paste.ini:
ini.options_present:
- sections:
  test:
    testkey: 'testval'
    secondoption: 'secondvalue'
```

```
test1:
  testkey1: 'testval121'
```

options present in file and not specified in sections dict will be untouched

changes dict will contain the list of changes made

`salt.states.ini_manage.sections_absent` (*name*, *sections=None*)

```
/home/saltminion/api-paste.ini:
ini.sections_absent:
- sections:
  - test
  - test1
```

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

`salt.states.ini_manage.sections_present` (*name*, *sections=None*)

```
/home/saltminion/api-paste.ini:
ini.sections_present:
- sections:
  test:
    testkey: testval
    secondoption: secondvalue
  test1:
    testkey1: 'testval121'
```

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

### 30.27.53 salt.states.ipmi

#### Manage IPMI devices over LAN

The following configuration defaults can be defined in the minion, master config or pillar:

```
ipmi.config:
  api_host: 127.0.0.1
  api_user: admin
  api_pass: apassword
  api_port: 623
  api_kg: None
```

Every call can override the config defaults:

```
ensure myipmi system is set to network boot:
  ipmi.boot_device:
    - name: network
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
    - api_kg: None
```

```
ensure myipmi system is powered on:
  ipmi.power:
    - name: boot
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
```

`salt.states.ipmi.boot_device` (*name='default', \*\*kwargs*)

Request power state change

**name = default**

- network -- Request network boot
- hd -- Boot from hard drive
- safe -- Boot from hard drive, requesting `safe mode`
- optical -- boot from CD/DVD/BD drive
- setup -- Boot into setup utility
- default -- remove any IPMI directed boot device request

**kwargs**

- api\_host=localhost
- api\_user=admin
- api\_pass=
- api\_port=623
- api\_kg=None

`salt.states.ipmi.power` (*name='power\_on', wait=300, \*\*kwargs*)

Request power state change

**name**

**Ensure power state one of:**

- power\_on -- system turn on
- power\_off -- system turn off (without waiting for OS)
- shutdown -- request OS proper shutdown
- reset -- reset (without waiting for OS)
- boot -- If system is off, then `on`, else `reset`

**wait** wait X seconds for the job to complete before forcing. (defaults to 300 seconds)

**kwargs**

- api\_host=localhost
- api\_user=admin
- api\_pass=
- api\_port=623
- api\_kg=None

`salt.states.ipmi.user_absent`(*name*, *channel=14*, *\*\*kwargs*)

Remove user Delete all user (uid) records having the matching name.

**name** string name of user to delete

**channel** channel to remove user access from defaults to 14 for auto.

**kwargs**

- `api_host=localhost`
- `api_user=admin`
- `api_pass=`
- `api_port=623`
- `api_kg=None`

`salt.states.ipmi.user_present`(*name*, *uid*, *password*, *channel=14*, *callback=False*, *link\_auth=True*, *ipmi\_msg=True*, *privilege\_level='administrator'*, *\*\*kwargs*)

Ensure IPMI user and user privileges.

**name** name of user (limit 16 bytes)

**uid** user id number (1 to 7)

**password** user password (limit 16 bytes)

**channel** ipmi channel defaults to 14 for auto

**callback** User Restricted to Callback

**False** = User Privilege Limit is determined by the User Privilege Limit parameter `privilege_level`, for both callback and non-callback connections.

**True** = User Privilege Limit is determined by the `privilege_level` parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they `call in` to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

**link\_auth** User Link authentication True/False user name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.

**ipmi\_msg** User IPMI Messaging True/False user name and password information will be used for IPMI Messaging. In this case, `IPMI Messaging` refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for `activatallow_authing` the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.) `ipmi_msg`

**privilege\_level**

- `callback`
- `user`
- `operator`
- `administrator`
- `proprietary`
- `no_access`

**kwargs**

- api\_host=localhost
- api\_user=admin
- api\_pass=
- api\_port=623
- api\_key=None

### 30.27.54 salt.states.ipset

#### Management of ipsets

This is an ipset-specific module designed to manage IPsets for use in IPTables Firewalls.

```

setname:
  ipset.set_present:
    - set_type: bitmap:ip
    - range: 192.168.0.0/16
    - comment: True

setname:
  ipset.set_absent:
    - set_type: bitmap:ip
    - range: 192.168.0.0/16
    - comment: True

setname_entries:
  ipset.present:
    - set_name: setname
    - entry: 192.168.0.3
    - comment: Hello
    - require:
      - ipset: baz

setname_entries:
  ipset.present:
    - set_name: setname
    - entry:
      - 192.168.0.3
      - 192.168.1.3
    - comment: Hello
    - require:
      - ipset: baz

setname_entries:
  ipset.absent:
    - set_name: setname
    - entry:
      - 192.168.0.3
      - 192.168.1.3
    - comment: Hello
    - require:
      - ipset: baz

setname:
  ipset.flush:

```

`salt.states.ipset.absent`(*name*, *entry=None*, *entries=None*, *family='ipv4'*, *\*\*kwargs*)

New in version 2014.7.0.

Remove a entry or entries from a chain

**name** A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.

**family** Network family, ipv4 or ipv6.

`salt.states.ipset.flush`(*name*, *family='ipv4'*, *\*\*kwargs*)

New in version 2014.7.0.

Flush current ipset set

**family** Networking family, either ipv4 or ipv6

`salt.states.ipset.present`(*name*, *entry=None*, *family='ipv4'*, *\*\*kwargs*)

New in version 2014.7.0.

Append a entry to a set

**name** A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.

**entry** A single entry to add to a set or a list of entries to add to a set

**family** Network family, ipv4 or ipv6.

`salt.states.ipset.set_absent`(*name*, *family='ipv4'*, *\*\*kwargs*)

New in version 2014.7.0.

Verify the set is absent.

**family** Networking family, either ipv4 or ipv6

`salt.states.ipset.set_present`(*name*, *set\_type*, *family='ipv4'*, *\*\*kwargs*)

New in version 2014.7.0.

Verify the chain is exist.

**name** A user-defined set name.

**set\_type** The type for the set

**family** Networking family, either ipv4 or ipv6

## 30.27.55 salt.states.iptables

### Management of iptables

This is an iptables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic *firewall* state.

```
httpd:
  iptables.append:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
```

```
- sport: 1025:65535
- save: True

httpd:
  iptables.append:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match:
      - state
      - comment
    - comment: "Allow HTTP"
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  iptables.append:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match:
      - state
      - comment
    - comment: "Allow HTTP"
    - connstate: NEW
    - source: '127.0.0.1'
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

.. Invert Rule
httpd:
  iptables.append:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match:
      - state
      - comment
    - comment: "Allow HTTP"
    - connstate: NEW
    - source: '! 127.0.0.1'
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  iptables.append:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match:
      - state
```

```
- comment
- comment: "Allow HTTP"
- connstate: NEW
- source: 'not 127.0.0.1'
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True
```

httpd:

```
iptables.append:
- table: filter
- family: ipv6
- chain: INPUT
- jump: ACCEPT
- match: state

- dports:
  - 80
  - 443
- proto: tcp
- sport: 1025:65535
- save: True
```

httpd:

```
iptables.insert:
- position: 1
- table: filter
- chain: INPUT
- jump: ACCEPT
- match: state
- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True
```

httpd:

```
iptables.insert:
- position: 1
- table: filter
- family: ipv6
- chain: INPUT
- jump: ACCEPT
- match: state
```

```

- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

```

httpd:

```

iptables.delete:
- table: filter
- chain: INPUT
- jump: ACCEPT
- match: state
- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

```

httpd:

```

iptables.delete:
- position: 1
- table: filter
- chain: INPUT
- jump: ACCEPT
- match: state
- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

```

httpd:

```

iptables.delete:
- table: filter
- family: ipv6
- chain: INPUT
- jump: ACCEPT
- match: state
- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

```

default to accept:

```

iptables.set_policy:
- chain: INPUT
- policy: ACCEPT

```

---

**Note:** Various functions of the `iptables` module use the `--check` option. If the version of `iptables` on the target system does not include this option, an alternate version of this check will be performed using the output of `iptables-save`. This may have unintended consequences on legacy releases of `iptables`.

---

`salt.states.iptables.append`(*name*, *family*='ipv4', *\*\*kwargs*)

New in version 0.17.0.

Append a rule to a chain

**name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**family** Network family, ipv4 or ipv6.

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: `--state` is specified as *connstate* instead of *state* (not to be confused with *ctstate*).

Jump options that doesn't take arguments should be passed in with an empty string.

`salt.states.iptables.chain_absent(name, table='filter', family='ipv4')`

New in version 2014.1.0.

Verify the chain is absent.

**family** Networking family, either ipv4 or ipv6

`salt.states.iptables.chain_present(name, table='filter', family='ipv4')`

New in version 2014.1.0.

Verify the chain is exist.

**name** A user-defined chain name.

**table** The table to own the chain.

**family** Networking family, either ipv4 or ipv6

`salt.states.iptables.delete(name, family='ipv4', **kwargs)`

New in version 2014.1.0.

Delete a rule to a chain

**name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**family** Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: `--state` is specified as *connstate* instead of *state* (not to be confused with *ctstate*).

Jump options that doesn't take arguments should be passed in with an empty string.

`salt.states.iptables.flush(name, family='ipv4', **kwargs)`

New in version 2014.1.0.

Flush current iptables state

**family** Networking family, either ipv4 or ipv6

`salt.states.iptables.insert(name, family='ipv4', **kwargs)`

New in version 2014.1.0.

Insert a rule into a chain

**name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**family** Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: `--state` is specified as *connstate* instead of *state* (not to be confused with *ctstate*).

Jump options that doesn't take arguments should be passed in with an empty string.

`salt.states.iptables.mod_aggregate` (*low, chunks, running*)

The `mod_aggregate` function which looks up all rules in the available low chunks and merges them into a single rules ref in the present low data

`salt.states.iptables.set_policy` (*name, family='ipv4', \*\*kwargs*)

New in version 2014.1.0.

Sets the default policy for iptables firewall tables

**family** Networking family, either `ipv4` or `ipv6`

**policy** The requested table policy

### 30.27.56 salt.states.jboss7

Manage JBoss 7 Application Server via CLI interface

New in version 2015.5.0.

This state uses `jboss-cli.sh` script from JBoss installation and parses its output to determine execution result.

In order to run each state, `jboss_config` dictionary with the following properties must be passed:

```
jboss:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: 'jbossadm'
  cli_password: 'jbossadm'
```

If controller doesn't require password, then passing `cli_user` and `cli_password` parameters is not obligatory.

Example of application deployment:

```
application_deployed:
  jboss7.deployed:
    - artifact:
      artifactory_url: http://artifactory.intranet.company.com/artifactory
      repository: 'ext-release-local'
      artifact_id: 'webcomponent'
      group_id: 'com.company.application'
      packaging: 'war'
      version: '0.1'
      target_dir: '/tmp'
    - jboss_config:
      cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
      controller: 10.11.12.13:9999
      cli_user: 'jbossadm'
      cli_password: 'jbossadm'
```

Since same dictionary with configuration will be used in all the states, it is much more convenient to move `jboss` configuration and other properties to pillar. For example, configuration of `jboss` server, artifactory address and application version could be moved to pillars:

```
application_deployed:
  jboss7.deployed:
    - artifact:
      artifactory_url: {{ pillar['artifactory']['url'] }}
      repository: {{ pillar['artifactory']['repository'] }}
```

```

artifact_id: 'webcomponent'
group_id: 'com.company.application'
packaging: 'war'
version: {{ pillar['webcomponent-artifact']['version'] }}
latest_snapshot: {{ pillar['webcomponent-artifact']['latest_snapshot'] }}
repository: {{ pillar['webcomponent-artifact']['repository'] }}
- jboss_config: {{ pillar['jboss'] }}

```

Configuration in pillars:

```

artifactory:
  url: 'http://artifactory.intranet.company.com/artifactory'
  repository: 'libs-snapshots-local'

webcomponent-artifact:
  repository: 'libs-snapshots-local'
  latest_snapshot: True
  version: -1 #If latest_snapshot then version is ignored

```

For the sake of brevity, examples for each state assume that `jboss_config` is moved to pillars.

**salt.states.jboss7.bindings\_exist**(*name, jboss\_config, bindings*)

Ensures that given JNDI binding are present on the server. If a binding doesn't exist on the server it will be created. If it already exists its value will be changed.

**jboss\_config**: Dict with connection properties (see state description)

**bindings**: Dict with bindings to set.

Example:

```

jndi_entries_created:
  jboss7.bindings_exist:
    - bindings:
      'java:global/sampleapp/environment': 'DEV'
      'java:global/sampleapp/configurationFile': '/var/opt/sampleapp/config.properties'
    - jboss_config: {{ pillar['jboss'] }}

```

**salt.states.jboss7.datasource\_exists**(*name, jboss\_config, datasource\_properties, recreate=False*)

Ensures that a datasource with given properties exist on the jboss instance. If datasource doesn't exist, it is created, otherwise only the properties that are different will be updated.

**name** Datasource property name

**jboss\_config** Dict with connection properties (see state description)

**datasource\_properties** Dict with datasource properties

**recreate** [False] If set to True and datasource exists it will be removed and created again. However, if there are deployments that depend on the datasource, it will not be possible to remove it.

Example:

```

sampleDS:
  jboss7.datasource_exists:
    - recreate: False
    - datasource_properties:
      driver-name: mysql
      connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'

```

```

jndi-name: 'java:jboss/datasources/sampleDS'
user-name: sampleuser
password: secret
min-pool-size: 3
use-java-context: True
- jboss_config: {{ pillar['jboss'] }}

```

`salt.states.jboss7.deployed`(*name, jboss\_config, artifact=None, salt\_source=None*)

Ensures that the given application is deployed on server.

**jboss\_config**: Dict with connection properties (see state description)

**artifact**:

If set, the artifact will be fetched from artifactory. This is a Dict object with the following properties:

- **artifactory\_url**: Full url to artifactory instance, for example: <http://artifactory.intranet.company.com/artifactory>
- **repository**: One of the repositories, for example: libs-snapshots, ext-release-local, etc..
- **artifact\_id**: Artifact ID of the artifact
- **group\_id**: Group ID of the artifact
- **packaging**: war/jar/ear, etc...
- **version**: Artifact version. If `latest_snapshot` is set to True, the value of this attribute will be ignored, and newest snapshot will be taken instead.
- **latest\_snapshot**: If set to True and repository is a snapshot repository it will automatically select the newest snapshot.
- **snapshot\_version**: Exact version of the snapshot (with timestamp). A snapshot version may have several builds and a way to differentiate is to provide a build timestamp.
- **target\_dir**: Temporary directory on minion where artifacts will be downloaded

**salt\_source**:

If set, the artifact to be deployed will be fetched from salt master. This is a Dict object with the following properties:

- **source**: File on salt master (eg. `salt://application-web-0.39.war`)
- **target\_file**: Temporary file on minion to save file to (eg. ``/tmp/application-web-0.39.war``)
- **undeploy**: Regular expression to match against existing deployments. If any deployment matches the regular expression then it will be undeployed.

The deployment consists of the following steps:

- Fetch artifact (salt filesystem, artifact or filesystem on minion)
- Check if same artifact is not deployed yet (perhaps with different version)
- Undeploy the artifact if it is already deployed
- Deploy the new artifact

Examples:

Deployment of a file from Salt file system:

```

application_deployed:
  jboss7.deployed:
    - salt_source:
      source: salt://application-web-0.39.war
      target_file: '/tmp/application-web-0.39.war'
      undeploy: 'application-web-.*'
    - jboss_config: {{ pillar['jboss'] }}

```

Here, application-web-0.39.war file is downloaded from Salt file system to /tmp/application-web-0.39.war file on minion. Existing deployments are checked if any of them matches `application-web-.\*` regular expression, and if so then it is undeployed before deploying the application. This is useful to automate deployment of new application versions.

JBoss state is capable of deploying artifacts directly from Artifactory repository. Here are some examples of deployments:

1. Deployment of released version of artifact from Artifactory.

```

application_deployed:
  jboss7.deployed:
    - artifact:
      artifactory_url: http://artifactory.intranet.company.com/artifactory
      repository: 'ext-release-local'
      artifact_id: 'webcomponent'
      group_id: 'com.company.application'
      packaging: 'war'
      version: '0.1'
      target_dir: '/tmp'
    - jboss_config: {{ pillar['jboss'] }}

```

This performs the following operations:

- Download artifact from artifactory. In the example above the artifact will be fetched from: <http://artifactory.intranet.company.com/artifactory/ext-release-local/com/company/application/webcomponent/0.1/webcomponent-0.1.war> As a rule, for released versions the artifacts are downloaded from: `artifactory_url/repository/group_id_with_slashed_instead_of_dots/artifact_id/version/artifact_id-version.packaging` This follows artifactory convention for artifact resolution. By default the artifact will be downloaded to /tmp directory on minion.
- Connect to JBoss via controller (defined in jboss\_config dict) and check if the artifact is not deployed already. In case of artifactory it will check if any deployment's name starts with artifact\_id value. If deployment already exists it will be undeployed
- Deploy the downloaded artifact to JBoss via cli interface.

2. Deployment of last updated version of given SNAPSHOT version of artifact from Artifactory.

```

application_deployed:
  jboss7.deployed:
    - artifact:
      artifactory_url: http://artifactory.intranet.company.com/artifactory
      repository: 'ext-snapshot-local'
      artifact_id: 'webcomponent'
      group_id: 'com.company.application'
      packaging: 'war'
      version: '0.1-SNAPSHOT'
    - jboss_config: {{ pillar['jboss'] }}

```

Deploying snapshot version involves an additional step of resolving the exact version of the artifact (including the timestamp), which is not necessary when deploying a release. In the example above first a request will be made to retrieve the update timestamp from: <http://artifactory.intranet.company.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/maven-metadata.xml>

Then the artifact will be fetched from [http://artifactory.intranet.company.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/webcomponent-RESOLVED\\_SNAPSHOT\\_VERSION.war](http://artifactory.intranet.company.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/webcomponent-RESOLVED_SNAPSHOT_VERSION.war)

---

**Note:** In order to perform a snapshot deployment you have to:

- Set repository to a snapshot repository.
  - Choose a version that ends with ``SNAPSHOT" string. Snapshot repositories have a different layout and provide some extra information that is needed for deployment of the last or a specific snapshot.
- 

3.Deployment of SNAPSHOT version (with exact timestamp) of artifact from Artifactory.

If you need to deploy an exact version of the snapshot you may provide `snapshot_version` parameter.

```
application_deployed:
  jboss7.deployed:
    - artifact:
      artifactory_url: http://artifactory.intranet.company.com/artifactory
      repository: 'ext-snapshot-local'
      artifact_id: 'webcomponent'
      group_id: 'com.company.application'
      packaging: 'war'
      version: '0.1-SNAPSHOT'
      snapshot_version: '0.1-20141023.131756-19'
    - jboss_config: {{ pillar['jboss'] }}
```

In this example the artifact will be retrieved from: <http://artifactory.intranet.company.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/webcomponent-0.1-20141023.131756-19.war>

4.Deployment of latest snapshot of artifact from Artifactory.

```
application_deployed:
  jboss7.deployed:
    - artifact:
      artifactory_url: http://artifactory.intranet.company.com/artifactory
      repository: 'ext-snapshot-local'
      artifact_id: 'webcomponent'
      group_id: 'com.company.application'
      packaging: 'war'
      latest_snapshot: True
    - jboss_config: {{ pillar['jboss'] }}
```

Instead of providing an exact version of a snapshot it is sometimes more convenient to get the newest version. If `artifact.latest_snapshot` is set to `True`, then the newest snapshot will be downloaded from Artifactory. In this case it is not necessary to specify version. This is particularly useful when integrating with CI tools that will deploy the current snapshot to the Artifactory.

`salt.states.jboss7.reloaded` (*name, jboss\_config, timeout=60, interval=5*)

Reloads configuration of jboss server.

**jboss\_config:** Dict with connection properties (see state description)

**timeout:** Time to wait until jboss is back in running state. Default timeout is 60s.

**interval:** Interval between state checks. Default interval is 5s. Decreasing the interval may slightly decrease waiting time but be aware that every status check is a call to jboss-cli which is a java process. If interval is smaller than process cleanup time it may easily lead to excessive resource consumption.

This step performs the following operations:

- Ensures that server is in running or reload-required state (by reading server-state attribute)
- Reloads configuration
- Waits for server to reload and be in running state

Example:

```
configuration_reloaded:
  jboss7.reloaded:
    - jboss_config: {{ pillar['jboss'] }}
```

### 30.27.57 salt.states.keyboard

#### Management of keyboard layouts

The keyboard layout can be managed for the system:

```
us:
  keyboard.system
```

Or it can be managed for XOrg:

```
us:
  keyboard.xorg
```

**salt.states.keyboard.system**(*name*)

Set the keyboard layout for the system

**name** The keyboard layout to use

**salt.states.keyboard.xorg**(*name*)

Set the keyboard layout for XOrg

**layout** The keyboard layout to use

### 30.27.58 salt.states.keystone

#### Management of Keystone users

**depends**

- keystoneclient Python module

**configuration** See *salt.modules.keystone* for setup instructions.

```
Keystone tenants:
  keystone.tenant_present:
    - names:
      - admin
      - demo
```

```

    - service

Keystone roles:
  keystone.role_present:
    - names:
      - admin
      - Member

admin:
  keystone.user_present:
    - password: R00T_4CC3SS
    - email: admin@domain.com
    - roles:
      admin: # tenants
        - admin # roles
      service:
        - admin
        - Member
    - require:
      - keystone: Keystone tenants
      - keystone: Keystone roles

nova:
  keystone.user_present:
    - password: '$up3rn0v4'
    - email: nova@domain.com
    - tenant: service
    - roles:
      service:
        - admin
    - require:
      - keystone: Keystone tenants
      - keystone: Keystone roles

demo:
  keystone.user_present:
    - password: 'd3m0n$trati0n'
    - email: demo@domain.com
    - tenant: demo
    - roles:
      demo:
        - Member
    - require:
      - keystone: Keystone tenants
      - keystone: Keystone roles

nova service:
  keystone.service_present:
    - name: nova
    - service_type: compute
    - description: OpenStack Compute Service

```

`salt.states.keystone.endpoint_absent` (*name*, *profile=None*, *\*\*connection\_args*)

Ensure that the endpoint for a service doesn't exist in Keystone catalog

**name** The name of the service whose endpoints should not exist

`salt.states.keystone.endpoint_present` (*name*, *publicurl=None*, *internalurl=None*, *adminurl=None*, *region='RegionOne'*, *profile=None*, *\*\*connection\_args*)

Ensure the specified endpoints exists for service

**name** The Service name

**public url** The public url of service endpoint

**internal url** The internal url of service endpoint

**admin url** The admin url of the service endpoint

**region** The region of the endpoint

`salt.states.keystone.role_absent` (*name*, *profile=None*, *\*\*connection\_args*)

Ensure that the keystone role is absent.

**name** The name of the role that should not exist

`salt.states.keystone.role_present` (*name*, *profile=None*, *\*\*connection\_args*)

Ensures that the keystone role exists

**name** The name of the role that should be present

`salt.states.keystone.service_absent` (*name*, *profile=None*, *\*\*connection\_args*)

Ensure that the service doesn't exist in Keystone catalog

**name** The name of the service that should not exist

`salt.states.keystone.service_present` (*name*, *service\_type*, *description=None*, *profile=None*, *\*\*connection\_args*)

Ensure service present in Keystone catalog

**name** The name of the service

**service\_type** The type of Openstack Service

**description (optional)** Description of the service

`salt.states.keystone.tenant_absent` (*name*, *profile=None*, *\*\*connection\_args*)

Ensure that the keystone tenant is absent.

**name** The name of the tenant that should not exist

`salt.states.keystone.tenant_present` (*name*, *description=None*, *enabled=True*, *profile=None*, *\*\*connection\_args*)

Ensures that the keystone tenant exists

**name** The name of the tenant to manage

**description** The description to use for this tenant

**enabled** Availability state for this tenant

`salt.states.keystone.user_absent` (*name*, *profile=None*, *\*\*connection\_args*)

Ensure that the keystone user is absent.

**name** The name of the user that should not exist

`salt.states.keystone.user_present` (*name*, *password*, *email*, *tenant=None*, *enabled=True*, *roles=None*, *profile=None*, *\*\*connection\_args*)

Ensure that the keystone user is present with the specified properties.

**name** The name of the user to manage

**password** The password to use for this user

**email** The email address for this user

**tenant** The tenant for this user

**enabled** Availability state for this user

**roles** The roles the user should have under given tenants. Passed as a dictionary mapping tenant names to a list of roles in this tenant, i.e.:

```
roles:
  admin:  # tenant
    - admin # role
  service:
    - admin
    - Member
```

### 30.27.59 salt.states.kmod

#### Loading and unloading of kernel modules

The Kernel modules on a system can be managed cleanly with the kmod state module:

```
kvm_amd:
  kmod.present
pcspkr:
  kmod.absent
```

**salt.states.kmod.absent** (*name, persist=False, comment=True*)

Verify that the named kernel module is not loaded

**name** The name of the kernel module to verify is not loaded

**persist** Delete module from `/etc/modules`

**comment** Don't remove module from `/etc/modules`, only comment it

**salt.states.kmod.present** (*name, persist=False*)

Ensure that the specified kernel module is loaded

**name** The name of the kernel module to verify is loaded

**persist** Also add module to `/etc/modules`

### 30.27.60 salt.states.layman

#### Management of Gentoo Overlays using layman

A state module to manage Gentoo package overlays via layman

```
sunrise:
  layman.present
```

**salt.states.layman.absent** (*name*)

Verify that the overlay is absent

**name** The name of the overlay to delete

`salt.states.layman.present`(*name*)  
Verify that the overlay is present  
**name** The name of the overlay to add

### 30.27.61 salt.states.libvirt

#### Manage libvirt certificates

This state uses the external pillar in the master to call for the generation and signing of certificates for systems running libvirt:

```
libvirt_keys:  
  libvirt.keys
```

`salt.states.libvirt.keys`(*name*, *basepath*='/etc/pki')  
Manage libvirt keys.  
**name** The name variable used to track the execution  
**basepath** Defaults to /etc/pki, this is the root location used for libvirt keys on the hypervisor

### 30.27.62 salt.states.linux\_acl

Linux File Access Control Lists

Ensure a Linux ACL is present

```
root:  
  acl.present:  
    - name: /root  
    - acl_type: user  
    - acl_name: damian  
    - perms: rwx
```

Ensure a Linux ACL does not exist

```
root:  
  acl.absent:  
    - name: /root  
    - acl_type: user  
    - acl_name: damian  
    - perms: rwx
```

`salt.states.linux_acl.absent`(*name*, *acl\_type*, *acl\_name*, *perms*, *recurse*=False)  
Ensure a Linux ACL does not exist

`salt.states.linux_acl.present`(*name*, *acl\_type*, *acl\_name*, *perms*, *recurse*=False)  
Ensure a Linux ACL is present

### 30.27.63 salt.states.locale

#### Management of languages/locales

The locale can be managed for the system:

```
en_US.UTF-8:
  locale.system
```

**salt.states.locale.present**(*name*)

Generate a locale if it is not present

New in version 2014.7.0.

**name** The name of the locale to be present

**salt.states.locale.system**(*name*)

Set the locale for the system

**name** The name of the locale to use

### 30.27.64 salt.states.lvm

#### Management of Linux logical volumes

A state module to manage LVMs

```
/dev/sda:
  lvm.pv_present

my_vg:
  lvm.vg_present:
    - devices: /dev/sda

lvroot:
  lvm.lv_present:
    - vname: my_vg
    - size: 10G
    - stripes: 5
    - stripesize: 8K
```

**salt.states.lvm.lv\_absent**(*name*, *vgname=None*)

Remove a given existing logical volume from a named existing volume group

**name** The logical volume to remove

**vgname** The volume group name

**salt.states.lvm.lv\_present**(*name*, *vgname=None*, *size=None*, *extents=None*, *snapshot=None*, *pv=''*,  
\*\**kwargs*)

Create a new logical volume

**name** The name of the logical volume

**vgname** The volume group name for this logical volume

**size** The initial size of the logical volume

**extents** The number of logical extents to allocate

**snapshot** The name of the snapshot

**pv** The physical volume to use

**kwargs** Any supported options to lvcreate. See *linux\_lvm* for more details.

`salt.states.lvm.pv_absent(name)`

Ensure that a Physical Device is not being used by lvm

**name** The device name to initialize.

`salt.states.lvm.pv_present(name, **kwargs)`

Set a physical device to be used as an LVM physical volume

**name** The device name to initialize.

**kwargs** Any supported options to pvcreate. See *linux\_lvm* for more details.

`salt.states.lvm.vg_absent(name)`

Remove an LVM volume group

**name** The volume group to remove

`salt.states.lvm.vg_present(name, devices=None, **kwargs)`

Create an LVM volume group

**name** The volume group name to create

**devices** A list of devices that will be added to the volume group

**kwargs** Any supported options to vgcreate. See *linux\_lvm* for more details.

### 30.27.65 salt.states.lvs\_server

#### Management of LVS (Linux Virtual Server) Real Server

`salt.states.lvs_server.absent(name, protocol=None, service_address=None, server_address=None)`

Ensure the LVS Real Server in specified service is absent.

**name** The name of the LVS server.

**protocol** The service protocol(only support tcp, udp and fwmark service).

**service\_address** The LVS service address.

**server\_address** The LVS real server address.

`salt.states.lvs_server.present(name, protocol=None, service_address=None, server_address=None, packet_forward_method='dr', weight=1)`

Ensure that the named service is present.

**name** The LVS server name

**protocol** The service protocol

**service\_address** The LVS service address

**server\_address** The real server address.

**packet\_forward\_method** The LVS packet forwarding method(dr for direct routing, tunnel for tunneling, nat for network access translation).

**weight** The capacity of a server relative to the others in the pool.

```

lvsrs:
  lvs_server.present:
    - protocol: tcp
    - service_address: 1.1.1.1:80
    - server_address: 192.168.0.11:8080
    - packet_forward_method: dr
    - weight: 10

```

### 30.27.66 salt.states.lvs\_service

#### Management of LVS (Linux Virtual Server) Service

**salt.states.lvs\_service.absent** (*name, protocol=None, service\_address=None*)

Ensure the LVS service is absent.

**name** The name of the LVS service

**protocol** The service protocol

**service\_address** The LVS service address

**salt.states.lvs\_service.present** (*name, protocol=None, service\_address=None, scheduler='wlc'*)

Ensure that the named service is present.

**name** The LVS service name

**protocol** The service protocol

**service\_address** The LVS service address

**scheduler** Algorithm for allocating TCP connections and UDP datagrams to real servers.

```

lvstest:
  lvs_service.present:
    - service_address: 1.1.1.1:80
    - protocol: tcp
    - scheduler: rr

```

### 30.27.67 salt.states.lxc

#### Manage Linux Containers

**salt.states.lxc.absent** (*name, stop=False*)

Ensure a container is not present, destroying it if present

**name** Name of the container to destroy

**stop** stop before destroying default: false

New in version 2015.5.2.

```

web01:
  lxc.absent

```

**salt.states.lxc.cloned** (*name, orig, snapshot=True, size=None, vgname=None, profile=None*)

Deprecated since version 2015.5.0: Use [lxc.present](#)

**salt.states.lxc.created** (*name, \*\*kwargs*)

Deprecated since version 2015.5.0: Use [lxc.present](#)

`salt.states.lxc.edited_conf` (*name*, *lxc\_conf=None*, *lxc\_conf\_unset=None*)

**Warning:** This state is unsuitable for setting parameters that appear more than once in an LXC config file, or parameters which must appear in a certain order (such as when configuring more than one network interface). It is slated to be replaced, and as of version 2015.5.0 it is deprecated.

Edit LXC configuration options

```
setconf:
  lxc.edited_conf:
    - name: ubuntu
    - lxc_conf:
      - network.ipv4.ip: 10.0.3.6
    - lxc_conf_unset:
      - lxc.utsname
```

`salt.states.lxc.frozen` (*name*, *start=True*)

New in version 2015.5.0.

Ensure that a container is frozen

**Note:** This state does not enforce the existence of the named container, it just freezes the container if it is running. To ensure that the named container exists, use `lxc.present`.

**name** The name of the container

**start** [True] Start container first, if necessary. If `False`, then this state will fail if the container is not running.

```
web01:
  lxc.frozen

web02:
  lxc.frozen:
    - start: False
```

`salt.states.lxc.present` (*name*, *running=None*, *clone\_from=None*, *snapshot=False*, *profile=None*, *network\_profile=None*, *template=None*, *options=None*, *image=None*, *config=None*, *fstype=None*, *size=None*, *backing=None*, *vgname=None*, *lvname=None*)

Changed in version 2015.5.0: The `lxc.created` state has been renamed to `lxc.present`, and the `lxc.cloned` state has been merged into this state.

Create the named container if it does not exist

**name** The name of the container to be created

**running** [False]

- If `True`, ensure that the container is running
- If `False`, ensure that the container is stopped
- If `None`, do nothing with regards to the running state of the container

New in version 2015.5.0.

**clone\_from** Create named container as a clone of the specified container

**snapshot** [False] Use Copy On Write snapshots (LVM). Only supported with `clone_from`.

**profile** Profile to use in container creation (see the *LXC Tutorial* for more information). Values in a profile will be overridden by the parameters listed below.

**network\_profile** Network Profile to use in container creation (see the *LXC Tutorial* for more information). Values in a profile will be overridden by the parameters listed below.

New in version 2015.5.2.

### Container Creation Arguments

**template** The template to use. E.g., `ubuntu` or `fedora`. Conflicts with the `image` argument.

---

**Note:** The `download` template requires the following three parameters to be defined in `options`:

- `dist` - The name of the distribution
- `release` - Release name/version
- `arch` - Architecture of the container

The available images can be listed using the `lxc.images` function.

---

**options** New in version 2015.5.0.

Template-specific options to pass to the `lxc-create` command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:

```
web01:
  lxc.present:
    - template: download
    - options:
      dist: centos
      release: 6
      arch: amd64
```

Remember to double-indent the options, due to *how PyYAML works*.

**image** A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.

**backing** The type of storage to use. Set to `lvm` to use an LVM group. Defaults to filesystem within `/var/lib/lxc`.

**fstype** Filesystem type to use on LVM logical volume

**size** Size of the volume to create. Only applicable if `backing` is set to `lvm`.

**vgname** [`lxc`] Name of the LVM volume group in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.

**lvname** Name of the LVM logical volume in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.

`salt.states.lxc.running`(*name*, *restart=False*)

Changed in version 2015.5.0: The `lxc.started` state has been renamed to `lxc.running`

Ensure that a container is running

---

**Note:** This state does not enforce the existence of the named container, it just starts the container if it is not running. To ensure that the named container exists, use `lxc.present`.

---

**name** The name of the container

**restart** [`False`] Restart container if it is already running

```
web01:
  lxc.running

web02:
  lxc.running:
    - restart: True
```

`salt.states.lxc.set_pass` (*name*, *\*\*kwargs*)

Deprecated since version 2015.5.0.

This state function has been disabled, as it did not conform to design guidelines. Specifically, due to the fact that `lxc.set_password` uses `chpasswd(8)` to set the password, there was no method to make this action idempotent (in other words, the password would be changed every time). This makes this state redundant, since the following state will do the same thing:

```
setpass:
  module.run:
    - name: set_pass
    - m_name: root
    - password: secret
```

`salt.states.lxc.started` (*name*, *restart=False*)

Deprecated since version 2015.5.0: Use `lxc.running`

`salt.states.lxc.stopped` (*name*, *kill=False*)

Ensure that a container is stopped

---

**Note:** This state does not enforce the existence of the named container, it just stops the container if it running or frozen. To ensure that the named container exists, use `lxc.present`, or use the `lxc.absent` state to ensure that the container does not exist.

---

**name** The name of the container

**kill** [False] Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop containers like this irrespective of this argument.

New in version 2015.5.0.

```
web01:
  lxc.stopped
```

### 30.27.68 salt.states.makeconf

#### Management of Gentoo make.conf

A state module to manage Gentoo's `make.conf` file

```
makeopts:
  makeconf.present:
    - value: '-j3'
```

`salt.states.makeconf.absent` (*name*)

Verify that the variable is not in the `make.conf`.

**name** The variable name. This will automatically be converted to upper case since variables in `make.conf` are in upper case

`salt.states.makeconf.present`(*name*, *value=None*, *contains=None*, *excludes=None*)

Verify that the variable is in the `make.conf` and has the provided settings. If `value` is set, `contains` and `excludes` will be ignored.

**name** The variable name. This will automatically be converted to upper case since variables in `make.conf` are in upper case

**value** Enforce that the value of the variable is set to the provided value

**contains** Enforce that the value of the variable contains the provided value

**excludes** Enforce that the value of the variable does not contain the provided value.

### 30.27.69 salt.states.mdadm

#### Managing software RAID with mdadm

A state module for creating or destroying software RAID devices.

```
/dev/md0:
raid.present:
- level: 5
- devices:
  - /dev/xvdd
  - /dev/xvde
  - /dev/xvdf
- chunk: 256
- run: True
```

`salt.states.mdadm.absent`(*name*)

Verify that the raid is absent

**name** The name of raid device to be destroyed

```
/dev/md0:
raid:
- absent
```

`salt.states.mdadm.present`(*name*, *level*, *devices*, *\*\*kwargs*)

Verify that the raid is present

Changed in version 2014.7.0.

**name** The name of raid device to be created

**level** The RAID level to use when creating the raid.

**devices** A list of devices used to build the array.

Example:

```
/dev/md0:
raid.present:
- level: 5
- devices:
  - /dev/xvdd
  - /dev/xvde
```

```
- /dev/xvdf
- chunk: 256
- run: True
```

### 30.27.70 salt.states.memcached

#### States for Management of Memcached Keys

New in version 2014.1.0.

**salt.states.memcached.absent**(*name*, *value=None*, *host='127.0.0.1'*, *port=11211*, *time=0*)

Ensure that a memcached key is not present.

**name** The key

**value** [None] If specified, only ensure that the key is absent if it matches the specified value.

**host** The memcached server IP address

**port** The memcached server port

```
foo:
  memcached.absent

bar:
  memcached.absent:
    - host: 10.0.0.1
```

**salt.states.memcached.managed**(*name*, *value=None*, *host='127.0.0.1'*, *port=11211*, *time=0*, *min\_compress\_len=0*)

Manage a memcached key.

**name** The key to manage

**value** The value to set for that key

**host** The memcached server IP address

**port** The memcached server port

```
foo:
  memcached.managed:
    - value: bar
```

### 30.27.71 salt.states.modjk

State to control Apache modjk

**salt.states.modjk.worker\_activated**(*name*, *workers=None*, *profile='default'*)

Activate all the workers in the modjk load balancer

Example:

```
loadbalancer:
  modjk.worker_activated:
    - workers:
      - app1
      - app2
```

`salt.states.modjk.worker_disabled` (*name*, *workers=None*, *profile='default'*)  
 Disable all the workers in the modjk load balancer

Example:

```
loadbalancer:
  modjk.worker_disabled:
    - workers:
      - app1
      - app2
```

`salt.states.modjk.worker_recover` (*name*, *workers=None*, *profile='default'*)  
 Recover all the workers in the modjk load balancer

Example:

```
loadbalancer:
  modjk.worker_recover:
    - workers:
      - app1
      - app2
```

`salt.states.modjk.worker_stopped` (*name*, *workers=None*, *profile='default'*)  
 Stop all the workers in the modjk load balancer

Example:

```
loadbalancer:
  modjk.worker_stopped:
    - workers:
      - app1
      - app2
```

### 30.27.72 salt.states.modjk\_worker

#### Manage modjk workers

Send commands to a **modjk** load balancer via the peer system.

This module can be used with the `prereq` requisite to remove/add the worker from the load balancer before deploying/restarting service.

Mandatory Settings:

- The minion needs to have permission to publish the **modjk.\*** functions (see [here](#) for information on configuring peer publishing permissions)
- The modjk load balancer must be configured as stated in the **modjk** execution module *documentation*

`salt.states.modjk_worker.activate` (*name*, *lbn*, *target*, *profile='default'*, *expr\_form='glob'*)  
 Activate the named worker from the lbn load balancers at the targeted minions

Example:

```
disable-before-deploy:
  modjk_worker.activate:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - expr_form: grain
```

`salt.states.modjk_worker.disable`(*name, lbn, target, profile='default', expr\_form='glob'*)

Disable the named worker from the lbn load balancers at the targeted minions. The worker will get traffic only for current sessions and won't get new ones.

Example:

```
disable-before-deploy:
  modjk_worker.disable:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - expr_form: grain
```

`salt.states.modjk_worker.stop`(*name, lbn, target, profile='default', expr\_form='glob'*)

Stop the named worker from the lbn load balancers at the targeted minions. The worker won't get any traffic from the lbn.

Example:

```
disable-before-deploy:
  modjk_worker.stop:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - expr_form: grain
```

### 30.27.73 salt.states.module

#### Execution of Salt modules from within states

These states allow individual execution module calls to be made via states. To call a single module function use a `module.run` state:

```
mine.send:
  module.run:
    - name: network.interfaces
```

Note that this example is probably unnecessary to use in practice, since the `mine_functions` and `mine_interval` config parameters can be used to schedule updates for the mine (see [here](#) for more info).

It is sometimes desirable to trigger a function call after a state is executed, for this the `module.wait` state can be used:

```
mine.send:
  module.wait:
    - name: network.interfaces
    - watch:
      - file: /etc/network/interfaces
```

All arguments that the `module` state does not consume are passed through to the execution module function being executed:

```
fetch_out_of_band:
  module.run:
    - name: git.fetch
    - cwd: /path/to/my/repo
```

```
- user: myuser
- opts: '--all'
```

Due to how the state system works, if a module function accepts an argument called, `name`, then `m_name` must be used to specify that argument, to avoid a collision with the `name` argument. For example:

```
disable_nfs:
  module.run:
    - name: service.disable
    - m_name: nfs
```

Note that some modules read all or some of the arguments from a list of keyword arguments. For example:

```
mine.send:
  module.run:
    - func: network.ip_addrs
    - kwargs:
      interface: eth0
```

`salt.states.module.mod_watch(name, **kwargs)`

Run a single module function

**name** The module function to execute

**returner** Specify the returner to send the return of the module execution to

**\*\*kwargs** Pass any arguments needed to execute the function

`salt.states.module.run(name, **kwargs)`

Run a single module function

**name** The module function to execute

**returner** Specify the returner to send the return of the module execution to

**\*\*kwargs** Pass any arguments needed to execute the function

`salt.states.module.wait(name, **kwargs)`

Run a single module function only if the watch statement calls it

**name** The module function to execute

**\*\*kwargs** Pass any arguments needed to execute the function

---

**Note:** Like the `cmd.run` state, this state will return `True` but not actually execute, unless one of the following two things happens:

1. The state has a [watch requisite](#), and the state which it is watching changes.
  2. Another state has a [watch\\_in requisite](#) which references this state, and the state with the `watch_in` changes.
- 

### 30.27.74 salt.states.mongodb\_database

Management of MongoDB databases

Only deletion is supported, creation doesn't make sense and can be done using `mongodb_user.present`

`salt.states.mongodb_database.absent` (*name*, *user=None*, *password=None*, *host=None*,  
*port=None*)

Ensure that the named database is absent

**name** The name of the database to remove

**user** The user to connect as (must be able to create the user)

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

### 30.27.75 salt.states.mongodb\_user

#### Management of MongoDB users

---

**Note:** This module requires PyMongo to be installed.

---

`salt.states.mongodb_user.absent` (*name*, *user=None*, *password=None*, *host=None*, *port=None*,  
*database='admin'*)

Ensure that the named user is absent

**name** The name of the user to remove

**user** MongoDB user with sufficient privilege to create the user

**password** Password for the admin user specified by the `user` parameter

**host** The hostname/IP address of the MongoDB server

**port** The port on which MongoDB is listening

**database** The database from which to remove the user specified by the `name` parameter

`salt.states.mongodb_user.present` (*name*, *passwd*, *database='admin'*, *user=None*, *password=None*,  
*host='localhost'*, *port=27017*)

Ensure that the user is present with the specified properties

**name** The name of the user to manage

**passwd** The password of the user to manage

**user** MongoDB user with sufficient privilege to create the user

**password** Password for the admin user specified with the `user` parameter

**host** The hostname/IP address of the MongoDB server

**port** The port on which MongoDB is listening

**database** The database in which to create the user

---

**Note:** If the database doesn't exist, it will be created.

---

Example:

```
mongouser-myapp:
  mongodb_user.present:
    - name: myapp
    - passwd: password-of-myapp
    # Connect as admin:sekrit
```

```
- user: admin
- password: sekret
```

### 30.27.76 salt.states.mount

#### Mounting of filesystems

Mount any type of mountable filesystem with the mounted function:

```
/mnt/sdb:
  mount.mounted:
    - device: /dev/sdb1
    - fstype: ext4
    - mkmnt: True
    - opts:
      - defaults

/srv/bigdata:
  mount.mounted:
    - device: UUID=066e0200-2867-4ebe-b9e6-f30026ca2314
    - fstype: xfs
    - opts: nobootwait,noatime,nodiratime,nobarrier,logbufs=8
    - dump: 0
    - pass_num: 2
    - persist: True
    - mkmnt: True
```

**salt.states.mount.mod\_watch**(*name*, *user=None*, *\*\*kwargs*)

The mounted watcher, called to invoke the watch command.

**name** The name of the mount point

**salt.states.mount.mounted**(*name*, *device*, *fstype*, *mkmnt=False*, *opts='defaults'*, *dump=0*, *pass\_num=0*, *config='/etc/fstab'*, *persist=True*, *mount=True*, *user=None*, *match\_on='auto'*)

Verify that a device is mounted

**name** The path to the location where the device is to be mounted

**device** The device name, typically the device node, such as `/dev/sdb1` or `UUID=066e0200-2867-4ebe-b9e6-f30026ca2314` or `LABEL=DATA`

**fstype** The filesystem type, this will be `xfs`, `ext2/3/4` in the case of classic filesystems, and `fuse` in the case of fuse mounts

**mkmnt** If the mount point is not present then the state will fail, set `mkmnt: True` to create the mount point if it is otherwise not present

**opts** A list object of options or a comma delimited list

**dump** The dump value to be passed into the fstab, Default is 0

**pass\_num** The pass value to be passed into the fstab, Default is 0

**config** Set an alternative location for the fstab, Default is `/etc/fstab`

**persist** Set if the mount should be saved in the fstab, Default is `True`

**mount** Set if the mount should be mounted immediately, Default is `True`

**user** The user to own the mount; this defaults to the user salt is running as on the minion

**match\_on** A name or list of fstab properties on which this state should be applied. Default is `auto`, a special value indicating to guess based on `fstype`. In general, `auto` matches on name for recognized special devices and device otherwise.

`salt.states.mount.swap` (*name, persist=True, config='/etc/fstab'*)

Activates a swap device

```
/root/swapfile:
  mount.swap
```

---

**Note:** swap does not currently support LABEL

---

`salt.states.mount.unmounted` (*name, device, config='/etc/fstab', persist=False, user=None*)

New in version 0.17.0.

Verify that a device is not mounted

**name** The path to the location where the device is to be unmounted from

New in version 2015.5.0.

**device** The device to be unmounted.

**config** Set an alternative location for the fstab, Default is `/etc/fstab`

**persist** Set if the mount should be purged from the fstab, Default is `False`

**user** The user to own the mount; this defaults to the user salt is running as on the minion

### 30.27.77 salt.states.mysql\_database

#### Management of MySQL databases (schemas)

**depends**

- MySQLdb Python module

**configuration** See `salt.modules.mysql` for setup instructions.

The `mysql_database` module is used to create and manage MySQL databases. Databases can be set as either absent or present.

```
frank:
  mysql_database.present
```

`salt.states.mysql_database.absent` (*name, \*\*connection\_args*)

Ensure that the named database is absent

**name** The name of the database to remove

`salt.states.mysql_database.present` (*name, \*\*connection\_args*)

Ensure that the named database is present with the specified properties

**name** The name of the database to manage

### 30.27.78 salt.states.mysql\_grants

#### Management of MySQL grants (user permissions)

##### depends

- MySQLdb Python module

**configuration** See `salt.modules.mysql` for setup instructions.

The `mysql_grants` module is used to grant and revoke MySQL permissions.

The name you pass in purely symbolic and does not have anything to do with the grant itself.

The database parameter needs to specify a `'priv_level'` in the same specification as defined in the MySQL documentation:

- \*
- \*\*
- db\_name.\*
- db\_name.tbl\_name
- etc...

```
frank_exempledb:
  mysql_grants.present:
    - grant: select,insert,update
    - database: exempledb.*
    - user: frank
    - host: localhost

frank_otherdb:
  mysql_grants.present:
    - grant: all privileges
    - database: otherdb.*
    - user: frank

restricted_singletable:
  mysql_grants.present:
    - grant: select
    - database: somedb.sometable
    - user: joe
```

`salt.states.mysql_grants.absent` (*name, grant=None, database=None, user=None, host='localhost', grant\_option=False, escape=True, \*\*connection\_args*)

Ensure that the grant is absent

**name** The name (key) of the grant to add

**grant** The grant `priv_type` (i.e. `select,insert,update` OR `all privileges`)

**database** The database `priv_level` (i.e. `db.tbl` OR `db.*`)

**user** The user to apply the grant to

**host** The network/host that the grant should apply to

```
salt.states.mysql_grants.present(name, grant=None, database=None, user=None,
                                  host='localhost', grant_option=False, escape=True, re-
                                  voke_first=False, ssl_option=False, **connection_args)
```

Ensure that the grant is present with the specified properties

**name** The name (key) of the grant to add

**grant** The grant priv\_type (i.e. select,insert,update OR all privileges)

**database** The database priv\_level (i.e. db.tbl OR db.\*)

**user** The user to apply the grant to

**host** The network/host that the grant should apply to

**grant\_option** Adds the WITH GRANT OPTION to the defined grant. Default is `False`

**escape** Defines if the database value gets escaped or not. Default is `True`

**revoke\_first** By default, MySQL will not do anything if you issue a command to grant privileges that are more restrictive than what's already in place. This effectively means that you cannot downgrade permissions without first revoking permissions applied to a db.table/user pair first.

To have Salt forcibly revoke perms before applying a new grant, enable the ``revoke_first`` options.

WARNING: This will *remove* permissions for a database before attempting to apply new permissions. There is no guarantee that new permissions will be applied correctly which can leave your database security in an unknown and potentially dangerous state. Use with caution!

Default is `False`

**ssl\_option** Adds the specified ssl options for the connecting user as requirements for this grant. Value is a list of single-element dicts corresponding to the list of ssl options to use.

Possible key/value pairings for the dicts in the value:

```
- SSL: True
- X509: True
- SUBJECT: <subject>
- ISSUER: <issuer>
- CIPHER: <cipher>
```

The non-boolean ssl options take a string as their values, which should be an appropriate value as specified by the MySQL documentation for these options.

Default is `False` (no ssl options will be used)

### 30.27.79 salt.states.mysql\_query

#### Execution of MySQL queries

New in version 2014.7.0.

##### depends

- MySQLdb Python module

**configuration** See `salt.modules.mysql` for setup instructions.

The `mysql_query` module is used to execute queries on MySQL databases. Its output may be stored in a file or in a grain.

```

query_id:
  mysql_query.run
    - database: my_database
    - query: "SELECT * FROM table;"
    - output: "/tmp/query_id.txt"

```

**salt.states.mysql\_query.run**(*name, database, query, output=None, grain=None, key=None, overwrite=True, \*\*connection\_args*)

Execute an arbitrary query on the specified database

**name** Used only as an ID

**database** The name of the database to execute the query on

**query** The query to execute

**output** grain: output in a grain other: the file to store results None: output to the result comment (default)

**grain:** grain to store the output (need output=grain)

**key:** the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.

**overwrite:** The file or grain will be overwritten if it already exists (default)

### 30.27.80 salt.states.mysql\_user

#### Management of MySQL users

##### depends

- MySQLdb Python module

**configuration** See *salt.modules.mysql* for setup instructions.

```

frank:
  mysql_user.present:
    - host: localhost
    - password: bobcat

```

New in version 0.16.2: Authentication overrides have been added.

The MySQL authentication information specified in the minion config file can be overridden in states using the following arguments: `connection_host`, `connection_port`, `connection_user`, `connection_pass`, `connection_db`, `connection_unix_socket`, `connection_default_file` and `connection_charset`.

```

frank:
  mysql_user.present:
    - host: localhost
    - password: "bob@cat"
    - connection_user: someuser
    - connection_pass: somepass
    - connection_charset: utf8
    - saltenv:
      - LC_ALL: "en_US.utf8"

```

`salt.states.mysql_user.absent` (*name*, *host*='localhost', *\*\*connection\_args*)

Ensure that the named user is absent

**name** The name of the user to remove

`salt.states.mysql_user.present` (*name*, *host*='localhost', *password*=None, *password\_hash*=None, *allow\_passwordless*=False, *unix\_socket*=False, *\*\*connection\_args*)

Ensure that the named user is present with the specified properties. A passwordless user can be configured by omitting `password` and `password_hash`, and setting `allow_passwordless` to `True`.

**name** The name of the user to manage

**host** Host for which this user/password combo applies

**password** The password to use for this user. Will take precedence over the `password_hash` option if both are specified.

**password\_hash** The password in hashed form. Be sure to quote the password because YAML doesn't like the \*. A password hash can be obtained from the `mysql` command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+-----+
| PASSWORD('mypass') |
+-----+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-----+
1 row in set (0.00 sec)
```

**allow\_passwordless** If `True`, then `password` and `password_hash` can be omitted to permit a passwordless login.

New in version 0.16.2.

**unix\_socket** If `True` and `allow_passwordless` is `True`, the `unix_socket` auth plugin will be used.

### 30.27.81 salt.states.network

#### Configuration of network interfaces

The network module is used to create and manage network settings, interfaces can be set as either managed or ignored. By default all interfaces are ignored unless specified.

**Note:** Prior to version 2014.1.0, only RedHat-based systems (RHEL, CentOS, Scientific Linux, etc.) are supported. Support for Debian/Ubuntu is new in 2014.1.0 and should be considered experimental.

Other platforms are not yet supported.

```
system:
  network.system:
    - enabled: True
    - hostname: server1.example.com
    - gateway: 192.168.0.1
    - gatewaydev: eth0
    - nozeroconf: True
    - nisdomain: example.com
    - require_reboot: True

eth0:
```

```
network.managed:
  - enabled: True
  - type: eth
  - proto: none
  - ipaddr: 10.1.0.1
  - netmask: 255.255.255.0
  - dns:
    - 8.8.8.8
    - 8.8.4.4

routes:
  network.routes:
    - name: eth0

    - gatewaydev: eth0
    - nozeroconf: True
    - nisdomain: example.com
    - require_reboot: True
    - apply_hostname: True

.. note::
    Apply changes to hostname immediately.

.. versionadded:: 2015.5.0

```

**Note:** When managing bridged interfaces on a Debian or Ubuntu based system, the ports argument is required. Red Hat systems will ignore the argument.

`salt.states.network.managed`(*name*, *type*, *enabled=True*, *\*\*kwargs*)

Ensure that the named interface is configured properly.

**name** The name of the interface to manage

**type** Type of interface and configuration.

**enabled** Designates the state of this interface.

**kwargs** The IP parameters for this interface.

`salt.states.network.routes`(*name*, *\*\*kwargs*)

Manage network interface static routes.

**name** Interface name to apply the route to.

**kwargs** Named routes

`salt.states.network.system`(*name*, *\*\*kwargs*)

Ensure that global network settings are configured properly.

**name** Custom name to represent this configuration change.

**kwargs** The global parameters for the system.

### 30.27.82 salt.states.nftables

#### Management of nftables

This is an nftables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic *firewall* state.

```
httpd:
  nftables.append:
    - table: filter
    - chain: input
    - jump: accept
    - match: state
    - connstate: new
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.append:
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.insert:
    - position: 1
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.insert:
    - position: 1
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True
```

```

httpd:
  nftables.delete:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

```

```

httpd:
  nftables.delete:
    - position: 1
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

```

```

httpd:
  nftables.delete:
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

```

**salt.states.nftables.append**(*name*, *family*='ipv4', *\*\*kwargs*)

New in version 0.17.0.

Append a rule to a chain

**name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**family** Network family, ipv4 or ipv6.

All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

**salt.states.nftables.chain\_absent**(*name*, *table*='filter', *family*='ipv4')

New in version 2014.7.0.

Verify the chain is absent.

**family** Networking family, either ipv4 or ipv6

**salt.states.nftables.chain\_present**(*name*, *table*='filter', *table\_type*=None, *hook*=None, *priority*=None, *family*='ipv4')

New in version 2014.7.0.

Verify the chain is exist.

**name** A user-defined chain name.

**table** The table to own the chain.

**family** Networking family, either ipv4 or ipv6

`salt.states.nftables.delete` (*name*, *family='ipv4'*, *\*\*kwargs*)

New in version 2014.7.0.

Delete a rule to a chain

**name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**family** Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

`salt.states.nftables.flush` (*name*, *family='ipv4'*, *\*\*kwargs*)

New in version 2014.7.0.

Flush current nftables state

**family** Networking family, either ipv4 or ipv6

`salt.states.nftables.insert` (*name*, *family='ipv4'*, *\*\*kwargs*)

New in version 2014.7.0.

Insert a rule into a chain

**name** A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

**family** Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

### 30.27.83 salt.states.npm

#### Installation of NPM Packages

These states manage the installed packages for node.js using the Node Package Manager (npm). Note that npm must be installed for these states to be available, so npm states should include a requisite to a pkg.installed state for the package which provides npm (simply `npm` in most cases). Example:

```
npm:
  pkg.installed

yaml:
  npm.installed:
    - require:
      - pkg: npm
```

`salt.states.npm.bootstrap` (*name*, *user=None*)

Bootstraps a node.js application.

Will execute ``npm install --json`` on the specified directory.

**user** The user to run NPM with

New in version 0.17.0.

`salt.states.npm.installed`(*name*, *pkgs=None*, *dir=None*, *user=None*, *force\_reinstall=False*, *registry=None*, *env=None*)

Verify that the given package is installed and is at the correct version (if specified).

```
coffee-script:
  npm.installed:
    - user: someuser

coffee-script@1.0.1:
  npm.installed: []
```

**name** The package to install

Changed in version 2014.7.2: This parameter is no longer lowercased by salt so that case-sensitive NPM package names will work.

**pkgs** A list of packages to install with a single npm invocation; specifying this argument will ignore the `name` argument

New in version 2014.7.0.

**dir** The target directory in which to install the package, or `None` for global installation

**user** The user to run NPM with

New in version 0.17.0.

**registry** The NPM registry from which to install the package

New in version 2014.7.0.

**env** A list of environment variables to be set prior to execution. The format is the same as the `cmd.run` state function.

New in version 2014.7.0.

**force\_reinstall** Install the package even if it is already installed

`salt.states.npm.removed`(*name*, *dir=None*, *user=None*)

Verify that the given package is not installed.

**dir** The target directory in which to install the package, or `None` for global installation

**user** The user to run NPM with

New in version 0.17.0.

### 30.27.84 salt.states.ntp

#### Management of NTP servers

New in version 2014.1.0.

This state is used to manage NTP servers. Currently only Windows is supported.

```
win_ntp:
  ntp.managed:
    - servers:
      - pool.ntp.org
      - us.pool.ntp.org
```

**salt.states.ntp.managed**(*name, servers=None*)

Manage NTP servers

**servers** A list of NTP servers

### 30.27.85 salt.states.openstack\_config

Manage OpenStack configuration file settings.

**maintainer** Jeffrey C. Ollie <jeff@ocjtech.us>

**maturity** new

**depends**

**platform** linux

**salt.states.openstack\_config.absent**(*name, filename, section, parameter=None*)

Ensure a value is not set in an OpenStack configuration file.

**filename** The full path to the configuration file

**section** The section in which the parameter will be set

**parameter (optional)** The parameter to change. If the parameter is not supplied, the name will be used as the parameter.

**salt.states.openstack\_config.present**(*name, filename, section, value, parameter=None*)

Ensure a value is set in an OpenStack configuration file.

**filename** The full path to the configuration file

**section** The section in which the parameter will be set

**parameter (optional)** The parameter to change. If the parameter is not supplied, the name will be used as the parameter.

**value** The value to set

### 30.27.86 salt.states.pagerduty

#### Create an Event in PagerDuty

New in version 2014.1.0.

This state is useful for creating events on the PagerDuty service during state runs.

```
server-warning-message:
  pagerduty.create_event:
    - name: 'This is a server warning message'
    - details: 'This is a much more detailed message'
    - service_key: 9abcd123456789efabcde362783cdbaf
    - profile: my-pagerduty-account
```

`salt.states.pagerduty.create_event` (*name, details, service\_key, profile*)  
 Create an event on the PagerDuty service

```
server-warning-message:
  pagerduty.create_event:
    - name: 'This is a server warning message'
    - details: 'This is a much more detailed message'
    - service_key: 9abcd123456789efabcde362783cdbaf
    - profile: my-pagerduty-account
```

The following parameters are required:

**name** This is a short description of the event.

**details** This can be a more detailed description of the event.

**service\_key** This key can be found by using `pagerduty.list_services`.

**profile** This refers to the configuration profile to use to connect to the PagerDuty service.

### 30.27.87 salt.states.pecl

#### Installation of PHP Extensions Using pecl

These states manage the installed pecl extensions. Note that `php-pear` must be installed for these states to be available, so pecl states should include a requisite to a `pkg.installed` state for the package which provides pecl (`php-pear` in most cases). Example:

```
php-pear:
  pkg.installed

mongo:
  pecl.installed:
    - require:
      - pkg: php-pear
```

`salt.states.pecl.installed` (*name, version=None, defaults=False, force=False, preferred\_state='stable'*)

New in version 0.17.0.

Make sure that a pecl extension is installed.

**name** The pecl extension name to install

**version** The pecl extension version to install. This option may be ignored to install the latest stable version.

**defaults** Use default answers for extensions such as `pecl_http` which ask questions before installation. Without this option, the `pecl.installed` state will hang indefinitely when trying to install these extensions.

**force** Whether to force the installed version or not

**preferred\_state** The pecl extension state to install

`salt.states.pecl.removed` (*name*)

Make sure that a pecl extension is not installed.

**name** The pecl extension name to uninstall

### 30.27.88 salt.states.pip\_state

#### Installation of Python Packages Using pip

These states manage system installed python packages. Note that pip must be installed for these states to be available, so pip states should include a requisite to a pkg.installed state for the package which provides pip (python-pip in most cases). Example:

```
python-pip:
  pkg.installed

virtualenvwrapper:
  pip.installed:
    - require:
      - pkg: python-pip
```

```
salt.states.pip_state.installed(name, pkgs=None, pip_bin=None, requirements=None,
env=None, bin_env=None, use_wheel=False,
no_use_wheel=False, log=None, proxy=None, time-
out=None, repo=None, editable=None, find_links=None,
index_url=None, extra_index_url=None, no_index=False,
mirrors=None, build=None, target=None, down-
load=None, download_cache=None, source=None, up-
grade=False, force_reinstall=False, ignore_installed=False,
exists_action=None, no_deps=False, no_install=False,
no_download=False, install_options=None,
global_options=None, user=None, no_chown=False,
cwd=None, activate=False, pre_releases=False, cert=None,
allow_all_external=False, allow_external=None, al-
low_unverified=None, process_dependency_links=False,
env_vars=None, use_vt=False)
```

Make sure the package is installed

**name** The name of the python package to install. You can also specify version numbers here using the standard operators ==, >=, <=. If requirements is given, this parameter will be ignored.

Example:

```
django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - require:
      - pkg: python-pip
```

This will install the latest Django version greater than 1.6 but less than 1.7.

**requirements** Path to a pip requirements file. If the path begins with salt:// the file will be transferred from the master file server.

**user** The user under which to run pip

**use\_wheel** [False] Prefer wheel archives (requires pip>=1.4)

**no\_use\_wheel** [False] Force to not use wheel archives (requires pip>=1.4)

**log** Log file where a complete (maximum verbosity) record will be kept

**proxy** Specify a proxy in the form `user:passwd@proxy.server:port`. Note that the `user:password@` is optional and required only if you are behind an authenticated proxy. If you provide `user@proxy.server:port` then you will be prompted for a password.

**timeout** Set the socket timeout (default 15 seconds)

**editable** install something editable (i.e. `git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed`)

**find\_links** URL to look for packages at

**index\_url** Base URL of Python Package Index

**extra\_index\_url** Extra URLs of package indexes to use in addition to `index_url`

**no\_index** Ignore package index

**mirrors** Specific mirror URL(s) to query (automatically adds `--use-mirrors`)

**build** Unpack packages into `build` dir

**target** Install packages into `target` dir

**download** Download packages into `download` instead of installing them

**download\_cache** Cache downloaded packages in `download_cache` dir

**source** Check out `editable` packages into `source` dir

**upgrade** Upgrade all packages to the newest available version

**force\_reinstall** When upgrading, reinstall all packages even if they are already up-to-date.

**ignore\_installed** Ignore the installed packages (reinstalling instead)

**exists\_action** Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup

**no\_deps** Ignore package dependencies

**no\_install** Download and unpack all packages, but don't actually install them

**no\_chown** When user is given, do not attempt to copy and chown a requirements file

**cwd** Current working directory to run pip from

**activate** Activates the virtual environment, if given via `bin_env`, before running install.

Deprecated since version 2014.7.2: If `bin_env` is given, pip will already be sourced from that virtualenv, making `activate` effectively a noop.

**pre\_releases** Include pre-releases in the available versions

**cert** Provide a path to an alternate CA bundle

**allow\_all\_external** Allow the installation of all externally hosted files

**allow\_external** Allow the installation of externally hosted files (comma separated list)

**allow\_unverified** Allow the installation of insecure and unverifiable files (comma separated list)

**process\_dependency\_links** Enable the processing of dependency links

**bin\_env** [None] Absolute path to a virtual environment directory or absolute path to a pip executable. The example below assumes a virtual environment has been created at `/foo/.virtualenvs/bar`.

**env\_vars** Add or modify environment variables. Useful for tweaking build steps, such as specifying `INCLUDE` or `LIBRARY` paths in Makefiles, build scripts or compiler calls. This must be in the form of a dictionary or a mapping.

Example:

```
django:
  pip.installed:
    - name: django_app
    - env_vars:
      CUSTOM_PATH: /opt/django_app
      VERBOSE: True
```

**use\_vt** Use VT terminal emulation (see output while installing)

Example:

```
django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - bin_env: /foo/.virtualenvs/bar
    - require:
      - pkg: python-pip
```

Or

Example:

```
django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - bin_env: /foo/.virtualenvs/bar/bin/pip
    - require:
      - pkg: python-pip
```

---

### Attention

The following arguments are deprecated, do not use.

---

**pip\_bin** [None] Deprecated, use `bin_env`

**env** [None] Deprecated, use `bin_env`

Changed in version 0.17.0: `use_wheel` option added.

**install\_options**

Extra arguments to be supplied to the `setup.py` install command. If you are using an option with a directory path, be sure to use absolute path.

Example:

```
django:
  pip.installed:
    - name: django
    - install_options:
      - --prefix=/blah
    - require:
      - pkg: python-pip
```

**global\_options** Extra global options to be supplied to the `setup.py` call before the install command.

New in version 2014.1.3.

---

### Attention

As of Salt 0.17.0 the pip state **needs** an importable pip module. This usually means having the system's pip package installed or running Salt from an active `virtualenv`.

The reason for this requirement is because pip already does a pretty good job parsing its own requirements. It makes no sense for Salt to do pip requirements parsing and validation before passing them to the pip library. It's functionality duplication and it's more error prone.

---

```
salt.states.pip_state.removed(name, requirements=None, bin_env=None, log=None, proxy=None,
                               timeout=None, user=None, cwd=None, use_vt=False)
```

Make sure that a package is not installed.

**name** The name of the package to uninstall

**user** The user under which to run pip

**bin\_env** [None] the pip executable or virtualenv to use

**use\_vt** Use VT terminal emulation (see output while installing)

```
salt.states.pip_state.uptodate(name, bin_env=None, user=None, cwd=None, use_vt=False)
```

New in version 2015.5.0.

Verify that the system is completely up to date.

**name** The name has no functional value and is only used as a tracking reference

**user** The user under which to run pip

**bin\_env** the pip executable or virtualenv to use

**use\_vt** Use VT terminal emulation (see output while installing)

### 30.27.89 salt.states.pkg

#### Installation of packages using OS package managers such as yum or apt-get

Salt can manage software packages via the pkg state module, packages can be set up to be installed, latest, removed and purged. Package management declarations are typically rather simple:

```
vim:
  pkg.installed
```

A more involved example involves pulling from a custom repository. Note that the pkgrepo has a `require_in` clause. This is necessary and can not be replaced by a `require` clause in the pkg.

```
base:
  pkgrepo.managed:
    - humanname: Logstash PPA
    - name: ppa:wolfnet/logstash
    - dist: precise
    - file: /etc/apt/sources.list.d/logstash.list
    - keyid: 28B04E4A
    - keyserver: keyserver.ubuntu.com
    - require_in:
      - pkg: logstash

logstash:
  pkg.installed
```

```
salt.states.pkg.installed(name, version=None, refresh=None, fromrepo=None, skip_verify=False,
                          skip_suggestions=False, pkgs=None, sources=None, allow_updates=False,
                          pkg_verify=False, normalize=True, **kwargs)
```

Ensure that the package is installed, and that it is the correct version (if specified).

#### Parameters

- **name** (*str*) -- The name of the package to be installed. This parameter is ignored if either ``pkgs`` or ``sources`` is used. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the ``sources`` option detailed below.
- **version** (*str*) -- Install a specific version of a package. This option is ignored if either ``pkgs`` or ``sources`` is used. Currently, this option is supported for the following pkg providers: *apt*, *ebuild*, *pacman*, *yumpkg*, and *zypper*. The version number includes the release designation where applicable, to allow Salt to target a specific release of a given version. When in doubt, using the `pkg.latest_version` function for an uninstalled package will tell you the version available.

```
# salt myminion pkg.latest_version httpd
myminion:
  2.2.15-30.el6.centos
```

Also, while this function is not yet implemented for all pkg frontends, `pkg.list_repo_pkgs` will show all versions available in the various repositories for a given package, irrespective of whether or not it is installed.

```
# salt myminion pkg.list_repo_pkgs httpd
myminion:
  -----
  base:
    |_
    -----
    httpd:
      2.2.15-29.el6.centos
  updates:
    |_
    -----
    httpd:
      2.2.15-30.el6.centos
```

The version strings returned by either of these functions can be used as version specifiers in pkg states.

- **refresh** (*bool*) -- Update the repo database of available packages prior to installing the requested package.
- **fromrepo** (*str*) -- Specify a repository from which to install

**Note:** Distros which use APT (Debian, Ubuntu, etc.) do not have a concept of repositories, in the same way as YUM-based distros do. When a source is added, it is assigned to a given release. Consider the following source configuration:

```
deb http://ppa.launchpad.net/saltstack/salt/ubuntu precise main
```

The packages provided by this source would be made available via the `precise` release, therefore `fromrepo` would need to be set to `precise` for Salt to install the package from this source.

Having multiple sources in the same release may result in the default install candidate being newer than what is desired. If this is the case, the desired version must be specified using the `version` parameter.

If the `pkgs` parameter is being used to install multiple packages in the same state, then instead of using `version`, use the method of version specification described in the **Multiple Package Installation Options** section below.

Running the shell command `apt-cache policy pkgname` on a minion can help elucidate the APT configuration and aid in properly configuring states:

```
root@saltmaster:~# salt ubuntu01 cmd.run 'apt-cache policy ffmpeg'
ubuntu01:
  ffmpeg:
  Installed: (none)
  Candidate: 7:0.10.11-1~precise1
  Version table:
     7:0.10.11-1~precise1 0
        500 http://ppa.launchpad.net/jon-severinsson/ffmpeg/ubuntu/ precise/main
     4:0.8.10-0ubuntu0.12.04.1 0
        500 http://us.archive.ubuntu.com/ubuntu/ precise-updates/main amd64 Pack
        500 http://security.ubuntu.com/ubuntu/ precise-security/main amd64 Packa
     4:0.8.1-0ubuntu1 0
        500 http://us.archive.ubuntu.com/ubuntu/ precise/main amd64 Packages
```

The release is located directly after the source's URL. The actual release name is the part before the slash, so to install version `4:0.8.10-0ubuntu0.12.04.1` either `precise-updates` or `precise-security` could be used for the `fromrepo` value.

- **skip\_verify** (*bool*) -- Skip the GPG verification check for the package to be installed
- **skip\_suggestions** (*bool*) -- Force strict package naming. Disables lookup of package alternatives.

New in version 2014.1.1.

- **pkgs** (*list*) -- A list of packages to install from a software repository. All packages listed under `pkgs` will be installed via a single command.

Example:

```
mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar
      - baz
    - hold: True
```

**NOTE:** For `apt`, `ebuild`, `pacman`, `yumpkg`, and `zypper`, version numbers can be specified in the `pkgs` argument. For example:

```
mypkgs:
  pkg.installed:
    - pkgs:
      - foo
```

```
- bar: 1.2.3-4
- baz
```

Additionally, *ebuild*, *pacman* and *zypper* support the `<`, `<=`, `>=`, and `>` operators for more control over what versions will be installed. For

Example:

```
mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: '>=1.2.3-4'
      - baz
```

**NOTE:** When using comparison operators, the expression must be enclosed in quotes to avoid a YAML render error.

With *ebuild* is also possible to specify a use flag list and/or if the given packages should be in `package.accept_keywords` file and/or the overlay from which you want the package to be installed.

For example:

```
mypkgs:
  pkg.installed:
    - pkgs:
      - foo: '~'
      - bar: '~>=1.2:slot::overlay[use,-otheruse]'
      - baz
```

#### Multiple Package Installation Options: (not supported in Windows or pkgng)

- **sources** (*list*) -- A list of packages to install, along with the source URI or local path from which to install each package. In the example below, `foo`, `bar`, `baz`, etc. refer to the name of the package, as it would appear in the output of the `pkg.version` or `pkg.list_pkgs` salt CLI commands.

```
mypkgs:
  pkg.installed:
    - sources:
      - foo: salt://rpms/foo.rpm
      - bar: http://somesite.org/bar.rpm
      - baz: ftp://someothersite.org/baz.rpm
      - qux: /minion/path/to/qux.rpm
```

- **allow\_updates** (*bool*) -- Allow the package to be updated outside Salt's control (e.g. auto updates on Windows). This means a package on the Minion can have a newer version than the latest available in the repository without enforcing a re-installation of the package.

New in version 2014.7.0.

Example:

```
httpd:
  pkg.installed:
    - fromrepo: mycustomrepo
```

```

- skip_verify: True
- skip_suggestions: True
- version: 2.0.6~ubuntu3
- refresh: True
- allow_updates: True
- hold: False

```

- **pkg\_verify** (*bool*) -- New in version 2014.7.0.

For requested packages that are already installed and would not be targeted for upgrade or downgrade, use `pkg.verify` to determine if any of the files installed by the package have been altered. If files have been altered, the `reinstall` option of `pkg.install` is used to force a reinstall. Types to ignore can be passed to `pkg.verify` (see example below). Currently, this option is supported for the following `pkg` providers: *yumpkg*.

Examples:

```

httpd:
  pkg.installed:
    - version: 2.2.15-30.el6.centos
    - pkg_verify: True

```

```

mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: 1.2.3-4
      - baz
    - pkg_verify:
      - ignore_types: [config,doc]

```

- **normalize** (*bool*) -- Normalize the package name by removing the architecture. Default is True. This is useful for poorly created packages which might include the architecture as an actual part of the name such as kernel modules which match a specific kernel version.

New in version 2014.7.0.

Example:

```

gpfs.gplbin-2.6.32-279.31.1.el6.x86_64:
  pkg.installed:
    - normalize: False

```

- **kwargs** -- These are specific to each OS. If it does not apply to the execution module for your OS, it is ignored.

**param bool hold** Force the package to be held at the current installed version. Currently works with YUM & APT based systems.

New in version 2014.7.0.

**param list names** A list of packages to install from a software repository. Each package will be installed individually by the package manager.

**Warning:** Unlike `pkgs`, the `names` parameter cannot specify a version. In addition, it makes a separate call to the package management frontend to install each package, whereas `pkgs` makes just a single call. It is therefore recommended to use `pkgs` instead of `names` to install multiple packages, both for the additional features and the performance improvement that it brings.

**param bool `install_recommends`** Whether to install the packages marked as recommended. Default is True. Currently only works with APT based systems.

New in version 2015.5.0.

```
httpd:
  pkg.installed:
    - install_recommends: False
```

**param bool `only_upgrade`** Only upgrade the packages, if they are already installed. Default is False. Currently only works with APT based systems.

New in version 2015.5.0.

```
httpd:
  pkg.installed:
    - only_upgrade: True
```

**Returns** A dictionary containing the state of the software installation

Rtype dict

`salt.states.pkg.latest`(*name*, *refresh=None*, *fromrepo=None*, *skip\_verify=False*, *pkgs=None*, *\*\*kwargs*)

Ensure that the named package is installed and the latest available package. If the package can be updated, this state function will update the package. Generally it is better for the `installed` function to be used, as `latest` will update the package whenever a new package is available.

**name** The name of the package to maintain at the latest available version. This parameter is ignored if `pkgs` is used.

**fromrepo** Specify a repository from which to install

**skip\_verify** Skip the GPG verification check for the package to be installed

**refresh** Update the repo database of available packages prior to installing the requested package.

Multiple Package Installation Options:

(Not yet supported for: Windows, FreeBSD, OpenBSD, MacOS, and Solaris pkgutil)

**pkgs** A list of packages to maintain at the latest available version.

```
mypkgs:
  pkg.latest:
    - pkgs:
      - foo
      - bar
      - baz
```

**install\_recommends** Whether to install the packages marked as recommended. Default is True. Currently only works with APT based systems.

New in version 2015.5.0.

```
httpd:
  pkg.latest:
    - install_recommends: False
```

**only\_upgrade** Only upgrade the packages, if they are already installed. Default is False. Currently only works with APT based systems.

New in version 2015.5.0.

```
httpd:
  pkg.latest:
    - only_upgrade: True
```

**salt.states.pkg.mod\_aggregate** (*low, chunks, running*)

The `mod_aggregate` function which looks up all packages in the available low chunks and merges them into a single pkgs ref in the present low data

**salt.states.pkg.purged** (*name, version=None, pkgs=None, \*\*kwargs*)

Verify that a package is not installed, calling `pkg.purge` if necessary to purge the package. All configuration files are also removed.

**name** The name of the package to be purged.

**version** The version of the package that should be removed. Don't do anything if the package is installed with an unmatching version.

Multiple Package Options:

**pkgs** A list of packages to purge. Must be passed as a python list. The `name` parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.

**salt.states.pkg.removed** (*name, version=None, pkgs=None, \*\*kwargs*)

Verify that a package is not installed, calling `pkg.remove` if necessary to remove the package.

**name** The name of the package to be removed.

**version** The version of the package that should be removed. Don't do anything if the package is installed with an unmatching version.

Multiple Package Options:

**pkgs** A list of packages to remove. Must be passed as a python list. The `name` parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.

**salt.states.pkg.uptodate** (*name, refresh=False, \*\*kwargs*)

New in version 2014.7.0.

Verify that the system is completely up to date.

**name** The name has no functional value and is only used as a tracking reference

**refresh** refresh the package database before checking for new upgrades

**kwargs** Any keyword arguments to pass through to `pkg.upgrade`.

New in version 2015.5.0.

### 30.27.90 salt.states.pkgng

#### Manage package remote repo using FreeBSD pkgng

Salt can manage the URL pkgng pulls packages from. ATM the state and module are small so use cases are typically rather simple:

```
pkgng_clients:
  pkgng.update_packaging_site:
    - name: "http://192.168.0.2"
```

`salt.states.pkgng.update_packaging_site` (*name*)

### 30.27.91 salt.states.pkgrepo

#### Management of APT/YUM package repos

Package repositories for APT-based and YUM-based distros can be managed with these states. Here is some example SLS:

```
base:
  pkgrepo.managed:
    - humaname: CentOS-$releasever - Base
    - mirrorlist: http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=os
    - comments:
      - '#http://mirror.centos.org/centos/$releasever/os/$basearch/'
    - gpgcheck: 1
    - gpgkey: file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6
```

```
base:
  pkgrepo.managed:
    - humaname: Logstash PPA
    - name: deb http://ppa.launchpad.net/wolfnet/logstash/ubuntu precise main
    - dist: precise
    - file: /etc/apt/sources.list.d/logstash.list
    - keyid: 28B04E4A
    - keyserver: keyserver.ubuntu.com
    - require_in:
      - pkg: logstash

  pkg.latest:
    - name: logstash
    - refresh: True
```

```
base:
  pkgrepo.managed:
    - humaname: deb-multimedia
    - name: deb http://www.deb-multimedia.org stable main
    - file: /etc/apt/sources.list.d/deb-multimedia.list
    - key_url: salt://deb-multimedia/files/marillat.pub
```

```
base:
  pkgrepo.managed:
    - humaname: Google Chrome
    - name: deb http://dl.google.com/linux/chrome/deb/ stable main
    - dist: stable
    - file: /etc/apt/sources.list.d/chrome-browser.list
    - require_in:
      - pkg: google-chrome-stable
    - gpgcheck: 1
    - key_url: https://dl-ssl.google.com/linux/linux_signing_key.pub
```

```
base:
  pkgrepo.managed:
    - ppa: wolfnet/logstash
  pkg.latest:
    - name: logstash
    - refresh: True
```

**Note:** On Ubuntu systems, the `python-software-properties` package should be installed for better support of PPA repositories. To check if this package is installed, run `dpkg -l python-software-properties`.

Also, some Ubuntu releases have a [bug](#) in their `python-software-properties` package, a missing dependency on `pycurl`, so `python-pycurl` will need to be manually installed if it is not present once `python-software-properties` is installed.

On Ubuntu & Debian systems, the `python-apt` package is required to be installed. To check if this package is installed, run `dpkg -l python-software-properties`. `python-apt` will need to be manually installed if it is not present.

`salt.states.pkgrepo.absent` (*name*, *\*\*kwargs*)

This function deletes the specified repo on the system, if it exists. It is essentially a wrapper around `pkg.del_repo`.

**name** The name of the package repo, as it would be referred to when running the regular package manager commands.

**ppa** On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name.

```
logstash-ppa:
  pkgrepo.absent:
    - ppa: wolfnet/logstash
```

**ppa\_auth** For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the `username/password` can be specified. This is required for matching if the name format uses the ```ppa:``` specifier and is private (requires `username/password` to access, which is encoded in the URI).

```
logstash-ppa:
  pkgrepo.absent:
    - ppa: wolfnet/logstash
    - ppa_auth: username:password
```

`salt.states.pkgrepo.managed` (*name*, *ppa=None*, *\*\*kwargs*)

This state manages software package repositories. Currently, `yum`, `apt`, and `zypper` repositories are supported.

YUM OR ZYPPER-BASED SYSTEMS

**Note:** One of `baseurl` or `mirrorlist` below is required. Additionally, note that this state is not presently capable of managing more than one repo in a single repo file, so each instance of this state will manage a single repo file containing the configuration for a single repo.

---

**name** This value will be used in two ways: Firstly, it will be the repo ID, as seen in the entry in square brackets (e.g. `[foo]`) for a given repo. Secondly, it will be the name of the file as stored in `/etc/yum.repos.d` (e.g. `/etc/yum.repos.d/foo.conf`).

**humanname** This is used as the ``name"` value in the repo file in `/etc/yum.repos.d/` (or `/etc/zypp/repos.d` for Suse distros).

**baseurl** The URL to a yum repository

**mirrorlist** A URL which points to a file containing a collection of baseurls

**comments** Sometimes you want to supply additional information, but not as enabled configuration. Anything supplied for this list will be saved in the repo configuration with a comment marker (`#`) in front.

Additional configuration values seen in yum repo files, such as `gpgkey` or `gpgcheck`, will be used directly as key-value pairs. For example:

```
foo:
  pkgrepo.managed:
    - humanname: Personal repo for foo
    - baseurl: https://mydomain.tld/repo/foo/$releasever/$basearch
    - gpgkey: file:///etc/pki/rpm-gpg/foo-signing-key
    - gpgcheck: 1
```

## APT-BASED SYSTEMS

**ppa** On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name. The keyid will be queried from launchpad and everything else is set automatically. You can override any of the below settings by simply setting them as you would normally. For example:

```
logstash-ppa:
  pkgrepo.managed:
    - ppa: wolfnet/logstash
```

**ppa\_auth** For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be passed as an HTTP Basic style username/password combination.

```
logstash-ppa:
  pkgrepo.managed:
    - ppa: wolfnet/logstash
    - ppa_auth: username:password
```

**name** On apt-based systems this must be the complete entry as it would be seen in the `sources.list` file. This can have a limited subset of components (i.e. ``main'`) which can be added/modified with the `comps` option.

```
precise-repo:
  pkgrepo.managed:
    - name: deb http://us.archive.ubuntu.com/ubuntu precise main
```

**Note:** The above example is intended as a more readable way of configuring the SLS, it is equivalent to the following:

```
'deb http://us.archive.ubuntu.com/ubuntu precise main':
  pkgrepo.managed
```

**disabled** Toggles whether or not the repo is used for resolving dependencies and/or installing packages.

**enabled** Enables the repository, even if the repository has been disabled, in order for the respective package requiring the repository can be found and installed.

**comps** On apt-based systems, comps dictate the types of packages to be installed from the repository (e.g. main, nonfree, ...). For purposes of this, comps should be a comma-separated list.

**file** The filename for the .list that the repository is configured in. It is important to include the full-path AND make sure it is in a directory that APT will look in when handling packages

**dist** This dictates the release of the distro the packages should be built for. (e.g. unstable). This option is rarely needed.

**keyid** The KeyID of the GPG key to install. This option also requires the `keyserver` option to be set.

**keyserver** This is the name of the keyserver to retrieve gpg keys from. The `keyid` option must also be set for this option to work.

**key\_url** URL to retrieve a GPG key from. Allows the usage of `http://`, `https://` as well as `salt://`.

---

**Note:** Use either `keyid/keyserver` or `key_url`, but not both.

---

**consolidate** If set to true, this will consolidate all sources definitions to the `sources.list` file, cleanup the now unused files, consolidate components (e.g. main) for the same URI, type, and architecture to a single line, and finally remove comments from the `sources.list` file. The `consolidate` will run every time the state is processed. The option only needs to be set on one repo managed by salt to take effect.

**refresh\_db** If set to false this will skip refreshing the apt package database on debian based systems.

**require\_in** Set this to a list of `pkg.installed` or `pkg.latest` to trigger the running of `apt-get update` prior to attempting to install these packages. Setting a `require_in` in the `pkg` will not work for this.

### 30.27.92 salt.states.portage\_config

#### Management of Portage package configuration on Gentoo

A state module to manage Portage configuration on Gentoo

```
salt:
  portage_config.flags:
    - use:
      - openssl
```

`salt.states.portage_config.flags` (*name*, *use=None*, *accept\_keywords=None*, *env=None*, *license=None*, *properties=None*, *unmask=False*, *mask=False*)

Enforce the given flags on the given package or DEPEND atom.

**Warning:** In most cases, the affected package(s) need to be rebuilt in order to apply the changes.

**name** The name of the package or its DEPEND atom

**use** A list of USE flags

**accept\_keywords** A list of keywords to accept. ~ARCH means current host arch, and will be translated into a line without keywords

**env** A list of environment files

**license** A list of accepted licenses

**properties** A list of additional properties

**unmask** A boolean to unmask the package

**mask** A boolean to mask the package

### 30.27.93 salt.states.ports

Manage software from FreeBSD ports

New in version 2014.1.0.

---

**Note:** It may be helpful to use a higher timeout when running a `ports.installed` state, since compiling the port may exceed Salt's timeout.

```
salt -t 1200 '*' state.highstate
```

---

`salt.states.ports.installed`(*name*, *options=None*)

Verify that the desired port is installed, and that it was compiled with the desired options.

**options** Make sure that the desired non-default options are set

**Warning:** Any build options not passed here assume the default values for the port, and are not just differences from the existing cached options from a previous `make config`.

Example usage:

```
security/nmap:
  ports.installed:
    - options:
      - IPV6: off
```

### 30.27.94 salt.states.postgres\_database

#### Management of PostgreSQL databases

The `postgres_database` module is used to create and manage Postgres databases. Databases can be set as either absent or present

```
frank:
  postgres_database.present
```

`salt.states.postgres_database.absent`(*name*, *user=None*, *maintenance\_db=None*, *db\_password=None*, *db\_host=None*, *db\_port=None*, *db\_user=None*)

Ensure that the named database is absent

**name** The name of the database to remove

**db\_user** database username if different from config or default  
**db\_password** user password if any password for a specified user  
**db\_host** Database host if different from config or default  
**db\_port** Database port if different from config or default  
**user** System user all operations should be performed on behalf of

New in version 0.17.0.

```
salt.states.postgres_database.present(name,          tablespace=None,      encoding=None,
                                       lc_collate=None, lc_ctype=None,  owner=None,  tem-
                                       plate=None,   user=None,   maintenance_db=None,
                                       db_password=None, db_host=None, db_port=None,
                                       db_user=None)
```

Ensure that the named database is present with the specified properties. For more information about all of these options see `man createdb(1)`

**name** The name of the database to manage  
**tablespace** Default tablespace for the database  
**encoding** The character encoding scheme to be used in this database  
**lc\_collate** The LC\_COLLATE setting to be used in this database  
**lc\_ctype** The LC\_CTYPE setting to be used in this database  
**owner** The username of the database owner  
**template** The template database from which to build this database  
**user** System user all operations should be performed on behalf of  
**db\_user** database username if different from config or default  
**db\_password** user password if any password for a specified user  
**db\_host** Database host if different from config or default  
**db\_port** Database port if different from config or default

New in version 0.17.0.

### 30.27.95 salt.states.postgres\_extension

#### Management of PostgreSQL extensions (e.g.: postgis)

The `postgres_extensions` module is used to create and manage Postgres extensions.

```
adminpack:
  postgres_extension.present
```

New in version 2014.7.0.

```
salt.states.postgres_extension.absent(name,          if_exists=None,      restrict=None,  cas-
                                       cade=None,   user=None,   maintenance_db=None,
                                       db_password=None, db_host=None, db_port=None,
                                       db_user=None)
```

Ensure that the named extension is absent

**name** Extension name of the extension to remove

**cascade** Drop on cascade

**if\_exists** Add if exist slug

**restrict** Add restrict slug

**maintenance\_db** Database to act on

**user** System user all operations should be performed on behalf of

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

```
salt.states.postgres_extension.present(name,          if_not_exists=None,    schema=None,
                                       ext_version=None, from_version=None, user=None,
                                       maintenance_db=None, db_password=None,
                                       db_host=None, db_port=None, db_user=None)
```

Ensure that the named extension is present with the specified privileges

**name** The name of the extension to manage

**if\_not\_exists** Add a if\_not\_exists switch to the ddl statement

**schema** Schema to install the extension into

**from\_version** Old extension version if already installed

**ext\_version** version to install

**user** System user all operations should be performed on behalf of

**maintenance\_db** Database to act on

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

### 30.27.96 salt.states.postgres\_group

#### Management of PostgreSQL groups (roles)

The postgres\_group module is used to create and manage Postgres groups.

```
frank:
  postgres_group.present
```

```
salt.states.postgres_group.absent(name,          user=None,          maintenance_db=None,
                                       db_password=None, db_host=None, db_port=None,
                                       db_user=None)
```

Ensure that the named group is absent

**name** The groupname of the group to remove

**user** System user all operations should be performed on behalf of

New in version 0.17.0.

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

**salt.states.postgres\_group.present** (*name*, *createdb=*None, *createroles=*None, *createuser=*None, *encrypted=*None, *superuser=*None, *inherit=*None, *login=*None, *replication=*None, *password=*None, *refresh\_password=*None, *groups=*None, *user=*None, *maintenance\_db=*None, *db\_password=*None, *db\_host=*None, *db\_port=*None, *db\_user=*None)

Ensure that the named group is present with the specified privileges Please note that the user/group notion in postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

**name** The name of the group to manage

**createdb** Is the group allowed to create databases?

**createroles** Is the group allowed to create other roles/users

**createuser** Alias to create roles, and history problem, in postgresql normally createuser == superuser

**encrypted** Should the password be encrypted in the system catalog?

**login** Should the group have login perm

**inherit** Should the group inherit permissions

**superuser** Should the new group be a ``superuser``

**replication** Should the new group be allowed to initiate streaming replication

**password** The Group's password It can be either a plain string or a md5 postgresql hashed password:

```
'md5{MD5OF({password}{role}}'
```

If encrypted is None or True, the password will be automatically encrypted to the previous format if it is not already done.

**refresh\_password** Password refresh flag

Boolean attribute to specify whether to password comparison check should be performed.

If refresh\_password is None or False, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL

**groups** A string of comma separated groups the group should be in

**user** System user all operations should be performed on behalf of

New in version 0.17.0.

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

### 30.27.97 salt.states.postgres\_schema

#### Management of PostgreSQL schemas

The postgres\_schemas module is used to create and manage Postgres schemas.

```
public:
  postgres_schema.present 'dbname' 'name'
```

**salt.states.postgres\_schema.absent**(*dbname*, *name*, *db\_user=None*, *db\_password=None*,  
*db\_host=None*, *db\_port=None*)

Ensure that the named schema is absent

**dbname** The database's name will work on

**name** The name of the schema to remove

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

**salt.states.postgres\_schema.present**(*dbname*, *name*, *owner=None*, *db\_user=None*,  
*db\_password=None*, *db\_host=None*, *db\_port=None*)

Ensure that the named schema is present in the database.

**dbname** The database's name will work on

**name** The name of the schema to manage

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

### 30.27.98 salt.states.postgres\_user

#### Management of PostgreSQL users (roles)

The postgres\_users module is used to create and manage Postgres users.

```
frank:
  postgres_user.present
```

**salt.states.postgres\_user.absent**(*name*, *user=None*, *maintenance\_db=None*, *db\_password=None*,  
*db\_host=None*, *db\_port=None*, *db\_user=None*)

Ensure that the named user is absent

**name** The username of the user to remove

**user** System user all operations should be performed on behalf of

New in version 0.17.0.

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

**db\_port** Database port if different from config or default

**salt.states.postgres\_user.present** (*name, createdb=None, createroles=None, createuser=None, encrypted=None, superuser=None, replication=None, inherit=None, login=None, password=None, refresh\_password=None, groups=None, user=None, maintenance\_db=None, db\_password=None, db\_host=None, db\_port=None, db\_user=None*)

Ensure that the named user is present with the specified privileges Please note that the user/group notion in postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

**name** The name of the user to manage

**createdb** Is the user allowed to create databases?

**createroles** Is the user allowed to create other users?

**createuser** Alias to create roles

**encrypted** Should the password be encrypted in the system catalog?

**login** Should the group have login perm

**inherit** Should the group inherit permissions

**superuser** Should the new user be a ``superuser``

**replication** Should the new user be allowed to initiate streaming replication

**password** The user's password It can be either a plain string or a md5 postgresql hashed password:

```
'md5{MD5OF({password}{role}}'
```

If encrypted is None or True, the password will be automatically encrypted to the previous format if it is not already done.

**refresh\_password** Password refresh flag

Boolean attribute to specify whether to password comparison check should be performed.

If refresh\_password is None or False, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL

**groups** A string of comma separated groups the user should be in

**user** System user all operations should be performed on behalf of

New in version 0.17.0.

**db\_user** database username if different from config or default

**db\_password** user password if any password for a specified user

**db\_host** Database host if different from config or default

`db_port` Database port if different from config or default

### 30.27.99 salt.states.powerpath

#### Powerpath configuration support

Allows configuration of EMC Powerpath. Currently only addition/deletion of licenses is supported.

```
key:
  powerpath.license_present: []
```

`salt.states.powerpath.license_absent` (*name*)

Ensures that the specified PowerPath license key is absent on the host.

**name** The license key to ensure is absent

`salt.states.powerpath.license_present` (*name*)

Ensures that the specified PowerPath license key is present on the host.

**name** The license key to ensure is present

### 30.27.100 salt.states.process

#### Process Management

Ensure a process matching a given pattern is absent.

```
httpd-absent:
  process.absent:
    - name: apache2
```

`salt.states.process.absent` (*name*, *user=None*, *signal=None*)

Ensures that the named command is not running.

**name** The pattern to match.

**user** The user process belongs

**signal** Signal to send to the process(es).

### 30.27.101 salt.states.pyenv

#### Managing python installations with pyenv

This module is used to install and manage python installations with pyenv. Different versions of python can be installed, and uninstalled. pyenv will be installed automatically the first time it is needed and can be updated later. This module will *not* automatically install packages which pyenv will need to compile the versions of python.

If pyenv is run as the root user then it will be installed to `/usr/local/pyenv`, otherwise it will be installed to the users `~/.pyenv` directory. To make pyenv available in the shell you may need to add the `pyenv/shims` and `pyenv/bin` directories to the users `PATH`. If you are installing as root and want other users to be able to access pyenv then you will need to add `pyenv_ROOT` to their environment.

This is how a state configuration could look like:

```

pyenv-deps:
  pkg.installed:
    - pkgs:
      - make
      - build-essential
      - libssl-dev
      - zlib1g-dev
      - libbz2-dev
      - libreadline-dev
      - libsqlite3-dev
      - wget
      - curl
      - llvm
python-2.6:
  pyenv.absent:
    - require:
      - pkg: pyenv-deps
python-2.7.6:
  pyenv.installed:
    - default: True
    - require:
      - pkg: pyenv-deps

```

**salt.states.pyenv.absent**(*name*, *user=None*)

Verify that the specified python is not installed with pyenv. pyenv is installed if necessary.

**name** The version of python to uninstall

**user: None** The user to run pyenv as.

New in version 0.17.0.

New in version 0.16.0.

**salt.states.pyenv.install\_pyenv**(*name*, *user=None*)

Install pyenv if not installed. Allows you to require pyenv be installed prior to installing the plugins. Useful if you want to install pyenv plugins via the git or file modules and need them installed before installing any rubies.

Use the pyenv.root configuration option to set the path for pyenv if you want a system wide install that is not in a user home dir.

**user: None** The user to run pyenv as.

**salt.states.pyenv.installed**(*name*, *default=False*, *user=None*)

Verify that the specified python is installed with pyenv. pyenv is installed if necessary.

**name** The version of python to install

**default** [False] Whether to make this python the default.

**user: None** The user to run pyenv as.

New in version 0.17.0.

New in version 0.16.0.

### 30.27.102 salt.states.pyrax\_queues

#### Manage Rackspace Queues

New in version 2015.5.0.

Create and destroy Rackspace queues. Be aware that this interacts with Rackspace's services, and so may incur charges.

This module uses `pyrax`, which can be installed via `package`, or `pip`. This module is greatly inspired by `boto_*` modules from SaltStack code source.

```
myqueue:
  pyrax_queues.present:
    - provider: my-pyrax

myqueue:
  pyrax_queues.absent:
    - provider: my-pyrax
```

`salt.states.pyrax_queues.absent`(*name*, *provider*)

Ensure the named Rackspace queue is deleted.

**name** Name of the Rackspace queue.

**provider** Salt Cloud provider

`salt.states.pyrax_queues.present`(*name*, *provider*)

Ensure the RackSpace queue exists.

**name** Name of the Rackspace queue.

**provider** Salt Cloud Provider

### 30.27.103 salt.states.quota

#### Management of POSIX Quotas

The quota can be managed for the system:

```
/:
  quota.mode:
    mode: off
    quotatype: user
```

`salt.states.quota.mode`(*name*, *mode*, *quotatype*)

Set the quota for the system

**name** The filesystem to set the quota mode on

**mode** Whether the quota system is on or off

**quotatype** Must be `user` or `group`

### 30.27.104 salt.states.rabbitmq\_cluster

#### Manage RabbitMQ Clusters

Example:

```
rabbit@rabbit.example.com:
  rabbitmq_cluster.join:
    - user: rabbit
    - host: rabbit.example.com
```

**salt.states.rabbitmq\_cluster.join**(*name, host, user='rabbit', ram\_node=None, runas='root'*)

Ensure the current node joined to a cluster with node [user@host](#)

**name** Irrelevant, not used (recommended: [user@host](#))

**user** The user of node to join to (default: rabbit)

**host** The host of node to join to

**ram\_node** Join node as a RAM node

**runas** The user to run the rabbitmq command as

**salt.states.rabbitmq\_cluster.joined**(*name, host, user='rabbit', ram\_node=None, runas='root'*)

Ensure the current node joined to a cluster with node [user@host](#)

**name** Irrelevant, not used (recommended: [user@host](#))

**user** The user of node to join to (default: rabbit)

**host** The host of node to join to

**ram\_node** Join node as a RAM node

**runas** The user to run the rabbitmq command as

### 30.27.105 salt.states.rabbitmq\_plugin

#### Manage RabbitMQ Plugins

New in version 2014.1.0.

Example:

```
some_plugin:
  rabbitmq_plugin.enabled: []
```

**salt.states.rabbitmq\_plugin.disabled**(*name, runas=None*)

Ensure the RabbitMQ plugin is disabled.

**name** The name of the plugin

**runas** The user to run the rabbitmq-plugin command as

**salt.states.rabbitmq\_plugin.enabled**(*name, runas=None*)

Ensure the RabbitMQ plugin is enabled.

**name** The name of the plugin

**runas** The user to run the rabbitmq-plugin command as

### 30.27.106 salt.states.rabbitmq\_policy

#### Manage RabbitMQ Policies

**maintainer** Benn Eichhorn <benn@getlocalmeasure.com>

**maturity** new

**platform** all

Example:

```
rabbit_policy:
  rabbitmq_policy.present:
    - name: HA
    - pattern: '.*'
    - definition: '{"ha-mode": "all"}'
```

**salt.states.rabbitmq\_policy.absent**(*name*, *vhost*='/', *runas*=None)

Ensure the named policy is absent

Reference: <http://www.rabbitmq.com/ha.html>

**name** The name of the policy to remove

**runas** Name of the user to run the command as

**salt.states.rabbitmq\_policy.present**(*name*, *pattern*, *definition*, *priority*=0, *vhost*='/', *runas*=None)

Ensure the RabbitMQ policy exists.

Reference: <http://www.rabbitmq.com/ha.html>

**name** Policy name

**pattern** A regex of queues to apply the policy to

**definition** A json dict describing the policy

**priority** Priority (defaults to 0)

**vhost** Virtual host to apply to (defaults to '/')

**runas** Name of the user to run the command as

### 30.27.107 salt.states.rabbitmq\_user

#### Manage RabbitMQ Users

Example:

```
rabbit_user:
  rabbitmq_user.present:
    - password: password
    - force: True
    - tags:
      - monitoring
      - user
    - perms:
      - '/':
```

```

- '.*'
- '.*'
- '.*'
- runas: rabbitmq

```

`salt.states.rabbitmq_user.absent`(*name*, *runas=None*)

Ensure the named user is absent

**name** The name of the user to remove

**runas** User to run the command

`salt.states.rabbitmq_user.present`(*name*, *password=None*, *force=False*, *tags=None*, *perms=()*, *runas=None*)

Ensure the RabbitMQ user exists.

**name** User name

**password** User's password, if one needs to be set

**force** If user exists, forcibly change the password

**tags** Optional list of tags for the user

**perms** A list of dicts with vhost keys and 3-tuple values

**runas** Name of the user to run the command

### 30.27.108 salt.states.rabbitmq\_vhost

#### Manage RabbitMQ Virtual Hosts

Example:

```

virtual_host:
  rabbitmq_vhost.present:
    - user: rabbit_user
    - conf: .*
    - write: .*
    - read: .*

```

`salt.states.rabbitmq_vhost.absent`(*name*, *runas=None*)

Ensure the RabbitMQ Virtual Host is absent

**name** Name of the Virtual Host to remove

**runas** User to run the command

Deprecated since version Beryllium.

`salt.states.rabbitmq_vhost.present`(*name*, *user=None*, *owner=None*, *conf=None*, *write=None*, *read=None*, *runas=None*)

Ensure the RabbitMQ VHost exists.

**name** VHost name

**user** Initial user permission to set on the VHost, if present

Deprecated since version Beryllium.

- owner** Initial owner permission to set on the VHost, if present  
Deprecated since version Beryllium.
- conf** Initial conf string to apply to the VHost and user. Defaults to `*`  
Deprecated since version Beryllium.
- write** Initial write permissions to apply to the VHost and user. Defaults to `*`  
Deprecated since version Beryllium.
- read** Initial read permissions to apply to the VHost and user. Defaults to `*`  
Deprecated since version Beryllium.
- runas** Name of the user to run the command  
Deprecated since version Beryllium.

### 30.27.109 salt.states.rbenv

#### Managing Ruby installations with rbenv

This module is used to install and manage ruby installations with rbenv and the ruby-build plugin. Different versions of ruby can be installed, and uninstalled. Rbenv will be installed automatically the first time it is needed and can be updated later. This module will *not* automatically install packages which rbenv will need to compile the versions of ruby. If your version of ruby fails to install, refer to the ruby-build documentation to verify you are not missing any dependencies: <https://github.com/sstephenson/ruby-build/wiki>

If rbenv is run as the root user then it will be installed to `/usr/local/rbenv`, otherwise it will be installed to the users `~/.rbenv` directory. To make rbenv available in the shell you may need to add the `rbenv/shims` and `rbenv/bin` directories to the users `PATH`. If you are installing as root and want other users to be able to access rbenv then you will need to add `RBENV_ROOT` to their environment.

The following state configuration demonstrates how to install Ruby 1.9.x and 2.x using rbenv on Ubuntu/Debian:

```
rbenv-deps:
  pkg.installed:
    - names:
      - bash
      - git
      - openssl
      - libssl-dev
      - make
      - curl
      - autoconf
      - bison
      - build-essential
      - libssl-dev
      - libyaml-dev
      - libreadline6-dev
      - zlib1g-dev
      - libncurses5-dev

ruby-1.9.3-p429:
  rbenv.absent:
    - require:
      - pkg: rbenv-deps
```

```

ruby-2.0.0-p598:
  rbenv.installed:
    - default: True
    - require:
      - pkg: rbenv-deps

```

`salt.states.rbenv.absent` (*name*, *user=None*)

Verify that the specified ruby is not installed with rbenv. Rbenv is installed if necessary.

**name** The version of ruby to uninstall

**user: None** The user to run rbenv as.

New in version 0.17.0.

New in version 0.16.0.

`salt.states.rbenv.install_rbenv` (*name*, *user=None*)

Install rbenv if not installed. Allows you to require rbenv be installed prior to installing the plugins. Useful if you want to install rbenv plugins via the git or file modules and need them installed before installing any rubies.

Use the `rbenv.root` configuration option to set the path for rbenv if you want a system wide install that is not in a user home dir.

**user: None** The user to run rbenv as.

`salt.states.rbenv.installed` (*name*, *default=False*, *user=None*)

Verify that the specified ruby is installed with rbenv. Rbenv is installed if necessary.

**name** The version of ruby to install

**default** [False] Whether to make this ruby the default.

**user: None** The user to run rbenv as.

New in version 0.17.0.

New in version 0.16.0.

### 30.27.110 salt.states.rdp

Manage RDP Service on Windows servers

`salt.states.rdp.disabled` (*name*)

Disable the RDP service

`salt.states.rdp.enabled` (*name*)

Enable the RDP service and make sure access to the RDP port is allowed in the firewall configuration

### 30.27.111 salt.states.redismod

#### Management of Redis server

New in version 2014.7.0.

**depends**

- redis Python module

**configuration** See `salt.modules.redis` for setup instructions.

```
key_in_redis:
  redis.string:
    - value: string data
```

The redis server information specified in the minion config file can be overridden in states using the following arguments: `host`, `port`, `db`, `password`.

```
key_in_redis:
  redis.string:
    - value: string data
    - host: localhost
    - port: 6379
    - db: 0
    - password: somuchkittycat
```

`salt.states.redismod.absent` (*name*, *keys=None*, *\*\*connection\_args*)

Ensure key absent from redis

**name** Key to ensure absent from redis

**keys** list of keys to ensure absent, name will be ignored if this is used

`salt.states.redismod.string` (*name*, *value*, *expire=None*, *expireat=None*, *\*\*connection\_args*)

Ensure that the key exists in redis with the value specified

**name** Redis key to manage

**value** Data to persist in key

**expire** Sets time to live for key in seconds

**expireat** Sets expiration time for key via UNIX timestamp, overrides *expire*

### 30.27.112 salt.states.reg

#### Manage the Windows registry

Many python developers think of registry keys as if they were python keys in a dictionary which is not the case. The windows registry is broken down into the following components:

##### Hives

This is the top level of the registry. They all begin with HKEY. - HKEY\_CLASSES\_ROOT (HKCR) - HKEY\_CURRENT\_USER (HKCU) - HKEY\_LOCAL\_MACHINE (HKLM) - HKEY\_USER (HKU) - HKEY\_CURRENT\_CONFIG

##### Keys

Hives contain keys. These are basically the folders beneath the hives. They can contain any number of subkeys.

## Values or Entries

Values or Entries are the name/data pairs beneath the keys and subkeys. All keys have a default name/data pair. It is usually ``(Default)"="(value not set)". The actual value for the name and the date is Null. The registry editor will display ``(Default)" and ``(value not set)".

### Example

The following example is taken from the windows startup portion of the registry: `[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run]` `"RTHDVCPL"="\C:\\Program Files\\Realtek\\Audio\\HDA\\RtkNGUI64.exe" -s` `"NvBackend"="\C:\\Program Files (x86)\\NVIDIA Corporation\\Update Core\\NvBackend.exe"` `"BTMTrayAgent"="rundll32.exe \\C:\\Program Files (x86)\\Intel\\Bluetooth\\btmshellex.dll",TrayApp"` In this example these are the values for each:

Hive: `HKEY_LOCAL_MACHINE`

Key and subkeys: `SOFTWARE\Microsoft\Windows\CurrentVersion\Run`

Value:

- There are 3 value names: `RTHDVCPL`, `NvBackend`, and `BTMTrayAgent`
- Each value name has a corresponding value

`salt.states.reg.absent(name, vname=None)`

Ensure a registry value is removed. To remove a key use `key_absent`.

Example:

```
'HKEY_CURRENT_USER\SOFTWARE\Salt\version':
  reg.absent
```

In the above example the path is interpreted as follows: - `HKEY_CURRENT_USER` is the hive - `SOFTWARE\Salt` is the key - `version` is the value name So the value `version` will be deleted from the `SOFTWARE\Salt` key in the `HKEY_CURRENT_USER` hive.

`salt.states.reg.key_absent(name, force=False)`

New in version 2015.5.4.

Ensure a registry key is removed. This will remove a key and all value entries it contains. It will fail if the key contains subkeys.

#### Parameters

- **name** (*str*) -- A string representing the full path to the key to be removed to include the hive and the keypath. The hive can be any of the following: - `HKEY_LOCAL_MACHINE` or `HKLM` - `HKEY_CURRENT_USER` or `HKCU` - `HKEY_USER` or `HKU`
- **force** (*bool*) -- A boolean value indicating that all subkeys should be deleted with the key. If `force=False` and subkeys exists beneath the key you want to delete, `key_absent` will fail. Use with caution. The default is `False`.

**Returns** Returns a dictionary showing the results of the registry operation.

**Return type** `dict`

The following example will delete the `SOFTWARE\Salt` key and all subkeys under the `HKEY_CURRENT_USER` hive.

Example:

```
'HKEY_CURRENT_USER\SOFTWARE\Salt':  
  reg.key_absent:  
    - force: True
```

In the above example the path is interpreted as follows: - HKEY\_CURRENT\_USER is the hive - SOFTWARE\Salt is the key

`salt.states.reg.present`(*name*, *value=None*, *vname=None*, *vdata=None*, *vtype='REG\_SZ'*, *reflection=True*)

Ensure a registry key or value is present.

#### Parameters

- **name** (*str*) -- A string value representing the full path of the key to include the HIVE, Key, and all Subkeys. For example:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Salt
```

Valid hive values include:

- HKEY\_CURRENT\_USER or HKCU
- HKEY\_LOCAL\_MACHINE or HKLM
- HKEY\_USERS or HKU

- **value** (*str*) -- Deprecated. Use *vname* and *vdata* instead. Included here for backwards compatibility.
- **vname** (*str*) -- The name of the value you'd like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value
- **vdata** (*str*) -- The value you'd like to set for the Key. If a value name (*vname*) is passed, this will be the data for that value name. If not, this will be the (Default) value for the key.

The type for the (Default) value is always REG\_SZ and cannot be changed. This parameter is optional. If not passed, the Key will be created with.

- **vtype** (*str*) -- The value type for the data you wish to store in the registry. Valid values are:
  - REG\_BINARY
  - REG\_DWORD
  - REG\_EXPAND\_SZ
  - REG\_MULTI\_SZ
  - REG\_SZ (Default)
- **reflection** (*bool*) -- On 64 bit machines a duplicate value will be created in the Wow6432Node for 32bit programs. This only applies to the SOFTWARE key. This option is ignored on 32bit operating systems. This value defaults to True. Set it to False to disable reflection.

**Returns** Returns a dictionary showing the results of the registry operation.

**Return type** `dict`

The following example will set the (Default) value for the SOFTWARE\Salt key in the HKEY\_CURRENT\_USER hive to 0.15.3. The value will not be reflected in Wow6432Node:

Example:

```
HKEY_CURRENT_USER\SOFTWARE\Salt:
  reg.present:
    - vdata: 0.15.3
    - reflection: False
```

The following example will set the value for the `version` entry under the `SOFTWARE\Salt` key in the `HKEY_CURRENT_USER` hive to `0.15.3`. The value will be reflected in `Wow6432Node`:

Example:

```
HKEY_CURRENT_USER\SOFTWARE\Salt:
  reg.present:
    - vname: version
    - vdata: 0.15.3
```

In the above example the path is interpreted as follows: - `HKEY_CURRENT_USER` is the hive - `SOFTWARE\Salt` is the key - `vname` is the value name ('version') that will be created under the key - `vdata` is the data that will be assigned to 'version'

### 30.27.113 salt.states.rvm

#### Managing Ruby installations and gemsets with Ruby Version Manager (RVM)

This module is used to install and manage ruby installations and gemsets with RVM, the Ruby Version Manager. Different versions of ruby can be installed and gemsets created. RVM itself will be installed automatically if it's not present. This module will not automatically install packages that RVM depends on or ones that are needed to build ruby. If you want to run RVM as an unprivileged user (recommended) you will have to create this user yourself. This is how a state configuration could look like:

```
rvm:
  group.present: []
  user.present:
    - gid: rvm
    - home: /home/rvm
    - require:
      - group: rvm

rvm-deps:
  pkg.installed:
    - pkgs:
      - bash
      - coreutils
      - gzip
      - bzip2
      - gawk
      - sed
      - curl
      - git-core
      - subversion

mri-deps:
  pkg.installed:
    - pkgs:
      - build-essential
      - openssl
```

- libreadline6
- libreadline6-dev
- curl
- git-core
- zlib1g
- zlib1g-dev
- libssl-dev
- libyaml-dev
- libsqlite3-0
- libsqlite3-dev
- sqlite3
- libxml2-dev
- libxslt1-dev
- autoconf
- libc6-dev
- libncurses5-dev
- automake
- libtool
- bison
- subversion
- ruby

jruby-deps:

pkg.installed:

- pkgs:
  - curl
  - g++
  - openjdk-6-jre-headless

ruby-1.9.2:

rvm.installed:

- default: True
- user: rvm
- require:
  - pkg: rvm-deps
  - pkg: mri-deps
- user: rvm

jruby:

rvm.installed:

- user: rvm
- require:
  - pkg: rvm-deps
  - pkg: jruby-deps
- user: rvm

rgemset:

rvm.gemset\_present:

- ruby: jruby
- user: rvm
- require:
  - rvm: jruby

mygemset:

rvm.gemset\_present:

- ruby: ruby-1.9.2
- user: rvm
- require:

```
- rvm: ruby-1.9.2
```

`salt.states.rvm.gemset_present`(*name*, *ruby*='default', *user*=None)

Verify that the gemset is present.

**name** The name of the gemset.

**ruby: default** The ruby version this gemset belongs to.

**user: None** The user to run rvm as.

New in version 0.17.0.

`salt.states.rvm.installed`(*name*, *default*=False, *user*=None)

Verify that the specified ruby is installed with RVM. RVM is installed when necessary.

**name** The version of ruby to install

**default** [False] Whether to make this ruby the default.

**user: None** The user to run rvm as.

New in version 0.17.0.

### 30.27.114 salt.states.saltmod

#### Control the Salt command interface

This state is intended for use from the Salt Master. It provides access to sending commands down to minions as well as access to executing master-side modules. These state functions wrap Salt's *Python API*.

See also:

More Orchestrate documentation

- [Full Orchestrate Tutorial](#)
- [The Orchestrate runner](#)

`salt.states.saltmod.function`(*name*, *tgt*, *ssh*=False, *tgt\_type*=None, *expr\_form*=None, *ret*='',  
*expect\_minions*=False, *fail\_minions*=None, *fail\_function*=None,  
*arg*=None, *kwarg*=None, *timeout*=None)

Execute a single module function on a remote minion via salt or salt-ssh

**name** The name of the function to run, aka cmd.run or pkg.install

**tgt** The target specification, aka '\*' for all minions

**tgt\_type** | **expr\_form** The target type, defaults to glob

**arg** The list of arguments to pass into the function

**kwarg** The list of keyword arguments to pass into the function

**ret** Optionally set a single or a list of returners to use

**expect\_minions** An optional boolean for failing if some minions do not respond

**fail\_minions** An optional list of targeted minions where failure is an option

**fail\_function** An optional string that points to a salt module that returns True or False based on the returned data dict for individual minions

**ssh** Set to *True* to use the ssh client instead of the standard salt client

`salt.states.saltmod.runner`(*name*, *\*\*kwargs*)

Execute a runner module on the master

New in version 2014.7.0.

**name** The name of the function to run

**kwargs** Any keyword arguments to pass to the runner function

```
run-manage-up:
  salt.runner:
    - name: manage.up
```

`salt.states.saltmod.state`(*name*, *tgt*, *ssh=False*, *tgt\_type=None*, *expr\_form=None*, *ret=''*, *highstate=None*, *sls=None*, *top=None*, *env=None*, *test=False*, *pillar=None*, *expect\_minions=False*, *fail\_minions=None*, *allow\_fail=0*, *concurrent=False*, *timeout=None*, *queue=False*)

Invoke a state run on a given target

**name** An arbitrary name used to track the state execution

**tgt** The target specification for the state run.

**tgt\_type** | **expr\_form** The target type to resolve, defaults to glob

**ret** Optionally set a single or a list of returners to use

**highstate** Defaults to None, if set to True the target systems will ignore any sls references specified in the sls option and call state.highstate on the targeted minions

**top** Should be the name of a top file. If set state.top is called with this top file instead of state.sls.

**sls** A group of sls files to execute. This can be defined as a single string containing a single sls file, or a list of sls files

**test** Pass `test=true` through to the state function

**pillar** Pass the `pillar` kwarg through to the state function

**saltenv** The default salt environment to pull sls files from

**ssh** Set to `True` to use the ssh client instead of the standard salt client

**roster** In the event of using salt-ssh, a roster system can be set

**expect\_minions** An optional boolean for failing if some minions do not respond

**fail\_minions** An optional list of targeted minions where failure is an option

**allow\_fail** Pass in the number of minions to allow for failure before setting the result of the execution to False

**concurrent** Allow multiple state runs to occur at once.

WARNING: This flag is potentially dangerous. It is designed for use when multiple state runs can safely be run at the same Do not use this flag for performance optimization.

**queue** Pass `queue=true` through to the state function

Examples:

Run a list of sls files via `state.sls` on target minions:

```
webservers:
  salt.state:
    - tgt: 'web*'
    - sls:
      - apache
```

```

- django
- core
- saltenv: prod

```

Run a full state.highstate on target minions.

```

databases:
  salt.state:
    - tgt: role:database
    - tgt_type: grain
    - highstate: True

```

`salt.states.saltmod.wait_for_event`(*name*, *id\_list*, *event\_id='id'*, *timeout=300*)

Watch Salt's event bus and block until a condition is met

New in version 2014.7.0.

**name** An event tag to watch for; supports Reactor-style globbing.

**id\_list** A list of event identifiers to watch for -- usually the minion ID. Each time an event tag is matched the event data is inspected for `event_id`, if found it is removed from `id_list`. When `id_list` is empty this function returns success.

**event\_id** [*id*] The name of a key in the event data. Default is `id` for the minion ID, another common value is `name` for use with orchestrating salt-cloud events.

**timeout** [*300*] The maximum time in seconds to wait before failing.

The following example blocks until all the listed minions complete a restart and reconnect to the Salt master:

```

reboot_all_minions:
  salt.function:
    - name: system.reboot
    - tgt: '*'

wait_for_reboots:
  salt.wait_for_event:
    - name: salt/minion/*/start
    - id_list:
      - jerry
      - stuart
      - dave
      - phil
      - kevin
      - mike
    - require:
      - salt: reboot_all_minions

```

`salt.states.saltmod.wheel`(*name*, *\*\*kwargs*)

Execute a wheel module on the master

New in version 2014.7.0.

**name** The name of the function to run

**kwargs** Any keyword arguments to pass to the wheel function

```

accept_minion_key:
  salt.wheel:
    - name: key.accept
    - match: frank

```

### 30.27.115 salt.states.schedule

#### Management of the Salt scheduler

```
job3:
  schedule.present:
    - function: test.ping
    - seconds: 3600
    - splay: 10
```

This will schedule the command: test.ping every 3600 seconds (every hour) splaying the time between 0 and 10 seconds

```
job2:
  schedule.present:
    - function: test.ping
    - seconds: 15
    - splay:
      - start: 10
      - end: 20
```

This will schedule the command: test.ping every 3600 seconds (every hour) splaying the time between 10 and 20 seconds

```
job1:
  schedule.present:
    - function: state.sls
    - job_args:
      - httpd
    - job_kwargs:
      test: True
    - when:
      - Monday 5:00pm
      - Tuesday 3:00pm
      - Wednesday 5:00pm
      - Thursday 3:00pm
      - Friday 5:00pm
```

This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Requires that python-dateutil is installed on the minion.

```
job1:
  schedule.present:
    - function: state.sls
    - job_args:
      - httpd
    - job_kwargs:
      test: True
    - cron: '*/*5 * * * *'
```

Scheduled jobs can also be specified using the format used by cron. This will schedule the command: state.sls httpd test=True to run every 5 minutes. Requires that python-croniter is installed on the minion.

```
job1:
  schedule.present:
```

```

- function: state.sls
- job_args:
  - httpd
- job_kwargs:
  test: True
- when:
  - Monday 5:00pm
  - Tuesday 3:00pm
  - Wednesday 5:00pm
  - Thursday 3:00pm
  - Friday 5:00pm
- returner: xmpp
- return_config: xmpp_state_run

```

This will schedule the command: `state.sls httpd test=True` at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Using the `xmpp` returner to return the results of the scheduled job, with the alternative configuration options found in the `xmpp_state_run` section.

`salt.states.schedule.absent`(*name*, *\*\*kwargs*)

Ensure a job is absent from the schedule

**name** The unique name that is given to the scheduled job.

`salt.states.schedule.present`(*name*, *\*\*kwargs*)

Ensure a job is present in the schedule

**name** The unique name that is given to the scheduled job.

**seconds** The scheduled job will be executed after the specified number of seconds have passed.

**minutes** The scheduled job will be executed after the specified number of minutes have passed.

**hours** The scheduled job will be executed after the specified number of hours have passed.

**days** The scheduled job will be executed after the specified number of days have passed.

**when** This will schedule the job at the specified time(s). The `when` parameter must be a single value or a dictionary with the date string(s) using the `dateutil` format. Requires `python-dateutil`.

**cron** This will schedule the job at the specified time(s) using the `crontab` format. Requires `python-croniter`.

**function** The function that should be executed by the scheduled job.

**job\_args** The arguments that will be used by the scheduled job.

**job\_kwargs** The keyword arguments that will be used by the scheduled job.

**maxrunning** Ensure that there are no more than N copies of a particular job running.

**jid\_include** Include the job into the job cache.

**splay** The amount of time in seconds to splay a scheduled job. Can be specified as a single value in seconds or as a dictionary range with `'start'` and `'end'` values.

**range** This will schedule the command within the range specified. The `range` parameter must be a dictionary with the date strings using the `dateutil` format. Requires `python-dateutil`.

**once** This will schedule a job to run once on the specified date.

**once\_fmt** The default date format is ISO 8601 but can be overridden by also specifying the `once_fmt` option.

**enabled** Whether the job should be enabled or disabled. Value should be a boolean.

**return\_job** Whether to return information to the Salt master upon job completion.

**metadata** Using the metadata parameter special values can be associated with a scheduled job. These values are not used in the execution of the job, but can be used to search for specific jobs later if combined with the `return_job` parameter. The metadata parameter must be specified as a dictionary, otherwise it will be ignored.

**returner** The returner to use to return the results of the scheduled job.

**return\_config** The alternative configuration to use for returner configuration options.

### 30.27.116 salt.states.selinux

#### Management of SELinux rules

If SELinux is available for the running system, the mode can be managed and booleans can be set.

```
enforcing:
  selinux.mode

samba_create_home_dirs:
  selinux.boolean:
    - value: True
    - persist: True
```

---

**Note:** Use of these states require that the `selinux` execution module is available.

---

`salt.states.selinux.boolean` (*name*, *value*, *persist=False*)

Set up an SELinux boolean

**name** The name of the boolean to set

**value** The value to set on the boolean

**persist** Defaults to False, set persist to true to make the boolean apply on a reboot

`salt.states.selinux.mode` (*name*)

Verifies the mode SELinux is running in, can be set to enforcing or permissive

**name** The mode to run SELinux in, permissive or enforcing

### 30.27.117 salt.states.serverdensity\_device

#### Monitor Server with Server Density

New in version 2014.7.0.

**Server Density** Is a hosted monitoring service.

**Warning:** This state module is beta. It might be changed later to include more or less automation.

---

**Note:** This state module requires a pillar for authentication with Server Density:

```
serverdensity:
  api_token: "b97da80a41c4f61bfff05975ee51eb1aa"
  account_url: "https://your-account.serverdensity.io"
```

**Note:** Although Server Density allows duplicate device names in its database, this module will raise an exception if you try monitoring devices with the same name.

Example:

```
'server_name':
  serverdensity_device.monitored
```

```
salt.states.serverdensity_device.monitored(name,      group=None,      salt_name=True,
                                             salt_params=True, **params)
```

Device is monitored with Server Density.

**name** Device name in Server Density.

**salt\_name** If True (default), takes the name from the `id` grain. If False, the provided name is used.

**group** Group name under which device will appear in Server Density dashboard. Default - *None*.

**salt\_params** If True (default), needed config parameters will be sourced from grains and from `status.all_status`.

**params** Add parameters that you want to appear in the Server Density dashboard. Will overwrite the `salt_params` parameters. For more info, see the [API docs](#).

Usage example:

```
'server_name':
  serverdensity_device.monitored
```

```
'server_name':
  serverdensity_device.monitored:
    - group: web-servers
```

```
'my_special_server':
  serverdensity_device.monitored:
    - salt_name: False
    - group: web-servers
    - cpuCores: 2
    - os: CentOS
```

### 30.27.118 salt.states.service

#### Starting or restarting of services and daemons

Services are defined as system daemons typically started with system init or rc scripts, services can be defined as running or dead.

```
httpd:
  service.running: []
```

The service can also be set to be started at runtime via the `enable` option:

```
openvpn:
  service.running:
    - enable: True
```

By default if a service is triggered to refresh due to a watch statement the service is by default restarted. If the desired behavior is to reload the service, then set the reload value to True:

```
redis:
  service.running:
    - enable: True
    - reload: True
    - watch:
      - pkg: redis
```

---

**Note:** More details regarding watch can be found in the [Requisites](#) documentation.

---

**salt.states.service.dead**(*name*, *enable=None*, *sig=None*, *\*\*kwargs*)

Ensure that the named service is dead by stopping the service if it is running

**name** The name of the init or rc script used to manage the service

**enable** Set the service to be enabled at boot time, **True** sets the service to be enabled, **False** sets the named service to be disabled. The default is **None**, which does not enable or disable anything.

**sig** The string to search for when looking for the service process with ps

**salt.states.service.disabled**(*name*, *\*\*kwargs*)

Verify that the service is disabled on boot, only use this state if you don't want to manage the running process, remember that if you want to disable a service to use the `enable: False` option for the running or dead function.

**name** The name of the init or rc script used to manage the service

**salt.states.service.enabled**(*name*, *\*\*kwargs*)

Verify that the service is enabled on boot, only use this state if you don't want to manage the running process, remember that if you want to enable a running service to use the `enable: True` option for the running or dead function.

**name** The name of the init or rc script used to manage the service

**salt.states.service.mod\_watch**(*name*, *sfun=None*, *sig=None*, *reload=False*, *full\_restart=False*, *force=False*, *\*\*kwargs*)

The service watcher, called to invoke the watch command.

**name** The name of the init or rc script used to manage the service

**sfun** The original function which triggered the mod\_watch call (*service.running*, for example).

**sig** The string to search for when looking for the service process with ps

**salt.states.service.running**(*name*, *enable=None*, *sig=None*, *\*\*kwargs*)

Verify that the service is running

**name** The name of the init or rc script used to manage the service

**enable** Set the service to be enabled at boot time, **True** sets the service to be enabled, **False** sets the named service to be disabled. The default is **None**, which does not enable or disable anything.

**sig** The string to search for when looking for the service process with ps

### 30.27.119 salt.states.slack

#### Send a message to Slack

This state is useful for sending messages to Slack during state runs.

New in version 2015.5.0.

```
slack-message:
  slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

The api key can be specified in the master or minion configuration like below:

```
slack:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

**salt.states.slack.post\_message**(*name, channel, from\_name, message, api\_key=None*)  
Send a message to a Slack room.

```
slack-message:
  slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

The following parameters are required:

**name** The unique name for this event.

**channel** The room to send the message to. Can either be the ID or the name.

**from\_name** The name of that is to be shown in the ``from" field. If not specified, defaults to.

**message** The message that is to be sent to the Hipchat room.

The following parameters are optional:

**api\_key** The api key for Slack to use for authentication, if not specified in the configuration options of master or minion.

### 30.27.120 salt.states.smtp

#### Sending Messages via SMTP

New in version 2014.7.0.

This state is useful for firing messages during state runs, using the XMPP protocol

```
server-warning-message:
  smtp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-smtp-account
    - recipient: admins@example.com
```

**salt.states.smtp.send\_msg**(*name, recipient, subject, sender, profile, use\_ssl=True*)  
Send a message via SMTP

```
server-warning-message:
  smtp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-smtp-account
    - subject: 'Message from Salt'
    - recipient: admin@example.com
    - sender: admin@example.com
    - use_ssl: True
```

**name** The message to send via SMTP

### 30.27.121 salt.states.splunk\_search

Splunk Search State Module

New in version 2015.5.0.

This state is used to ensure presence of splunk searches.

```
server-warning-message:
  splunk_search.present:
    - name: This is the splunk search name
    - search: index=main sourcetype=
```

**salt.states.splunk\_search.absent** (*name*, *profile='splunk'*)  
Ensure a search is absent

```
API Error Search:
  splunk_search.absent
```

The following parameters are required:

**name** This is the name of the search in splunk

**salt.states.splunk\_search.present** (*name*, *profile='splunk'*, *\*\*kwargs*)  
Ensure a search is present

```
API Error Search:
  splunk_search.present:
    search: index=main sourcetype=blah
    template: alert_5min
```

The following parameters are required:

**name** This is the name of the search in splunk

### 30.27.122 salt.states.ssh\_auth

#### Control of entries in SSH authorized\_key files

The information stored in a user's SSH authorized key file can be easily controlled via the `ssh_auth` state. Defaults can be set by the `enc`, `options`, and `comment` keys. These defaults can be overridden by including them in the name.

Since the YAML specification limits the length of simple keys to 1024 characters, and since SSH keys are often longer than that, you may have to use a YAML `explicit key`, as demonstrated in the second example below.

```

AAAAB3NzaC1kc3MAAACBAL0sQ9fJ5bYTEyY==:
  ssh_auth.present:
    - user: root
    - enc: ssh-dss

? AAAAB3NzaC1kc3MAAACBAL0sQ9fJ5bYTEyY==...
:
  ssh_auth.present:
    - user: root
    - enc: ssh-dss

thatch:
  ssh_auth.present:
    - user: root
    - source: salt://ssh_keys/thatch.id_rsa.pub

sshkeys:
  ssh_auth.present:
    - user: root
    - enc: ssh-rsa
    - options:
      - option1="value1"
      - option2="value2 flag2"
    - comment: myuser
    - names:
      - AAAAB3NzaC1kc3MAAACBAL0sQ9fJ5bYTEyY==
      - ssh-dss AAAAB3NzaCL0sQ9fJ5bYTEyY== user@domain
      - option3="value3" ssh-dss AAAAB3NzaC1kcQ9J5bYTEyY== other@testdomain
      - AAAAB3NzaC1kcQ9fJFF435bYTEyY== newcomment

```

**salt.states.ssh\_auth.absent**(*name*, *user*, *enc*='ssh-rsa', *comment*='', *options*=None, *config*='ssh/authorized\_keys')

Verifies that the specified SSH key is absent

**name** The SSH key to manage

**user** The user who owns the SSH authorized keys file to modify

**enc** Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss

**comment** The comment to be placed with the SSH public key

**options** The options passed to the key, pass a list object

**config** The location of the authorized keys file relative to the user's home directory, defaults to "ssh/authorized\_keys"

**salt.states.ssh\_auth.present**(*name*, *user*, *enc*='ssh-rsa', *comment*='', *source*='', *options*=None, *config*='ssh/authorized\_keys', *\*\*kwargs*)

Verifies that the specified SSH key is present for the specified user

**name** The SSH key to manage

**user** The user who owns the SSH authorized keys file to modify

**enc** Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss

**comment** The comment to be placed with the SSH public key

**source** The source file for the key(s). Can contain any number of public keys, in standard ``authorized\_keys`` format. If this is set, comment, enc, and options will be ignored.

---

**Note:** The source file must contain keys in the format `<enc> <key> <comment>`. If you have generated a keypair using PuTTYgen, then you will need to do the following to retrieve an OpenSSH-compatible public key.

1. In PuTTYgen, click Load, and select the *private* key file (not the public key), and click Open.
  2. Copy the public key from the box labeled Public key for pasting into OpenSSH authorized\_keys file.
  3. Paste it into a new file.
- 

**options** The options passed to the key, pass a list object

**config** The location of the authorized keys file relative to the user's home directory, defaults to `".ssh/authorized_keys"`

### 30.27.123 salt.states.ssh\_known\_hosts

#### Control of SSH known\_hosts entries

Manage the information stored in the known\_hosts files.

```
github.com:
  ssh_known_hosts:
    - present
    - user: root
    - fingerprint: 16:27:ac:a5:76:28:2d:36:63:1b:56:4d:eb:df:a6:48

example.com:
  ssh_known_hosts:
    - absent
    - user: root
```

**salt.states.ssh\_known\_hosts.absent** (*name*, *user=None*, *config=None*)

Verifies that the specified host is not known by the given user

**name** The host name

**user** The user who owns the ssh authorized keys file to modify

**config** The location of the authorized keys file relative to the user's home directory, defaults to `".ssh/known_hosts"`. If no user is specified, defaults to `"/etc/ssh/ssh_known_hosts"`. If present, must be an absolute path when a user is not specified.

**salt.states.ssh\_known\_hosts.present** (*name*, *user=None*, *fingerprint=None*,  
*key=None*, *port=None*, *enc=None*, *config=None*,  
*hash\_hostname=True*, *hash\_known\_hosts=True*)

Verifies that the specified host is known by the specified user

On many systems, specifically those running with openssh 4 or older, the enc option must be set, only openssh 5 and above can detect the key type.

**name** The name of the remote host (e.g. `github.com`)

**user** The user who owns the ssh authorized keys file to modify

**fingerprint** The fingerprint of the key which must be present in the known\_hosts file (optional if key specified)

- key** The public key which must be present in the `known_hosts` file (optional if fingerprint specified)
- port** optional parameter, port which will be used to when requesting the public key from the remote host, defaults to port 22.
- enc** Defines what type of key is being used, can be `ed25519`, `ecdsa ssh-rsa` or `ssh-dss`
- config** The location of the authorized keys file relative to the user's home directory, defaults to `".ssh/known_hosts"`. If no user is specified, defaults to `"/etc/ssh/ssh_known_hosts"`. If present, must be an absolute path when a user is not specified.
- hash\_hostname** [True] Hash all hostnames and addresses in the known hosts file.  
 Deprecated since version Carbon: Please use `hash_known_hosts` instead.
- hash\_known\_hosts** [True] Hash all hostnames and addresses in the known hosts file.

### 30.27.124 salt.states.stateconf

#### Stateconf System

The stateconf system is intended for use only with the stateconf renderer. This State module presents the `set` function. This function does not execute any functionality, but is used to interact with the stateconf renderer.

- `salt.states.stateconf.context(name, **kwargs)`  
 No-op state to support state config via the stateconf renderer.
- `salt.states.stateconf.set(name, **kwargs)`  
 No-op state to support state config via the stateconf renderer.

### 30.27.125 salt.states.status

Minion status monitoring

Maps to the `status` execution module.

- `salt.states.status.loadavg(name, maximum=None, minimum=None)`  
 Return the current load average for the specified minion. Available values for `name` are `1-min`, `5-min` and `15-min`. `minimum` and `maximum` values should be passed in as strings.
- `salt.states.status.process(name)`  
 Return whether the specified signature is found in the process tree. This differs slightly from the `services` states, in that it may refer to a process that is not managed via the `init` system.

### 30.27.126 salt.states.supervisord

#### Interaction with the Supervisor daemon

```
wsgi_server:
  supervisord.running:
    - require:
      - pkg: supervisor
    - watch:
      - file: /etc/nginx/sites-enabled/wsgi_server.conf
```

`salt.states.supervisord.dead`(*name*, *user=None*, *conf\_file=None*, *bin\_env=None*)

Ensure the named service is dead (not running).

**name** Service name as defined in the supervisor configuration file

**user** Name of the user to run the supervisorctl command

New in version 0.17.0.

**conf\_file** path to supervisorctl config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

`salt.states.supervisord.mod_watch`(*name*, *restart=True*, *update=False*, *user=None*,  
*conf\_file=None*, *bin\_env=None*, *\*\*kwargs*)

`salt.states.supervisord.running`(*name*, *restart=False*, *update=False*, *user=None*, *conf\_file=None*,  
*bin\_env=None*)

Ensure the named service is running.

**name** Service name as defined in the supervisor configuration file

**restart** Whether to force a restart

**update** Whether to update the supervisor configuration.

**user** Name of the user to run the supervisorctl command

New in version 0.17.0.

**conf\_file** path to supervisorctl config file

**bin\_env** path to supervisorctl bin or path to virtualenv with supervisor installed

### 30.27.127 salt.states.svn

#### Manage SVN repositories

Manage repository checkouts via the svn vcs system. Note that subversion must be installed for these states to be available, so svn states should include a requisite to a pkg.installed state for the package which provides subversion (subversion in most cases). Example:

```
subversion:
  pkg.installed

http://unladen-swallow.googlecode.com/svn/trunk/:
  svn.latest:
    - target: /tmp/swallow
```

`salt.states.svn.dirty`(*name*, *target*, *user=None*, *username=None*, *password=None*, *ignore\_unversioned=False*)

Determine if the working directory has been changed.

`salt.states.svn.export`(*name*, *target=None*, *rev=None*, *user=None*, *username=None*, *password=None*,  
*force=False*, *overwrite=False*, *externals=True*, *trust=False*)

Export a file or directory from an SVN repository

**name** Address and path to the file or directory to be exported.

**target** Name of the target directory where the checkout will put the working directory

**rev** [None] The name revision number to checkout. Enable ``force`` if the directory already exists.

**user** [None] Name of the user performing repository management operations

**username** [None] The user to access the name repository with. The svn default is the current user

**password** Connect to the Subversion server with this password

New in version 0.17.0.

**force** [False] Continue if conflicts are encountered

**overwrite** [False] Overwrite existing target

**externals** [True] Change to False to not checkout or update externals

**trust** [False] Automatically trust the remote server. SVN's --trust-server-cert

**salt.states.svn.latest** (*name, target=None, rev=None, user=None, username=None, password=None, force=False, externals=True, trust=False*)

Checkout or update the working directory to the latest revision from the remote repository.

**name** Address of the name repository as passed to ``svn checkout``

**target** Name of the target directory where the checkout will put the working directory

**rev** [None] The name revision number to checkout. Enable ``force`` if the directory already exists.

**user** [None] Name of the user performing repository management operations

**username** [None] The user to access the name repository with. The svn default is the current user

**password** Connect to the Subversion server with this password

New in version 0.17.0.

**force** [False] Continue if conflicts are encountered

**externals** [True] Change to False to not checkout or update externals

**trust** [False] Automatically trust the remote server. SVN's --trust-server-cert

### 30.27.128 salt.states.sysctl

#### Configuration of the Linux kernel using sysctl

Control the kernel sysctl system.

```
vm.swappiness:
  sysctl.present:
    - value: 20
```

**salt.states.sysctl.present** (*name, value, config=None*)

Ensure that the named sysctl value is set in memory and persisted to the named configuration file. The default sysctl configuration file is /etc/sysctl.conf

**name** The name of the sysctl value to edit

**value** The sysctl value to apply

**config** The location of the sysctl configuration file. If not specified, the proper location will be detected based on platform.

## 30.27.129 salt.states.syslog\_ng

### State module for syslog\_ng

**maintainer** Tibor Benke <btibi@sch.bme.hu>

**maturity** new

**depends** cmd, ps, syslog\_ng

**platform** all

Users can generate syslog-ng configuration files from YAML format or use plain ones and reload, start, or stop their syslog-ng by using this module.

### Details

The service module is not available on all system, so this module includes *syslog\_ng.reloaded*, *syslog\_ng.stopped*, and *syslog\_ng.started* functions. If the service module is available on the computers, users should use that.

Users can generate syslog-ng configuration with *syslog\_ng.config* function. For more information see *syslog-ng* state usage.

### Syslog-ng configuration file format

The syntax of a configuration snippet in *syslog-ng.conf*:

```
object_type object_id {<options>;
```

These constructions are also called statements. There are options inside of them:

```
option(parameter1, parameter2); option2(parameter1, parameter2);
```

You can find more information about syslog-ng's configuration syntax in the Syslog-ng Admin guide: <http://www.balabit.com/sites/default/files/documents/syslog-ng-ose-3.5-guides/en/syslog-ng-ose-v3.5-guide-admin/html-single/index.html#syslog-ng.conf.5>

**salt.states.syslog\_ng.config**(*name*, *config*, *write=True*)

Builds syslog-ng configuration.

*name* : the id of the Salt document *config* : the parsed YAML code *write* : if True, it writes the config into the configuration file, otherwise just returns it

**salt.states.syslog\_ng.reloaded**(*name*)

Reloads syslog-ng.

**salt.states.syslog\_ng.started**(*name=None*, *user=None*, *group=None*, *chroot=None*, *caps=None*, *no\_caps=False*, *pidfile=None*, *enable\_core=False*, *fd\_limit=None*, *verbose=False*, *debug=False*, *trace=False*, *yydebug=False*, *persist\_file=None*, *control=None*, *worker\_threads=None*, *\*args*, *\*\*kwargs*)

Ensures, that syslog-ng is started via the given parameters.

Users shouldn't use this function, if the service module is available on their system.

**salt.states.syslog\_ng.stopped**(*name=None*)

Kills syslog-ng.

### 30.27.130 salt.states.sysrc

`salt.states.sysrc.absent`(*name*, *\*\*kwargs*)

Ensure a sysrc variable is absent.

**name** The variable name to set

**file** (optional) The rc file to add the variable to.

**jail** (option) the name or JID of the jail to set the value in.

`salt.states.sysrc.managed`(*name*, *value*, *\*\*kwargs*)

Ensure a sysrc variable is set to a specific value.

**name** The variable name to set

**value** Value to set the variable to

**file** (optional) The rc file to add the variable to.

**jail** (option) the name or JID of the jail to set the value in.

### 30.27.131 salt.states.test

#### Test States

Provide test case states that enable easy testing of things to do with state calls, e.g. running, calling, logging, output filtering etc.

```

always-passes-with-any-kwarg:
  test.nop:
    - name: foo
    - something: else
    - foo: bar

always-passes:
  test.succeed_without_changes:
    - name: foo

always-fails:
  test.fail_without_changes:
    - name: foo

always-changes-and-succeeds:
  test.succeed_with_changes:
    - name: foo

always-changes-and-fails:
  test.fail_with_changes:
    - name: foo

my-custom-combo:
  test.configurable_test_state:
    - name: foo
    - changes: True
    - result: False
    - comment: bar.baz

```

`salt.states.test.configurable_test_state(name, changes=True, result=True, comment='')`

A configurable test state which determines its output based on the inputs.

New in version 2014.7.0.

**name:** A unique string.

**changes:** Do we return anything in the changes field? Accepts True, False, and 'Random' Default is True

**result:** Do we return successfully or not? Accepts True, False, and 'Random' Default is True

**comment:** String to fill the comment field with. Default is ''

`salt.states.test.fail_with_changes(name)`

Returns failure and changes is not empty.

New in version 2014.7.0.

**name:** A unique string.

`salt.states.test.fail_without_changes(name)`

Returns failure.

New in version 2014.7.0.

**name:** A unique string.

`salt.states.test.mod_watch(name, sfun=None, **kwargs)`

Call this function via a watch statement

New in version 2014.7.0.

Any parameters in the state return dictionary can be customized by adding the keywords `result`, `comment`, and `changes`.

```
this_state_will_return_changes:
  test.succeed_with_changes

this_state_will_NOT_return_changes:
  test.succeed_without_changes

this_state_is_watching_another_state:
  test.succeed_without_changes:
    - comment: 'This is a custom comment'
    - watch:
      - test: this_state_will_return_changes
      - test: this_state_will_NOT_return_changes

this_state_is_also_watching_another_state:
  test.succeed_without_changes:
    - watch:
      - test: this_state_will_NOT_return_changes
```

`salt.states.test.nop(name, **kwargs)`

A no-op state that does nothing. Useful in conjunction with the `use` requisite, or in templates which could otherwise be empty due to jinja rendering

New in version 2015.5.6.

`salt.states.test.succeed_with_changes(name)`

Returns successful and changes is not empty

New in version 2014.7.0.

**name:** A unique string.

`salt.states.test.succeed_without_changes` (*name*)

Returns successful.

New in version 2014.7.0.

**name** A unique string.

### 30.27.132 `salt.states.timezone`

#### Management of timezones

The timezone can be managed for the system:

```
America/Denver:
  timezone.system
```

The system and the hardware clock are not necessarily set to the same time. By default, the hardware clock is set to localtime, meaning it is set to the same time as the system clock. If *utc* is set to True, then the hardware clock will be set to UTC, and the system clock will be an offset of that.

```
America/Denver:
  timezone.system:
    - utc: True
```

The Ubuntu community documentation contains an explanation of this setting, as it applies to systems that dual-boot with Windows. This is explained in greater detail [here](#).

`salt.states.timezone.system` (*name*, *utc=True*)

Set the timezone for the system.

**name** The name of the timezone to use (e.g.: America/Denver)

**utc** Whether or not to set the hardware clock to UTC (default is True)

### 30.27.133 `salt.states.tls`

#### Enforce state for SSL/TLS

`salt.states.tls.valid_certificate` (*name*, *weeks=0*, *days=0*, *hours=0*, *minutes=0*, *seconds=0*)

Verify that a TLS certificate is valid now and (optionally) will be valid for the time specified through weeks, days, hours, minutes, and seconds.

### 30.27.134 `salt.states.tomcat`

This state uses the manager webapp to manage Apache tomcat webapps This state requires the manager webapp to be enabled

The following grains/pillar should be set:

```
tomcat-manager:user: admin user name
tomcat-manager:passwd: password
```

and also configure a user in the conf/tomcat-users.xml file:

```
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
  <role rolename="manager-script"/>
  <user username="tomcat" password="tomcat" roles="manager-script"/>
</tomcat-users>
```

Notes:

- Not supported multiple version on the same context path
- **More information about tomcat manager:** <http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html>
- **if you use only this module for deployments you might want to restrict** access to the manager so its only accessible via localhost for more info: [http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring\\_Manager\\_Application\\_Access](http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access)

- Tested on:

**JVM Vendor:** Sun Microsystems Inc.

**JVM Version:** 1.6.0\_43-b01

**OS Architecture:** amd64

**OS Name:** Linux

**OS Version:** 2.6.32-358.el6.x86\_64

**Tomcat Version:** Apache Tomcat/7.0.37

`salt.states.tomcat.mod_watch`(*name*, *url*='http://localhost:8080/manager', *timeout*=180)

The tomcat watcher function. When called it will reload the webapp in question

`salt.states.tomcat.undeployed`(*name*, *url*='http://localhost:8080/manager', *timeout*=180)

Enforce that the WAR will be un-deployed from the server

**name** the context path to deploy

**url** [<http://localhost:8080/manager>] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request to the tomcat manager

Example:

```
jenkins:
  tomcat.undeployed:
    - name: /ran
    - require:
      - service: application-service
```

`salt.states.tomcat.wait`(*name*, *url*='http://localhost:8080/manager', *timeout*=180)

Wait for the tomcat manager to load

Notice that if tomcat is not running we won't wait for it start and the state will fail. This state can be required in the tomcat.war\_deployed state to make sure tomcat is running and that the manager is running as well and ready for deployment

**url** [<http://localhost:8080/manager>] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request to the tomcat manager

Example:

```

tomcat-service:
  service.running:
    - name: tomcat
    - enable: True

wait-for-tomcatmanager:
  tomcat.wait:
    - timeout: 300
    - require:
      - service: tomcat-service

jenkins:
  tomcat.war_deployed:
    - name: /ran
    - war: salt://jenkins-1.2.4.war
    - require:
      - tomcat: wait-for-tomcatmanager

```

**salt.states.tomcat.war\_deployed**(*name*, *war*, *force=False*, *url='http://localhost:8080/manager'*, *timeout=180*, *temp\_war\_location=None*)

Enforce that the WAR will be deployed and started in the context path it will make use of WAR versions

**for more info:** <http://tomcat.apache.org/tomcat-7.0-doc/config/context.html#Naming>

**name** the context path to deploy

**war** absolute path to WAR file (should be accessible by the user running tomcat) or a path supported by the salt.modules.cp.get\_url function

**force** force deploy even if version strings are the same, False by default.

**url** [<http://localhost:8080/manager>] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request to the tomcat manager

**temp\_war\_location** [None] use another location to temporarily copy to war file by default the system's temp directory is used

Example:

```

jenkins:
  tomcat.war_deployed:
    - name: /ran
    - war: salt://jenkins-1.2.4.war
    - require:
      - service: application-service

```

### 30.27.135 salt.states.user

#### Management of user accounts

The user module is used to create and manage user settings, users can be set as either absent or present

```

fred:
  user.present:
    - fullname: Fred Jones
    - shell: /bin/zsh
    - home: /home/fred
    - uid: 4000

```

```
- gid: 4000
- groups:
  - wheel
  - storage
  - games

testuser:
  user.absent
```

`salt.states.user.absent` (*name*, *purge=False*, *force=False*)

Ensure that the named user is absent

**name** The name of the user to remove

**purge** Set purge to True to delete all of the user's files as well as the user, Default is False.

**force** If the user is logged in, the absent state will fail. Set the force option to True to remove the user even if they are logged in. Not supported in FreeBSD and Solaris, Default is False.

`salt.states.user.present` (*name*, *uid=None*, *gid=None*, *gid\_from\_name=False*, *groups=None*, *optional\_groups=None*, *remove\_groups=True*, *home=None*, *createhome=True*, *password=None*, *enforce\_password=True*, *empty\_password=False*, *shell=None*, *unique=True*, *system=False*, *fullname=None*, *roomnumber=None*, *workphone=None*, *homephone=None*, *loginclass=None*, *date=None*, *mindays=None*, *maxdays=None*, *inactdays=None*, *warn-days=None*, *expire=None*, *win\_homedrive=None*, *win\_profile=None*, *win\_logonscript=None*, *win\_description=None*)

Ensure that the named user is present with the specified properties

**name** The name of the user to manage

**uid** The user id to assign, if left empty then the next available user id will be assigned

**gid** The default group id. Also accepts group name.

**gid\_from\_name** If True, the default group id will be set to the id of the group with the same name as the user, Default is False.

**groups** A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the minion, the state will fail. If set to the empty list, the user will be removed from all groups except the default group.

**optional\_groups** A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the minion, the state will silently ignore it.

NOTE: If the same group is specified in both ``groups`` and ``optional\_groups``, then it will be assumed to be required and not optional.

**remove\_groups** Remove groups that the user is a member of that weren't specified in the state, Default is True.

**home** The custom login directory of user. Uses default value of underlying system if not set. Notice that this directory does not have to exist. This also the location of the home directory to create if createhome is set to True.

**createhome** If False, the home directory will not be created if it doesn't exist. Please note that directories leading up to the home directory will NOT be created, Default is True.

**password** A password hash to set for the user. This field is only supported on Linux, FreeBSD, NetBSD, OpenBSD, and Solaris. If the `empty_password` argument is set to True then password is ignored. For Windows this is the plain text password.

Changed in version 0.16.0: BSD support added.

**enforce\_password** Set to False to keep the password from being changed if it has already been set and the password hash differs from what is specified in the ``password" field. This option will be ignored if ``password" is not specified, Default is True.

**empty\_password** Set to True to enable password-less login for user, Default is False.

**shell** The login shell, defaults to the system default shell

**unique** Require a unique UID, Default is True.

**system** Choose UID in the range of FIRST\_SYSTEM\_UID and LAST\_SYSTEM\_UID, Default is False.

**loginclass** The login class, defaults to empty (BSD only)

User comment field (GECOS) support (currently Linux, BSD, and MacOS only):

The below values should be specified as strings to avoid ambiguities when the values are loaded. (Especially the phone and room number fields which are likely to contain numeric data)

**fullname** The user's full name

**roomnumber** The user's room number (not supported in MacOS)

**workphone** The user's work phone number (not supported in MacOS)

**homephone** The user's home phone number (not supported in MacOS)

Changed in version 2014.7.0: Shadow attribute support added.

Shadow attributes support (currently Linux only):

The below values should be specified as integers.

**date** Date of last change of password, represented in days since epoch (January 1, 1970).

**mindays** The minimum number of days between password changes.

**maxdays** The maximum number of days between password changes.

**inactdays** The number of days after a password expires before an account is locked.

**warndays** Number of days prior to maxdays to warn users.

**expire** Date that account expires, represented in days since epoch (January 1, 1970).

The below parameters apply to windows only:

**win\_homedrive (Windows Only)** The drive letter to use for the home directory. If not specified the home directory will be a unc path. Otherwise the home directory will be mapped to the specified drive. Must be a letter followed by a colon. Because of the colon, the value must be surrounded by single quotes. ie: - win\_homedrive: `U:

Changed in version 2015.5.7: Backported from 2015.8.0

**win\_profile (Windows Only)** The custom profile directory of the user. Uses default value of underlying system if not set.

Changed in version 2015.5.7: Backported from 2015.8.0

**win\_logonscript (Windows Only)** The full path to the logon script to run when the user logs in.

Changed in version 2015.5.7: Backported from 2015.8.0

**win\_description (Windows Only)** A brief description of the purpose of the users account.

Changed in version 2015.5.7: Backported from 2015.8.0

### 30.27.136 salt.states.vbox\_guest

VirtualBox Guest Additions installer state

`salt.states.vbox_guest.additions_installed(name, reboot=False, upgrade_os=False)`  
Ensure that the VirtualBox Guest Additions are installed. Uses the CD, connected by VirtualBox.

**name** The name has no functional value and is only used as a tracking reference.

**reboot** [False] Restart OS to complete installation.

**upgrade\_os** [False] Upgrade OS (to ensure the latests version of kernel and developer tools installed).

`salt.states.vbox_guest.additions_removed(name, force=False)`  
Ensure that the VirtualBox Guest Additions are removed. Uses the CD, connected by VirtualBox.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host` is usually `Right Ctrl`).

**name** The name has no functional value and is only used as a tracking reference.

**force** Force VirtualBox Guest Additions removing.

`salt.states.vbox_guest.grant_access_to_shared_folders_to(name, users=None)`  
Grant access to auto-mounted shared folders to the users.

User is specified by it's name. To grant access for several users use argument *users*.

**name** Name of the user to grant access to auto-mounted shared folders to.

**users** List of names of users to grant access to auto-mounted shared folders to. If specified, *name* will not be taken into account.

### 30.27.137 salt.states.virtualenv

Setup of Python virtualenv sandboxes.

New in version 0.17.0.

`salt.states.virtualenv_mod.managed(name, venv_bin=None, requirements=None, system_site_packages=False, distribute=False, use_wheel=False, clear=False, python=None, extra_search_dir=None, never_download=None, prompt=None, user=None, no_chown=False, cwd=None, index_url=None, extra_index_url=None, pre_releases=False, no_deps=False, pip_download=None, pip_download_cache=None, pip_exists_action=None, proxy=None, use_vt=False, env_vars=None)`

Create a virtualenv and optionally manage it with pip

**name** Path to the virtualenv

**requirements** Path to a pip requirements file. If the path begins with `salt://` the file will be transferred from the master file server.

**cwd** Path to the working directory where ``pip install`` is executed.

**user** The user under which to run virtualenv and pip

**no\_chown: False** When user is given, do not attempt to copy and chown a requirements file (needed if the requirements file refers to other files via relative paths, as the copy-and-chown procedure does not account for such files)

**use\_wheel** [False] Prefer wheel archives (requires pip>=1.4)

**no\_deps**: False Pass `--no-deps` to `pip`.

**pip\_exists\_action**: None Default action of pip when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup

**proxy**: None Proxy address which is passed to `pip install`

**env\_vars** Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs `INCLUDE_PATH` set to pick up a header file while compiling.

Also accepts any kwargs that the `virtualenv` module will.

```
/var/www/myvirtualenv.com:
  virtualenv.managed:
    - system_site_packages: False
    - requirements: salt://REQUIREMENTS.txt
```

### 30.27.138 salt.states.win\_dns\_client

Module for configuring DNS Client on Windows systems

**salt.states.win\_dns\_client.dns\_dhcp** (*name, interface='Local Area Connection'*)

Configure the DNS server list from DHCP Server

**salt.states.win\_dns\_client.dns\_exists** (*name, servers=None, interface='Local Area Connection', replace=False*)

Configure the DNS server list in the specified interface

Example:

```
config_dns_servers:
  win_dns_client.dns_exists:
    - replace: True #remove any servers not in the "servers" list, default is False
    - servers:
      - 8.8.8.8
      - 8.8.8.9
```

**salt.states.win\_dns\_client.primary\_suffix** (*name, suffix=None, updates=False*)

New in version 2014.7.0.

Configure the global primary DNS suffix of a DHCP client.

**suffix** [None] The suffix which is advertised for this client when acquiring a DHCP lease When none is set, the explicitly configured DNS suffix will be removed.

**updates** [False] Allow syncing the DNS suffix with the AD domain when the client's AD domain membership changes

```
primary_dns_suffix:
  win_dns_client.primary_suffix:
    - suffix: sub.domain.tld
    - updates: True
```

### 30.27.139 salt.states.win\_firewall

State for configuring Windows Firewall

**salt.states.win\_firewall.add\_rule** (*name, localport, protocol='tcp', action='allow', dir='in'*)

Add a new firewall rule (Windows only)

`salt.states.win_firewall.disabled(name)`  
Disable all the firewall profiles (Windows only)

### 30.27.140 salt.states.win\_network

#### Configuration of network interfaces on Windows hosts

New in version 2014.1.0.

This module provides the `network` state(s) on Windows hosts. DNS servers, IP addresses and default gateways can currently be managed.

Below is an example of the configuration for an interface that uses DHCP for both DNS servers and IP addresses:

```
Local Area Connection #2:
network.managed:
  - dns_proto: dhcp
  - ip_proto: dhcp
```

---

**Note:** Both the `dns_proto` and `ip_proto` arguments are required.

---

Static DNS and IP addresses can be configured like so:

```
Local Area Connection #2:
network.managed:
  - dns_proto: static
  - dns_servers:
    - 8.8.8.8
    - 8.8.4.4
  - ip_proto: static
  - ip_addrs:
    - 10.2.3.4/24
```

---

**Note:** IP addresses are specified using the format `<ip-address>/<subnet-length>`. Salt provides a convenience function called `ip.get_subnet_length` to calculate the subnet length from a netmask.

---

Optionally, if you are setting a static IP address, you can also specify the default gateway using the `gateway` parameter:

```
Local Area Connection #2:
network.managed:
  - dns_proto: static
  - dns_servers:
    - 8.8.8.8
    - 8.8.4.4
  - ip_proto: static
  - ip_addrs:
    - 10.2.3.4/24
  - gateway: 10.2.3.1
```

`salt.states.win_network.managed(name, dns_proto=None, dns_servers=None, ip_proto=None, ip_addrs=None, gateway=None, enabled=True, **kwargs)`  
Ensure that the named interface is configured properly.

**name** The name of the interface to manage

**dns\_proto** [None] Set to `static` and use the `dns_servers` parameter to provide a list of DNS name-servers. set to `dhcp` to use DHCP to get the DNS servers.

**dns\_servers** [None] A list of static DNS servers.

**ip\_proto** [None] Set to `static` and use the `ip_addrs` and (optionally) `gateway` parameters to provide a list of static IP addresses and the default gateway. Set to `dhcp` to use DHCP.

**ip\_addrs** [None] A list of static IP addresses.

**gateway** [None] A list of static IP addresses.

**enabled** [True] Set to `False` to ensure that this interface is disabled.

### 30.27.141 salt.states.win\_path

Manage the Windows System PATH

`salt.states.win_path.absent`(*name*)

Remove the directory from the SYSTEM path

**index**: where the directory should be placed in the PATH (default: 0)

Example:

```
'C:\sysinternals':
  win_path.absent
```

`salt.states.win_path.exists`(*name*, *index=None*)

Add the directory to the system PATH at index location

**index**: where the directory should be placed in the PATH (default: None) [Note: Providing no index will append directory to PATH and will not enforce its location within the PATH.]

Example:

```
'C:\python27':
  win_path.exists

'C:\sysinternals':
  win_path.exists:
    index: 0
```

### 30.27.142 salt.states.win\_servermanager

Manage Windows features via the ServerManager powershell module

`salt.states.win_servermanager.installed`(*name*, *recurse=False*, *force=False*)

Install the windows feature

**name**: short name of the feature (the right column in `win_servermanager.list_available`)

**recurse**: install all sub-features as well

**force**: if the feature is installed but on of its sub-features are not installed set this to `True` to force the installation of the sub-features

Note: Some features require reboot after un/installation. If so, until the server is restarted other features can not be installed!

Example:

Run `salt MinionName win_servermanager.list_available` to get a list of available roles and features. Use the name in the right column. Do not use the role or feature names mentioned in the PKGMGR documentation. In this example for IIS-WebServerRole the name to be used is Web-Server.

```
ISWebserverRole:
  win_servermanager.installed:
    - force: True
    - recurse: True
    - name: Web-Server
```

`salt.states.win_servermanager.removed(name)`

Remove the windows feature

**name:** short name of the feature (the right column in `win_servermanager.list_available`)

---

**Note:** Some features require a reboot after uninstallation. If so the feature will not be completely uninstalled until the server is restarted.

---

Example:

Run `salt MinionName win_servermanager.list_installed` to get a list of all features installed. Use the top name listed for each feature, not the indented one. Do not use the role or feature names mentioned in the PKGMGR documentation.

```
ISWebserverRole:
  win_servermanager.removed:
    - name: Web-Server
```

### 30.27.143 salt.states.win\_system

#### Management of Windows system information

New in version 2014.1.0.

This state is used to manage system information such as the computer name and description.

```
ERIK-WORKSTATION:
  system.computer_name: []

This is Erik's computer, don't touch!:
  system.computer_desc: []
```

`salt.states.win_system.computer_desc(name)`

Manage the computer's description field

**name** The desired computer description

`salt.states.win_system.computer_name(name)`

Manage the computer's name

**name** The desired computer name

### 30.27.144 salt.states.win\_update

#### Management of the windows update agent

New in version 2014.7.0.

Set windows updates to run by category. Default behavior is to install all updates that do not require user interaction to complete.

Optionally set `category` to a category of your choice to only install certain updates. Default is to set to install all available updates.

The following example will install all Security and Critical Updates, and download but not install standard updates.

```
updates:
  win_update.installed:
    - categories:
      - 'Critical Updates'
      - 'Security Updates'
    - skips:
      - downloaded
  win_update.downloaded:
    - categories:
      - 'Updates'
    - skips:
      - downloaded
```

You can also specify a number of features about the update to have a fine grain approach to specific types of updates. These are the following features/states of updates available for configuring:

```
'UI' - User interaction required, skipped by default
'downloaded' - Already downloaded, included by default
'present' - Present on computer, skipped by default
'installed' - Already installed, skipped by default
'reboot' - Reboot required, included by default
'hidden' - Skip updates that have been hidden, skipped by default
'software' - Software updates, included by default
'driver' - driver updates, included by default
```

The following example installs all driver updates that don't require a reboot: .. code-block:: yaml

```
gryffindor:
  win_update.installed:
    • skips: - driver: True - software: False - reboot: False
```

To just update your windows machine, add this your sls:

```
class salt.states.win_update.PyWinUpdater(categories=None, skipUI=True, skipDown-
loaded=False, skipInstalled=True, skipReboot=False,
skipPresent=False, skipSoftwareUpdates=False,
skipDriverUpdates=False, skipHidden=True)
```

**AutoSearch()**

**Download()**

**GetAvailableCategories()**

**GetCategories()****GetDownloadResults()****GetInstallationResults()****Install()****Search**(*searchString*)**SetCategories**(*categories*)**SetSkip**(*skip, state*)**SetSkips**(*skips*)**salt.states.win\_update.downloaded**(*name, categories=None, skips=None, retries=10*)

Cache updates for later install.

**name:** if categories is left empty, it will be assumed that you are passing the category option through the name. These are separate because you can only have one name, but can have multiple categories.

**categories:** the list of categories to be downloaded. These are simply strings in the update's information, so there is no enumeration of the categories available. Some known categories:

```
Updates
Windows 7
Critical Updates
Security Updates
Update Rollups
```

**skips:** a list of features of the updates to cull by. Available features:

```
'UI' - User interaction required, skipped by default
'downloaded' - Already downloaded, skipped by default (downloading)
'present' - Present on computer, included by default (installing)
'installed' - Already installed, skipped by default
'reboot' - Reboot required, included by default
'hidden' - skip those updates that have been hidden.
'software' - Software updates, included by default
'driver' - driver updates, skipped by default
```

**retries** Number of retries to make before giving up. This is total, not per step.

**salt.states.win\_update.installed**(*name, categories=None, skips=None, retries=10*)

Install specified windows updates.

**name:** if categories is left empty, it will be assumed that you are passing the category option through the name. These are separate because you can only have one name, but can have multiple categories.

**categories:** the list of categories to be downloaded. These are simply strings in the update's information, so there is no enumeration of the categories available. Some known categories:

```
Updates
Windows 7
Critical Updates
Security Updates
Update Rollups
```

**skips:** a list of features of the updates to cull by. Available features:

```
'UI' - User interaction required, skipped by default
'downloaded' - Already downloaded, skipped by default (downloading)
```

```
'present' - Present on computer, included by default (installing)
'installed' - Already installed, skipped by default
'reboot' - Reboot required, included by default
'hidden' - skip those updates that have been hidden.
'software' - Software updates, included by default
'driver' - driver updates, skipped by default
```

**retries** Number of retries to make before giving up. This is total, not per step.

### 30.27.145 salt.states.winrepo

Manage Windows Package Repository

**salt.states.winrepo.genrepo** (*name, force=False, allow\_empty=False*)

Refresh the winrepo.p file of the repository (salt-run winrepo.genrepo)

If **force** is True no checks will be made and the repository will be generated if **allow\_empty** is True then the state will not return an error if there are 0 packages,

---

**Note:** This state only loads on minions that have the **roles: salt-master** grain set.

---

Example:

```
winrepo:
  winrepo.genrepo
```

### 30.27.146 salt.states.xmpp

#### Sending Messages over XMPP

New in version 2014.1.0.

This state is useful for firing messages during state runs, using the XMPP protocol

```
server-warning-message:
  xmpp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-xmpp-account
    - recipient: admins@xmpp.example.com/salt
```

**salt.states.xmpp.send\_msg** (*name, recipient, profile*)

Send a message to an XMPP user

```
server-warning-message:
  xmpp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-xmpp-account
    - recipient: admins@xmpp.example.com/salt
```

**name** The message to send to the XMPP user

### 30.27.147 salt.states.zcbuildout

#### Management of zc.buildout

This module is inspired from minitage's buildout maker (<https://github.com/minitage/minitage/blob/master/src/minitage/core/makers/>

New in version Boron.

---

**Note:** This state module is beta; the API is subject to change and no promise as to performance or functionality is yet present

---

#### Available Functions

- built

```
installed1
  buildout.installed:
    - name: /path/to/buildout

installed2
  buildout.installed:
    - name: /path/to/buildout
    - parts:
      - a
      - b
    - python: /path/to/pythonpath/bin/python
    - unless: /bin/test_something_installed
    - onlyif: /bin/test_else_installed
```

`salt.states.zcbuildout.installed`(*name*, *config*='buildout.cfg', *quiet*=False, *parts*=None, *user*=None, *env*=(), *buildout\_ver*=None, *test\_release*=False, *distribute*=None, *new\_st*=None, *offline*=False, *newest*=False, *python*='/usr/bin/python', *debug*=False, *verbose*=False, *unless*=None, *onlyif*=None, *use\_vt*=False, *loglevel*='debug')

Install buildout in a specific directory

It is a thin wrapper to `modules.buildout.buildout`

**name** directory to execute in

**quiet**

do not output console & logs

**config** buildout config to use (default: buildout.cfg)

**parts** specific buildout parts to run

**user** user used to run buildout as

New in version 2014.1.4.

**env** environment variables to set when running

**buildout\_ver** force a specific buildout version (1 | 2)

**test\_release** buildout accept test release

**new\_st** Forcing use of `setuptools` >= 0.7

**distribute** use distribute over setuptools if possible

**offline** does buildout run offline

**python** python to use

**debug** run buildout with -D debug flag

**onlyif** Only execute cmd if statement on the host return 0

**unless** Do not execute cmd if statement on the host return 0

**newest** run buildout in newest mode

**verbose** run buildout in verbose mode (-vvvvv)

**use\_vt** Use the new salt VT to stream output [experimental]

**loglevel** loglevel for buildout commands

### 30.27.148 salt.states.zk\_concurrency

#### Control concurrency of steps within state execution using zookeeper

This module allows you to ``wrap" a state's execution with concurrency control. This is useful to protect against all hosts executing highstate simultaneously if your services don't all HUP restart. The common way of protecting against this is to run in batch mode, but that doesn't protect from another person running the same batch command (and thereby having 2x the number of nodes deploying at once).

This module will block while acquiring a slot, meaning that however the command gets called it will coordinate with zookeeper to ensure that no more than max\_concurrency steps are executing with a single path.

```

acquire_lock:
  zk_concurrency.lock:
    - zk_hosts: 'zookeeper:2181'
    - path: /trafficserver
    - max_concurrency: 4
    - prereq:
      - service: trafficserver

trafficserver:
  service.running:
    - watch:
      - file: /etc/trafficserver/records.config

/etc/trafficserver/records.config:
  file.managed:
    - source: salt://records.config

release_lock:
  zk_concurrency.unlock:
    - path: /trafficserver
    - require:
      - service: trafficserver
  
```

This example would allow the file state to change, but would limit the concurrency of the trafficserver service restart to 4.

`salt.states.zk_concurrency.lock`(*path*, *zk\_hosts*, *identifier=None*, *max\_concurrency=1*, *timeout=None*, *ephemeral\_lease=False*)  
Block state execution until you are able to get the lock (or hit the timeout)

`salt.states.zk_concurrency.unlock`(*path*, *zk\_hosts=None*, *identifier=None*, *max\_concurrency=1*, *ephemeral\_lease=False*)  
Remove lease from semaphore

## 30.28 Execution Modules

Salt execution modules are the functions called by the **salt** command.

---

**Note:** Salt execution modules are different from state modules and cannot be called directly within state files. You must use the *module* state module to call execution modules within state runs.

---

See also:

*Full list of builtin modules*

Salt ships with many modules that cover a wide variety of tasks.

### 30.28.1 Modules Are Easy to Write!

Writing Salt execution modules is straightforward.

A Salt execution module is a Python or [Cython](#) module placed in a directory called `_modules/` within the *file\_roots* as specified by the master config file. By default this is `/srv/salt/_modules` on Linux systems.

Modules placed in `_modules/` will be synced to the minions when any of the following Salt functions are called:

- `state.apply`
- `saltutil.sync_modules`
- `saltutil.sync_all`

Note that a module's default name is its filename (i.e. `foo.py` becomes module `foo`), but that its name can be overridden by using a `__virtual__` function.

If a Salt module has errors and cannot be imported, the Salt minion will continue to load without issue and the module with errors will simply be omitted.

If adding a Cython module the file must be named `<module name>.pyx` so that the loader knows that the module needs to be imported as a Cython module. The compilation of the Cython module is automatic and happens when the minion starts, so only the `*.pyx` file is required.

### 30.28.2 Cross-Calling Modules

All of the Salt execution modules are available to each other and modules can call functions available in other execution modules.

The variable `__salt__` is packed into the modules after they are loaded into the Salt minion.

The `__salt__` variable is a [Python dictionary](#) containing all of the Salt functions. Dictionary keys are strings representing the names of the modules and the values are the functions themselves.

Salt modules can be cross-called by accessing the value in the `__salt__` dict:

```
def foo(bar):
    return __salt__['cmd.run'](bar)
```

This code will call the *run* function in the *cmd* and pass the argument *bar* to it.

### 30.28.3 Preloaded Execution Module Data

When interacting with execution modules often it is nice to be able to read information dynamically about the minion or to load in configuration parameters for a module.

Salt allows for different types of data to be loaded into the modules by the minion.

#### Grains Data

The values detected by the Salt Grains on the minion are available in a *dict* named `__grains__` and can be accessed from within callable objects in the Python modules.

To see the contents of the grains dictionary for a given system in your deployment run the `grains.items()` function:

```
salt 'hostname' grains.items --output=pprint
```

Any value in a grains dictionary can be accessed as any other Python dictionary. For example, the grain representing the minion ID is stored in the `id` key and from an execution module, the value would be stored in `__grains__['id']`.

#### Module Configuration

Since parameters for configuring a module may be desired, Salt allows for configuration information from the minion configuration file to be passed to execution modules.

Since the minion configuration file is a YAML document, arbitrary configuration data can be passed in the minion config that is read by the modules. It is therefore **strongly** recommended that the values passed in the configuration file match the module name. A value intended for the `test` execution module should be named `test.<value>`.

The `test` execution module contains usage of the module configuration and the default configuration file for the minion contains the information and format used to pass data to the modules. `salt.modules.test`, `conf/minion`.

### 30.28.4 Printout Configuration

Since execution module functions can return different data, and the way the data is printed can greatly change the presentation, Salt has a printout configuration.

When writing a module the `__outputter__` dictionary can be declared in the module. The `__outputter__` dictionary contains a mapping of function name to Salt Outputter.

```
__outputter__ = {
    'run': 'txt'
}
```

This will ensure that the text outputter is used.

### 30.28.5 Virtual Modules

Virtual modules let you override the name of a module in order to use the same name to refer to one of several similar modules. The specific module that is loaded for a virtual name is selected based on the current platform or environment.

For example, packages are managed across platforms using the `pkg` module. `pkg` is a virtual module name that is an alias for the specific package manager module that is loaded on a specific system (for example, `yumpkg` on RHEL/CentOS systems, and `aptpkg` on Ubuntu).

Virtual module names are set using the `__virtual__` function and the *virtual name*.

### 30.28.6 `__virtual__` Function

The `__virtual__` function returns either a *string*, `True`, `False`, or `False` with an *error string*. If a string is returned then the module is loaded using the name of the string as the virtual name. If `True` is returned the module is loaded using the current module name. If `False` is returned the module is not loaded. `False` lets the module perform system checks and prevent loading if dependencies are not met.

Since `__virtual__` is called before the module is loaded, `__salt__` will be unavailable as it will not have been packed into the module at this point in time.

---

**Note:** Modules which return a string from `__virtual__` that is already used by a module that ships with Salt will `_override_` the stock module.

---

#### Returning Error Information from `__virtual__`

Optionally, modules may additionally return a list of reasons that a module could not be loaded. For example, if a dependency for `'my_mod'` was not met, a `__virtual__` function could do as follows:

```
return False, 'My Module must be installed before this module can be used.'
```

#### Examples

The package manager modules are among the best examples of using the `__virtual__` function. A table of all the virtual `pkg` modules can be found [here](#).

#### Overriding Virtual Module Providers

Salt often uses OS grains (`os`, `osrelease`, `os_family`, etc.) to determine which module should be loaded as the virtual module for `pkg`, `service`, etc. Sometimes this OS detection is incomplete, with new distros popping up, existing distros changing init systems, etc. The virtual modules likely to be affected by this are in the list below (click each item for more information):

- `pkg`
- `service`
- `user`
- `shadow`
- `group`

If Salt is using the wrong module for one of these, first of all, please [report it on the issue tracker](#), so that this issue can be resolved for a future release. To make it easier to troubleshoot, please also provide the `grains.items` output, taking care to redact any sensitive information.

Then, while waiting for the SaltStack development team to fix the issue, Salt can be made to use the correct module using the `providers` option in the minion config file:

```
providers:
  service: systemd
  pkg: aptpkg
```

The above example will force the minion to use the `systemd` module to provide service management, and the `aptpkg` module to provide package management.

### 30.28.7 `__virtualname__`

`__virtualname__` is a variable that is used by the documentation build system to know the virtual name of a module without calling the `__virtual__` function. Modules that return a string from the `__virtual__` function must also set the `__virtualname__` variable.

To avoid setting the virtual name string twice, you can implement `__virtual__` to return the value set for `__virtualname__` using a pattern similar to the following:

```
# Define the module's virtual name
__virtualname__ = 'pkg'

def __virtual__():
    '''
    Confine this module to Mac OS with Homebrew.
    '''

    if salt.utils.which('brew') and __grains__['os'] == 'MacOS':
        return __virtualname__
    return False
```

### 30.28.8 Documentation

Salt execution modules are documented. The `sys.doc()` function will return the documentation for all available modules:

```
salt '*' sys.doc
```

The `sys.doc` function simply prints out the docstrings found in the modules; when writing Salt execution modules, please follow the formatting conventions for docstrings as they appear in the other modules.

#### Adding Documentation to Salt Modules

It is strongly suggested that all Salt modules have documentation added.

To add documentation add a [Python docstring](#) to the function.

```
def spam(eggs):
    '''
    A function to make some spam with eggs!

    CLI Example::

        salt '*' test.spam eggs
    '''
    return eggs
```

Now when the `sys.doc` call is executed the docstring will be cleanly returned to the calling terminal.

Documentation added to execution modules in docstrings will automatically be added to the online web-based documentation.

### Add Execution Module Metadata

When writing a Python docstring for an execution module, add information about the module using the following field lists:

```
:maintainer:    Thomas Hatch <thatch@saltstack.com>, Seth House <shouse@saltstack.com>
:maturity:      new
:depends:        python-mysqldb
:platform:      all
```

The `maintainer` field is a comma-delimited list of developers who help maintain this module.

The `maturity` field indicates the level of quality and testing for this module. Standard labels will be determined.

The `depends` field is a comma-delimited list of modules that this module depends on.

The `platform` field is a comma-delimited list of platforms that this module is known to run on.

### 30.28.9 Log Output

You can call the logger from custom modules to write messages to the minion logs. The following code snippet demonstrates writing log messages:

```
import logging

log = logging.getLogger(__name__)

log.info('Here is Some Information')
log.warning('You Should Not Do That')
log.error('It Is Busted')
```

### 30.28.10 Private Functions

In Salt, Python callable objects contained within an execution module are made available to the Salt minion for use. The only exception to this rule is a callable object with a name starting with an underscore `_`.

## Objects Loaded Into the Salt Minion

```
def foo(bar):
    return bar

class baz:
    def __init__(self, quo):
        pass
```

## Objects NOT Loaded into the Salt Minion

```
def _foobar(baz): # Preceded with an _
    return baz

cheese = {} # Not a callable Python object
```

**Note:** Some callable names also end with an underscore `_`, to avoid keyword clashes with Python keywords. When using execution modules, or state modules, with these in them the trailing underscore should be omitted.

### 30.28.11 Useful Decorators for Modules

#### Depends Decorator

When writing execution modules there are many times where some of the module will work on all hosts but some functions have an external dependency, such as a service that needs to be installed or a binary that needs to be present on the system.

Instead of trying to wrap much of the code in large try/except blocks, a decorator can be used.

If the dependencies passed to the decorator don't exist, then the salt minion will remove those functions from the module on that host.

If a `fallback_function` is defined, it will replace the function instead of removing it

```
import logging

from salt.utils.decorators import depends

log = logging.getLogger(__name__)

try:
    import dependency_that_sometimes_exists
except ImportError as e:
    log.trace('Failed to import dependency_that_sometimes_exists: {0}'.format(e))

@depends('dependency_that_sometimes_exists')
def foo():
    '''
    Function with a dependency on the "dependency_that_sometimes_exists" module,
    if the "dependency_that_sometimes_exists" is missing this function will not exist
    '''
    return True
```

```

def _fallback():
    """
    Fallback function for the depends decorator to replace a function with
    """
    return '"dependency_that_sometimes_exists" needs to be installed for this function to exist'

@depends('dependency_that_sometimes_exists', fallback_function=_fallback)
def foo():
    """
    Function with a dependency on the "dependency_that_sometimes_exists" module.
    If the "dependency_that_sometimes_exists" is missing this function will be
    replaced with "_fallback"
    """
    return True

```

In addition to global dependencies the depends decorator also supports raw booleans.

```

from salt.utils.decorators import depends

HAS_DEP = False
try:
    import dependency_that_sometimes_exists
    HAS_DEP = True
except ImportError:
    pass

@depends(HAS_DEP)
def foo():
    return True

```

## 30.29 Master Tops

Salt includes a number of built-in subsystems to generate top file data, they are listed listed at *Full list of builtin master tops modules*.

The source for the built-in Salt master tops can be found here: <https://github.com/saltstack/salt/blob/develop/salt/tops>

## 30.30 Full list of builtin master tops modules

<i>cobbler</i>	Cobbler Tops
<i>ext_nodes</i>	External Nodes Classifier
<i>mongo</i>	Read tops data from a mongodb collection
<i>reclass_adapter</i>	Read tops data from a reclass database

### 30.30.1 salt.tops.cobbler

#### Cobbler Tops

Cobbler Tops is a master tops subsystem used to look up mapping information from Cobbler via its API. The same `cobbler.*` parameters are used for both the Cobbler tops and Cobbler pillar modules.

```

master_tops:
  cobbler: {}
cobbler.url: https://example.com/cobbler_api #default is http://localhost/cobbler_api
cobbler.user: username # default is no username
cobbler.password: password # default is no password

```

## Module Documentation

`salt.tops.cobbler.top(**kwargs)`

Look up top data in Cobbler for a minion.

### 30.30.2 salt.tops.ext\_nodes

#### External Nodes Classifier

The External Nodes Classifier is a master tops subsystem that retrieves mapping information from major configuration management systems. One of the most common external nodes classifiers system is provided by Cobbler and is called `cobbler-ext-nodes`.

The `cobbler-ext-nodes` command can be used with this configuration:

```

master_tops:
  ext_nodes: cobbler-ext-nodes

```

It is noteworthy that the Salt system does not directly ingest the data sent from the `cobbler-ext-nodes` command, but converts the data into information that is used by a Salt top file.

Any command can replace the call to `'cobbler-ext-nodes'` above, but currently the data must be formatted in the same way that the standard `'cobbler-ext-nodes'` does.

See (admittedly degenerate and probably not complete) example:

```

classes:
  - basepackages
  - database

```

The above essentially is the same as a top.sls containing the following:

```

base:
  '*':
    - basepackages
    - database

base:
  '*':
    - basepackages
    - database

```

`salt.tops.ext_nodes.top(**kwargs)`

Run the command configured

### 30.30.3 salt.tops.mongo

Read tops data from a mongodb collection

This module will load tops data from a mongo collection. It uses the node's id for lookups.

#### Salt Master Mongo Configuration

The module shares the same base mongo connection variables as `salt.returners.mongo_return`. These variables go in your master config file.

- `mongo.db` - The mongo database to connect to. Defaults to 'salt'.
- `mongo.host` - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaults to 'salt'.
- `mongo.port` - The port that the mongo database is running on. Defaults to 27017.
- `mongo.user` - The username for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''.
- `mongo.password` - The password for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''.

#### Configuring the Mongo Tops Subsystem

```
master_tops:
  mongo:
    collection: tops
    id_field: _id
    re_replace: ""
    re_pattern: \.example\.com
    states_field: states
    environment_field: environment
```

#### Module Documentation

`salt.tops.mongo.top(**kwargs)`

Connect to a mongo database and read per-node tops data.

##### Parameters:

- `collection`: The mongodb collection to read data from. Defaults to 'tops'.
- `id_field`: The field in the collection that represents an individual minion id. Defaults to '\_id'.
- `re_pattern`: If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. `re_pattern` will be used to match the name, and `re_replace` will be used to replace it. Backrefs are supported as they are in the Python standard library. If `None`, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to `None`.
- `re_replace`: Use as the replacement value in node ids matched with `re_pattern`. Defaults to ``. Feel free to use backreferences here.
- `states_field`: The name of the field providing a list of states.
- `environment_field`: The name of the field providing the environment. Defaults to `environment`.

### 30.30.4 salt.tops.reclass\_adapter

Read tops data from a reclass database

This `master_tops` plugin provides access to the `reclass` database, such that state information (top data) are retrieved from `reclass`.

You can find more information about `reclass` at <http://reclass.pantsfullofunix.net>.

To use the plugin, add it to the `master_tops` list in the Salt master config and tell `reclass` by way of a few options how and where to find the inventory:

```
master_tops:
  reclass:
    storage_type: yaml_fs
    inventory_base_uri: /srv/salt
```

This would cause `reclass` to read the inventory from YAML files in `/srv/salt/nodes` and `/srv/salt/classes`.

If you are also using `reclass` as `ext_pillar` plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for `ext_pillar` and `master_tops`):

```
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
  reclass_source_path: ~/code/reclass

ext_pillar:
  - reclass: *reclass

master_tops:
  reclass: *reclass
```

If you want to run `reclass` from source, rather than installing it, you can either let the master know via the `PYTHON-PATH` environment variable, or by setting the configuration option, like in the example above.

```
salt.tops.reclass_adapter.top(**kwargs)
    Query reclass for the top data (states of the minions).
```

## 30.31 Full list of builtin wheel modules

<code>config</code>	Manage the master configuration file
<code>error</code>	Error generator to enable integration testing of salt wheel error handling
<code>file_roots</code>	Read in files from the <code>file_root</code> and save files to the file root
<code>key</code>	Wheel system wrapper for key system
<code>minions</code>	Wheel system wrapper for connected minions
<code>pillar_roots</code>	The <code>pillar_roots</code> wheel module is used to manage files under the pillar roots directories on the master server.

### 30.31.1 salt.wheel.config

Manage the master configuration file

```
salt.wheel.config.apply(key, value)
```

Set a single key

---

**Note:** This will strip comments from your config file

---

`salt.wheel.config.update_config`(*file\_name*, *yaml\_contents*)

Update master config with *yaml\_contents*.

Writes *yaml\_contents* to a file named *file\_name.conf* under the folder specified by `default_include`. This folder is named `master.d` by default. Please look at `include-configuration` for more information.

Example low data:

```
data = {
  'username': 'salt',
  'password': 'salt',
  'fun': 'config.update_config',
  'file_name': 'gui',
  'yaml_contents': {'id': 1},
  'client': 'wheel',
  'eauth': 'pam',
}
```

`salt.wheel.config.values`()

Return the raw values of the config file

### 30.31.2 salt.wheel.error

Error generator to enable integration testing of salt wheel error handling

`salt.wheel.error.error`(*name=None*, *message=''*)

If *name* is `None` Then return empty dict

Otherwise raise an exception with `__name__` from *name*, *message* from *message*

CLI Example:

```
salt-wheel error
salt-wheel error.error name="Exception" message="This is an error."
```

### 30.31.3 salt.wheel.file\_roots

Read in files from the *file\_root* and save files to the file root

`salt.wheel.file_roots.find`(*path*, *saltenv='base'*, *env=None*)

Return a dict of the files located with the given *path* and environment

`salt.wheel.file_roots.list_env`(*saltenv='base'*, *env=None*)

Return all of the file paths found in an environment

`salt.wheel.file_roots.list_roots`()

Return all of the files names in all available environments

`salt.wheel.file_roots.read`(*path*, *saltenv='base'*, *env=None*)

Read the contents of a text file, if the file is binary then

`salt.wheel.file_roots.write`(*data*, *path*, *saltenv='base'*, *index=0*, *env=None*)

Write the named file, by default the first file found is written, but the *index* of the file can be specified to write to a lower priority file root

### 30.31.4 salt.wheel.key

Wheel system wrapper for key system

`salt.wheel.key.accept(match)`  
Accept keys based on a glob match

`salt.wheel.key.accept_dict(match)`  
Accept keys based on a dict of keys

`salt.wheel.key.delete(match)`  
Delete keys based on a glob match

`salt.wheel.key.delete_dict(match)`  
Delete keys based on a dict of keys

`salt.wheel.key.finger(match)`  
Return the matching key fingerprints

`salt.wheel.key.gen(id_=None, keysize=2048)`  
Generate a key pair. No keys are stored on the master, a keypair is returned as a dict containing pub and priv keys

`salt.wheel.key.gen_accept(id_, keysize=2048, force=False)`  
Generate a key pair then accept the public key. This function returns the key pair in a dict, only the public key is preserved on the master.

`salt.wheel.key.key_str(match)`  
Return the key strings

`salt.wheel.key.list_(match)`  
List all the keys under a named status

`salt.wheel.key.list_all()`  
List all the keys

`salt.wheel.key.reject(match)`  
Reject keys based on a glob match

`salt.wheel.key.reject_dict(match)`  
Reject keys based on a dict of keys

### 30.31.5 salt.wheel.minions

Wheel system wrapper for connected minions

`salt.wheel.minions.connected()`  
List all connected minions on a salt-master

### 30.31.6 salt.wheel.pillar\_roots

The `pillar_roots` wheel module is used to manage files under the pillar roots directories on the master server.

`salt.wheel.pillar_roots.find(path, saltenv='base', env=None)`  
Return a dict of the files located with the given path and environment

`salt.wheel.pillar_roots.list_env(saltenv='base', env=None)`  
Return all of the file paths found in an environment

`salt.wheel.pillar_roots.list_roots()`

Return all of the files names in all available environments

`salt.wheel.pillar_roots.read(path, saltenv='base', env=None)`

Read the contents of a text file, if the file is binary then

`salt.wheel.pillar_roots.write(data, path, saltenv='base', index=0, env=None)`

Write the named file, by default the first file found is written, but the index of the file can be specified to write to a lower priority file root

## 30.32 Full list of builtin beacon modules

<i>btmp</i>	Beacon to fire events at failed login of users
<i>diskusage</i>	Beacon to monitor disk usage.
<i>inotify</i>	Watch files and translate the changes into salt events
<i>journald</i>	A simple beacon to watch journald for specific entries
<i>load</i>	Beacon to emit system load averages
<i>network_info</i>	Beacon to monitor statistics from ethernet adapters
<i>service</i>	Send events covering service status
<i>sh</i>	Watch the shell commands being executed actively.
<i>twilio_txt_msg</i>	Beacon to emit Twilio text messages
<i>wtmp</i>	Beacon to fire events at login of users as registered in the wtmp file

### 30.32.1 salt.beacons.btmp

Beacon to fire events at failed login of users

```
beacons:  
  btmp: {}
```

`salt.beacons.btmp.beacon(config)`

Read the last btmp file and return information on the failed logins

```
beacons:  
  btmp: {}
```

### 30.32.2 salt.beacons.diskusage

Beacon to monitor disk usage.

New in version 2015.5.0.

**depends** python-psutil

`salt.beacons.diskusage.beacon(config)`

Monitor the disk usage of the minion

Specify thresholds for each disk and only emit a beacon if any of them are exceeded.

code\_block:: yaml

```
beacons:
```

```
  diskusage:
```

- /: 63%
- /mnt/nfs: 50%

### 30.32.3 salt.beacons.inotify

Watch files and translate the changes into salt events

#### depends

- pyinotify Python module  $\geq$  0.9.5

**Caution** Using generic mask options like open, access, ignored, and closed\_nowrite with reactors can easily cause the reactor to loop on itself.

`salt.beacons.inotify.beacon` (*config*)

Watch the configured files

Example Config

```
beacons:
  inotify:
    /path/to/file/or/dir:
      mask:
        - open
        - create
        - close_write
      recurse: True
      auto_add: True
```

The mask list can contain the following events (the default mask is create, delete, and modify):

- access File accessed
- attrib File metadata changed
- close\_nowrite Unwritable file closed
- close\_write Writable file closed
- create File created in watched directory
- delete File deleted from watched directory
- delete\_self Watched file or directory deleted
- modify File modified
- moved\_from File moved out of watched directory
- moved\_to File moved into watched directory
- move\_self Watched file moved
- open File opened

The mask can also contain the following options:

- dont\_follow Don't dereference symbolic links
- excl\_unlink Omit events for children after they have been unlinked
- oneshot Remove watch after one event
- onlydir Operate only if name is directory

**recurse:** Recursively watch files in the directory

**auto\_add:** Automatically start watching files that are created in the watched directory

### 30.32.4 salt.beacons.journald

A simple beacon to watch journald for specific entries

`salt.beacons.journald.beacon` (*config*)

The journald beacon allows for the systemd journal to be parsed and linked objects to be turned into events.

This beacons config will return all sshd journal entries

```
beacons:
  journald:
    sshd:
      SYSLOG_IDENTIFIER: sshd
      PRIORITY: 6
```

### 30.32.5 salt.beacons.load

Beacon to emit system load averages

`salt.beacons.load.beacon` (*config*)

Emit the load averages of this host.

Specify thresholds for each load average and only emit a beacon if any of them are exceeded.

```
beacons:
  - load:
    - 1m:
      - 0.0
      - 2.0
    - 5m:
      - 0.0
      - 1.5
    - 15m:
      - 0.1
      - 1.0
```

### 30.32.6 salt.beacons.network\_info

Beacon to monitor statistics from ethernet adapters

New in version 2015.5.0.

`salt.beacons.network_info.beacon` (*config*)

Emit the network statistics of this host.

Specify thresholds for each network stat and only emit a beacon if any of them are exceeded.

`code_block::` yaml

Emit beacon when any values are equal to configured values.

```
beacons:
  network_info:
```

**eth0:**

- type: equal
- bytes\_sent: 100000
- bytes\_recv: 100000
- packets\_sent: 100000
- packets\_recv: 100000
- errin: 100
- errout: 100
- dropin: 100
- dropout: 100

Emit beacon when any values are greater than to configured values.

**beacons:****network\_info:****eth0:**

- type: greater
- bytes\_sent: 100000
- bytes\_recv: 100000
- packets\_sent: 100000
- packets\_recv: 100000
- errin: 100
- errout: 100
- dropin: 100
- dropout: 100

### 30.32.7 salt.beacons.service

Send events covering service status

`salt.beacons.service.beacon`(*config*)

Scan for the configured services and fire events

Example Config

```
beacons:
  service:
    salt-master:
    mysql:
```

The config above sets up beacons to check for the salt-master and mysql services.

The config also supports two other parameters for each service:

*onchangeonly*: when *onchangeonly* is True the beacon will fire events only when the service status changes. Otherwise, it will fire an event at each beacon interval. The default is False.

*uncleanshutdown*: If *uncleanshutdown* is present it should point to the location of a pid file for the service. Most services will not clean up this pid file if they are shutdown uncleanly (e.g. via *kill -9*) or if they are terminated through a crash such as a segmentation fault. If the file is present, then the beacon will add *uncleanshutdown: True* to the event. If not present, the field will be False. The field is only added when the service is NOT running. Omitting the configuration variable altogether will turn this feature off.

Here is an example that will fire an event whenever the state of nginx changes and report an uncleanshutdown. This example is for Arch, which places nginx's pid file in */run*.

```
beacons:
  service:
    nginx:
      onchangeonly: True
      uncleanshutdown: /run/nginx.pid
```

### 30.32.8 salt.beacons.sh

Watch the shell commands being executed actively. This beacon requires *strace*.

`salt.beacons.sh.beacon` (*config*)

Scan the shell execve routines. This beacon will convert all login shells

```
beacons:
  sh: {}
```

### 30.32.9 salt.beacons.twilio\_txt\_msg

Beacon to emit Twilio text messages

`salt.beacons.twilio_txt_msg.beacon` (*config*)

Emit a dict name `texts` whose value is a list of texts.

```
beacons:
  twilio_txt_msg:
    account_sid: "<account sid>"
    auth_token: "<auth token>"
    twilio_number: "+15555555555"
    interval: 10
```

### 30.32.10 salt.beacons.wtmp

Beacon to fire events at login of users as registered in the *wtmp* file

```
beacons:
  wtmp: {}
```

`salt.beacons.wtmp.beacon` (*config*)

Read the last *wtmp* file and return information on the logins

```
beacons:
  wtmp: {}
```

## 30.33 Full list of builtin sdb modules

<i>etcd_db</i>	etcd Database Module
<i>keyring_db</i>	Keyring Database Module
<i>memcached</i>	Memcached sdb Module
<i>sqlite3</i>	SQLite sdb Module

### 30.33.1 salt.sdb.etcd\_db

etcd Database Module

**maintainer** SaltStack

**maturity** New

**depends** python-etcd

**platform** all

New in version 2015.5.0.

This module allows access to the etcd database using an `sdb://` URI. This package is located at <https://pypi.python.org/pypi/python-etcd>.

Like all sdb modules, the etcd module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
myetcd:
  driver: etcd
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

The `driver` refers to the etcd module, `etcd.host` refers to the host that is hosting the etcd database and `etcd.port` refers to the port on that host.

```
password: sdb://myetcd/mypassword
```

`salt.sdb.etcd_db.get(key, service=None, profile=None)`

Get a value from the etcd service

`salt.sdb.etcd_db.set_(key, value, service=None, profile=None)`

Set a key/value pair in the etcd service

### 30.33.2 salt.sdb.keyring\_db

Keyring Database Module

**maintainer** SaltStack

**maturity** New

**depends** keyring

**platform** all

This module allows access to the keyring package using an `sdb://` URI. This package is located at <https://pypi.python.org/pypi/keyring>.

Care must be taken when using keyring. Not all keyend backends are supported on all operating systems. Also, many backends require an agent to be running in order to work. For instance, the `Secret Service` backend requires a compatible agent such as `gnome-keyring-daemon` or `kwallet` to be running. The `keyczar` backend does not seem to enjoy the benefits of an agent, and so using it will require either that the password is typed in manually (which is unreasonable for the `salt-minion` and `salt-master` daemons, especially in production) or an agent is written for it.

Like all `sdb` modules, the `keyring` module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
mykeyring:
  driver: keyring
  service: system
```

The `driver` refers to the keyring module, `service` refers to the service that will be used inside of keyring (which may be likened unto a database table) and `mykeyring` refers to the name that will appear in the URI:

```
password: sdb://mykeyring/mypassword
```

The underlying backend configuration must be configured via keyring itself. For examples and documentation, see keyring:

<https://pypi.python.org/pypi/keyring>

New in version 2014.1.4.

`salt.sdb.keyring_db.get(key, service=None, profile=None)`

Get a value from a keyring service

`salt.sdb.keyring_db.set_(key, value, service=None, profile=None)`

Set a key/value pair in a keyring service

### 30.33.3 salt.sdb.memcached

Memcached `sdb` Module

**maintainer** SaltStack

**maturity** New

**depends** python-memcached

**platform** all

This module allows access to memcached using an `sdb://` URI. This package is located at <https://pypi.python.org/pypi/python-memcached>.

Like all `sdb` modules, the `memcached` module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
mymemcache:
  driver: memcached
  host: localhost
  port: 11211
```

The `driver` refers to the memcached module, `host` and `port` the memcached server to connect to (defaults to `localhost` and `11211`, and `mymemcached` refers to the name that will appear in the URI:

```
password: sdb://mymemcached/mykey
```

`salt.sdb.memcached.get(key, profile=None)`  
Get a value from memcached

`salt.sdb.memcached.set_(key, value, profile=None)`  
Set a key/value pair in memcached

### 30.33.4 salt.sdb.sqlite3

SQLite sdb Module

**maintainer** SaltStack

**maturity** New

**platform** all

This module allows access to sqlite3 using an `sdb://` URI

Like all sdb modules, the `sqlite3` module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```
mysqlite:
  driver: sqlite3
  database: /tmp/sdb.sqlite
  table: sdb
  create_table: True
```

The `driver` refers to the `sqlite3` module, `database` refers to the `sqlite3` database file. `table` is the table within the db that will hold keys and values (defaults to `sdb`). The database and table will be created if they do not exist.

#### Advanced Usage:

Instead of a table name, it is possible to provide custom SQL statements to create the table(s) and get and set values.

`salt.sdb.sqlite3.get(key, profile=None)`  
Get a value from sqlite3

`salt.sdb.sqlite3.set_(key, value, profile=None)`  
Set a key/value pair in sqlite3

---

## Salt Best Practices

---

Salt's extreme flexibility leads to many questions concerning the structure of configuration files.

This document exists to clarify these points through examples and code.

### 31.1 General rules

1. Modularity and clarity should be emphasized whenever possible.
2. Create clear relations between pillars and states.
3. Use variables when it makes sense but don't overuse them.
4. Store sensitive data in pillar.
5. Don't use grains for matching in your pillar top file for any sensitive pillars.

### 31.2 Structuring States and Formulas

When structuring Salt States and Formulas it is important to begin with the directory structure. A proper directory structure clearly defines the functionality of each state to the user via visual inspection of the state's name.

Reviewing the [MySQL Salt Formula](#) it is clear to see the benefits to the end-user when reviewing a sample of the available states:

```
/srv/salt/mysql/files/  
/srv/salt/mysql/client.sls  
/srv/salt/mysql/map.jinja  
/srv/salt/mysql/python.sls  
/srv/salt/mysql/server.sls
```

This directory structure would lead to these states being referenced in a top file in the following way:

```
base:  
  'web*':  
    - mysql.client  
    - mysql.python  
  'db*':  
    - mysql.server
```

This clear definition ensures that the user is properly informed of what each state will do.

Another example comes from the [vim-formula](#):

```
/srv/salt/vim/files/  
/srv/salt/vim/absent.sls  
/srv/salt/vim/init.sls  
/srv/salt/vim/map.jinja  
/srv/salt/vim/nerdtree.sls  
/srv/salt/vim/pyflakes.sls  
/srv/salt/vim/salt.sls
```

Once again viewing how this would look in a top file:

/srv/salt/top.sls:

```
base:  
  'web*':  
    - vim  
    - vim.nerdtree  
    - vim.pyflakes  
    - vim.salt  
  'db*':  
    - vim.absent
```

The usage of a clear top-level directory as well as properly named states reduces the overall complexity and leads a user to both understand what will be included at a glance and where it is located.

In addition *Formulas* should be used as often as possible.

---

**Note:** Formulas repositories on the saltstack-formulas GitHub organization should not be pointed to directly from systems that automatically fetch new updates such as GitFS or similar tooling. Instead formulas repositories should be forked on GitHub or cloned locally, where unintended, automatic changes will not take place.

---

## 31.3 Structuring Pillar Files

*Pillars* are used to store secure and insecure data pertaining to minions. When designing the structure of the `/srv/pillar` directory, the pillars contained within should once again be focused on clear and concise data which users can easily review, modify, and understand.

The `/srv/pillar/` directory is primarily controlled by `top.sls`. It should be noted that the pillar `top.sls` is not used as a location to declare variables and their values. The `top.sls` is used as a way to include other pillar files and organize the way they are matched based on environments or grains.

An example `top.sls` may be as simple as the following:

/srv/pillar/top.sls:

```
base:  
  '*':  
    - packages
```

Or much more complicated, using a variety of matchers:

/srv/pillar/top.sls:

```

base:
  '*':
    - apache
dev:
  'os:Debian':
    - match: grain
    - vim
test:
  '* and not G@os: Debian':
    - match: compound
    - emacs

```

It is clear to see through these examples how the top file provides users with power but when used incorrectly it can lead to confusing configurations. This is why it is important to understand that the top file for pillar is not used for variable definitions.

Each SLS file within the `/srv/pillar/` directory should correspond to the states which it matches.

This would mean that the `apache` pillar file should contain data relevant to Apache. Structuring files in this way once again ensures modularity, and creates a consistent understanding throughout our Salt environment. Users can expect that pillar variables found in an Apache state will live inside of an Apache pillar:

`/srv/pillar/apache.sls:`

```

apache:
  lookup:
    name: httpd
    config:
      tmpl: /etc/httpd/httpd.conf

```

While this pillar file is simple, it shows how a pillar file explicitly relates to the state it is associated with.

## 31.4 Variable Flexibility

Salt allows users to define variables in SLS files. When creating a state variables should provide users with as much flexibility as possible. This means that variables should be clearly defined and easy to manipulate, and that sane defaults should exist in the event a variable is not properly defined. Looking at several examples shows how these different items can lead to extensive flexibility.

Although it is possible to set variables locally, this is generally not preferred:

`/srv/salt/apache/conf.sls:`

```

{% set name = 'httpd' %}
{% set tmpl = 'salt://apache/files/httpd.conf' %}

include:
  - apache

apache_conf:
  file.managed:
    - name: {{ name }}
    - source: {{ tmpl }}
    - template: jinja
    - user: root

```

```
- watch_in:
  - service: apache
```

When generating this information it can be easily transitioned to the pillar where data can be overwritten, modified, and applied to multiple states, or locations within a single state:

/srv/pillar/apache.sls:

```
apache:
  lookup:
    name: httpd
    config:
      tmpl: salt://apache/files/httpd.conf
```

/srv/salt/apache/conf.sls:

```
{% from "apache/map.jinja" import apache with context %}

include:
  - apache

apache_conf:
  file.managed:
    - name: {{ salt['pillar.get']('apache:lookup:name') }}
    - source: {{ salt['pillar.get']('apache:lookup:config:tmpl') }}
    - template: jinja
    - user: root
    - watch_in:
      - service: apache
```

This flexibility provides users with a centralized location to modify variables, which is extremely important as an environment grows.

## 31.5 Modularity Within States

Ensuring that states are modular is one of the key concepts to understand within Salt. When creating a state a user must consider how many times the state could be re-used, and what it relies on to operate. Below are several examples which will iteratively explain how a user can go from a state which is not very modular to one that is:

/srv/salt/apache/init.sls:

```
httpd:
  pkg.installed: []
  service.running:
    - enable: True

/etc/httpd/httpd.conf:
  file.managed:
    - source: salt://apache/files/httpd.conf
    - template: jinja
    - watch_in:
      - service: httpd
```

The example above is probably the worst-case scenario when writing a state. There is a clear lack of focus by naming both the pkg/service, and managed file directly as the state ID. This would lead to changing multiple requires within this state, as well as others that may depend upon the state.

Imagine if a require was used for the httpd package in another state, and then suddenly it's a custom package. Now changes need to be made in multiple locations which increases the complexity and leads to a more error prone configuration.

There is also the issue of having the configuration file located in the init, as a user would be unable to simply install the service and use the default conf file.

Our second revision begins to address the referencing by using `- name`, as opposed to direct ID references:

`/srv/salt/apache/init.sls:`

```
apache:
  pkg.installed:
    - name: httpd
  service.running:
    - name: httpd
    - enable: True

apache_conf:
  file.managed:
    - name: /etc/httpd/httpd.conf
    - source: salt://apache/files/httpd.conf
    - template: jinja
    - watch_in:
      - service: apache
```

The above init file is better than our original, yet it has several issues which lead to a lack of modularity. The first of these problems is the usage of static values for items such as the name of the service, the name of the managed file, and the source of the managed file. When these items are hard coded they become difficult to modify and the opportunity to make mistakes arises. It also leads to multiple edits that need to occur when changing these items (imagine if there were dozens of these occurrences throughout the state!). There is also still the concern of the configuration file data living in the same state as the service and package.

In the next example steps will be taken to begin addressing these issues. Starting with the addition of a map.jinja file (as noted in the [Formula documentation](#)), and modification of static values:

`/srv/salt/apache/map.jinja:`

```
{% set apache = salt['grains.filter_by']({
  'Debian': {
    'server': 'apache2',
    'service': 'apache2',
    'conf': '/etc/apache2/apache.conf',
  },
  'RedHat': {
    'server': 'httpd',
    'service': 'httpd',
    'conf': '/etc/httpd/httpd.conf',
  },
}, merge=salt['pillar.get']('apache:lookup')) %}
```

`/srv/pillar/apache.sls:`

```
apache:
  lookup:
    config:
      tmpl: salt://apache/files/httpd.conf
```

/srv/salt/apache/init.sls:

```
{% from "apache/map.jinja" import apache with context %}

apache:
  pkg.installed:
    - name: {{ apache.server }}
  service.running:
    - name: {{ apache.service }}
    - enable: True

apache_conf:
  file.managed:
    - name: {{ apache.conf }}
    - source: {{ salt['pillar.get']('apache:lookup:config:tmpl') }}
    - template: jinja
    - user: root
    - watch_in:
      - service: apache
```

The changes to this state now allow us to easily identify the location of the variables, as well as ensuring they are flexible and easy to modify. While this takes another step in the right direction, it is not yet complete. Suppose the user did not want to use the provided conf file, or even their own configuration file, but the default apache conf. With the current state setup this is not possible. To attain this level of modularity this state will need to be broken into two states.

/srv/salt/apache/map.jinja:

```
{% set apache = salt['grains.filter_by']({
  'Debian': {
    'server': 'apache2',
    'service': 'apache2',
    'conf': '/etc/apache2/apache.conf',
  },
  'RedHat': {
    'server': 'httpd',
    'service': 'httpd',
    'conf': '/etc/httpd/httpd.conf',
  },
}, merge=salt['pillar.get']('apache:lookup')) %}
```

/srv/pillar/apache.sls:

```
apache:
  lookup:
    config:
      tmpl: salt://apache/files/httpd.conf
```

/srv/salt/apache/init.sls:

```
{% from "apache/map.jinja" import apache with context %}

apache:
  pkg.installed:
    - name: {{ apache.server }}
  service.running:
    - name: {{ apache.service }}
    - enable: True
```

/srv/salt/apache/conf.sls:

```
{% from "apache/map.jinja" import apache with context %}

include:
  - apache

apache_conf:
  file.managed:
    - name: {{ apache.conf }}
    - source: {{ salt['pillar.get']('apache:lookup:config:templ') }}
    - template: jinja
    - user: root
    - watch_in:
      - service: apache
```

This new structure now allows users to choose whether they only wish to install the default Apache, or if they wish, overwrite the default package, service, configuration file location, or the configuration file itself. In addition to this the data has been broken between multiple files allowing for users to identify where they need to change the associated data.

## 31.6 Storing Secure Data

Secure data refers to any information that you would not wish to share with anyone accessing a server. This could include data such as passwords, keys, or other information.

As all data within a state is accessible by EVERY server that is connected it is important to store secure data within pillar. This will ensure that only those servers which require this secure data have access to it. In this example a use can go from an insecure configuration to one which is only accessible by the appropriate hosts:

/srv/salt/mysql/testerdb.sls:

```
testdb:
  mysql_database.present:
    - name: testerdb
```

/srv/salt/mysql/user.sls:

```
include:
  - mysql.testerdb

testdb_user:
  mysql_user.present:
    - name: frank
    - password: "test3rdb"
```

```
- host: localhost
- require:
  - sls: mysql.testerdB
```

Many users would review this state and see that the password is there in plain text, which is quite problematic. It results in several issues which may not be immediately visible.

The first of these issues is clear to most users -- the password being visible in this state. This means that any minion will have a copy of this, and therefore the password which is a major security concern as minions may not be locked down as tightly as the master server.

The other issue that can be encountered is access by users on the master. If everyone has access to the states (or their repository), then they are able to review this password. Keeping your password data accessible by only a few users is critical for both security and peace of mind.

There is also the issue of portability. When a state is configured this way it results in multiple changes needing to be made. This was discussed in the sections above but it is a critical idea to drive home. If states are not portable it may result in more work later!

Fixing this issue is relatively simple, the content just needs to be moved to the associated pillar:

/srv/pillar/mysql.sls:

```
mysql:
  lookup:
    name: testerdB
    password: test3rdb
    user: frank
    host: localhost
```

/srv/salt/mysql/testerdB.sls:

```
testdB:
  mysql_database.present:
    - name: {{ salt['pillar.get']('mysql:lookup:name') }}
```

/srv/salt/mysql/user.sls:

```
include:
  - mysql.testerdB

testdB_user:
  mysql_user.present:
    - name: {{ salt['pillar.get']('mysql:lookup:user') }}
    - password: {{ salt['pillar.get']('mysql:lookup:password') }}
    - host: {{ salt['pillar.get']('mysql:lookup:host') }}
    - require:
      - sls: mysql.testerdB
```

Now that the database details have been moved to the associated pillar file, only machines which are targeted via pillar will have access to these details. Access to users who should not be able to review these details can also be prevented while ensuring that they are still able to write states which take advantage of this information.

---

## Hardening Salt

---

This topic contains tips you can use to secure and harden your Salt environment. How you best secure and harden your Salt environment depends heavily on how you use Salt, where you use Salt, how your team is structured, where you get data from, and what kinds of access (internal and external) you require.

### 32.1 General hardening tips

- Restrict who can directly log into your Salt master system.
- Use SSH keys secured with a passphrase to gain access to the Salt master system.
- Track and secure SSH keys and any other login credentials you and your team need to gain access to the Salt master system.
- Use a hardened bastion server or a VPN to restrict direct access to the Salt master from the internet.
- Don't expose the Salt master any more than what is required.
- Harden the system as you would with any high-priority target.
- Keep the system patched and up-to-date.
- Use tight firewall rules.

### 32.2 Salt hardening tips

- Subscribe to [salt-users](#) or [salt-announce](#) so you know when new Salt releases are available. Keep your systems up-to-date with the latest patches.
- Use Salt's Client *ACL system* to avoid having to give out root access in order to run Salt commands.
- Use Salt's Client *ACL system* to restrict which users can run what commands.
- Use *external Pillar* to pull data into Salt from external sources so that non-sysadmins (other teams, junior admins, developers, etc) can provide configuration data without needing access to the Salt master.
- Make heavy use of SLS files that are version-controlled and go through a peer-review/code-review process before they're deployed and run in production. This is good advice even for ``one-off" CLI commands because it helps mitigate typos and mistakes.
- Use salt-api, SSL, and restrict authentication with the *external auth* system if you need to expose your Salt master to external services.

- Make use of Salt's event system and *reactor* to allow minions to signal the Salt master without requiring direct access.
- Run the `salt-master` daemon as non-root.
- Disable which modules are loaded onto minions with the *disable\_modules* setting. (for example, disable the `cmd` module if it makes sense in your environment.)
- Look through the fully-commented sample *master* and *minion* config files. There are many options for securing an installation.
- Run *masterless-mode* minions on particularly sensitive minions. There is also *Salt SSH* or the *modules.sudo* if you need to further restrict a minion.

---

## Troubleshooting

---

The intent of the troubleshooting section is to introduce solutions to a number of common issues encountered by users and the tools that are available to aid in developing States and Salt code.

### 33.1 Troubleshooting the Salt Master

If your Salt master is having issues such as minions not returning data, slow execution times, or a variety of other issues, the following links contain details on troubleshooting the most common issues encountered:

#### 33.1.1 Troubleshooting the Salt Master

##### Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the master in the foreground:

```
# salt-master -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as `monit`, `runit`, or `supervisord`, should omit the `-d` argument to the daemons and run them in the foreground.

##### What Ports does the Master Need Open?

For the master, TCP ports 4505 and 4506 need to be open. If you've put both your Salt master and minion in debug mode and don't see an acknowledgment that your minion has connected, it could very well be a firewall interfering with the connection. See our [firewall configuration](#) page for help opening the firewall on various platforms.

If you've opened the correct TCP ports and still aren't seeing connections, check that no additional access control system such as `SELinux` or `AppArmor` is blocking Salt.

##### Too many open files

The salt-master needs at least 2 sockets per host that connects to it, one for the Publisher and one for response port. Thus, large installations may, upon scaling up the number of minions accessing a given master, encounter:

```
12:45:29,289 [salt.master ][INFO ] Starting Salt worker process 38
Too many open files
sock != -1 (tcp_listener.cpp:335)
```

The solution to this would be to check the number of files allowed to be opened by the user running salt-master (root by default):

```
[root@salt-master ~]# ulimit -n
1024
```

If this value is not equal to at least twice the number of minions, then it will need to be raised. For example, in an environment with 1800 minions, the `nofile` limit should be set to no less than 3600. This can be done by creating the file `/etc/security/limits.d/99-salt.conf`, with the following contents:

```
root      hard    nofile   4096
root      soft    nofile   4096
```

Replace `root` with the user under which the master runs, if different.

If your master does not have an `/etc/security/limits.d` directory, the lines can simply be appended to `/etc/security/limits.conf`.

As with any change to resource limits, it is best to stay logged into your current shell and open another shell to run `ulimit -n` again and verify that the changes were applied correctly. Additionally, if your master is running `upstart`, it may be necessary to specify the `nofile` limit in `/etc/default/salt-master` if `upstart` isn't respecting your resource limits:

```
limit nofile 4096 4096
```

---

**Note:** The above is simply an example of how to set these values, and you may wish to increase them even further if your Salt master is doing more than just running Salt.

---

## Salt Master Stops Responding

There are known bugs with ZeroMQ versions less than 2.1.11 which can cause the Salt master to not respond properly. If you're running a ZeroMQ version greater than or equal to 2.1.9, you can work around the bug by setting the `sysctl net.core.rmem_max` and `net.core.wmem_max` to 16777216. Next, set the third field in `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` to at least 16777216.

You can do it manually with something like:

```
# echo 16777216 > /proc/sys/net/core/rmem_max
# echo 16777216 > /proc/sys/net/core/wmem_max
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_rmem
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_wmem
```

Or with the following Salt state:

```
1 net.core.rmem_max:
2   sysctl:
3     - present
4     - value: 16777216
5
```

```

6 net.core.wmem_max:
7   sysctl:
8     - present
9     - value: 16777216
10
11 net.ipv4.tcp_rmem:
12   sysctl:
13     - present
14     - value: 4096 87380 16777216
15
16 net.ipv4.tcp_wmem:
17   sysctl:
18     - present
19     - value: 4096 87380 16777216

```

### Live Python Debug Output

If the master seems to be unresponsive, a SIGUSR1 can be passed to the salt-master threads to display what piece of code is executing. This debug information can be invaluable in tracking down bugs.

To pass a SIGUSR1 to the master, first make sure the minion is running in the foreground. Stop the service if it is running as a daemon, and start it in the foreground like so:

```
# salt-master -l debug
```

Then pass the signal to the master when it seems to be unresponsive:

```
# killall -SIGUSR1 salt-master
```

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon, be sure to include this information if possible.

### Live Salt-Master Profiling

When faced with performance problems one can turn on master process profiling by sending it SIGUSR2.

```
# killall -SIGUSR2 salt-master
```

This will activate `yappi` profiler inside salt-master code, then after some time one must send SIGUSR2 again to stop profiling and save results to file. If run in foreground salt-master will report filename for the results, which are usually located under `/tmp` on Unix-based OSes and `c:\temp` on windows.

Results can then be analyzed with `kcachegrind` or similar tool.

### Commands Time Out or Do Not Return Output

Depending on your OS (this is most common on Ubuntu due to `apt-get`) you may sometimes encounter times where a `state.apply`, or other long running commands do not return output.

---

**Note:** A number of timing issues were resolved in the 2014.1 release of Salt. Upgrading to at least this version is strongly recommended if timeouts persist.

---

By default the timeout is set to 5 seconds. The timeout value can easily be increased by modifying the `timeout` line within your `/etc/salt/master` configuration file.

### Passing the `-c` Option to Salt Returns a Permissions Error

Using the `-c` option with the Salt command modifies the configuration directory. When the configuration file is read it will still base data off of the `root_dir` setting. This can result in unintended behavior if you are expecting files such as `/etc/salt/pki` to be pulled from the location specified with `-c`. Modify the `root_dir` setting to address this behavior.

### Salt Master Doesn't Return Anything While Running jobs

When a command being run via Salt takes a very long time to return (package installations, certain scripts, etc.) the master may drop you back to the shell. In most situations the job is still running but Salt has exceeded the set timeout before returning. Querying the job queue will provide the data of the job but is inconvenient. This can be resolved by either manually using the `-t` option to set a longer timeout when running commands (by default it is 5 seconds) or by modifying the master configuration file: `/etc/salt/master` and setting the `timeout` value to change the default timeout for all commands, and then restarting the salt-master service.

### Salt Master Auth Flooding

In large installations, care must be taken not to overwhelm the master with authentication requests. Several options can be set on the master which mitigate the chances of an authentication flood from causing an interruption in service.

---

**Note:** `recon_default`:

The average number of seconds to wait between reconnection attempts.

**recon\_max:** The maximum number of seconds to wait between reconnection attempts.

**recon\_randomize:** A flag to indicate whether the `recon_default` value should be randomized.

**acceptance\_wait\_time:** The number of seconds to wait for a reply to each authentication request.

**random\_reauth\_delay:** The range of seconds across which the minions should attempt to randomize authentication attempts.

**auth\_timeout:** The total time to wait for the authentication process to complete, regardless of the number of attempts.

---

### Salt Master Umask

The salt master uses a cache to track jobs as they are published and returns come back. The recommended umask for a salt-master is `022`, which is the default for most users on a system. Incorrect umasks can result in permission-denied errors when the master tries to access files in its cache.

## 33.2 Troubleshooting the Salt Minion

In the event that your Salt minion is having issues, a variety of solutions and suggestions are available. Please refer to the following links for more information:

### 33.2.1 Troubleshooting the Salt Minion

#### Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the minion in the foreground:

```
# salt-minion -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as [monit](#), [runit](#), or [supervisord](#), should omit the `-d` argument to the daemons and run them in the foreground.

#### What Ports does the Minion Need Open?

No ports need to be opened on the minion, as it makes outbound connections to the master. If you've put both your Salt master and minion in debug mode and don't see an acknowledgment that your minion has connected, it could very well be a firewall interfering with the connection. See our [firewall configuration](#) page for help opening the firewall on various platforms.

If you have netcat installed, you can check port connectivity from the minion with the `nc` command:

```
$ nc -v -z salt.master.ip.addr 4505
Connection to salt.master.ip.addr 4505 port [tcp/unknown] succeeded!
$ nc -v -z salt.master.ip.addr 4506
Connection to salt.master.ip.addr 4506 port [tcp/unknown] succeeded!
```

The [Nmap](#) utility can also be used to check if these ports are open:

```
# nmap -sS -q -p 4505-4506 salt.master.ip.addr

Starting Nmap 6.40 ( http://nmap.org ) at 2013-12-29 19:44 CST
Nmap scan report for salt.master.ip.addr (10.0.0.10)
Host is up (0.0026s latency).
PORT      STATE SERVICE
4505/tcp  open  unknown
4506/tcp  open  unknown
MAC Address: 00:11:22:AA:BB:CC (Intel)

Nmap done: 1 IP address (1 host up) scanned in 1.64 seconds
```

If you've opened the correct TCP ports and still aren't seeing connections, check that no additional access control system such as [SELinux](#) or [AppArmor](#) is blocking Salt.

#### Using salt-call

The `salt-call` command was originally developed for aiding in the development of new Salt modules. Since then, many applications have been developed for running any Salt module locally on a minion. These range from the original intent of `salt-call` (development assistance), to gathering more verbose output from calls like `state.apply`.

When initially creating your state tree, it is generally recommended to invoke highstates by running `state.apply` directly from the minion with `salt-call`, rather than remotely from the master. This displays far more information about the execution than calling it remotely. For even more verbosity, increase the `loglevel` using the `-l` argument:

```
# salt-call -l debug state.apply
```

The main difference between using `salt` and using `salt-call` is that `salt-call` is run from the minion, and it only runs the selected function on that minion. By contrast, `salt` is run from the master, and requires you to specify the minions on which to run the command using salt's [targeting system](#).

### Live Python Debug Output

If the minion seems to be unresponsive, a `SIGUSR1` can be passed to the process to display what piece of code is executing. This debug information can be invaluable in tracking down bugs.

To pass a `SIGUSR1` to the minion, first make sure the minion is running in the foreground. Stop the service if it is running as a daemon, and start it in the foreground like so:

```
# salt-minion -l debug
```

Then pass the signal to the minion when it seems to be unresponsive:

```
# killall -SIGUSR1 salt-minion
```

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon, be sure to include this information if possible.

### Multiprocessing in Execution Modules

As is outlined in [github issue #6300](#), Salt cannot use python's multiprocessing pipes and queues from execution modules. Multiprocessing from the execution modules is perfectly viable, it is just necessary to use Salt's event system to communicate back with the process.

The reason for this difficulty is that python attempts to pickle all objects in memory when communicating, and it cannot pickle function objects. Since the Salt loader system creates and manages function objects this causes the pickle operation to fail.

### Salt Minion Doesn't Return Anything While Running Jobs Locally

When a command being run via Salt takes a very long time to return (package installations, certain scripts, etc.) the minion may drop you back to the shell. In most situations the job is still running but Salt has exceeded the set timeout before returning. Querying the job queue will provide the data of the job but is inconvenient. This can be resolved by either manually using the `-t` option to set a longer timeout when running commands (by default it is 5 seconds) or by modifying the minion configuration file: `/etc/salt/minion` and setting the `timeout` value to change the default timeout for all commands, and then restarting the `salt-minion` service.

---

**Note:** Modifying the minion timeout value is not required when running commands from a Salt Master. It is only required when running commands locally on the minion.

---

## 33.3 Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the minion and/or master in the foreground:

```
salt-master -l debug
salt-minion -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as [monit](#), [runit](#), or [supervisord](#), should omit the `-d` argument to the daemons and run them in the foreground.

### 33.4 What Ports do the Master and Minion Need Open?

No ports need to be opened up on each minion. For the master, TCP ports 4505 and 4506 need to be open. If you've put both your Salt master and minion in debug mode and don't see an acknowledgment that your minion has connected, it could very well be a firewall.

You can check port connectivity from the minion with the `nc` command:

```
nc -v -z salt.master.ip 4505
nc -v -z salt.master.ip 4506
```

There is also a [firewall configuration](#) document that might help as well.

If you've enabled the right TCP ports on your operating system or Linux distribution's firewall and still aren't seeing connections, check that no additional access control system such as [SELinux](#) or [AppArmor](#) is blocking Salt.

### 33.5 Using salt-call

The `salt-call` command was originally developed for aiding in the development of new Salt modules. Since then, many applications have been developed for running any Salt module locally on a minion. These range from the original intent of `salt-call`, development assistance, to gathering more verbose output from calls like `state.apply`.

When initially creating your state tree, it is generally recommended to invoke `state.apply` directly from the minion with `salt-call`, rather than remotely from the master. This displays far more information about the execution than calling it remotely. For even more verbosity, increase the loglevel using the `-l` argument:

```
salt-call -l debug state.apply
```

The main difference between using `salt` and using `salt-call` is that `salt-call` is run from the minion, and it only runs the selected function on that minion. By contrast, `salt` is run from the master, and requires you to specify the minions on which to run the command using salt's [targeting system](#).

### 33.6 Too many open files

The salt-master needs at least 2 sockets per host that connects to it, one for the Publisher and one for response port. Thus, large installations may, upon scaling up the number of minions accessing a given master, encounter:

```
12:45:29,289 [salt.master      ][INFO      ] Starting Salt worker process 38
Too many open files
sock != -1 (tcp_listener.cpp:335)
```

The solution to this would be to check the number of files allowed to be opened by the user running salt-master (root by default):

```
[root@salt-master ~]# ulimit -n
1024
```

And modify that value to be at least equal to the number of minions x 2. This setting can be changed in limits.conf as the nfile value(s), and activated upon new a login of the specified user.

So, an environment with 1800 minions, would need  $1800 \times 2 = 3600$  as a minimum.

## 33.7 Salt Master Stops Responding

There are known bugs with ZeroMQ versions less than 2.1.11 which can cause the Salt master to not respond properly. If you're running a ZeroMQ version greater than or equal to 2.1.9, you can work around the bug by setting the sysctls `net.core.rmem_max` and `net.core.wmem_max` to 16777216. Next, set the third field in `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` to at least 16777216.

You can do it manually with something like:

```
# echo 16777216 > /proc/sys/net/core/rmem_max
# echo 16777216 > /proc/sys/net/core/wmem_max
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_rmem
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_wmem
```

Or with the following Salt state:

```
1 net.core.rmem_max:
2   sysctl:
3     - present
4     - value: 16777216
5
6 net.core.wmem_max:
7   sysctl:
8     - present
9     - value: 16777216
10
11 net.ipv4.tcp_rmem:
12   sysctl:
13     - present
14     - value: 4096 87380 16777216
15
16 net.ipv4.tcp_wmem:
17   sysctl:
18     - present
19     - value: 4096 87380 16777216
```

## 33.8 Salt and SELinux

Currently there are no SELinux policies for Salt. For the most part Salt runs without issue when SELinux is running in Enforcing mode. This is because when the minion executes as a daemon the type context is changed to `initrc_t`.

The problem with SELinux arises when using salt-call or running the minion in the foreground, since the type context stays `unconfined_t`.

This problem is generally manifest in the rpm install scripts when using the pkg module. Until a full SELinux Policy is available for Salt the solution to this issue is to set the execution context of `salt-call` and `salt-minion` to `rpm_exec_t`:

```
# CentOS 5 and RHEL 5:
chcon -t system_u:system_r:rpm_exec_t:s0 /usr/bin/salt-minion
chcon -t system_u:system_r:rpm_exec_t:s0 /usr/bin/salt-call

# CentOS 6 and RHEL 6:
chcon system_u:object_r:rpm_exec_t:s0 /usr/bin/salt-minion
chcon system_u:object_r:rpm_exec_t:s0 /usr/bin/salt-call
```

This works well, because the `rpm_exec_t` context has very broad control over other types.

## 33.9 Red Hat Enterprise Linux 5

Salt requires Python 2.6 or 2.7. Red Hat Enterprise Linux 5 and its variants come with Python 2.4 installed by default. When installing on RHEL 5 from the [EPEL repository](#) this is handled for you. But, if you run Salt from git, be advised that its dependencies need to be installed from EPEL and that Salt needs to be run with the `python26` executable.

## 33.10 Common YAML Gotchas

An extensive list of YAML idiosyncrasies has been compiled:

### 33.10.1 YAML Idiosyncrasies

One of Salt's strengths, the use of existing serialization systems for representing SLS data, can also backfire. [YAML](#) is a general purpose system and there are a number of things that would seem to make sense in an sls file that cause YAML issues. It is wise to be aware of these issues. While reports or running into them are generally rare they can still crop up at unexpected times.

#### Spaces vs Tabs

[YAML uses spaces](#), period. Do not use tabs in your SLS files! If strange errors are coming up in rendering SLS files, make sure to check that no tabs have crept in! In Vim, after enabling search highlighting with: `:set hlsearch`, you can check with the following key sequence in normal mode (you can hit `ESC` twice to be sure): `/`, `Ctrl-v`, `Tab`, then hit `Enter`. Also, you can convert tabs to 2 spaces by these commands in Vim: `:set tabstop=2 expandtab` and then `:retab`.

#### Indentation

The suggested syntax for YAML files is to use 2 spaces for indentation, but YAML will follow whatever indentation system that the individual file uses. Indentation of two spaces works very well for SLS files given the fact that the data is uniform and not deeply nested.

## Nested Dictionaries

When `dicts` are nested within other data structures (particularly lists), the indentation logic sometimes changes. Examples of where this might happen include `context` and `default` options from the `file.managed` state:

```
/etc/http/conf/http.conf:
  file:
    - managed
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - context:
      custom_var: "override"
    - defaults:
      custom_var: "default value"
      other_var: 123
```

Notice that while the indentation is two spaces per level, for the values under the `context` and `defaults` options there is a four-space indent. If only two spaces are used to indent, then those keys will be considered part of the same dictionary that contains the `context` key, and so the data will not be loaded correctly. If using a double indent is not desirable, then a deeply-nested dict can be declared with curly braces:

```
/etc/http/conf/http.conf:
  file:
    - managed
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - context: {
      custom_var: "override" }
    - defaults: {
      custom_var: "default value",
      other_var: 123 }
```

Here is a more concrete example of how YAML actually handles these indentations, using the Python interpreter on the command line:

```
>>> import yaml
>>> yaml.safe_load('''mystate:
...   file.managed:
...     - context:
...       some: var''')
{'mystate': {'file.managed': [{'context': {'some': 'var'}}]}}
>>> yaml.safe_load('''mystate:
...   file.managed:
...     - context:
...       some: var''')
{'mystate': {'file.managed': [{'some': 'var', 'context': None}]}}
```

Note that in the second example, `some` is added as another key in the same dictionary, whereas in the first example, it's the start of a new dictionary. That's the distinction. `context` is a common example because it is a keyword arg for many functions, and should contain a dictionary.

### True/False, Yes/No, On/Off

PyYAML will load these values as boolean `True` or `False`. Un-capitalized versions will also be loaded as booleans (`true`, `false`, `yes`, `no`, `on`, and `off`). This can be especially problematic when constructing Pillar data. Make sure that your Pillars which need to use the string versions of these values are enclosed in quotes.

### Integers are Parsed as Integers

NOTE: This has been fixed in salt 0.10.0, as of this release passing an integer that is preceded by a 0 will be correctly parsed

When passing `integers` into an SLS file, they are passed as integers. This means that if a state accepts a string value and an integer is passed, that an integer will be sent. The solution here is to send the integer as a string.

This is best explained when setting the mode for a file:

```
/etc/vimrc:
  file:
    - managed
    - source: salt://edit/vimrc
    - user: root
    - group: root
    - mode: 644
```

Salt manages this well, since the mode is passed as 644, but if the mode is zero padded as 0644, then it is read by YAML as an integer and evaluated as an octal value, 0644 becomes 420. Therefore, if the file mode is preceded by a 0 then it needs to be passed as a string:

```
/etc/vimrc:
  file:
    - managed
    - source: salt://edit/vimrc
    - user: root
    - group: root
    - mode: '0644'
```

### YAML does not like ``Double Short Decs``

If I can find a way to make YAML accept ``Double Short Decs`` then I will, since I think that double short decs would be awesome. So what is a ``Double Short Dec``? It is when you declare a multiple short decs in one ID. Here is a standard short dec, it works great:

```
vim:
  pkg.installed
```

The short dec means that there are no arguments to pass, so it is not required to add any arguments, and it can save space.

YAML though, gets upset when declaring multiple short decs, for the record...

THIS DOES NOT WORK:

```
vim:
  pkg.installed
  user.present
```

Similarly declaring a short dec in the same ID dec as a standard dec does not work either...

ALSO DOES NOT WORK:

```
fred:
  user.present
  ssh_auth.present:
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred
```

The correct way is to define them like this:

```
vim:
  pkg.installed: []
  user.present: []

fred:
  user.present: []
  ssh_auth.present:
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred
```

Alternatively, they can be defined the ``old way'', or with multiple ``full decs'':

```
vim:
  pkg:
    - installed
  user:
    - present

fred:
  user:
    - present
  ssh_auth:
    - present
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred
```

### YAML support only plain ASCII

According to YAML specification, only ASCII characters can be used.

Within double-quotes, special characters may be represented with C-style escape sequences starting with a backslash (\).

Examples:

```
- micro: "\u00b5"
- copyright: "\u00A9"
- A: "\x41"
- alpha: "\u0251"
- Alef: "\u05d0"
```

List of usable [Unicode characters](#) will help you to identify correct numbers.

Python can also be used to discover the Unicode number for a character:

```
repr(u"Text with wrong characters i need to figure out")
```

This shell command can find wrong characters in your SLS files:

```
find . -name '*.sls' -exec grep --color='auto' -P -n '[^\x00-\x7F]' \{\} \;
```

Alternatively you can toggle the `yaml_utf8` setting in your master configuration file. This is still an experimental setting but it should manage the right encoding conversion in salt after yaml states compilations.

### Underscores stripped in Integer Definitions

If a definition only includes numbers and underscores, it is parsed by YAML as an integer and all underscores are stripped. To ensure the object becomes a string, it should be surrounded by quotes. [More information here](#).

Here's an example:

```
>>> import yaml
>>> yaml.safe_load('2013_05_10')
20130510
>>> yaml.safe_load('"2013_05_10"')
'2013_05_10'
```

### Automatic datetime conversion

If there is a value in a YAML file formatted `2014-01-20 14:23:23` or similar, YAML will automatically convert this to a Python `datetime` object. These objects are not msgpack serializable, and so may break core salt functionality. If values such as these are needed in a salt YAML file (specifically a configuration file), they should be formatted with surrounding strings to force YAML to serialize them as strings:

```
>>> import yaml
>>> yaml.safe_load('2014-01-20 14:23:23')
datetime.datetime(2014, 1, 20, 14, 23, 23)
>>> yaml.safe_load('"2014-01-20 14:23:23"')
'2014-01-20 14:23:23'
```

Additionally, numbers formatted like XXXX-XX-XX will also be converted (or YAML will attempt to convert them, and error out if it doesn't think the date is a real one). Thus, for example, if a minion were to have an ID of 4017-16-20 the minion would not start because YAML would complain that the date was out of range. The workaround is the same, surround the offending string with quotes:

```
>>> import yaml
>>> yaml.safe_load('4017-16-20')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/usr/local/lib/python2.7/site-packages/yaml/__init__.py", line 93, in safe_load
    return load(stream, SafeLoader)
  File "/usr/local/lib/python2.7/site-packages/yaml/__init__.py", line 71, in load
    return loader.get_single_data()
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 39, in get_single_data
    return self.construct_document(node)
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 43, in construct_document
    data = self.construct_object(node)
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 88, in construct_object
    data = constructor(self, node)
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 312, in construct_yaml_time
    return datetime.date(year, month, day)
ValueError: month must be in 1..12
>>> yaml.safe_load('"4017-16-20"')
'4017-16-20'
```

### 33.11 Live Python Debug Output

If the minion or master seems to be unresponsive, a SIGUSR1 can be passed to the processes to display where in the code they are running. If encountering a situation like this, this debug information can be invaluable. First make sure the master or minion are running in the foreground:

```
salt-master -l debug
salt-minion -l debug
```

Then pass the signal to the master or minion when it seems to be unresponsive:

```
killall -SIGUSR1 salt-master
killall -SIGUSR1 salt-minion
```

Also under BSD and Mac OS X in addition to SIGUSR1 signal, debug subroutine set up for SIGINFO which has an advantage of being sent by Ctrl+T shortcut.

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon this information can be invaluable.

### 33.12 Salt 0.16.x minions cannot communicate with a 0.17.x master

As of release 0.17.1 you can no longer run different versions of Salt on your Master and Minion servers. This is due to a protocol change for security purposes. The Salt team will continue to attempt to ensure versions are as backwards compatible as possible.

## 33.13 Debugging the Master and Minion

A list of common `master` and `minion` troubleshooting steps provide a starting point for resolving issues you may encounter.

---

## Developing Salt

---

### 34.1 Overview

In its most typical use, Salt is a software application in which clients, called ``minions" can be commanded and controlled from a central command server called a ``master".

Commands are normally issued to the minions (via the master) by calling a client script simply called, `salt'.

Salt features a pluggable transport system to issue commands from a master to minions. The default transport is ZeroMQ.

### 34.2 Salt Client

#### 34.2.1 Overview

The salt client is run on the same machine as the Salt Master and communicates with the salt-master to issue commands and to receive the results and display them to the user.

The primary abstraction for the salt client is called `LocalClient'.

When LocalClient wants to publish a command to minions, it connects to the master by issuing a request to the master's ReqServer (TCP: 4506)

The LocalClient system listens to responses for its requests by listening to the master event bus publisher (master\_event\_pub.ipc).

### 34.3 Salt Master

#### 34.3.1 Overview

The salt-master daemon runs on the designated Salt master and performs functions such as authenticating minions, sending, and receiving requests from connected minions and sending and receiving requests and replies to the `salt' CLI.

### 34.3.2 Moving Pieces

When a Salt master starts up, a number of processes are started, all of which are called `salt-master' in a process-list but have various role categories.

Among those categories are:

- Publisher
- EventPublisher
- MWorker

### 34.3.3 Publisher

The Publisher process is responsible for sending commands over the designated transport to connected minions. The Publisher is bound to the following:

- TCP: port 4505
- IPC: publish\_pull.ipc

Each salt minion establishes a connection to the master Publisher.

### 34.3.4 EventPublisher

The EventPublisher publishes events onto the event bus. It is bound to the following:

- IPC: master\_event\_pull.ipc
- IPC: master\_event\_pub.ipc

### 34.3.5 MWorker

Worker processes manage the back-end operations for the Salt Master.

The number of workers is equivalent to the number of `worker\_threads' specified in the master configuration and is always at least one.

Workers are bound to the following:

- IPC: workers.ipc

### 34.3.6 ReqServer

The Salt request server takes requests and distributes them to available MWorker processes for processing. It also receives replies back from minions.

**The ReqServer is bound to the following:**

- TCP: 4506
- IPC: workers.ipc

Each salt minion establishes a connection to the master ReqServer.

### 34.3.7 Job Flow

The Salt master works by always publishing commands to all connected minions and the minions decide if the command is meant for them by checking themselves against the command target.

The typical lifecycle of a salt job from the perspective of the master might be as follows:

- 1) A command is issued on the CLI. For example, ``salt my_minion test.ping``.
- 2) The ``salt`` command uses LocalClient to generate a request to the salt master by connecting to the ReqServer on TCP:4506 and issuing the job.
- 3) The salt-master ReqServer sees the request and passes it to an available MWorker over workers.ipc.
- 4) A worker picks up the request and handles it. First, it checks to ensure that the requested user has permissions to issue the command. Then, it sends the publish command to all connected minions. For the curious, this happens in `ClearFuncs.publish()`.
- 5) The worker announces on the master event bus that it is about to publish a job to connected minions. This happens by placing the event on the master event bus (`master_event_pull.ipc`) where the EventPublisher picks it up and distributes it to all connected event listeners on `master_event_pub.ipc`.
- 6) The message to the minions is encrypted and sent to the Publisher via IPC on `publish_pull.ipc`.
- 7) Connected minions have a TCP session established with the Publisher on TCP port 4505 where they await commands. When the Publisher receives the job over `publish_pull`, it sends the jobs across the wire to the minions for processing.
- 8) After the minions receive the request, they decrypt it and perform any requested work, if they determine that they are targeted to do so.
- 9) When the minion is ready to respond, it publishes the result of its job back to the master by sending the encrypted result back to the master on TCP 4506 where it is again picked up by the ReqServer and forwarded to an available MWorker for processing. (Again, this happens by passing this message across `workers.ipc` to an available worker.)
- 10) When the MWorker receives the job it decrypts it and fires an event onto the master event bus (`master_event_pull.ipc`). (Again for the curious, this happens in `AESFuncs._return()`.)
- 11) The EventPublisher sees this event and re-publishes it on the bus to all connected listeners of the master event bus (on `master_event_pub.ipc`). This is where the LocalClient has been waiting, listening to the event bus for minion replies. It gathers the job and stores the result.
- 12) When all targeted minions have replied or the timeout has been exceeded, the salt client displays the results of the job to the user on the CLI.

## 34.4 Salt Minion

### 34.4.1 Overview

The salt-minion is a single process that sits on machines to be managed by Salt. It can either operate as a stand-alone daemon which accepts commands locally via ``salt-call`` or it can connect back to a master and receive commands remotely.

When starting up, salt minions connect `_back_` to a master defined in the minion config file. The connect to two ports on the master:

- **TCP: 4505** This is the connection to the master Publisher. It is on this port that the minion receives jobs from the master.

- **TCP: 4506** This is the connection to the master ReqServer. It is on this port that the minion sends job results back to the master.

### 34.4.2 Event System

Similar to the master, a salt-minion has its own event system that operates over IPC by default. The minion event system operates on a push/pull system with IPC files at `minion_event_<unique_id>_pub.ipc` and `minion_event_<unique_id>_pull.ipc`.

The astute reader might ask why have an event bus at all with a single-process daemon. The answer is that the salt-minion may fork other processes as required to do the work without blocking the main salt-minion process and this necessitates a mechanism by which those processes can communicate with each other. Secondly, this provides a bus by which any user with sufficient permissions can read or write to the bus as a common interface with the salt minion.

### 34.4.3 Job Flow

When a salt minion starts up, it attempts to connect to the Publisher and the ReqServer on the salt master. It then attempts to authenticate and once the minion has successfully authenticated, it simply listens for jobs.

Jobs normally come either come from the `'salt-call'` script run by a local user on the salt minion or they can come directly from a master.

### 34.4.4 Master Job Flow

- 1) A master publishes a job that is received by a minion as outlined by the master's job flow above.
- 2) The minion is polling its receive socket that's connected to the master Publisher (TCP 4505 on master). When it detects an incoming message, it picks it up from the socket and decrypts it.
- 3) A new minion process or thread is created and provided with the contents of the decrypted message. The `_thread_return()` method is provided with the contents of the received message.
- 4) The new minion thread is created. The `_thread_return()` function starts up and actually calls out to the requested function contained in the job.
  5. The requested function runs and returns a result. [Still in thread.]
- 6) The result of the function that's run is encrypted and returned to the master's ReqServer (TCP 4506 on master). [Still in thread.]
- 7) Thread exits. Because the main thread was only blocked for the time that it took to initialize the worker thread, many other requests could have been received and processed during this time.

## 34.5 A Note on ClearFuncs vs. AESFuncs

A common source of confusion is determining when messages are passed in the clear and when they are passed using encryption. There are two rules governing this behaviour:

- 1) ClearFuncs is used for intra-master communication and during the initial authentication handshake between a minion and master during the key exchange.
  2. AESFuncs is used everywhere else.

## 34.6 Contributing

There is a great need for contributions to Salt and patches are welcome! The goal here is to make contributions clear, make sure there is a trail for where the code has come from, and most importantly, to give credit where credit is due!

There are a number of ways to contribute to Salt development.

For details on how to contribute documentation improvements please review *Writing Salt Documentation*.

### 34.6.1 Salt Coding Style

SaltStack has its own coding style guide that informs contributors on various coding approaches. Please review the [:ref:`Salt Coding Style<coding-style>`](#) documentation for information about Salt's particular coding patterns.

Within the [:ref:`Salt Coding Style<coding-style>`](#) documentation, there is a section about running Salt's `.pylintrc` file. SaltStack recommends running the `.pylintrc` file on any files you are changing with your code contribution before submitting a pull request to Salt's repository. Please see the [:ref:`Linting<pylint-instructions>`](#) documentation for more information.

#### Sending a GitHub pull request

Sending pull requests on GitHub is the preferred method for receiving contributions. The workflow advice below mirrors [GitHub's own guide](#) and is well worth reading.

1. Fork `saltstack/salt` on GitHub.
2. Make a local clone of your fork.

```
git clone git@github.com:my-account/salt.git
cd salt
```

3. Add `saltstack/salt` as a git remote.

```
git remote add upstream https://github.com/saltstack/salt.git
```

4. Create a new branch in your clone.

**Note:** A branch should have one purpose. For example, ``Fix bug X,`` or ``Add feature Y``. Multiple unrelated fixes and/or features should be isolated into separate branches.

If you're working on a bug or documentation fix, create your branch from the oldest release branch that contains the bug or requires the documentation update. See *Which Salt Branch?*

```
git fetch upstream
git checkout -b fix-broken-thing upstream/2015.5
```

If you're working on a feature, create your branch from the develop branch.

```
git fetch upstream
git checkout -b add-cool-feature upstream/develop
```

5. Edit and commit changes to your branch.

```
vim path/to/file1 path/to/file2
git diff
git add path/to/file1 path/to/file2
git commit
```

Write a short, descriptive commit title and a longer commit message if necessary.

---

**Note:** If your change fixes a bug or implements a feature already filed in the issue tracker, be sure to reference the issue number in the commit message body.

---

```
fix broken things in file1 and file2

Fixes #31337. The issue is now eradicated from file1 and file2.

# Please enter the commit message for your changes. Lines starting
# with '#' will be ignored, and an empty message aborts the commit.
# On branch fix-broken-thing
# Changes to be committed:
#   modified:   path/to/file1
#   modified:   path/to/file2
```

If you get stuck, there are many introductory Git resources on <http://help.github.com>.

6. Push your locally-committed changes to your GitHub fork,

---

**Note:** You may want to rebase before pushing to work out any potential conflicts.

---

```
git fetch upstream
git rebase upstream/2015.5 fix-broken-thing
git push --set-upstream origin fix-broken-thing
```

or,

```
git fetch upstream
git rebase upstream/develop add-cool-feature
git push --set-upstream origin add-cool-feature
```

7. Find the branch on your GitHub salt fork.

<https://github.com/my-account/salt/branches/fix-broken-thing>

8. Open a new pull request.

Click on **Pull Request** on the right near the top of the page,

<https://github.com/my-account/salt/pull/new/fix-broken-thing>

- (a) If your branch is a fix for a release branch, choose that as the base branch (e.g. 2015.5),

<https://github.com/my-account/salt/compare/saltstack:2015.5...fix-broken-thing>

If your branch is a feature, choose `develop` as the base branch,

<https://github.com/my-account/salt/compare/saltstack:develop...add-cool-feature>

- (b) Review that the proposed changes are what you expect.
- (c) Write a descriptive comment. Include links to related issues (e.g. `Fixes #31337.`) in the comment field.
- (d) Click **Create pull request**.

9. Salt project members will review your pull request and automated tests will run on it.

If you recognize any test failures as being related to your proposed changes or if a reviewer asks for modifications:

- (a) Make the new changes in your local clone on the same local branch.

- (b) Push the branch to GitHub again using the same commands as before.
- (c) New and updated commits will be added to the pull request automatically.
- (d) Feel free to add a comment to the discussion.

---

**Note:** Jenkins

Pull request against `saltstack/salt` are automatically tested on a variety of operating systems and configurations. On average these tests take 30 minutes. Depending on your GitHub notification settings you may also receive an email message about the test results.

Test progress and results can be found at <http://jenkins.saltstack.com/>.

---

### Which Salt branch?

GitHub will open pull requests against Salt's main branch, `deve lop`, by default. Ideally, features should go into `deve lop` and bug fixes and documentation changes should go into the oldest supported release branch affected by the bug or documentation update. See *Sending a GitHub pull request*.

If you have a bug fix or doc change and have already forked your working branch from `deve lop` and do not know how to rebase your commits against another branch, then submit it to `deve lop` anyway and we'll be sure to back-port it to the correct place.

### 34.6.2 The current release branch

The current release branch is the most recent stable release. Pull requests containing bug fixes should be made against the release branch.

The branch name will be a date-based name such as `2015.5`.

Bug fixes are made on this branch so that minor releases can be cut from this branch without introducing surprises and new features. This approach maximizes stability.

The Salt development team will "merge-forward" any fixes made on the release branch to the `deve lop` branch once the pull request has been accepted. This keeps the fix in isolation on the release branch and also keeps the `deve lop` branch up-to-date.

---

**Note:** Closing GitHub issues from commits

This "merge-forward" strategy requires that *the magic keywords to close a GitHub issue* appear in the commit message text directly. Only including the text in a pull request will not close the issue.

GitHub will close the referenced issue once the *commit* containing the magic text is merged into the default branch (`deve lop`). Any magic text input only into the pull request description will not be seen at the Git-level when those commits are merged-forward. In other words, only the commits are merged-forward and not the pull request.

---

### 34.6.3 The deve lop branch

The `deve lop` branch is unstable and bleeding-edge. Pull requests containing feature additions or non-bug-fix changes should be made against the `deve lop` branch.

The Salt development team will back-port bug fixes made to `deve lop` to the current release branch if the contributor cannot create the pull request against that branch.

## Keeping Salt Forks in Sync

Salt is advancing quickly. It is therefore critical to pull upstream changes from upstream into your fork on a regular basis. Nothing is worse than putting hard work into a pull request only to see bunches of merge conflicts because it has diverged too far from upstream.

See also:

[GitHub Fork a Repo Guide](#)

The following assumes `origin` is the name of your fork and `upstream` is the name of the main `saltstack/salt` repository.

1. View existing remotes.

```
git remote -v
```

2. Add the upstream remote.

```
# For ssh github
git remote add upstream git@github.com:saltstack/salt.git

# For https github
git remote add upstream https://github.com/saltstack/salt.git
```

3. Pull upstream changes into your clone.

```
git fetch upstream
```

4. Update your copy of the `develop` branch.

```
git checkout develop
git merge --ff-only upstream/develop
```

If Git complains that a fast-forward merge is not possible, you have local commits.

- Run `git pull --rebase origin develop` to rebase your changes on top of the upstream changes.
- Or, run `git branch <branch-name>` to create a new branch with your commits. You will then need to reset your `develop` branch before updating it with the changes from upstream.

If Git complains that local files will be overwritten, you have changes to files in your working directory. Run `git status` to see the files in question.

5. Update your fork.

```
git push origin develop
```

6. Repeat the previous two steps for any other branches you work with, such as the current release branch.

## Posting patches to the mailing list

Patches will also be accepted by email. Format patches using `git format-patch` and send them to the `salt-users` mailing list. The contributor will then get credit for the patch, and the Salt community will have an archive of the patch and a place for discussion.

## Backporting Pull Requests

If a bug is fixed on `develop` and the bug is also present on a currently-supported release branch it will need to be back-ported to all applicable branches.

**Note:** Most Salt contributors can skip these instructions

These instructions do not need to be read in order to contribute to the Salt project! The SaltStack team will back-port fixes on behalf of contributors in order to keep the contribution process easy.

These instructions are intended for frequent Salt contributors, advanced Git users, SaltStack employees, or independent souls who wish to back-port changes themselves.

It is often easiest to fix a bug on the oldest supported release branch and then merge that branch forward into `develop` (as described earlier in this document). When that is not possible the fix must be back-ported, or copied, into any other affected branches.

These steps assume a pull request #1234 has been merged into `develop`. And `upstream` is the name of the remote pointing to the main Salt repo.

1. Identify the oldest supported release branch that is affected by the bug.
2. Create a new branch for the back-port by reusing the same branch from the original pull request.

Name the branch `bp-<NNNN>` and use the number of the original pull request.

```
git fetch upstream refs/pull/1234/head:bp-1234
git checkout bp-1234
```

3. Find the parent commit of the original pull request.

The parent commit of the original pull request must be known in order to rebase onto a release branch. The easiest way to find this is on GitHub.

Open the original pull request on GitHub and find the first commit in the list of commits. Select and copy the SHA for that commit. The parent of that commit can be specified by appending `~1` to the end.

4. Rebase the new branch on top of the release branch.
  - `<release-branch>` is the branch identified in step #1.
  - `<orig-base>` is the SHA identified in step #3 -- don't forget to add `~1` to the end!

```
git rebase --onto <release-branch> <orig-base> bp-1234
```

Note, release branches prior to 2015.5 will not be able to make use of rebase and must use cherry-picking instead.

5. Push the back-port branch to GitHub and open a new pull request.

Opening a pull request for the back-port allows for the test suite and normal code-review process.

```
git push -u origin bp-1234
```

## Issue and Pull Request Labeling System

SaltStack uses several labeling schemes to help facilitate code contributions and bug resolution. See the [Labels and Milestones](#) documentation for more information.

## 34.7 Deprecating Code

Salt should remain backwards compatible, though sometimes, this backwards compatibility needs to be broken because a specific feature and/or solution is no longer necessary or required. At first one might think, let me change this code, it seems that it's not used anywhere else so it should be safe to remove. Then, once there's a new release, users complain about functionality which was removed and they were using it, etc. This should, at all costs, be avoided, and, in these cases, *that* specific code should be deprecated.

In order to give users enough time to migrate from the old code behavior to the new behavior, the deprecation time frame should be carefully determined based on the significance and complexity of the changes required by the user.

A deprecation warning should be in place for at least two major releases before the deprecated code and its accompanying deprecation warning are removed. More time should be given for more complex changes. For example, if the current release under development is Sodium, the deprecated code and associated warnings should remain in place and warn for at least Aluminum.

To help in this deprecation task, salt provides `salt.utils.warn_until`. The idea behind this helper function is to show the deprecation warning to the user until salt reaches the provided version. Once that provided version is equaled `salt.utils.warn_until` will raise a `RuntimeError` making salt stop its execution. This stoppage is unpleasant and will remind the developer that the deprecation limit has been reached and that the code can then be safely removed.

Consider the following example:

```
def some_function(bar=False, foo=None):
    if foo is not None:
        salt.utils.warn_until(
            'Aluminum',
            'The \'foo\' argument has been deprecated and its '
            'functionality removed, as such, its usage is no longer '
            'required.'
        )
```

Development begins on the Aluminum release when the Magnesium branch is forked from the develop branch. Once this occurs, all uses of the `warn_until` function targeting Aluminum, along with the code they are warning about should be removed from the code.

## 34.8 Dunder Dictionaries

Salt provides several special ``dunder'' dictionaries as a convenience for Salt development. These include `__opts__`, `__context__`, `__salt__`, and others. This document will describe each dictionary and detail where they exist and what information and/or functionality they provide.

### 34.8.1 `__opts__`

#### Available in

- All loader modules

The `__opts__` dictionary contains all of the options passed in the configuration file for the master or minion.

---

**Note:** In many places in salt, instead of pulling raw data from the `__opts__` dict, configuration data should be pulled from the salt *get* functions such as `config.get`, aka - `__salt__['config.get']('foo:bar')` The *get* functions also allow for

dict traversal via the `:` delimiter. Consider using get functions whenever using `__opts__` or `__pillar__` and `__grains__` (when using grains for configuration data)

The configuration file data made available in the `__opts__` dictionary is the configuration data relative to the running daemon. If the modules are loaded and executed by the master, then the master configuration data is available, if the modules are executed by the minion, then the minion configuration is available. Any additional information passed into the respective configuration files is made available

### 34.8.2 `__salt__`

#### Available in

- Execution Modules
- State Modules
- Returners

`__salt__` contains the execution module functions. This allows for all functions to be called as they have been set up by the salt loader.

```
__salt__['cmd.run']('fdisk -l')
__salt__['network.ip_addrs']()
```

### 34.8.3 `__grains__`

#### Available in

- Execution Modules
- State Modules
- Returners
- External Pillar

The `__grains__` dictionary contains the grains data generated by the minion that is currently being worked with. In execution modules, state modules and returners this is the grains of the minion running the calls, when generating the external pillar the `__grains__` is the grains data from the minion that the pillar is being generated for.

### 34.8.4 `__pillar__`

#### Available in

- Execution Modules
- State Modules
- Returners

The `__pillar__` dictionary contains the pillar for the respective minion.

### 34.8.5 `__context__`

`__context__` exists in state modules and execution modules.

During a state run the `__context__` dictionary persists across all states that are run and then is destroyed when the state ends.

When running an execution module `__context__` persists across all module executions until the modules are refreshed; such as when `saltutil.sync_all` or `state.apply` are executed.

A great place to see how to use `__context__` is in the `cp.py` module in `salt/modules/cp.py`. The fileclient authenticates with the master when it is instantiated and then is used to copy files to the minion. Rather than create a new fileclient for each file that is to be copied down, one instance of the fileclient is instantiated in the `__context__` dictionary and is reused for each file. Here is an example from `salt/modules/cp.py`:

```
if not 'cp.fileclient' in __context__:
    __context__['cp.fileclient'] = salt.fileclient.get_file_client(__opts__)
```

---

**Note:** Because `__context__` may or may not have been destroyed, always be sure to check for the existence of the key in `__context__` and generate the key before using it.

---

## 34.9 External Pillars

Salt provides a mechanism for generating pillar data by calling external pillar interfaces. This document will describe an outline of an `ext_pillar` module.

### 34.9.1 Location

Salt expects to find your `ext_pillar` module in the same location where it looks for other python modules. If the `extension_modules` option in your Salt master configuration is set, Salt will look for a `pillar` directory under there and load all the modules it finds. Otherwise, it will look in your Python site-packages `salt/pillar` directory.

### 34.9.2 Configuration

The external pillars that are called when a minion refreshes its pillars is controlled by the `ext_pillar` option in the Salt master configuration. You can pass a single argument, a list of arguments or a dictionary of arguments to your pillar:

```
ext_pillar:
- example_a: some argument
- example_b:
  - argumentA
  - argumentB
- example_c:
  keyA: valueA
  keyB: valueB
```

### 34.9.3 The Module

### 34.9.4 Imports and Logging

Import modules your external pillar module needs. You should first include generic modules that come with stock Python:

```
import logging
```

And then start logging. This is an idiomatic way of setting up logging in Salt:

```
log = logging.getLogger(__name__)
```

Finally, load modules that are specific to what you are doing. You should catch import errors and set a flag that the `__virtual__` function can use later.

```
try:
    import weird_thing
    EXAMPLE_A_LOADED = True
except ImportError:
    EXAMPLE_A_LOADED = False
```

### 34.9.5 Options

If you define an `__opts__` dictionary, it will be merged into the `__opts__` dictionary handed to the `ext_pillar` function later. This is a good place to put default configuration items. The convention is to name things `module-name.option`.

```
__opts__ = { 'example_a.someconfig': 137 }
```

### 34.9.6 Initialization

If you define an `__init__` function, it will be called with the following signature:

```
def __init__( __opts__ ):
    # Do init work here
```

**Note:** The `__init__` function is ran every time a particular minion causes the external pillar to be called, so don't put heavy initialization code here. The `__init__` functionality is a side-effect of the Salt loader, so it may not be as useful in pillars as it is in other Salt items.

### 34.9.7 `__virtual__`

If you define a `__virtual__` function, you can control whether or not this module is visible. If it returns `False` then Salt ignores this module. If it returns a string, then that string will be how Salt identifies this external pillar in its `ext_pillar` configuration. If you're not renaming the module, simply return `True` in the `__virtual__` function, which is the same as if this function did not exist, then, the name Salt's `ext_pillar` will use to identify this module is its conventional name in Python.

This is useful to write modules that can be installed on all Salt masters, but will only be visible if a particular piece of software your module requires is installed.

```
# This external pillar will be known as `example_a`
def __virtual__():
    if EXAMPLE_A_LOADED:
        return True
    return False
```

```
# This external pillar will be known as `something_else`
__virtualname__ = 'something_else'

def __virtual__():
    if EXAMPLE_A_LOADED:
        return __virtualname__
    return False
```

### 34.9.8 ext\_pillar

This is where the real work of an external pillar is done. If this module is active and has a function called `ext_pillar`, whenever a minion updates its pillar this function is called.

How it is called depends on how it is configured in the Salt master configuration. The first argument is always the current pillar dictionary, this contains pillar items that have already been added, starting with the data from `pillar_roots`, and then from any already-ran external pillars.

Using our example above:

```
ext_pillar( id, pillar, 'some argument' )           # example_a
ext_pillar( id, pillar, 'argumentA', 'argumentB' ) # example_b
ext_pillar( id, pillar, keyA='valueA', keyB='valueB' } ) # example_c
```

In the `example_a` case, `pillar` will contain the items from the `pillar_roots`, in `example_b` `pillar` will contain that plus the items added by `example_a`, and in `example_c` `pillar` will contain that plus the items added by `example_b`. In all three cases, `id` will contain the ID of the minion making the pillar request.

This function should return a dictionary, the contents of which are merged in with all of the other pillars and returned to the minion. **Note:** this function is called once for each minion that fetches its pillar data.

```
def ext_pillar( minion_id, pillar, *args, **kwargs ):

    my_pillar = {}

    # Do stuff

    return my_pillar
```

You shouldn't just add items to `pillar` and return that, since that will cause Salt to merge data that already exists. Rather, just return the items you are adding or changing. You could, however, use `pillar` in your module to make some decision based on pillar data that already exists.

This function has access to some useful globals:

`__opts__` A dictionary of mostly Salt configuration options. If you had an `__opts__` dictionary defined in your module, those values will be included.

- `__salt__` A dictionary of Salt module functions, useful so you don't have to duplicate functions that already exist. E.g. `__salt__['cmd.run']('ls -l')` *Note*, runs on the *master*
- `__grains__` A dictionary of the grains of the minion making this pillar call.

### 34.9.9 Example configuration

As an example, if you wanted to add external pillar via the `cmd_json` external pillar, add something like this to your master config:

```
ext_pillar:
  - cmd_json: 'echo {"arg\":\"value\"}'
```

### 34.9.10 Reminder

Just as with traditional pillars, external pillars must be refreshed in order for minions to see any fresh data:

```
salt '*' saltutil.refresh_pillar
```

## 34.10 Installing Salt for development

Clone the repository using:

```
git clone https://github.com/saltstack/salt
```

**Note:** tags

Just cloning the repository is enough to work with Salt and make contributions. However, fetching additional tags from git is required to have Salt report the correct version for itself. To do this, first add the git repository as an upstream source:

```
git remote add upstream https://github.com/saltstack/salt
```

Fetching tags is done with the git `'fetch'` utility:

```
git fetch --tags upstream
```

Create a new `virtualenv`:

```
virtualenv /path/to/your/virtualenv
```

On Arch Linux, where Python 3 is the default installation of Python, use the `virtualenv2` command instead of `virtualenv`.

**Note:** Using system Python modules in the `virtualenv`

To use already-installed python modules in `virtualenv` (instead of having pip download and compile new ones), run `virtualenv --system-site-packages` Using this method eliminates the requirement to install the salt

dependencies again, although it does assume that the listed modules are all installed in the system PYTHONPATH at the time of virtualenv creation.

---

Activate the virtualenv:

```
source /path/to/your/virtualenv/bin/activate
```

Install Salt (and dependencies) into the virtualenv:

```
pip install M2Crypto      # Don't install on Debian/Ubuntu (see below)
pip install pyzmq PyYAML pycrypto msgpack-python jinja2 psutil
pip install -e ./salt    # the path to the salt git clone from above
```

**Note:** Installing M2Crypto

swig and libssl-dev are required to build M2Crypto. To fix the error command 'swig' failed with exit status 1 while installing M2Crypto, try installing it with the following command:

```
env SWIG_FEATURES="-cpperraswarn -includeall -D__uname -m`__ -I/usr/include/openssl" pip install M2Crypto
```

Debian and Ubuntu systems have modified openssl libraries and mandate that a patched version of M2Crypto be installed. This means that M2Crypto needs to be installed via apt:

```
apt-get install python-m2crypto
```

This also means that pulling in the M2Crypto installed using apt requires using `--system-site-packages` when creating the virtualenv.

If you're using a platform other than Debian or Ubuntu, and you are installing M2Crypto via pip instead of a system package, then you will also need the gcc compiler.

---

**Note:** Installing psutil

Python header files are required to build this module, otherwise the pip install will fail. If your distribution separates binaries and headers into separate packages, make sure that you have the headers installed. In most Linux distributions which split the headers into their own package, this can be done by installing the `python-dev` or `python-devel` package. For other platforms, the package will likely be similarly named.

---

**Note:** Installing dependencies on OS X.

You can install needed dependencies on OS X using homebrew or macports. See [OS X Installation](#)

---

**Warning:** Installing on RedHat-based Distros

If installing from pip (or from source using `setup.py install`), be advised that the `yum-utils` package is needed for Salt to manage packages on RedHat-based systems.

### 34.10.1 Running a self-contained development version

During development it is easiest to be able to run the Salt master and minion that are installed in the virtualenv you created above, and also to have all the configuration, log, and cache files contained in the virtualenv as well.

---

Copy the master and minion config files into your virtualenv:

```
mkdir -p /path/to/your/virtualenv/etc/salt
cp ./salt/conf/master /path/to/your/virtualenv/etc/salt/master
cp ./salt/conf/minion /path/to/your/virtualenv/etc/salt/minion
```

Edit the master config file:

1. Uncomment and change the `user: root` value to your own user.
2. Uncomment and change the `root_dir: /` value to point to `/path/to/your/virtualenv`.
3. If you are running version 0.11.1 or older, uncomment, and change the `pidfile: /var/run/salt-master.pid` value to point to `/path/to/your/virtualenv/salt-master.pid`.
4. If you are also running a non-development version of Salt you will have to change the `publish_port` and `ret_port` values as well.

Edit the minion config file:

1. Repeat the edits you made in the master config for the `user` and `root_dir` values as well as any port changes.
2. If you are running version 0.11.1 or older, uncomment, and change the `pidfile: /var/run/salt-minion.pid` value to point to `/path/to/your/virtualenv/salt-minion.pid`.
3. Uncomment and change the `master: salt` value to point at localhost.
4. Uncomment and change the `id:` value to something descriptive like ```saltdev```. This isn't strictly necessary but it will serve as a reminder of which Salt installation you are working with.
5. If you changed the `ret_port` value in the master config because you are also running a non-development version of Salt, then you will have to change the `master_port` value in the minion config to match.

---

**Note:** Using `salt-call` with a [Standalone Minion](#)

If you plan to run `salt-call` with this self-contained development environment in a masterless setup, you should invoke `salt-call` with `-c /path/to/your/virtualenv/etc/salt` so that salt can find the minion config file. Without the `-c` option, Salt finds its config files in `/etc/salt`.

---

Start the master and minion, accept the minion's key, and verify your local Salt installation is working:

```
cd /path/to/your/virtualenv
salt-master -c ./etc/salt -d
salt-minion -c ./etc/salt -d
salt-key -c ./etc/salt -L
salt-key -c ./etc/salt -A
salt -c ./etc/salt '*' test.ping
```

Running the master and minion in debug mode can be helpful when developing. To do this, add `-l debug` to the calls to `salt-master` and `salt-minion`. If you would like to log to the console instead of to the log file, remove the `-d`.

Once the minion starts, you may see an error like the following:

```
zmq.core.error.ZMQError: ipc path "/path/to/your/virtualenv/
var/run/salt/minion/minion_event_7824dcbcf7a8f6755939af70b96249f_pub.ipc"
is longer than 107 characters (sizeof(sockaddr_un.sun_path)).
```

This means that the path to the socket the minion is using is too long. This is a system limitation, so the only workaround is to reduce the length of this path. This can be done in a couple different ways:

1. Create your virtualenv in a path that is short enough.
2. Edit the `sock_dir` minion config variable and reduce its length. Remember that this path is relative to the value you set in `root_dir`.

**NOTE:** The socket path is limited to 107 characters on Solaris and Linux, and 103 characters on BSD-based systems.

---

**Note:** File descriptor limits

Ensure that the system open file limit is raised to at least 2047:

```
# check your current limit
ulimit -n

# raise the limit. persists only until reboot
# use 'limit descriptors 2047' for c-shell
ulimit -n 2047
```

To set file descriptors on OSX, refer to the [OS X Installation](#) instructions.

---

## Changing Default Paths

Instead of updating your configuration files to point to the new root directory and having to pass the new configuration directory path to all of Salt's CLI tools, you can explicitly tweak the default system paths that Salt expects:

```
GENERATE_SALT_SYSPATHS=1 pip --global-option='--salt-root-dir=/path/to/your/virtualenv/' \
  install -e ./salt # the path to the salt git clone from above
```

You can now call all of Salt's CLI tools without explicitly passing the configuration directory.

## Additional Options

In case you want to distribute your virtualenv, you probably don't want to include Salt's clone `.git/` directory, and, without it, Salt won't report the accurate version. You can tell `setup.py` to generate the hardcoded version information which is distributable:

```
GENERATE_SALT_SYSPATHS=1 WRITE_SALT_VERSION=1 pip --global-option='--salt-root-dir=/path/to/your/virtualenv/' \
  install -e ./salt # the path to the salt git clone from above
```

Instead of passing those two environmental variables, you can just pass a single one which will trigger the other two:

```
MIMIC_SALT_INSTALL=1 pip --global-option='--salt-root-dir=/path/to/your/virtualenv/' \
  install -e ./salt # the path to the salt git clone from above
```

This last one will grant you an editable salt installation with hardcoded system paths and version information.

### 34.10.2 Installing Salt from the Python Package Index

If you are installing using `easy_install`, you will need to define a `USE_SETUPTOOLS` environment variable, otherwise dependencies will not be installed:

```
USE_SETUPTOOLS=1 easy_install salt
```

### 34.10.3 Editing and previewing the documentation

You need `sphinx-build` command to build the docs. In Debian/Ubuntu this is provided in the `python-sphinx` package. Sphinx can also be installed to a virtualenv using `pip`:

```
pip install Sphinx
```

Change to salt documentation directory, then:

```
cd doc; make html
```

- This will build the HTML docs. Run `make` without any arguments to see the available make targets, which include `html`, `man`, and `text`.
- The docs then are built within the `docs/_build/` folder. To update the docs after making changes, run `make` again.
- The docs use `reStructuredText` for markup. See a live demo at <http://rst.ninjs.org/>.
- The help information on each module or state is culled from the python code that runs for that piece. Find them in `salt/modules/` or `salt/states/`.
- To build the docs on Arch Linux, the `python2-sphinx` package is required. Additionally, it is necessary to tell `make` where to find the proper `sphinx-build` binary, like so:

```
make SPHINXBUILD=sphinx-build2 html
```

- To build the docs on RHEL/CentOS 6, the `python-sphinx10` package must be installed from EPEL, and the following make command must be used:

```
make SPHINXBUILD=sphinx-1.0-build html
```

Once you've updated the documentation, you can run the following command to launch a simple Python HTTP server to see your changes:

```
cd _build/html; python -m SimpleHTTPServer
```

### 34.10.4 Running unit and integration tests

Run the test suite with following command:

```
./setup.py test
```

See [here](#) for more information regarding the test suite.

### 34.10.5 Issue and Pull Request Labeling System

SaltStack uses several labeling schemes to help facilitate code contributions and bug resolution. See the *Labels and Milestones* documentation for more information.

## 34.11 GitHub Labels and Milestones

SaltStack uses several label categories, as well as milestones, to triage incoming issues and pull requests in the GitHub issue tracker. Labels are used to sort issues by type, priority, severity, status, functional area, functional group, and targeted release and pull requests by status, functional area, functional group, type of change, and test status. Milestones are used to indicate whether an issue is fully triaged or is scheduled to be fixed by SaltStack in an upcoming sprint.

### 34.11.1 Milestones

All issues are assigned to a milestone, whereas pull requests are almost never assigned to a milestone as the mean lifetime of pull requests is short enough that there is no need to track them temporally.

SaltStack uses milestones to indicate which issues are blocked on submitter or upstream actions, are approved, or are scheduled to be fixed or implemented in an upcoming sprint. If an issue is not attached to a sprint milestone, you are welcome to work on it at your own desire and convenience. If it is attached to a sprint milestone and you have already begun working on it or have a solution in mind or have other ideas related to the issue, you are encouraged to coordinate with the assignee via the GitHub issue tracker to create the best possible solution or implementation.

**Approved** The issue has been validated and has all necessary information.

**Blocked** The issue is waiting on actions by parties outside of SaltStack, such as receiving more information from the submitter or resolution of an upstream issue. This milestone is usually applied in conjunction with the labels `Info Needed`, `Question`, `Expected Behavior`, `Won't Fix For Now`, or `Upstream Bug`.

**Under Review** The issue is having further validation done by a SaltStack engineer.

**<Sprint>** The issue is being actively worked on by a SaltStack engineer. Sprint milestone names are constructed from the chemical symbol of the next release's codename and the number of sprints until that release is made. For example, if the next release codename is `NEON` and there are five sprints until that release, the corresponding sprint milestone will be called `Ne 5`. See `<topics/releases/version_numbers>` for a discussion of Salt's release codenames.

### 34.11.2 Labels

Labels are used to sort and describe issues and pull requests. Some labels are usually reserved for one or the other, though most labels may be applied to both.

New issues will receive at least one label and a milestone, and new pull requests will receive at least one label. Except for the *functional area* and *functional group* label categories, issues will generally receive only up to one label per category.

#### Type

Issues are categorized into one of several types. Type labels are almost never used for pull requests. GitHub treats pull requests like issues in many ways, so a pull request could be considered an issue with an implicit `Pull Request` type label applied.

**Feature** The issue is a request for new functionality including changes, enhancements, refactors, etc.

**Bug** The issue documents broken, incorrect, or confusing behavior. This label is always accompanied by a *severity label*.

**Duplicate** The issue is a duplicate of another feature request or bug report.

**Upstream Bug** The issue is a result of an upstream issue.

**Question** The issue is more of a question than a request for new features or a report of broken features, but can sometimes lead to further discussion or changes of confusing or incongruous behavior or documentation.

**Expected Behavior** The issue is a bug report of intended functionality.

## Priority

An issue's priority is relative to its *functional area*. If a bug report, for example, about `gitfs` indicates that all users of `gitfs` will encounter this bug, then a **P1** label will be applied, even though users who are not using `gitfs` will not encounter the bug. If a feature is requested by many users, it may be given a high priority.

**P1** The issue will be seen by all users.

**P2** The issue will be seen by most users.

**P3** The issue will be seen by about half of users.

**P4** The issue will not be seen by most users. Usually the issue is a very specific use case or corner case.

## Severity

Severity labels are almost always only applied to issues labeled **Bug**.

**Blocker** The issue is blocking an impending release.

**Critical** The issue causes data loss, crashes or hangs salt processes, makes the system unresponsive, etc.

**High Severity** The issue reports incorrect functionality, bad functionality, a confusing user experience, etc.

**Medium Severity** The issue reports cosmetic items, formatting, spelling, colors, etc.

## Functional Area

Many major components of Salt have corresponding GitHub labels. These labels are applied to all issues and pull requests as is reasonably appropriate. They are useful in organizing issues and pull requests according to the source code relevant to issues or the source code changed by pull requests.

- Execution Module
- File Servers
- Grains
- Multi-Master
- Packaging Related to packaging of Salt, not Salt's support for package management.
- Pillar
- RAET
- Returners
- Runners

- Salt-API
- Salt-Cloud
- Salt-SSH
- Salt-Syndic
- State Module
- Tests
- Transport
- Windows
- ZMQ

### Functional Group

These labels sort issues and pull requests according to the internal SaltStack engineering teams.

**Core** The issue or pull request relates to code that is central or existential to Salt itself.

**Platform** The issue or pull request relates to support and integration with various platforms like traditional operating systems as well as containers, platform-based utilities like filesystems, command schedulers, etc., and system-based applications like webservers, databases, etc.

**RIoT** The issue or pull request relates to support and integration with various abstract systems like cloud providers, hypervisors, API-based services, etc.

**Console** The issue or pull request relates to the SaltStack enterprise console.

**Documentation** The issue or pull request relates to documentation.

### Status

Status labels are used to define and track the state of issues and pull requests. Not all potential statuses correspond to a label, but some statuses are common enough that labels have been created for them. If an issue has not been moved beyond the `Blocked` milestone, it is very likely that it will only have a status label.

**Bugfix - back-port** The pull request needs to be back-ported to an older release branch. This is done by *recreating the pull request* against that branch. Once the back-port is completed, this label is replaced with a `Bugfix - [Done] back-ported` label. Normally, new features should go into the `develop` and bug fixes into the oldest supported release branch, see `<which-salt-branch>`.

**Bugfix - [Done] back-ported** The pull request has been back-ported to an older branch.

**Cannot Reproduce** The issue is a bug and has been reviewed by a SaltStack engineer, but it cannot be replicated with the provided information and context. Those involved with the bug will need to work through additional ideas until the bug can be isolated and verified.

**Confirmed** The issue is a bug and has been confirmed by a SaltStack engineer, who often documents a minimal working example that reproduces the bug.

**Fixed Pending Verification** The issue is a bug and has been fixed by one or more pull requests, which should link to the issue. Closure of the issue is contingent upon confirmation of resolution from the submitter. If the submitter reports a negative confirmation, this label is removed. If no response is given after a few weeks, then the issue will be assumed fixed and closed.

**Info Needed** The issue needs more information before it can be verified and resolved. For a feature request this may include a description of the use cases. Almost all bug reports need to include at least the versions of salt and its dependencies, the system type and version, commands used, debug logs, error messages, and relevant configs.

**Pending Changes** The pull request needs additional changes before it can be merged.

**Pending Discussion** The issue or pull request needs more discussion before it can be closed or merged. The status of the issue or pull request is not clear or apparent enough for definite action to be taken, or additional input from SaltStack, the submitter, or another party has been requested.

If the issue is not a pull request, once the discussion has arrived at a cogent conclusion, this label will be removed and the issue will be accepted. If it is a pull request, the results of the discussion may require additional changes and thus, a Pending Changes label.

**Won't Fix for Now** The issue is legitimate, but it is not something the SaltStack team is currently able or willing to fix or implement. Issues having this label may be revisited in the future.

### Type of Change

Every pull request should receive a change label. These labels measure the quantity of change as well as the significance of the change. The amount of change and the importance of the code area changed are considered, but often the depth of secondary code review required and the potential repercussions of the change may also advise the label choice.

Core code areas include: state compiler, crypto engine, master and minion and syndic daemons, transport, pillar rendering, loader, transport layer, event system, salt.utils, client, cli, logging, netapi, runner engine, templating engine, top file compilation, file client, file server, mine, salt-ssh, test runner, etc.

Non-core code usually constitutes the specific set of plugins for each of the several plugin layers of Salt: execution modules, states, runners, returners, clouds, etc.

### Minor Change

- Less than 64 lines changed, or
- Less than 8 core lines changed

### Medium Change

- Less than 256 lines changed, or
- Less than 64 core lines changed

### Master Change

- More than 256 lines changed, or
- More than 64 core lines changed

### Expert Change

- Needs specialized, in-depth review

### Test Status

These labels relate to the status of the automated tests that run on pull requests. If the tests on a pull request fail and are not overridden by one of these labels, the pull request submitter needs to update the code and/or tests so that the tests pass and the pull request can be merged.

**Lint** The pull request has passed all tests except for the code lint checker.

**Tests Passed** The pull request has passed all tests even though some test results are negative. Sometimes the automated testing infrastructure will encounter internal errors unrelated to the code change in the pull request that cause test runs to fail. These errors can be caused by cloud provider and network issues and also Jenkins issues like erroneously accumulating workspace artifacts, resource exhaustion, and bugs that arise from long running Jenkins processes.

## Other

These labels indicate miscellaneous issue types or statuses that are common or important enough to be tracked and sorted with labels.

**Awesome** The pull request implements an especially well crafted solution, or a very difficult but necessary change.

**Low Hanging Fruit** The issue is trivial or almost trivial to implement or fix. Issues having this label should be a good starting place for new contributors to Salt.

**Needs Testcase** The issue or pull request relates to a feature that needs test coverage. The pull request containing the tests should reference the issue or pull request having this label, whereupon the label should be removed.

**Regression** The issue is a bug that breaks functionality known to work in previous releases.

**Story** The issue is used by a SaltStack engineer to track progress on multiple related issues in a single place.

**ZD** The issue is related to a Zendesk customer support ticket.

**<Release>** The issue is scheduled to be implemented by <Release>. See <topics/releases/version\_numbers> for a discussion of Salt's release codenames.

## 34.12 Logging Internals

TODO

## 34.13 Modular Systems

When first working with Salt, it is not always clear where all of the modular components are and what they do. Salt comes loaded with more modular systems than many users are aware of, making Salt very easy to extend in many places.

The most commonly used modular systems are execution modules and states. But the modular systems extend well beyond the more easily exposed components and are often added to Salt to make the complete system more flexible.

### 34.13.1 Execution Modules

Execution modules make up the core of the functionality used by Salt to interact with client systems. The execution modules create the core system management library used by all Salt systems, including states, which interact with minion systems.

Execution modules are completely open ended in their execution. They can be used to do anything required on a minion, from installing packages to detecting information about the system. The only restraint in execution modules is that the defined functions always return a JSON serializable object.

For a list of all built in execution modules, click [here](#)

For information on writing execution modules, see [this page](#).

### 34.13.2 Interactive Debugging

Sometimes debugging with `print()` and extra logs sprinkled everywhere is not the best strategy.

IPython is a helpful debug tool that has an interactive python environment which can be embedded in python programs.

First the system will require IPython to be installed.

```
# Debian
apt-get install ipython

# Arch Linux
pacman -Syu ipython2

# RHEL/CentOS (via EPEL)
yum install python-ipython
```

Now, in the troubling python module, add the following line at a location where the debugger should be started:

```
test = 'test123'
import IPython; IPython.embed_kernel()
```

After running a Salt command that hits that line, the following will show up in the log file:

```
[CRITICAL] To connect another client to this kernel, use:
[IPKernelApp] --existing kernel-31271.json
```

Now on the system that invoked `embed_kernel`, run the following command from a shell:

```
# NOTE: use ipython2 instead of ipython for Arch Linux
ipython console --existing
```

This provides a console that has access to all the vars and functions, and even supports tab-completion.

```
print(test)
test123
```

To exit IPython and continue running Salt, press `Ctrl-d` to logout.

### 34.13.3 State Modules

State modules are used to define the state interfaces used by Salt States. These modules are restrictive in that they must follow a number of rules to function properly.

**Note:** State modules define the available routines in sls files. If calling an execution module directly is desired, take a look at the *module* state.

### 34.13.4 Auth

The auth module system allows for external authentication routines to be easily added into Salt. The *auth* function needs to be implemented to satisfy the requirements of an auth module. Use the *pam* module as an example.

### 34.13.5 Fileserver

The fileserver module system is used to create fileserver backends used by the Salt Master. These modules need to implement the functions used in the fileserver subsystem. Use the `gitfs` module as an example.

### 34.13.6 Grains

Grain modules define extra routines to populate grains data. All defined public functions will be executed and MUST return a Python dict object. The dict keys will be added to the grains made available to the minion.

### 34.13.7 Output

The output modules supply the outputter system with routines to display data in the terminal. These modules are very simple and only require the `output` function to execute. The default system outputter is the `nested` module.

### 34.13.8 Pillar

Used to define optional external pillar systems. The pillar generated via the filesystem pillar is passed into external pillars. This is commonly used as a bridge to database data for pillar, but is also the backend to the libvirt state used to generate and sign libvirt certificates on the fly.

### 34.13.9 Renderers

Renderers are the system used to render sls files into salt highdata for the state compiler. They can be as simple as the `py` renderer and as complex as `stateconf` and `pydsl`.

### 34.13.10 Returners

Returners are used to send data from minions to external sources, commonly databases. A full returner will implement all routines to be supported as an external job cache. Use the `redis` returner as an example.

### 34.13.11 Runners

Runners are purely master-side execution sequences. These range from simple reporting to orchestration engines like the `overstate`.

### 34.13.12 Tops

Tops modules are used to convert external data sources into top file data for the state system.

### 34.13.13 Wheel

The wheel system is used to manage master side management routines. These routines are primarily intended for the API to enable master configuration.

## 34.14 Package Providers

This page contains guidelines for writing package providers.

### 34.14.1 Package Functions

One of the most important features of Salt is package management. There is no shortage of package managers, so in the interest of providing a consistent experience in *pkg* states, there are certain functions that should be present in a package provider. Note that these are subject to change as new features are added or existing features are enhanced.

#### list\_pkgs

This function should declare an empty dict, and then add packages to it by calling *pkg\_resource.add\_pkg*, like so:

```
__salt__['pkg_resource.add_pkg'](ret, name, version)
```

The last thing that should be done before returning is to execute *pkg\_resource.sort\_pkglist*. This function does not presently do anything to the return dict, but will be used in future versions of Salt.

```
__salt__['pkg_resource.sort_pkglist'](ret)
```

`list_pkgs` returns a dictionary of installed packages, with the keys being the package names and the values being the version installed. Example return data:

```
{'foo': '1.2.3-4',
 'bar': '5.6.7-8'}
```

#### latest\_version

Accepts an arbitrary number of arguments. Each argument is a package name. The return value for a package will be an empty string if the package is not found or if the package is up-to-date. The only case in which a non-empty string is returned is if the package is available for new installation (i.e. not already installed) or if there is an upgrade available.

If only one argument was passed, this function return a string, otherwise a dict of name/version pairs is returned.

This function must also accept `**kwargs`, in order to receive the `fromrepo` and `repo` keyword arguments from `pkg` states. Where supported, these arguments should be used to find the install/upgrade candidate in the specified repository. The `fromrepo` kwarg takes precedence over `repo`, so if both of those kwargs are present, the repository specified in `fromrepo` should be used. However, if `repo` is used instead of `fromrepo`, it should still work, to preserve backwards compatibility with older versions of Salt.

#### version

Like `latest_version`, accepts an arbitrary number of arguments and returns a string if a single package name was passed, or a dict of name/value pairs if more than one was passed. The only difference is that the return values are the currently-installed versions of whatever packages are passed. If the package is not installed, an empty string is returned for that package.

## upgrade\_available

Deprecated and destined to be removed. For now, should just do the following:

```
return __salt__['pkg.latest_version'](name) != ''
```

## install

The following arguments are required and should default to None:

1. name (for single-package pkg states)
2. pkgs (for multiple-package pkg states)
3. sources (for binary package file installation)

The first thing that this function should do is call `pkg_resource.parse_targets` (see below). This function will convert the SLS input into a more easily parsed data structure. `pkg_resource.parse_targets` may need to be modified to support your new package provider, as it does things like parsing package metadata which cannot be done for every package management system.

```
pkg_params, pkg_type = __salt__['pkg_resource.parse_targets'](name,  
                                                            pkgs,  
                                                            sources)
```

Two values will be returned to the `install` function. The first of them will be a dictionary. The keys of this dictionary will be package names, though the values will differ depending on what kind of installation is being done:

- If `name` was provided (and `pkgs` was not), then there will be a single key in the dictionary, and its value will be `None`. Once the data has been returned, if the `version` keyword argument was provided, then it should replace the `None` value in the dictionary.
- If `pkgs` was provided, then `name` is ignored, and the dictionary will contain one entry for each package in the `pkgs` list. The values in the dictionary will be `None` if a version was not specified for the package, and the desired version if specified. See the **Multiple Package Installation Options** section of the `pkg.installed` state for more info.
- If `sources` was provided, then `name` is ignored, and the dictionary values will be the path/URI for the package.

The second return value will be a string with two possible values: `repository` or `file`. The `install` function can use this value (if necessary) to build the proper command to install the targeted package(s).

Both before and after the installing the target(s), you should run `list_pkgs` to obtain a list of the installed packages. You should then return the output of `salt.utils.compare_dicts()`

```
return salt.utils.compare_dicts(old, new)
```

## remove

Removes the passed package and return a list of the packages removed.

### 34.14.2 Package Repo Functions

There are some functions provided by `pkg` which are specific to package repositories, and not to packages themselves. When writing modules for new package managers, these functions should be made available as stated below, in order to provide compatibility with the `pkgrepo` state.

All repo functions should accept a `basedir` option, which defines which directory repository configuration should be found in. The default for this is dictated by the repo manager that is being used, and rarely needs to be changed.

```
basedir = '/etc/yum.repos.d'
__salt__['pkg.list_repos'](basedir)
```

#### `list_repos`

Lists the repositories that are currently configured on this system.

```
__salt__['pkg.list_repos']()
```

Returns a dictionary, in the following format:

```
{'reponame': 'config_key_1': 'config value 1',
  'config_key_2': 'config value 2',
  'config_key_3': ['list item 1 (when appropriate)',
                  'list item 2 (when appropriate)]}
```

#### `get_repo`

Displays all local configuration for a specific repository.

```
__salt__['pkg.get_repo'](repo='myrepo')
```

The information is formatted in much the same way as `list_repos`, but is specific to only one repo.

```
{'config_key_1': 'config value 1',
  'config_key_2': 'config value 2',
  'config_key_3': ['list item 1 (when appropriate)',
                  'list item 2 (when appropriate)]}
```

#### `del_repo`

Removes the local configuration for a specific repository. Requires a `repo` argument, which must match the locally configured name. This function returns a string, which informs the user as to whether or not the operation was a success.

```
__salt__['pkg.del_repo'](repo='myrepo')
```

## mod\_repo

Modify the local configuration for one or more option for a configured repo. This is also the way to create new repository configuration on the local system; if a repo is specified which does not yet exist, it will be created.

The options specified for this function are specific to the system; please refer to the documentation for your specific repo manager for specifics.

```
__salt__['pkg.mod_repo'](repo='myrepo', url='http://myurl.com/repo')
```

### 34.14.3 Low-Package Functions

In general, the standard package functions as describes above will meet your needs. These functions use the system's native repo manager (for instance, yum or the apt tools). In most cases, the repo manager is actually separate from the package manager. For instance, yum is usually a front-end for rpm, and apt is usually a front-end for dpkg. When possible, the package functions that use those package managers directly should do so through the low package functions.

It is normal and sane for `pkg` to make calls to `lowpkgs`, but `lowpkg` must never make calls to `pkg`. This affects functions which are required by both `pkg` and `lowpkg`, but the technique in `pkg` is more performant than what is available to `lowpkg`. When this is the case, the `lowpkg` function that requires that technique must still use the `lowpkg` version.

## list\_pkgs

Returns a dict of packages installed, including the package name and version. Can accept a list of packages; if none are specified, then all installed packages will be listed.

```
installed = __salt__['lowpkg.list_pkgs']('foo', 'bar')
```

Example output:

```
{'foo': '1.2.3-4',  
'bar': '5.6.7-8'}
```

## verify

Many (but not all) package management systems provide a way to verify that the files installed by the package manager have or have not changed. This function accepts a list of packages; if none are specified, all packages will be included.

```
installed = __salt__['lowpkg.verify']('httpd')
```

Example output:

```
{'/etc/httpd/conf/httpd.conf': {'mismatch': ['size', 'md5sum', 'mtime'],  
                                'type': 'config'}}
```

## file\_list

Lists all of the files installed by all packages specified. If not packages are specified, then all files for all known packages are returned.

```
installed = __salt__['lowpkg.file_list']('httpd', 'apache')
```

This function does not return which files belong to which packages; all files are returned as one giant list (hence the *file\_list* function name. However, This information is still returned inside of a dict, so that it can provide any errors to the user in a sane manner.

```
{'errors': ['package apache is not installed'],
 'files': ['/etc/httpd',
           '/etc/httpd/conf',
           '/etc/httpd/conf.d',
           '...SNIP...']}
```

## file\_dict

Lists all of the files installed by all packages specified. If not packages are specified, then all files for all known packages are returned.

```
installed = __salt__['lowpkg.file_dict']('httpd', 'apache', 'kernel')
```

Unlike *file\_list*, this function will break down which files belong to which packages. It will also return errors in the same manner as *file\_list*.

```
{'errors': ['package apache is not installed'],
 'packages': {'httpd': ['/etc/httpd',
                       '/etc/httpd/conf',
                       '...SNIP...'],
              'kernel': ['/boot/vmlinuz-2.6.32-279.el6.x86_64.hmac',
                         '/boot/System.map-2.6.32-279.el6.x86_64',
                         '...SNIP...']}}
```

## 34.15 Community Projects That Use Salt

Below is a list of repositories that show real world Salt applications that you can use to get started. Please note that these projects do not adhere to any standards and express a wide variety of ideas and opinions on how an action can be completed with Salt.

<https://github.com/terminalmage/djangocon2013-sls>

<https://github.com/jesusaurus/hpcs-salt-state>

<https://github.com/gravyboat/hungryadmin-sls>

<https://github.com/wunki/django-salted>

## 34.16 Salt Topology

Salt is based on a powerful, asynchronous, network topology using ZeroMQ. Many ZeroMQ systems are in place to enable communication. The central idea is to have the fastest communication possible.

### 34.16.1 Servers

The Salt Master runs 2 network services. First is the ZeroMQ PUB system. This service by default runs on port 4505 and can be configured via the `publish_port` option in the master configuration.

Second is the ZeroMQ REP system. This is a separate interface used for all bi-directional communication with minions. By default this system binds to port 4506 and can be configured via the `ret_port` option in the master.

### 34.16.2 PUB/SUB

The commands sent out via the salt client are broadcast out to the minions via ZeroMQ PUB/SUB. This is done by allowing the minions to maintain a connection back to the Salt Master and then all connections are informed to download the command data at once. The command data is kept extremely small (usually less than 1K) so it is not a burden on the network.

### 34.16.3 Return

The PUB/SUB system is a one way communication, so once a publish is sent out the PUB interface on the master has no further communication with the minion. The minion, after running the command, then sends the command's return data back to the master via the `ret_port`.

## 34.17 Translating Documentation

If you wish to help translate the Salt documentation to your language, please head over to the [Transifex](#) website and [signup](#) for an account.

Once registered, head over to the [Salt Translation Project](#), and either click on **Request Language** if you can't find yours, or, select the language for which you wish to contribute and click **Join Team**.

[Transifex](#) provides some useful reading resources on their [support domain](#), namely, some useful articles [directed to translators](#).

### 34.17.1 Building A Localized Version of the Documentation

While you're working on your translation on [Transifex](#), you might want to have a look at how it's rendering.

#### Install The Transifex Client

To interact with the [Transifex](#) web service you will need to install the `transifex-client`:

```
pip install transifex-client
```

## Configure The Transifex Client

Once installed, you will need to set it up on your computer. We created a script to help you with that:

```
.scripts/setup-transifex-config
```

## Download Remote Translations

There's a little script which simplifies the download process of the translations(which isn't that complicated in the first place). So, let's assume you're translating pt\_PT, Portuguese(Portugal). To download the translations, execute from the doc/ directory of your Salt checkout:

```
make download-translations SPHINXLANG=pt_PT
```

To download pt\_PT, Portuguese(Portugal), and nl, Dutch, you can use the helper script directly:

```
.scripts/download-translation-catalog pt_PT nl
```

## Build Localized Documentation

After the download process finishes, which might take a while, the next step is to build a localized version of the documentation. Following the pt\_PT example above:

```
make html SPHINXLANG=pt_PT
```

## View Localized Documentation

Open your browser, point it to the local documentation path and check the localized output you've just build.

## 34.18 Running The Tests

There are requirements, in addition to Salt's requirements, which need to be installed in order to run the test suite. Install one of the lines below, depending on the relevant Python version:

```
pip install -r dev_requirements_python26.txt
pip install -r dev_requirements_python27.txt
```

**Note:** In Salt 0.17, testing libraries were migrated into their own repo. To install them:

```
pip install git+https://github.com/saltstack/salt-testing.git#egg=SaltTesting
```

Failure to install SaltTesting will result in import errors similar to the following:

```
ImportError: No module named salttesting
```

Once all requirements are set, use `tests/runtests.py` to run all of the tests included in Salt's test suite. For more information, see `--help`.

An alternative way of invoking the test suite is available in `setup.py`:

```
./setup.py test
```

Instead of running the entire test suite, there are several ways to run only specific groups of tests or individual tests:

- Run unit tests only: `./tests/runtests.py --unit-tests`
- Run unit and integration tests for states: `./tests/runtests.py --state`
- Run integration tests for an individual module: `./tests/runtests.py -n integration.modules.virt`
- Run unit tests for an individual module: `./tests/runtests.py -n unit.modules.virt_test`
- Run an individual test by using the class and test name (this example is for the `test_default_kvm_profile` test in the `integration.module.virt`):  
`./tests/runtests.py -n integration.module.virt.VirtTest.test_default_kvm_profile`

### 34.18.1 Running Unit Tests Without Integration Test Daemons

Since the unit tests do not require a master or minion to execute, it is often useful to be able to run unit tests individually, or as a whole group, without having to start up the integration testing daemons. Starting up the master, minion, and syndic daemons takes a lot of time before the tests can even start running and is unnecessary to run unit tests. To run unit tests without invoking the integration test daemons, simply remove the `/tests` portion of the `runtests.py` command:

```
./runtests.py --unit
```

All of the other options to run individual tests, entire classes of tests, or entire test modules still apply.

### 34.18.2 Running Destructive Integration Tests

Salt is used to change the settings and behavior of systems. In order to effectively test Salt's functionality, some integration tests are written to make actual changes to the underlying system. These tests are referred to as "destructive tests". Some examples of destructive tests are changes may be testing the addition of a user or installing packages. By default, destructive tests are disabled and will be skipped.

Generally, destructive tests should clean up after themselves by attempting to restore the system to its original state. For instance, if a new user is created during a test, the user should be deleted after the related test(s) have completed. However, no guarantees are made that test clean-up will complete successfully. Therefore, running destructive tests should be done with caution.

---

**Note:** Running destructive tests will change the underlying system. Use caution when running destructive tests.

---

To run tests marked as destructive, set the `--run-destructive` flag:

```
./tests/runtests.py --run-destructive
```

### 34.18.3 Running Cloud Provider Tests

Salt's testing suite also includes integration tests to assess the successful creation and deletion of cloud instances using *Salt-Cloud* for providers supported by Salt-Cloud.

The cloud provider tests are off by default and run on sample configuration files provided in `tests/integration/files/conf/cloud.providers.d/`. In order to run the cloud provider tests, valid credentials, which differ per provider, must be supplied. Each credential item that must be supplied is indicated by an empty string value and should be edited by the user before running the tests. For example, DigitalOcean requires a client key and an api key to operate. Therefore, the default cloud provider configuration file for DigitalOcean looks like this:

```
digitalocean-config:
  provider: digital_ocean
  client_key: ''
  api_key: ''
  location: New York 1
```

As indicated by the empty string values, the `client_key` and the `api_key` must be provided:

```
digitalocean-config:
  provider: digital_ocean
  client_key: wFGEwgregeqw3435gDger
  api_key: GDE43t43REGTrkilg43934t34qT43t4dgegerGEgg
  location: New York 1
```

**Note:** When providing credential information in cloud provider configuration files, do not include the single quotes.

Once all of the valid credentials for the cloud provider have been supplied, the cloud provider tests can be run by setting the `--cloud-provider-tests` flag:

```
./tests/runtests.py --cloud-provider-tests
```

### 34.18.4 Running The Tests In A Docker Container

The test suite can be executed under a `docker` container using the `--docked` option flag. The `docker` container must be properly configured on the system invoking the tests and the container must have access to the internet.

Here's a simple usage example:

```
tests/runtests.py --docked=ubuntu-12.04 -v
```

The full `docker` container repository can also be provided:

```
tests/runtests.py --docked=salttest/ubuntu-12.04 -v
```

The SaltStack team is creating some containers which will have the necessary dependencies pre-installed. Running the test suite on a container allows destructive tests to run without making changes to the main system. It also enables the test suite to run under a different distribution than the one the main system is currently using.

The current list of test suite images is on Salt's [docker repository](#).

Custom `docker` containers can be provided by submitting a pull request against Salt's [docker Salt test containers repository](#).

## 34.19 Automated Test Runs

SaltStack maintains a Jenkins server to allow for the execution of tests across supported platforms. The tests executed from Salt's Jenkins server create fresh virtual machines for each test run, then execute destructive tests on the new, clean virtual machine.

When a pull request is submitted to Salt's repository on GitHub, Jenkins runs Salt's test suite on a couple of virtual machines to gauge the pull request's viability to merge into Salt's develop branch. If these initial tests pass, the pull request can then be merged into Salt's develop branch by one of Salt's core developers, pending their discretion. If the initial tests fail, core developers may request changes to the pull request. If the failure is unrelated to the changes in question, core developers may merge the pull request despite the initial failure.

Once the pull request is merged into Salt's develop branch, a new set of Jenkins virtual machines will begin executing the test suite. The develop branch tests have many more virtual machines to provide more comprehensive results.

There are a few other groups of virtual machines that Jenkins tests against, including past and current release branches. For a full list of currently running test environments, go to <http://jenkins.saltstack.com>.

### 34.19.1 Using Salt-Cloud on Jenkins

For testing Salt on Jenkins, SaltStack uses *Salt-Cloud* to spin up virtual machines. The script using Salt-Cloud to accomplish this is open source and can be found here: <https://github.com/saltstack/salt/blob/develop/tests/jenkins.py>

## 34.20 Writing Tests

Salt uses a test platform to verify functionality of components in a simple way. Two testing systems exist to enable testing salt functions in somewhat real environments. The two subsystems available are integration tests and unit tests.

Salt uses the python standard library unittest2 system for testing.

### 34.20.1 Naming Conventions

Any function in either integration test files or unit test files that is doing the actual testing, such as functions containing assertions, must start with `test_`:

```
def test_user_present(self):
```

When functions in test files are not prepended with `test_`, the function acts as a normal, helper function and is not run as a test by the test suite.

### 34.20.2 Integration Tests

The integration tests start up a number of salt daemons to test functionality in a live environment. These daemons include 2 salt masters, 1 syndic, and 2 minions. This allows the syndic interface to be tested and master/minion communication to be verified. All of the integration tests are executed as live salt commands sent through the started daemons.

Integration tests are particularly good at testing modules, states, and shell commands.

- [Writing integration tests](#)

### 34.20.3 Unit Tests

Direct unit tests are also available. These tests are good for testing internal functions.

- [Writing unit tests](#)

#### Integration Tests

The Salt integration tests come with a number of classes and methods which allow for components to be easily tested. These classes are generally inherited from and provide specific methods for hooking into the running integration test environment created by the integration tests.

It is noteworthy that since integration tests validate against a running environment that they are generally the preferred means to write tests.

The integration system is all located under `tests/integration` in the Salt source tree. Each directory within `tests/integration` corresponds to a directory in Salt's tree structure. For example, the integration tests for the `test.py` Salt module that is located in `salt/modules` should also be named `test.py` and reside in `tests/integration/modules`.

#### Adding New Directories

If the corresponding Salt directory does not exist within `tests/integration`, the new directory must be created along with the appropriate test file to maintain Salt's testing directory structure.

In order for Salt's test suite to recognize tests within the newly created directory, options to run the new integration tests must be added to `tests/runtests.py`. Examples of the necessary options that must be added can be found here: <https://github.com/saltstack/salt/blob/develop/tests/runtests.py>. The functions that need to be edited are `setup_additional_options`, `validate_options`, and `run_integration_tests`.

#### Integration Classes

The integration classes are located in `tests/integration/__init__.py` and can be extended therein. There are three classes available to extend:

**ModuleCase** Used to define executions run via the master to minions and to call single modules and states.

The available methods are as follows:

**run\_function:** Run a single salt function and condition the return down to match the behavior of the raw function call. This will run the command and only return the results from a single minion to verify.

**state\_result:** Return the result data from a single state return

**run\_state:** Run the `state.single` command and return the state return structure

**SyndicCase** Used to execute remote commands via a syndic, only used to verify the capabilities of the Syndic.

The available methods are as follows:

**run\_function:** Run a single salt function and condition the return down to match the behavior of the raw function call. This will run the command and only return the results from a single minion to verify.

**ShellCase** Shell out to the scripts which ship with Salt.

The available methods are as follows:

**run\_script**: Execute a salt script with the given argument string

**run\_salt**: Execute the salt command, pass in the argument string as it would be passed on the command line.

**run\_run**: Execute the salt-run command, pass in the argument string as it would be passed on the command line.

**run\_run\_plus**: Execute Salt run and the salt run function and return the data from each in a dict

**run\_key**: Execute the salt-key command, pass in the argument string as it would be passed on the command line.

**run\_cp**: Execute salt-cp, pass in the argument string as it would be passed on the command line.

**run\_call**: Execute salt-call, pass in the argument string as it would be passed on the command line.

### Examples

**Module Example via ModuleCase Class** Import the integration module, this module is already added to the python path by the test execution. Inherit from the `integration.ModuleCase` class.

Now the workhorse method `run_function` can be used to test a module:

```
import os
import integration

class TestModuleTest(integration.ModuleCase):
    """
    Validate the test module
    """
    def test_ping(self):
        """
        test.ping
        """
        self.assertTrue(self.run_function('test.ping'))

    def test_echo(self):
        """
        test.echo
        """
        self.assertEqual(self.run_function('test.echo', ['text']), 'text')
```

**Shell Example via ShellCase** Validating the shell commands can be done via shell tests:

```
import sys
import shutil
import tempfile

import integration

class KeyTest(integration.ShellCase):
    """
    Test salt-key script
    """
```

```

_call_binary_ = 'salt-key'

def test_list(self):
    """
    test salt-key -L
    """
    data = self.run_key('-L')
    expect = [
        'Unaccepted Keys:',
        'Accepted Keys:',
        'minion',
        'sub_minion',
        'Rejected:', '']
    self.assertEqual(data, expect)

```

This example verifies that the `salt-key` command executes and returns as expected by making use of the `run_key` method.

### Integration Test Files

Since using Salt largely involves configuring states, editing files, and changing system data, the integration test suite contains a directory named `files` to aid in testing functions that require files. Various Salt integration tests use these example files to test against instead of altering system files and data.

Each directory within `tests/integration/files` contain files that accomplish different tasks, based on the needs of the integration tests using those files. For example, `tests/integration/files/ssh` is used to bootstrap the test runner for `salt-ssh` testing, while `tests/integration/files/pillar` contains files storing data needed to test various pillar functions.

The `tests/integration/files` directory also includes an integration state tree. The integration state tree can be found at `tests/integration/files/file/base`.

The following example demonstrates how integration files can be used with `ModuleCase` to test states:

```

import os
import shutil
import integration

HFILE = os.path.join(integration.TMP, 'hosts')

class HostTest(integration.ModuleCase):
    """
    Validate the host state
    """

    def setUp(self):
        shutil.copyfile(os.path.join(integration.FILES, 'hosts'), HFILE)
        super(HostTest, self).setUp()

    def tearDown(self):
        if os.path.exists(HFILE):
            os.remove(HFILE)
        super(HostTest, self).tearDown()

    def test_present(self):
        """

```

```

host.present
'''
name = 'spam.bacon'
ip = '10.10.10.10'
ret = self.run_state('host.present', name=name, ip=ip)
result = self.state_result(ret)
self.assertTrue(result)
with open(HFILE) as fp_:
    output = fp_.read()
    self.assertIn('{0}\t\t{1}'.format(ip, name), output)

```

To access the integration files, a variable named `integration.FILES` points to the `tests/integration/files` directory. This is where the referenced `host.present` sls file resides.

In addition to the static files in the integration state tree, the location `integration.TMP` can also be used to store temporary files that the test system will clean up when the execution finishes.

### Destructive vs Non-Destructive Tests

Since Salt is used to change the settings and behavior of systems, one testing approach is to run tests that make actual changes to the underlying system. This is where the concept of destructive integration tests comes into play. Tests can be written to alter the system they are running on. This capability is what fills in the gap needed to properly test aspects of system management like package installation.

Any test that changes the underlying system in any way, such as creating or deleting users, installing packages, or changing permissions should include the `@destructive` decorator to signal system changes and should be written with care. System changes executed within a destructive test should also be restored once the related tests have completed. For example, if a new user is created to test a module, the same user should be removed after the test is completed to maintain system integrity.

To write a destructive test, import, and use the `destructiveTest` decorator for the test method:

```

import integration
from salttesting.helpers import destructiveTest

class DestructiveExampleModuleTest(integration.ModuleCase):
    '''
    Demonstrate a destructive test
    '''

    @destructiveTest
    @skipIf(os.getuid() != 0, 'you must be root to run this test')
    def test_user_not_present(self):
        '''
        This is a DESTRUCTIVE TEST it creates a new user on the minion.
        And then destroys that user.
        '''
        ret = self.run_state('user.present', name='salt_test')
        self.assertSaltTrueReturn(ret)
        ret = self.run_state('user.absent', name='salt_test')
        self.assertSaltTrueReturn(ret)

```

## Cloud Provider Tests

Cloud provider integration tests are used to assess *Salt-Cloud*'s ability to create and destroy cloud instances for various supported cloud providers. Cloud provider tests inherit from the ShellCase Integration Class.

Any new cloud provider test files should be added to the `tests/integration/cloud/providers/` directory. Each cloud provider test file also requires a sample cloud profile and cloud provider configuration file in the integration test file directory located at `tests/integration/files/conf/cloud.*.d/`.

The following is an example of the default profile configuration file for Digital Ocean, located at: `tests/integration/files/conf/cloud.profiles.d/digital_ocean.conf`:

```
digitalocean-test:
  provider: digitalocean-config
  image: Ubuntu 14.04 x64
  size: 512MB
```

Each cloud provider requires different configuration credentials. Therefore, sensitive information such as API keys or passwords should be omitted from the cloud provider configuration file and replaced with an empty string. The necessary credentials can be provided by the user by editing the provider configuration file before running the tests.

The following is an example of the default provider configuration file for Digital Ocean, located at: `tests/integration/files/conf/cloud.providers.d/digital_ocean.conf`:

```
digitalocean-config:
  provider: digital_ocean
  client_key: ''
  api_key: ''
  location: New York 1
```

In addition to providing the necessary cloud profile and provider files in the integration test suite file structure, appropriate checks for if the configuration files exist and contain valid information are also required in the test class's `setUp` function:

```
class LinodeTest(integration.ShellCase):
    """
    Integration tests for the Linode cloud provider in Salt-Cloud
    """

    def setUp(self):
        """
        Sets up the test requirements
        """
        super(LinodeTest, self).setUp()

        # check if appropriate cloud provider and profile files are present
        profile_str = 'linode-config:'
        provider = 'linode'
        providers = self.run_cloud('--list-providers')
        if profile_str not in providers:
            self.skipTest(
                'Configuration file for {0} was not found. Check {0}.conf files '
                'in tests/integration/files/conf/cloud.*.d/ to run these tests.'
                .format(provider)
            )

        # check if apikey and password are present
```

```

path = os.path.join(integration.FILES,
                    'conf',
                    'cloud.providers.d',
                    provider + '.conf')
config = cloud_providers_config(path)
api = config['linode-config']['linode']['apikey']
password = config['linode-config']['linode']['password']
if api == '' or password == '':
    self.skipTest(
        'An api key and password must be provided to run these tests. Check '
        'tests/integration/files/conf/cloud.providers.d/{0}.conf'.format(
            provider
        )
    )
)

```

Repeatedly creating and destroying instances on cloud providers can be costly. Therefore, cloud provider tests are off by default and do not run automatically. To run the cloud provider tests, the `--cloud-provider-tests` flag must be provided:

```
./tests/runtests.py --cloud-provider-tests
```

Since cloud provider tests do not run automatically, all provider tests must be preceded with the `@expensiveTest` decorator. The expensive test decorator is necessary because it signals to the test suite that the `--cloud-provider-tests` flag is required to run the cloud provider tests.

To write a cloud provider test, import, and use the `expensiveTest` decorator for the test function:

```

from salttesting.helpers import expensiveTest

@expensiveTest
def test_instance(self):
    """
    Test creating an instance on Linode
    """
    name = 'linode-testing'

    # create the instance
    instance = self.run_cloud('-p linode-test {0}'.format(name))
    str = '          {0}'.format(name)

    # check if instance with salt installed returned as expected
    try:
        self.assertIn(str, instance)
    except AssertionError:
        self.run_cloud('-d {0} --assume-yes'.format(name))
        raise

    # delete the instance
    delete = self.run_cloud('-d {0} --assume-yes'.format(name))
    str = '          True'
    try:
        self.assertIn(str, delete)
    except AssertionError:
        raise

```

## Writing Unit Tests

### Introduction

Like many software projects, Salt has two broad-based testing approaches -- integration testing and unit testing. While integration testing focuses on the interaction between components in a sandboxed environment, unit testing focuses on the singular implementation of individual functions.

### Preparing to Write a Unit Test

This guide assumes you've followed the [directions for setting up salt testing](#).

Unit tests should be written to the following specifications:

- All the tests for a specific module at salt/.../<module>.py need to be contained in a file called tests/unit/.../<module>\_test.py, e.g. the tests for salt/modules/fib.py need to be contained in a file called tests/unit/modules/fib\_test.py.
- The tests within tests/unit/modules/fib\_test.py file must be member functions of a class which subclasses salttesting.TestCase
- Each external resource used in the code to be tested, such as function calls, external data either globally available or passed in through the function arguments, file data, etc. needs to be mocked.
- Each raise and return statement of the code to be tested needs to be separately and independently tested.
- Test functions should contain only one test and contain all necessary mock data and mock code for that test.
- Test functions should be named test\_<fcn>\_<test-name> where <fcn> is the name of the function being tested and <test-name> describes which raise or return within the function is being tested and whether that raise or return statement is considered a success or a failure condition.

Most commonly, the following imports are necessary to create a unit test:

```
# Import Salt Testing libs
from salttesting import skipIf, TestCase
from salttesting.helpers import ensure_in_syspath
```

If you need mock support to your tests, please also import:

```
from salttesting.mock import NO_MOCK, NO_MOCK_REASON, MagicMock, patch, call
```

### A Simple Example

Let's assume that we're testing a very basic function in an imaginary Salt execution module. Given a module called fib.py that has a function called calculate(num\_of\_results), which given a num\_of\_results, produces a list of sequential Fibonacci numbers of that length.

A unit test to test this function might be commonly placed in a file called tests/unit/modules/fib\_test.py. The convention is to place unit tests for Salt execution modules in test/unit/modules/ and to name the tests module suffixed with \_test.py.

Tests are grouped around test cases, which are logically grouped sets of tests against a piece of functionality in the tested software. Test cases are created as Python classes in the unit test module. To return to our example, here's how we might write the skeleton for testing fib.py:

```
# Import Salt Testing libs
from salttesting import TestCase

# Import Salt execution module to test
from salt.modules import fib

# Create test case class and inherit from Salt's customized TestCase
class FibTestCase(TestCase):

    '''
    This class contains a set of functions that test salt.modules.fib.
    '''

    def test_fib(self):
        '''
        To create a unit test, we should prefix the name with `test_` so
        that it's recognized by the test runner.
        '''
        fib_five = (0, 1, 1, 2, 3)
        self.assertEqual(fib.calculate(5), fib_five)
```

At this point, the test can now be run, either individually or as a part of a full run of the test runner. To ease development, a single test can be executed:

```
tests/runtests.py -n unit.modules.fib_test
```

This will produce output indicating the success or failure of the tests in given test case. For more detailed results, one can also include a flag to increase verbosity:

```
tests/runtests.py -n unit.modules.fib_test -v
```

To review the results of a particular run, take a note of the log location given in the output for each test:

```
Logging tests on /var/folders/nl/d809xbq577l3qrbj3ymtpbq80000gn/T/salt-runtests.log
```

## Evaluating Truth

A longer discussion on the types of assertions one can make can be found by reading [Python's documentation on unit testing](#).

## Tests Using Mock Objects

In many cases, the very purpose of a Salt module is to interact with some external system, whether it be to control a database, manipulate files on a filesystem or many other examples. In these varied cases, it's necessary to design a unit test which can test the function whilst replacing functions which might actually call out to external systems. One might think of this as "blocking the exits" for code under tests and redirecting the calls to external systems with our own code which produces known results during the duration of the test.

To achieve this behavior, Salt makes heavy use of the [MagicMock](#) package.

To understand how one might integrate Mock into writing a unit test for Salt, let's imagine a scenario in which we're testing an execution module that's designed to operate on a database. Furthermore, let's imagine two separate methods, here presented in pseudo-code in an imaginary execution module called `db.py`.

```
def create_user(username):
    qry = 'CREATE USER {0}'.format(username)
    execute_query(qry)

def execute_query(qry):
    # Connect to a database and actually do the query...
```

Here, let's imagine that we want to create a unit test for the `create_user` function. In doing so, we want to avoid any calls out to an external system and so while we are running our unit tests, we want to replace the actual interaction with a database with a function that can capture the parameters sent to it and return pre-defined values. Therefore, our task is clear -- to write a unit test which tests the functionality of `create_user` while also replacing `execute_query` with a mocked function.

To begin, we set up the skeleton of our class much like we did before, but with additional imports for MagicMock:

```
# Import Salt Testing libs
from salttesting import TestCase

# Import Salt execution module to test
from salt.modules import db

# NEW! -- Import Mock libraries
from salttesting.mock import NO_MOCK, NO_MOCK_REASON, MagicMock, patch, call

# Create test case class and inherit from Salt's customized TestCase

# Skip this test case if we don't have access to mock!
@skipIf(NO_MOCK, NO_MOCK_REASON)
class DbTestCase(TestCase):
    def test_create_user(self):
        # First, we replace 'execute_query' with our own mock function
        db.execute_query = MagicMock()

        # Now that the exits are blocked, we can run the function under test.

        db.create_user('testuser')

        # We could now query our mock object to see which calls were made
        # to it.
        ## print db.execute_query.mock_calls

        '''
        We want to test to ensure that the correct query was formed. This
        is a contrived example, just designed to illustrate the concepts at
        hand.

        We're going to first construct a call() object that represents the
        way we expect our mocked execute_query() function to have been
        called. Then, we'll examine the list of calls that were actually
        made to to execute_function().

        By comparing our expected call to execute_query() with
        create_user()'s call to execute_query(), we can determine the
```

```

    success or failure of our unit test.
    '''

    expected_call = call('CREATE USER testuser')

    # Do the comparison! Will assert False if execute_query() was not
    # called with the given call

    db.execute_query.assert_has_calls(expected_call)

```

### Modifying `__salt__` In Place

At times, it becomes necessary to make modifications to a module's view of functions in its own `__salt__` dictionary. Luckily, this process is quite easy.

Below is an example that uses MagicMock's `patch` functionality to insert a function into `__salt__` that's actually a MagicMock instance.

```

def show_patch(self):
    with patch.dict(my_module.__salt__,
                    {'function.to_replace': MagicMock()}):
        # From this scope, carry on with testing, with a modified __salt__!

```

### A More Complete Example

Consider the following function from `salt/modules/linux_sysctl.py`.

```

def get(name):
    '''
    Return a single sysctl parameter for this minion

    CLI Example:

    .. code-block:: bash

        salt '*' sysctl.get net.ipv4.ip_forward
    '''
    cmd = 'sysctl -n {0}'.format(name)
    out = __salt__['cmd.run'](cmd)
    return out

```

This function is very simple, comprising only four source lines of code and having only one return statement, so we know only one test is needed. There are also two inputs to the function, the `name` function argument and the call to `__salt__['cmd.run']()`, both of which need to be appropriately mocked. Mocking a function parameter is straightforward, whereas mocking a function call will require, in this case, the use of MagicMock. For added isolation, we will also redefine the `__salt__` dictionary such that it only contains `'cmd.run'`.

```

# Import Salt Libs
from salt.modules import linux_sysctl

# Import Salt Testing Libs
from salttesting import skipIf, TestCase

```

```

from salttesting.helpers import ensure_in_syspath
from salttesting.mock import (
    MagicMock,
    patch,
    NO_MOCK,
    NO_MOCK_REASON
)

ensure_in_syspath('../..')

# Globals
linux_sysctl.__salt__ = {}

@skipIf(NO_MOCK, NO_MOCK_REASON)
class LinuxSysctlTestCase(TestCase):
    """
    TestCase for salt.modules.linux_sysctl module
    """

    def test_get(self):
        """
        Tests the return of get function
        """
        mock_cmd = MagicMock(return_value=1)
        with patch.dict(linux_sysctl.__salt__, {'cmd.run': mock_cmd}):
            self.assertEqual(linux_sysctl.get('net.ipv4.ip_forward'), 1)

if __name__ == '__main__':
    from integration import run_tests
    run_tests(LinuxSysctlTestCase, needs_daemon=False)

```

Since `get()` has only one raise or return statement and that statement is a success condition, the test function is simply named `test_get()`. As described, the single function call parameter, `name` is mocked with `net.ipv4.ip_forward` and `__salt__['cmd.run']` is replaced by a `MagicMock` function object. We are only interested in the return value of `__salt__['cmd.run']`, which `MagicMock` allows to be specified via `return_value=1`. Finally, the test itself tests for equality between the return value of `get()` and the expected return of 1. This assertion is expected to succeed because `get()` will determine its return value from `__salt__['cmd.run']`, which we have mocked to return 1.

### A Complex Example

Now consider the `assign()` function from the same `salt/modules/linux_sysctl.py` source file.

```

def assign(name, value):
    """
    Assign a single sysctl parameter for this minion

    CLI Example:

    .. code-block:: bash

        salt '*' sysctl.assign net.ipv4.ip_forward 1
    """

```

```

value = str(value)
sysctl_file = '/proc/sys/{0}'.format(name.replace('.', '/'))
if not os.path.exists(sysctl_file):
    raise CommandExecutionError('sysctl {0} does not exist'.format(name))

ret = {}
cmd = 'sysctl -w {0}="{1}"'.format(name, value)
data = __salt__['cmd.run_all'](cmd)
out = data['stdout']
err = data['stderr']

# Example:
#   # sysctl -w net.ipv4.tcp_rmem="4096 87380 16777216"
#   net.ipv4.tcp_rmem = 4096 87380 16777216
regex = re.compile(r'^{0}\s+=\s+{1}$'.format(re.escape(name),
                                           re.escape(value)))

if not regex.match(out) or 'Invalid argument' in str(err):
    if data['retcode'] != 0 and err:
        error = err
    else:
        error = out
    raise CommandExecutionError('sysctl -w failed: {0}'.format(error))
new_name, new_value = out.split(' = ', 1)
ret[new_name] = new_value
return ret

```

This function contains two raise statements and one return statement, so we know that we will need (at least) three tests. It has two function arguments and many references to non-builtin functions. In the tests below you will see that MagicMock's patch() method may be used as a context manager or as a decorator.

There are three test functions, one for each raise and return statement in the source function. Each function is self-contained and contains all and only the mocks and data needed to test the raise or return statement it is concerned with.

```

# Import Salt Libs
from salt.modules import linux_sysctl
from salt.exceptions import CommandExecutionError

# Import Salt Testing Libs
from salttesting import skipIf, TestCase
from salttesting.helpers import ensure_in_syspath
from salttesting.mock import (
    MagicMock,
    patch,
    NO_MOCK,
    NO_MOCK_REASON
)

ensure_in_syspath('../..')

# Globals
linux_sysctl.__salt__ = {}

@skipIf(NO_MOCK, NO_MOCK_REASON)
class LinuxSysctlTestCase(TestCase):
    '''

```

```

TestCase for salt.modules.linux_sysctl module
'''

@patch('os.path.exists', MagicMock(return_value=False))
def test_assign_proc_sys_failed(self):
    '''
    Tests if /proc/sys/<kernel-subsystem> exists or not
    '''
    cmd = {'pid': 1337, 'retcode': 0, 'stderr': '',
           'stdout': 'net.ipv4.ip_forward = 1'}
    mock_cmd = MagicMock(return_value=cmd)
    with patch.dict(linux_sysctl.__salt__, {'cmd.run_all': mock_cmd}):
        self.assertRaises(CommandExecutionError,
                           linux_sysctl.assign,
                           'net.ipv4.ip_forward', 1)

@patch('os.path.exists', MagicMock(return_value=True))
def test_assign_cmd_failed(self):
    '''
    Tests if the assignment was successful or not
    '''
    cmd = {'pid': 1337, 'retcode': 0, 'stderr':
           'sysctl: setting key "net.ipv4.ip_forward": Invalid argument',
           'stdout': 'net.ipv4.ip_forward = backward'}
    mock_cmd = MagicMock(return_value=cmd)
    with patch.dict(linux_sysctl.__salt__, {'cmd.run_all': mock_cmd}):
        self.assertRaises(CommandExecutionError,
                           linux_sysctl.assign,
                           'net.ipv4.ip_forward', 'backward')

@patch('os.path.exists', MagicMock(return_value=True))
def test_assign_success(self):
    '''
    Tests the return of successful assign function
    '''
    cmd = {'pid': 1337, 'retcode': 0, 'stderr': '',
           'stdout': 'net.ipv4.ip_forward = 1'}
    ret = {'net.ipv4.ip_forward': '1'}
    mock_cmd = MagicMock(return_value=cmd)
    with patch.dict(linux_sysctl.__salt__, {'cmd.run_all': mock_cmd}):
        self.assertEqual(linux_sysctl.assign(
                           'net.ipv4.ip_forward', 1), ret)

if __name__ == '__main__':
    from integration import run_tests
    run_tests(LinuxSysctlTestCase, needs_daemon=False)

```

## 34.21 raet

# RAET # Reliable Asynchronous Event Transport Protocol

See also:

[RAET Overview](#)

### 34.21.1 Protocol

Layering:

OSI Layers

7: Application: Format: Data (Stack to Application interface buffering etc) 6: Presentation: Format: Data (Encrypt-Decrypt convert to machine independent format) 5: Session: Format: Data (Interhost communications. Authentication. Groups) 4: Transport: Format: Segments (Reliable delivery of Message, Transactions, Segmentation, Error checking) 3: Network: Format: Packets/Datagrams (Addressing Routing) 2: Link: Format: Frames ( Reliable per frame communications connection, Media access controller ) 1: Physical: Bits (Transceiver communication connection not reliable)

Link is hidden from Raet Network is IP host address and Udp Port Transport is Raet transactions, service kind, tail error checking, Could include header signing as part of transport reliable delivery serialization of header Session is session id key exchange for signing. Grouping is Road (like 852 channel) Presentation is Encrypt Decrypt body Serialize Deserialize Body Application is body data dictionary

Header signing spans both the Transport and Session layers.

### 34.21.2 Header

JSON Header (Tradeoff some processing speed for extensibility, ease of use, readability)

Body initially JSON but support for ``packed" binary body

### 34.21.3 Packet

Header ASCII Safe JSON Header termination: Empty line given by double pair of carriage return linefeed /r/n/r/n  
10 13 10 13 ADAD 1010 1101 1010 1101

In json carriage return and newline characters cannot appear in a json encoded string unless they are escaped with backslash, so the 4 byte combination is illegal in valid json that does not have multi-byte unicode characters.

These means the header must be ascii safe so no multibyte utf-8 strings allowed in header.

Following Header Terminator is variable length signature block. This is binary and the length is provided in the header.

Following the signature block is the packet body or data. This may either be JSON or packed binary. The format is given in the json header

Finally is an optional tail block for error checking or encryption details

### 34.21.4 Header Fields

In UDP header

sh = source host sp = source port dh = destination host dp = destination port

In RAET Header

hk = header kind hl = header length

vn = version number

sd = Source Device ID dd = Destination Device ID cf = Corresponder Flag mf = Multicast Flag

si = Session ID ti = Transaction ID

sk = Service Kind pk = Packet Kind bf = Burst Flag (Send all Segments or Ordered packets without interleaved acks)

oi = Order Index dt = DateTime Stamp

sn = Segment Number sc = Segment Count

pf = Pending Segment Flag af = All Flag (Resent all Segments not just one)

nk = Auth header kind nl = Auth header length

bk = body kind bl = body length

tk = tail kind tl = tail length

**fg = flags packed (Flags) Default '00' hex string** 2 byte Hex string with bits (0, 0, af, pf, 0, bf, mf, cf) Zeros are TBD flags

### 34.21.5 Session Bootstrap

Minion sends packet with SID of Zero with public key of minions Public Private Key pair Master acks packet with SID of Zero to let minion know it received the request

Some time later Master sends packet with SID of zero that accepts the Minion

Minion

### 34.21.6 Session

Session is important for security. Want one session opened and then multiple transactions within session.

Session ID SID sid

GUID hash to guarantee uniqueness since no guarantee of nonvolatile storage or require file storage to keep last session ID used.

### 34.21.7 Service Types or Modular Services

Four Service Types

1. One or more maybe (unacknowledged repeat) maybe means no guarantee
2. **Exactly one at most (ack with retries) (duplicate detection idempotent)** at most means fixed number of retries has finite probability of failing B1) finite retries B2) infinite retries with exponential back-off up to a maximum delay
3. **Exactly one of sequence at most (sequence numbered)** Receiver requests retry of missing packet with same B1 or B2 retry type
4. **End to End (Application layer Request Response)** This is two B sub transactions

Initially unicast messaging Eventually support for Multicast

The use case for C) is to fragment large packets as once a UDP packet exceeds the frame size its reliability goes way down So its more reliable to fragment large packets.

Better approach might be to have more modularity. Services Levels

1. **Maybe one or more**
  - (a) **Fire and forget** no transaction either side
  - (b) **Repeat, no ack, no dupdet** repeat counter send side, no transaction on receive side

(c) **Repeat, no Ack, dupdet** repeat counter send side, dup detection transaction receive side

2. **More or Less Once**

(a) **retry finite, ack no dupdet** retry timer send side, finite number of retries ack receive side no dupdet

3. **At most Once**

(a) **retry finite, ack, dupdet** retry timer send side, finite number of retries ack receive side dupdet

4. **Exactly once**

(a) **ack retry** retry timer send side, ack and duplicate detection receive side Infinite retries with exponential backoff

5. **Sequential sequence number**

(a) reorder escrow

(b) Segmented packets

6. request response to application layer

Service Features

1. repeats
2. ack retry transaction id
3. sequence number duplicate detection out of order detection sequencing
4. rep-req

Always include transaction id since multiple transactions on same port So get duplicate detection for free if keep transaction alive but if use

A) Maybe one or more B1) At Least One B2) Exactly One C) One of sequence D) End to End

A) Sender creates transaction id for number of repeats but receiver does not keep transaction alive

B1) Sender creates transaction id keeps it for retries. Receiver keeps it to send ack then kills so retry could be duplicate not detected

B2) Sender creates transaction id keeps for retries Receiver keeps tid for acks on any retries so no duplicates.

C) Sender creates TID and Sequence Number. Receiver checks for out of order sequence and can request retry.

D) Application layer sends response. So question is do we keep transaction open or have response be new transaction. No because then we need a rep-req ID so might as well use the same transaction id. Just keep alive until get response.

Little advantage to B1 vs B2 not having duplicates.

So 4 service types

1. Maybe one or more (unacknowledged repeat)
2. Exactly One (At most one) (ack with retry) (duplicate detection idempotent)
3. One of Sequence (sequence numbered)
4. End to End

Also multicast or unicast

Modular Transaction Table

**Sender Side:** Transaction ID plus transaction source sender or receiver generated transaction id Repeat Counter  
 Retry Timer Retry Counter (finite retries) Redo Timer (infinite redos with exponential backoff) Sequence number without acks (look for resend requests) Sequence with ack (wait for ack before sending next in sequence)  
 Segmentation

**Receiver Side:** Nothing just accept packet Acknowledge (can delete transaction after acknowledge) No duplicate detection  
 Transaction timeout (keep transaction until timeout) Duplicate detection save transaction id duplicate detection timeout  
 Request resend of missing packet in sequence Sequence reordering with escrow timeout wait escrow before requesting resend  
 Unsegmentation (request resends of missing segment)

## 34.22 SaltStack Git Policy

The SaltStack team follows a git policy to maintain stability and consistency with the repository.

The git policy has been developed to encourage contributions and make contributing to Salt as easy as possible. Code contributors to SaltStack projects DO NOT NEED TO READ THIS DOCUMENT, because all contributions come into SaltStack via a single gateway to make it as easy as possible for contributors to give us code.

The primary rule of git management in SaltStack is to make life easy on contributors and developers to send in code. Simplicity is always a goal!

### 34.22.1 New Code Entry

All new SaltStack code is posted to the *develop* branch, which is the single point of entry. The only exception is when a bugfix to develop cannot be cleanly merged into a release branch and the bugfix needs to be rewritten for the release branch.

### 34.22.2 Release Branching

SaltStack maintains two types of releases, *Feature Releases* and *Point Releases*. A feature release is managed by incrementing the first or second release point number, so 0.10.5 -> 0.11.0 signifies a feature release and 0.11.0 -> 0.11.1 signifies a point release, also a hypothetical 0.42.7 -> 1.0.0 would also signify a feature release.

#### Feature Release Branching

Each feature release is maintained in a dedicated git branch derived from the last applicable release commit on develop. All file changes relevant to the feature release will be completed in the develop branch prior to the creation of the feature release branch. The feature release branch will be named after the relevant numbers to the feature release, which constitute the first two numbers. This means that the release branch for the 0.11.0 series is named 0.11.

A feature release branch is created with the following command:

```
# git checkout -b 0.11 # From the develop branch
# git push origin 0.11
```

#### Point Releases

Each point release is derived from its parent release branch. Constructing point releases is a critical aspect of Salt development and is managed by members of the core development team. Point releases comprise bug and security

fixes which are cherry picked from develop onto the aforementioned release branch. At the time when a core developer accepts a pull request a determination needs to be made if the commits in the pull request need to be backported to the release branch. Some simple criteria are used to make this determination:

- Is this commit fixing a bug? Backport
- Does this commit change or add new features in any way? Don't backport
- Is this a PEP8 or code cleanup commit? Don't backport
- Does this commit fix a security issue? Backport

Determining when a point release is going to be made is up to the project leader (Thomas Hatch). Generally point releases are made every 1-2 weeks or if there is a security fix they can be made sooner.

The point release is only designated by tagging the commit on the release branch with release number using the existing convention (version 0.11.1 is tagged with v0.11.1). From the tag point a new source tarball is generated and published to PyPI, and a release announcement is made.

## 34.23 Salt Conventions

### 34.23.1 Writing Salt Documentation

Salt's documentation is built using the [Sphinx](#) documentation system. It can be built in a large variety of output formats including HTML, PDF, ePub, and manpage.

All the documentation is contained in the main Salt repository. Speaking broadly, most of the narrative documentation is contained within the <https://github.com/saltstack/salt/blob/develop/doc> subdirectory and most of the reference and API documentation is written inline with Salt's Python code and extracted using a Sphinx extension.

#### Style

The Salt project recommends the [IEEE style guide](#) as a general reference for writing guidelines. Those guidelines are not strictly enforced but rather serve as an excellent resource for technical writing questions. The [NCBI style guide](#) is another very approachable resource.

#### Point-of-view

Use third-person perspective and avoid ``I'', ``we'', ``you'' forms of address. Identify the addressee specifically e.g., ``users should'', ``the compiler does'', etc.

#### Active voice

Use active voice and present-tense. Avoid filler words.

#### Title capitalization

Document titles and section titles within a page should follow normal sentence capitalization rules. Words that are capitalized as part of a regular sentence should be capitalized in a title and otherwise left as lowercase. Punctuation can be omitted unless it aids the intent of the title (e.g., exclamation points or question marks).

For example:

**This is a main heading**

=====

Paragraph.

**This is an exciting sub-heading!**

-----

Paragraph.

### Serial Commas

According to Wikipedia: In English punctuation, a serial comma or series comma (also called Oxford comma and Harvard comma) is a comma placed immediately before the coordinating conjunction (usually ``and'', ``or'', or ``nor'') in a series of three or more terms. For example, a list of three countries might be punctuated either as ``France, Italy, and Spain" (with the serial comma), or as ``France, Italy and Spain" (without the serial comma)."

When writing a list that includes three or more items, the serial comma should always be used.

### Documenting modules

Documentation for Salt's various module types is inline in the code. During the documentation build process it is extracted and formatted into the final HTML, PDF, etc format.

#### Inline documentation

Python has special multi-line strings called docstrings as the first element in a function or class. These strings allow documentation to live alongside the code and can contain special formatting. For example:

```
def my_function(value):
    """
    Upper-case the given value

    Usage:

    .. code-block:: python

        val = 'a string'
        new_val = myfunction(val)
        print(new_val) # 'A STRING'

    :param value: a string
    :return: a copy of ``value`` that has been upper-cased
    """
    return value.upper()
```

#### Specify a release for additions or changes

New functions or changes to existing functions should include a marker that denotes what Salt release will be affected. For example:

```
def my_function(value):  
    '''  
    Upper-case the given value  
  
    .. versionadded:: 2014.7.0  
  
    <...snip...>  
    '''  
    return value.upper()
```

For changes to a function:

```
def my_function(value, strip=False):  
    '''  
    Upper-case the given value  
  
    .. versionchanged:: Boron  
       Added a flag to also strip whitespace from the string.  
  
    <...snip...>  
    '''  
    if strip:  
        return value.upper().strip()  
    return value.upper()
```

### Adding module documentation to the index

Each module type has an index listing all modules of that type. For example: *Full list of builtin execution modules*, *Full list of builtin state modules*, *Full list of builtin renderer modules*. New modules must be added to the index manually.

1. Edit the file for the module type: `execution modules`, `state modules`, `renderer modules`, etc.
2. Add the new module to the alphabetized list.
3. *Build the documentation* which will generate an `.rst` file for the new module in the same directory as the `index.rst`.
4. Commit the changes to `index.rst` and the new `.rst` file and send a pull request.

### Cross-references

The Sphinx documentation system contains a wide variety of cross-referencing capabilities.

### Glossary entries

Link to [glossary entries](#) using the `term` role. A cross-reference should be added the first time a Salt-specific term is used in a document.

```
A common way to encapsulate master-side functionality is by writing a  
custom :term:`Runner Function`. Custom Runner Functions are easy to write.
```

## Index entries

Sphinx automatically generates many kinds of index entries, but it is occasionally useful to manually add items to the index.

One method is to use the `index directive` above the document or section that should appear in the index.

```
.. index:: ! Event, event bus, event system
   see: Reactor; Event
```

Another method is to use the `index role` inline with the text that should appear in the index. The index entry is created and the target text is left otherwise intact.

```
Information about the :index:`Salt Reactor`
-----
```

Paragraph.

## Documents and sections

Each document should contain a unique top-level label of the form:

```
.. _my-page:
```

```
My page
```

```
=====
```

Paragraph.

Unique labels can be linked using the `ref role`. This allows cross-references to survive document renames or movement.

```
For more information see :ref:`my-page`.
```

Note, the `:doc:` role should *not* be used to link documents together.

## Modules

Cross-references to Salt modules can be added using Sphinx's Python domain roles. For example, to create a link to the `test.ping` function:

```
A useful execution module to test active communication with a minion is the
:py:func:`test.ping <salt.modules.test.ping>` function.
```

Salt modules can be referenced as well:

```
The :py:mod:`test module <salt.modules.test>` contains many useful
functions for inspecting an active Salt connection.
```

The same syntax works for all modules types:

```
One of the workhorse state module functions in Salt is the
:py:func:`file.managed <salt.states.file.managed>` function.
```

### Settings

Individual settings in the Salt Master or Salt Minion configuration files are cross-referenced using two custom roles, `conf_master`, and `conf_minion`.

```
The :conf_minion:`minion ID <id>` setting is a unique identifier for a
single minion.
```

### Documentation Changes and Fixes

Documentation changes and fixes should be made against the earliest supported release branch that the update applies to. The practice of updating a release branch instead of making all documentation changes against Salt's main, default branch, `develop`, is necessary in order for the docs to be as up-to-date as possible when the docs are built.

The workflow mentioned above is also in line with the recommendations outlined in Salt's *Contributing* page. You can read more about how to choose where to submit documentation fixes by reading the *Which Salt branch?* section.

For an explanation of how to submit changes against various branches, see the *Sending a GitHub pull request* section. Specifically, see the section describing how to `Create a new branch` and the steps that follow.

### Building the documentation

1. Install Sphinx using a system package manager or pip. The package name is often of the form `python-sphinx`. There are no other dependencies.
2. Build the documentation using the provided Makefile or `.bat` file on Windows.

```
cd /path/to/salt/doc
make html
```

3. The generated documentation will be written to the `doc/_build/<format>` directory.
4. A useful method of viewing the HTML documentation locally is to start Python's built-in HTTP server:

```
cd /path/to/salt/doc/_build/html
python -m SimpleHTTPServer
```

Then pull up the documentation in a web browser at <http://localhost:8000/>.

### 34.23.2 Salt Formulas

Formulas are pre-written Salt States. They are as open-ended as Salt States themselves and can be used for tasks such as installing a package, configuring, and starting a service, setting up users or permissions, and many other common tasks.

All official Salt Formulas are found as separate Git repositories in the ```saltstack-formulas``` organization on GitHub: <https://github.com/saltstack-formulas>

As a simple example, to install the popular Apache web server (using the normal defaults for the underlying distro) simply include the `apache-formula` from a top file:

```
base:
  'web*':
    - apache
```

## Installation

Each Salt Formula is an individual Git repository designed as a drop-in addition to an existing Salt State tree. Formulas can be installed in the following ways.

### Adding a Formula as a GitFS remote

One design goal of Salt's GitFS fileserver backend was to facilitate reusable States. GitFS is a quick and natural way to use Formulas.

1. *Install and configure GitFS.*
2. Add one or more Formula repository URLs as remotes in the `gitfs_remotes` list in the Salt Master configuration file:

```
gitfs_remotes:
  - https://github.com/saltstack-formulas/apache-formula
  - https://github.com/saltstack-formulas/memcached-formula
```

**We strongly recommend forking a formula repository** into your own GitHub account to avoid unexpected changes to your infrastructure.

Many Salt Formulas are highly active repositories so pull new changes with care. Plus any additions you make to your fork can be easily sent back upstream with a quick pull request!

3. Restart the Salt master.

### Adding a Formula directory manually

Formulas are simply directories that can be copied onto the local file system by using Git to clone the repository or by downloading and expanding a tarball or zip file of the repository. The directory structure is designed to work with `file_roots` in the Salt master configuration.

1. Clone or download the repository into a directory:

```
mkdir -p /srv/formulas
cd /srv/formulas
git clone https://github.com/saltstack-formulas/apache-formula.git

# or

mkdir -p /srv/formulas
cd /srv/formulas
wget https://github.com/saltstack-formulas/apache-formula/archive/master.tar.gz
tar xf apache-formula-master.tar.gz
```

2. Add the new directory to `file_roots`:

```
file_roots:
  base:
    - /srv/salt
    - /srv/formulas/apache-formula
```

3. Restart the Salt Master.

## Usage

Each Formula is intended to be immediately usable with sane defaults without any additional configuration. Many formulas are also configurable by including data in Pillar; see the `pillar.example` file in each Formula repository for available options.

### Including a Formula in an existing State tree

Formula may be included in an existing `sls` file. This is often useful when a state you are writing needs to `require` or `extend` a state defined in the formula.

Here is an example of a state that uses the `epel-formula` in a `require` declaration which directs Salt to not install the `python26` package until after the EPEL repository has also been installed:

```
include:
  - epel

python26:
  pkg.installed:
    - require:
      - pkg: epel
```

### Including a Formula from a Top File

Some Formula perform completely standalone installations that are not referenced from other state files. It is usually cleanest to include these Formula directly from a Top File.

For example the easiest way to set up an OpenStack deployment on a single machine is to include the `openstack-standalone-formula` directly from a `top.sls` file:

```
base:
  'myopenstackmaster':
    - openstack
```

Quickly deploying OpenStack across several dedicated machines could also be done directly from a Top File and may look something like this:

```
base:
  'controller':
    - openstack.horizon
    - openstack.keystone
  'hyper-*':
    - openstack.nova
    - openstack.glance
```

```
'storage-*':  
  - openstack.swift
```

### Configuring Formula using Pillar

Salt Formulas are designed to work out of the box with no additional configuration. However, many Formula support additional configuration and customization through *Pillar*. Examples of available options can be found in a file named `pillar.example` in the root directory of each Formula repository.

### Using Formula with your own states

Remember that Formula are regular Salt States and can be used with all Salt's normal state mechanisms. Formula can be required from other States with *require* declarations, they can be modified using `extend`, they can be made to watch other states with *The `_in` versions of requisites*.

The following example uses the stock `apache-formula` alongside a custom state to create a vhost on a Debian/Ubuntu system and to reload the Apache service whenever the vhost is changed.

```
# Include the stock, upstream apache formula.  
include:  
  - apache  
  
# Use the watch_in requisite to cause the apache service state to reload  
# apache whenever the my-example-com-vhost state changes.  
my-example-com-vhost:  
  file:  
    - managed  
    - name: /etc/apache2/sites-available/my-example-com  
    - watch_in:  
      - service: apache
```

Don't be shy to read through the source for each Formula!

### Reporting problems & making additions

Each Formula is a separate repository on GitHub. If you encounter a bug with a Formula please file an issue in the respective repository! Send fixes and additions as a pull request. Add tips and tricks to the repository wiki.

### Writing Formulas

Each Formula is a separate repository in the `saltstack-formulas` organization on GitHub.

---

**Note:** Get involved creating new Formulas

The best way to create new Formula repositories for now is to create a repository in your own account on GitHub and notify a SaltStack employee when it is ready. We will add you to the contributors team on the `saltstack-formulas` organization and help you transfer the repository over. Ping a SaltStack employee on IRC (`#salt` on Freenode) or send an email to the `salt-users` mailing list.

There are a lot of repositories in that organization! Team members can manage which repositories they are subscribed to on GitHub's watching page: <https://github.com/watching>.

## Style

Maintainability, readability, and reusability are all marks of a good Salt sls file. This section contains several suggestions and examples.

```
# Deploy the stable master branch unless version overridden by passing
# Pillar at the CLI or via the Reactor.

deploy_myapp:
  git.latest:
    - name: git@github.com/myco/myapp.git
    - version: {{ salt.pillar.get('myapp:version', 'master') }}
```

**Use a descriptive State ID** The ID of a state is used as a unique identifier that may be referenced via other states in *requisites*. It must be unique across the whole state tree (*it is a key in a dictionary*, after all).

In addition a state ID should be descriptive and serve as a high-level hint of what it will do, or manage, or change. For example, `deploy_webapp`, or `apache`, or `reload_firewall`.

**Use `module.function` notation** So-called "short-declaration" notation is preferred for referencing state modules and state functions. It provides a consistent pattern of `module.function` shared between Salt States, the Reactor, Overstate, Salt Mine, the Scheduler, as well as with the CLI.

```
# Do
apache:
  pkg.installed:
    - name: httpd

# Don't
apache:
  pkg:
    - installed
    - name: httpd
```

Salt's state compiler will transform "short-decs" into the longer format *when compiling the human-friendly highstate structure into the machine-friendly lowstate structure*.

**Specify the `name` parameter** Use a unique and permanent identifier for the state ID and reserve `name` for data with variability.

The *name declaration* is a required parameter for all state functions. The state ID will implicitly be used as `name` if it is not explicitly set in the state.

In many state functions the `name` parameter is used for data that varies such as OS-specific package names, OS-specific file system paths, repository addresses, etc. Any time the ID of a state changes all references to that ID must also be changed. Use a permanent ID when writing a state the first time to future-proof that state and allow for easier refactors down the road.

**Comment state files** YAML allows comments at varying indentation levels. It is a good practice to comment state files. Use vertical whitespace to visually separate different concepts or actions.

```

# Start with a high-level description of the current sls file.
# Explain the scope of what it will do or manage.

# Comment individual states as necessary.
update_a_config_file:
  # Provide details on why an unusual choice was made. For example:
  #
  # This template is fetched from a third-party and does not fit our
  # company norm of using Jinja. This must be processed using Mako.
  file.managed:
    - name: /path/to/file.cfg
    - source: salt://path/to/file.cfg.template
    - template: mako

  # Provide a description or explanation that did not fit within the state
  # ID. For example:
  #
  # Update the application's last-deployed timestamp.
  # This is a workaround until Bob configures Jenkins to automate RPM
  # builds of the app.
  cmd.run:
    # FIXME: Joe needs this to run on Windows by next quarter. Switch these
    # from shell commands to Salt's file.managed and file.replace state
    # modules.
    - name: |
        touch /path/to/file_last_updated
        sed -e 's/foo/bar/g' /path/to/file_environment
    - onchanges:
      - file: a_config_file

```

Be careful to use Jinja comments for commenting Jinja code and YAML comments for commenting YAML code.

```

# BAD EXAMPLE
# The Jinja in this YAML comment is still executed!
# {% set apache_is_installed = 'apache' in salt.pkg.list_pkgs() %}

# GOOD EXAMPLE
# The Jinja in this Jinja comment will not be executed.
{# {% set apache_is_installed = 'apache' in salt.pkg.list_pkgs() %} #}

```

### Easy on the Jinja!

Jinja templating provides vast flexibility and power when building Salt sls files. It can also create an unmaintainable tangle of logic and data. Speaking broadly, Jinja is best used when kept apart from the states (as much as is possible).

Below are guidelines and examples of how Jinja can be used effectively.

**Know the evaluation and execution order** High-level knowledge of how Salt states are compiled and run is useful when writing states.

The default `renderer` setting in Salt is Jinja piped to YAML. Each is a separate step. Each step is not aware of the previous or following step. Jinja is not YAML aware, YAML is not Jinja aware; they cannot share variables or interact.

- Whatever the Jinja step produces must be valid YAML.

- Whatever the YAML step produces must be a valid *highstate data structure*. (This is also true of the final step for *any of the alternate renderers* in Salt.)
- Highstate can be thought of as a human-friendly data structure; easy to write and easy to read.
- Salt's state compiler validates the *highstate* and compiles it to low state.
- Low state can be thought of as a machine-friendly data structure. It is a list of dictionaries that each map directly to a function call.
- Salt's state system finally starts and executes on each ``chunk" in the low state. Remember that requisites are evaluated at runtime.
- The return for each function call is added to the ``running" dictionary which is the final output at the end of the state run.

The full evaluation and execution order:

```
Jinja -> YAML -> Highstate -> low state -> execution
```

**Avoid changing the underlying system with Jinja** Avoid calling commands from Jinja that change the underlying system. Commands run via Jinja do not respect Salt's dry-run mode (`test=True`)! This is usually in conflict with the idempotent nature of Salt states unless the command being run is also idempotent.

**Inspect the local system** A common use for Jinja in Salt states is to gather information about the underlying system. The `grains` dictionary available in the Jinja context is a great example of common data points that Salt itself has already gathered. Less common values are often found by running commands. For example:

```
{% set is_selinux_enabled = salt.cmd.run('sestatus') == '1' %}
```

This is usually best done with a variable assignment in order to separate the data from the state that will make use of the data.

**Gather external data** One of the most common uses for Jinja is to pull external data into the state file. External data can come from anywhere like API calls or database queries, but it most commonly comes from flat files on the file system or Pillar data from the Salt Master. For example:

```
{% set some_data = salt.pillar.get('some_data', {'sane default': True}) %}
{# or #}
{% import_yaml 'path/to/file.yaml' as some_data %}
{# or #}
{% import_json 'path/to/file.json' as some_data %}
{# or #}
{% import_text 'path/to/ssh_key.pub' as ssh_pub_key %}
{# or #}
{% from 'path/to/other_file.jinja' import some_data with context %}
```

This is usually best done with a variable assignment in order to separate the data from the state that will make use of the data.

**Light conditionals and looping** Jinja is extremely powerful for programmatically generating Salt states. It is also easy to overuse. As a rule of thumb, if it is hard to read it will be hard to maintain!

Separate Jinja control-flow statements from the states as much as is possible to create readable states. Limit Jinja within states to simple variable lookups.

Below is a simple example of a readable loop:

```
{% for user in salt.pillar.get('list_of_users', []) %}

{# Ensure unique state IDs when looping. #}
{{ user.name }}-{{ loop.index }}:
  user.present:
    - name: {{ user.name }}
    - shell: {{ user.shell }}

{% endfor %}
```

Avoid putting a Jinja conditionals within Salt states where possible. Readability suffers and the correct YAML indentation is difficult to see in the surrounding visual noise. Parameterization (discussed below) and variables are both useful techniques to avoid this. For example:

```
{# ---- Bad example ---- #}

apache:
  pkg.installed:
    {% if grains.os_family == 'RedHat' %}
    - name: httpd
    {% elif grains.os_family == 'Debian' %}
    - name: apache2
    {% endif %}

{# ---- Better example ---- #}

{% if grains.os_family == 'RedHat' %}
{% set name = 'httpd' %}
{% elif grains.os_family == 'Debian' %}
{% set name = 'apache2' %}
{% endif %}

apache:
  pkg.installed:
    - name: {{ name }}

{# ---- Good example ---- #}

{% set name = {
  'RedHat': 'httpd',
  'Debian': 'apache2',
}.get(grains.os_family) %}

apache:
  pkg.installed:
    - name: {{ name }}
```

Dictionaries are useful to effectively ``namespace" a collection of variables. This is useful with parameterization (discussed below). Dictionaries are also easily combined and merged. And they can be directly serialized into YAML which is often easier than trying to create valid YAML through templating. For example:

```
{# ---- Bad example ---- #}

haproxy_conf:
  file.managed:
    - name: /etc/haproxy/haproxy.cfg
    - template: jinja
    {% if 'external_loadbalancer' in grains.roles %}
    - source: salt://haproxy/external_haproxy.cfg
    {% elif 'internal_loadbalancer' in grains.roles %}
    - source: salt://haproxy/internal_haproxy.cfg
    {% endif %}
    - context:
      {% if 'external_loadbalancer' in grains.roles %}
      ssl_termination: True
      {% elif 'internal_loadbalancer' in grains.roles %}
      ssl_termination: False
      {% endif %}

{# ---- Better example ---- #}

{% load_yaml as haproxy_defaults %}
common_settings:
  bind_port: 80

internal_loadbalancer:
  source: salt://haproxy/internal_haproxy.cfg
  settings:
    bind_port: 8080
    ssl_termination: False

external_loadbalancer:
  source: salt://haproxy/external_haproxy.cfg
  settings:
    ssl_termination: True
{% endload %}

{% if 'external_loadbalancer' in grains.roles %}
{% set haproxy = haproxy_defaults['external_loadbalancer'] %}
{% elif 'internal_loadbalancer' in grains.roles %}
{% set haproxy = haproxy_defaults['internal_loadbalancer'] %}
{% endif %}

{% do haproxy.settings.update(haproxy_defaults.common_settings) %}

haproxy_conf:
  file.managed:
    - name: /etc/haproxy/haproxy.cfg
    - template: jinja
    - source: {{ haproxy.source }}
    - context: {{ haproxy.settings | yaml() }}
```

There is still room for improvement in the above example. For example, extracting into an external file or replacing the if-elif conditional with a function call to filter the correct data more succinctly. However, the state itself is simple and legible, the data is separate and also simple and legible. And those suggested improvements can be made at some

future date without altering the state at all!

**Avoid heavy logic and programming** Jinja is not Python. It was made by Python programmers and shares many semantics and some syntax but it does not allow for arbitrary Python function calls or Python imports. Jinja is a fast and efficient templating language but the syntax can be verbose and visually noisy.

Once Jinja use within an sls file becomes slightly complicated -- long chains of if-elif-elif-else statements, nested conditionals, complicated dictionary merges, wanting to use sets -- instead consider using a different Salt renderer, such as the Python renderer. As a rule of thumb, if it is hard to read it will be hard to maintain -- switch to a format that is easier to read.

Using alternate renderers is very simple to do using Salt's ``she-bang" syntax at the top of the file. The Python renderer must simply return the correct *highstate data structure*. The following example is a state tree of two sls files, one simple and one complicated.

/srv/salt/top.sls:

```
base:
  '*':
    - common_configuration
    - roles_configuration
```

/srv/salt/common\_configuration.sls:

```
common_users:
  user.present:
    - names: [larry, curly, moe]
```

/srv/salt/roles\_configuration:

```
#!/py
def run():
    list_of_roles = set()

    # This example has the minion id in the form 'web-03-dev'.
    # Easily access the grains dictionary:
    try:
        app, instance_number, environment = __grains__['id'].split('-')
        instance_number = int(instance_number)
    except ValueError:
        app, instance_number, environment = ['Unknown', 0, 'dev']

    list_of_roles.add(app)

    if app == 'web' and environment == 'dev':
        list_of_roles.add('primary')
        list_of_roles.add('secondary')
    elif app == 'web' and environment == 'staging':
        if instance_number == 0:
            list_of_roles.add('primary')
        else:
            list_of_roles.add('secondary')

    # Easily cross-call Salt execution modules:
    if __salt__['myutils.query_valid_ec2_instance']():
        list_of_roles.add('is_ec2_instance')
```

```

return {
    'set_roles_grains': {
        'grains.present': [
            {'name': 'roles'},
            {'value': list(list_of_roles)},
        ],
    },
}

```

**Jinja Macros** In Salt sls files Jinja macros are useful for one thing and one thing only: creating mini templates that can be reused and rendered on demand. Do not fall into the trap of thinking of macros as functions; Jinja is not Python (see above).

Macros are useful for creating reusable, parameterized states. For example:

```

{% macro user_state(state_id, user_name, shell='/bin/bash', groups=[]) %}
{{ state_id }}:
  user.present:
    - name: {{ user_name }}
    - shell: {{ shell }}
    - groups: {{ groups | json() }}
{% endmacro %}

{% for user_info in salt.pillar.get('my_users', []) %}
{{ user_state('user_number_' ~ loop.index, **user_info) }}
{% endfor %}

```

Macros are also useful for creating one-off "serializers" that can accept a data structure and write that out as a domain-specific configuration file. For example, the following macro could be used to write a php.ini config file:

/srv/salt/php.sls:

```

php_ini:
  file.managed:
    - name: /etc/php.ini
    - source: salt://php.ini.tmpl
    - template: jinja
    - context:
        php_ini_settings: {{ salt.pillar.get('php_ini', {}) | json() }}

```

/srv/pillar/php.sls:

```

php_ini:
  PHP:
    engine: 'On'
    short_open_tag: 'Off'
    error_reporting: 'E_ALL & ~E_DEPRECATED & ~E_STRICT'

```

/srv/salt/php.ini.tmpl:

```

{% macro php_ini_serializer(data) %}
{% for section_name, name_val_pairs in data.items() %}
[{{ section_name }}]
{% for name, val in name_val_pairs.items() -%}

```

```

{{ name }} = "{{ val }}"
{% endfor %}
{% endfor %}
{% endmacro %}

; File managed by Salt at <{{ source }}>.
; Your changes will be overwritten.

{{ php_ini_serializer(php_ini_settings) }}

```

### Abstracting static defaults into a lookup table

Separate data that a state uses from the state itself to increase the flexibility and reusability of a state.

An obvious and common example of this is platform-specific package names and file system paths. Another example is sane defaults for an application, or common settings within a company or organization. Organizing such data as a dictionary (aka hash map, lookup table, associative array) often provides a lightweight namespacing and allows for quick and easy lookups. In addition, using a dictionary allows for easily merging and overriding static values within a lookup table with dynamic values fetched from Pillar.

A strong convention in Salt Formulas is to place platform-specific data, such as package names and file system paths, into a file named `map.jinja` that is placed alongside the state files.

The following is an example from the MySQL Formula. The `grains.filter_by` function performs a lookup on that table using the `os_family` grain (by default).

The result is that the `mysql` variable is assigned to a *subset* of the lookup table for the current platform. This allows states to reference, for example, the name of a package without worrying about the underlying OS. The syntax for referencing a value is a normal dictionary lookup in Jinja, such as `{{ mysql['service'] }}` or the shorthand `{{ mysql.service }}`.

`map.jinja`:

```

{% set mysql = salt['grains.filter_by']({
    'Debian': {
        'server': 'mysql-server',
        'client': 'mysql-client',
        'service': 'mysql',
        'config': '/etc/mysql/my.cnf',
        'python': 'python-mysqldb',
    },
    'RedHat': {
        'server': 'mysql-server',
        'client': 'mysql',
        'service': 'mysqld',
        'config': '/etc/my.cnf',
        'python': 'MySQL-python',
    },
    'Gentoo': {
        'server': 'dev-db/mysql',
        'client': 'dev-db/mysql',
        'service': 'mysql',
        'config': '/etc/mysql/my.cnf',
        'python': 'dev-python/mysql-python',
    },
}, merge=salt['pillar.get']('mysql:lookup')) %}

```

Values defined in the map file can be fetched for the current platform in any state file using the following syntax:

```
{% from "mysql/map.jinja" import mysql with context %}

mysql-server:
  pkg.installed:
    - name: {{ mysql.server }}
  service.running:
    - name: {{ mysql.service }}
```

**Collecting common values** Common values can be collected into a *base* dictionary. This minimizes repetition of identical values in each of the `lookup_dict` sub-dictionaries. Now only the values that are different from the base must be specified of the alternates:

map.jinja:

```
{% set mysql = salt['grains.filter_by']({
  'default': {
    'server': 'mysql-server',
    'client': 'mysql-client',
    'service': 'mysql',
    'config': '/etc/mysql/my.cnf',
    'python': 'python-mysqldb',
  },
  'Debian': {
  },
  'RedHat': {
    'client': 'mysql',
    'service': 'mysqld',
    'config': '/etc/my.cnf',
    'python': 'MySQL-python',
  },
  'Gentoo': {
    'server': 'dev-db/mysql',
    'client': 'dev-db/mysql',
    'python': 'dev-python/mysql-python',
  },
},
merge=salt['pillar.get']('mysql:lookup'), base='default') %}
```

**Overriding values in the lookup table** Allow static values within lookup tables to be overridden. This is a simple pattern which once again increases flexibility and reusability for state files.

The `merge` argument in *filter\_by* specifies the location of a dictionary in Pillar that can be used to override values returned from the lookup table. If the value exists in Pillar it will take precedence.

This is useful when software or configuration files is installed to non-standard locations or on unsupported platforms. For example, the following Pillar would replace the `config` value from the call above.

```
mysql:
  lookup:
    config: /usr/local/etc/mysql/my.cnf
```

**Note:** Protecting Expansion of Content with Special Characters

When templating keep in mind that YAML does have special characters for quoting, flows, and other special structure and content. When a Jinja substitution may have special characters that will be incorrectly parsed by YAML care must be taken. It is a good policy to use the `yaml_encode` or the `yaml_dquote` Jinja filters:

```
{%- set foo = 7.7 %}
{% set bar = none %}
{% set baz = true %}
{% set zap = 'The word of the day is "salty."' %}
{% set zip = '"The quick brown fox . . ."' %}

foo: {{ foo|yaml_encode }}
bar: {{ bar|yaml_encode }}
baz: {{ baz|yaml_encode }}
zap: {{ zap|yaml_encode }}
zip: {{ zip|yaml_dquote }}
```

The above will be rendered as below:

```
foo: 7.7
bar: null
baz: true
zap: "The word of the day is \"salty\"."
zip: "\"The quick brown fox . . .\""
```

The `filter_by` function performs a simple dictionary lookup but also allows for fetching data from Pillar and overriding data stored in the lookup table. That same workflow can be easily performed without using `filter_by`; other dictionaries besides data from Pillar can also be used.

```
{% set lookup_table = {...} %}
{% do lookup_table.update(salt.pillar.get('my:custom:data')) %}
```

**When to use lookup tables** The `map.jinja` file is only a convention within Salt Formulas. This greater pattern is useful for a wide variety of data in a wide variety of workflows. This pattern is not limited to pulling data from a single file or data source. This pattern is useful in States, Pillar, the Reactor, and Overstate as well.

Working with a data structure instead of, say, a config file allows the data to be cobbled together from multiple sources (local files, remote Pillar, database queries, etc), combined, overridden, and searched.

Below are a few examples of what lookup tables may be useful for and how they may be used and represented.

**Platform-specific information** An obvious pattern and one used heavily in Salt Formulas is extracting platform-specific information such as package names and file system paths in a file named `map.jinja`. The pattern is explained in detail above.

**Sane defaults** Application settings can be a good fit for this pattern. Store default settings along with the states themselves and keep overrides and sensitive settings in Pillar. Combine both into a single dictionary and then write the application config or settings file.

The example below stores most of the Apache Tomcat `server.xml` file alongside the Tomcat states and then allows values to be updated or augmented via Pillar. (This example uses the BadgerFish format for transforming JSON to XML.)

`/srv/salt/tomcat/defaults.yaml:`

```
Server:
  '@port': '8005'
  '@shutdown': SHUTDOWN
  GlobalNamingResources:
    Resource:
      '@auth': Container
      '@description': User database that can be updated and saved
      '@factory': org.apache.catalina.users.MemoryUserDatabaseFactory
      '@name': UserDatabase
      '@pathname': conf/tomcat-users.xml
      '@type': org.apache.catalina.UserDatabase
  # <...snip...>
```

`/srv/pillar/tomcat.sls:`

```
appX:
  server_xml_overrides:
    Server:
      Service:
        '@name': Catalina
      Connector:
        '@port': '8009'
        '@protocol': AJP/1.3
        '@redirectPort': '8443'
    # <...snip...>
```

`/srv/salt/tomcat/server_xml.sls:`

```
{% import_yaml 'tomcat/defaults.yaml' as server_xml_defaults %}
{% set server_xml_final_values = salt.pillar.get(
  'appX:server_xml_overrides',
  default=server_xml_defaults,
  merge=True)
%}

appX_server_xml:
  file.serialize:
    - name: /etc/tomcat/server.xml
    - dataset: {{ server_xml_final_values | json() }}
    - formatter: xml_badgerfish
```

The `file.serialize` state can provide a shorthand for creating some files from data structures. There are also many examples within Salt Formulas of creating one-off “serializers” (often as Jinja macros) that reformat a data structure to a specific config file format. For example, `‘Nginx vhosts’` [\\_\\_](https://github.com/saltstack-formulas/nginx-formula/blob/5cad4512/nginx/ng/vhosts_config.sls) or the `‘php.ini’` [\\_\\_](https://github.com/saltstack-formulas/php-formula/blob/82e2cd3a/php/ng/files/php.ini):

`__`: [https://github.com/saltstack-formulas/nginx-formula/blob/5cad4512/nginx/ng/vhosts\\_config.sls](https://github.com/saltstack-formulas/nginx-formula/blob/5cad4512/nginx/ng/vhosts_config.sls) `__`:  
<https://github.com/saltstack-formulas/php-formula/blob/82e2cd3a/php/ng/files/php.ini>

**Environment specific information** A single state can be reused when it is parameterized as described in the section below, by separating the data the state will use from the state that performs the work. This can be the difference

between deploying *Application X* and *Application Y*, or the difference between production and development. For example:

/srv/salt/app/deploy.sls:

```
{# Load the map file. #}
{% import_yaml 'app/defaults.yaml' as app_defaults %}

{# Extract the relevant subset for the app configured on the current
machine (configured via a grain in this example). #}
{% app = app_defaults.get(salt.grains.get('role')) %}

{# Allow values from Pillar to (optionally) update values from the lookup
table. #}
{% do app_defaults.update(salt.pillar.get('myapp', {})) %}

deploy_application:
  git.latest:
    - name: {{ app.repo_url }}
    - version: {{ app.version }}
    - target: {{ app.deploy_dir }}

myco/myapp/deployed:
  event.send:
    - data:
        version: {{ app.version }}
    - onchanges:
        - git: deploy_application
```

/srv/salt/app/defaults.yaml:

```
appX:
  repo_url: git@github.com:myco/appX.git
  target: /var/www/appX
  version: master
appY:
  repo_url: git@github.com:myco/appY.git
  target: /var/www/appY
  version: v1.2.3.4
```

### Single-purpose SLS files

Each sls file in a Formula should strive to do a single thing. This increases the reusability of this file by keeping unrelated tasks from getting coupled together.

As an example, the base Apache formula should only install the Apache httpd server and start the httpd service. This is the basic, expected behavior when installing Apache. It should not perform additional changes such as set the Apache configuration file or create vhosts.

If a formula is single-purpose as in the example above, other formulas, and also other states can include and use that formula with *Requisites and Other Global State Arguments* without also including undesirable or unintended side-effects.

The following is a best-practice example for a reusable Apache formula. (This skips platform-specific options for brevity. See the full [apache-formula](#) for more.)

```
# apache/init.sls
apache:
  pkg.installed:
    [...]
  service.running:
    [...]

# apache/mod_wsgi.sls
include:
  - apache

mod_wsgi:
  pkg.installed:
    [...]
  - require:
    - pkg: apache

# apache/conf.sls
include:
  - apache

apache_conf:
  file.managed:
    [...]
  - watch_in:
    - service: apache
```

To illustrate a bad example, say the above Apache formula installed Apache and also created a default vhost. The `mod_wsgi` state would not be able to include the Apache formula to create that dependency tree without also installing the unneeded default vhost.

*Formulas should be reusable.* Avoid coupling unrelated actions together.

### Parameterization

*Parameterization is a key feature of Salt Formulas* and also for Salt States. Parameterization allows a single Formula to be reused across many operating systems; to be reused across production, development, or staging environments; and to be reused by many people all with varying goals.

Writing states, specifying ordering and dependencies is the part that takes the longest to write and to test. Filling those states out with data such as users or package names or file locations is the easy part. How many users, what those users are named, or where the files live are all implementation details that **should be parameterized**. This separation between a state and the data that populates a state creates a reusable formula.

In the example below the data that populates the state can come from anywhere -- it can be hard-coded at the top of the state, it can come from an external file, it can come from Pillar, it can come from an execution function call, or it can come from a database query. The state itself doesn't change regardless of where the data comes from. Production data will vary from development data will vary from data from one company to another, however the state itself stays the same.

```
{% set user_list = [
  {'name': 'larry', 'shell': 'bash'},
  {'name': 'curly', 'shell': 'bash'},
  {'name': 'moe', 'shell': 'zsh'},
] %}
```

```

{# or #}

{% set user_list = salt['pillar.get']('user_list') %}

{# or #}

{% load_json "default_users.json" as user_list %}

{# or #}

{% set user_list = salt['acme_utils.get_user_list']() %}

{% for user in list_list %}
  {{ user.name }}:
  user.present:
    - name: {{ user.name }}
    - shell: {{ user.shell }}
{% endfor %}

```

### Configuration

Formulas should strive to use the defaults of the underlying platform, followed by defaults from the upstream project, followed by sane defaults for the formula itself.

As an example, a formula to install Apache **should not** change the default Apache configuration file installed by the OS package. However, the Apache formula **should** include a state to change or override the default configuration file.

### Pillar overrides

Pillar lookups must use the safe `get()` and must provide a default value. Create local variables using the Jinja `set` construct to increase readability and to avoid potentially hundreds or thousands of function calls across a large state tree.

```

{% from "apache/map.jinja" import apache with context %}
{% set settings = salt['pillar.get']('apache', {}) %}

mod_status:
  file.managed:
    - name: {{ apache.conf_dir }}
    - source: {{ settings.get('mod_status_conf', 'salt://apache/mod_status.conf') }}
    - template: {{ settings.get('template_engine', 'jinja') }}

```

Any default values used in the Formula must also be documented in the `pillar.example` file in the root of the repository. Comments should be used liberally to explain the intent of each configuration value. In addition, users should be able copy-and-paste the contents of this file into their own Pillar to make any desired changes.

### Scripting

Remember that both State files and Pillar files can easily call out to Salt *execution modules* and have access to all the system grains as well.

```
{% if '/storage' in salt['mount.active']() %}
/usr/local/etc/myfile.conf:
  file:
    - symlink
    - target: /storage/myfile.conf
{% endif %}
```

Jinja macros to encapsulate logic or conditionals are discouraged in favor of *writing custom execution modules* in Python.

## Repository structure

A basic Formula repository should have the following layout:

```
foo-formula
|-- foo/
|   |-- map.jinja
|   |-- init.sls
|   `-- bar.sls
|-- CHANGELOG.rst
|-- LICENSE
|-- pillar.example
|-- README.rst
`-- VERSION
```

See also:

[template-formula](#)

The [template-formula](#) repository has a pre-built layout that serves as the basic structure for a new formula repository. Just copy the files from there and edit them.

### README.rst

The README should detail each available `.sls` file by explaining what it does, whether it has any dependencies on other formulas, whether it has a target platform, and any other installation or usage instructions or tips.

A sample skeleton for the `README.rst` file:

```
===
foo
===

Install and configure the F00 service.

.. note::

    See the full `Salt Formulas installation and usage instructions
    <http://docs.saltstack.com/en/latest/topics/development/conventions/formulas.html>`.

Available states
=====

.. contents::
   :local:
```

```

``foo``
-----

Install the ``foo`` package and enable the service.

``foo.bar``
-----

Install the ``bar`` package.

```

### CHANGELOG.rst

The `CHANGELOG.rst` file should detail the individual versions, their release date and a set of bullet points for each version highlighting the overall changes in a given version of the formula.

A sample skeleton for the `CHANGELOG.rst` file:

`CHANGELOG.rst`:

```

foo formula
=====

0.0.2 (2013-01-01)

- Re-organized formula file layout
- Fixed filename used for upstart logger template
- Allow for pillar message to have default if none specified

```

### Versioning

Formula are versioned according to Semantic Versioning, <http://semver.org/>.

**Note:** Given a version number MAJOR.MINOR.PATCH, increment the:

1. MAJOR version when you make incompatible API changes,
2. MINOR version when you add functionality in a backwards-compatible manner, and
3. PATCH version when you make backwards-compatible bug fixes.

Additional labels for pre-release and build metadata are available as extensions to the MAJOR.MINOR.PATCH format.

Formula versions are tracked using Git tags as well as the `VERSION` file in the formula repository. The `VERSION` file should contain the currently released version of the particular formula.

### Testing Formulas

A smoke-test for invalid Jinja, invalid YAML, or an invalid Salt state structure can be performed by with the `state.show_sls` function:

```
salt '*' state.show_sls apache
```

Salt Formulas can then be tested by running each `.sls` file via `state.apply` and checking the output for the success or failure of each state in the Formula. This should be done for each supported platform.

### 34.23.3 SaltStack Packaging Guide

Since Salt provides a powerful toolkit for system management and automation, the package can be split into a number of sub-tools. While packaging Salt as a single package containing all components is perfectly acceptable, the split packages should follow this convention.

#### Patching Salt For Distributions

The occasion may arise where Salt source and default configurations may need to be patched. It is preferable if Salt is only patched to include platform specific additions or to fix release time bugs. It is preferable that configuration settings and operations remain in the default state, as changes here lowers the user experience for users moving across distributions.

In the event where a packager finds a need to change the default configuration it is advised to add the files to the `master.d` or `minion.d` directories.

#### Source Files

Release packages should always be built from the source tarball distributed via pypi. Release packages should *NEVER* use a git checkout as the source for distribution.

#### Single Package

Shipping Salt as a single package, where the minion, master, and all tools are together is perfectly acceptable and practiced by distributions such as FreeBSD.

#### Split Package

Salt Should always be split in a standard way, with standard dependencies, this lowers cross distribution confusion about what components are going to be shipped with specific packages. These packages can be defined from the Salt Source as of Salt 2014.1.0:

#### Salt Common

The `salt-common` or `salt` package should contain the files provided by the salt python package, or all files distributed from the `salt/` directory in the source distribution packages. The documentation contained under the `doc/` directory can be a part of this package but splitting out a doc package is preferred. Since `salt-call` is the entry point to utilize the libs and is useful for all salt packages it is included in the `salt-common` package.

#### Name

- `salt` OR `salt-common`

**Files**

- *salt/\**
- *man/salt.7*
- *scripts/salt-call*
- *tests/\**
- *man/salt-call.1*

**Depends**

- *Python 2.6-2.7*
- *PyYAML*
- *Jinja2*

**Salt Master**

The *salt-master* package contains the applicable scripts, related man pages and init information for the given platform.

**Name**

- *salt-master*

**Files**

- *scripts/salt-master*
- *scripts/salt*
- *scripts/salt-run*
- *scripts/salt-key*
- *scripts/salt-cp*
- *pkg/<master init data>*
- *man/salt.1*
- *man/salt-master.1*
- *man/salt-run.1*
- *man/salt-key.1*
- *man/salt-cp.1*
- *conf/master*

**Depends**

- *Salt Common*
- *ZeroMQ >= 3.2*
- *PyZMQ >= 2.10*
- *PyCrypto*

- *M2Crypto*
- *Python MessagePack* (Messagepack C lib, or msgpack-pure)

### Salt Syndic

The Salt Syndic package can be rolled completely into the Salt Master package. Platforms which start services as part of the package deployment need to maintain a separate *salt-syndic* package (primarily Debian based platforms).

The Syndic may optionally not depend on anything more than the Salt Master since the master will bring in all needed dependencies, but fall back to the platform specific packaging guidelines.

#### Name

- *salt-syndic*

#### Files

- *scripts/salt-syndic*
- *pkg/<syndic init data>*
- *man/salt-syndic.1*

#### Depends

- *Salt Common*
- *Salt Master*
- *ZeroMQ* >= 3.2
- *PyZMQ* >= 2.10
- *PyCrypto*
- *M2Crypto*
- *Python MessagePack* (Messagepack C lib, or msgpack-pure)

### Salt Minion

The Minion is a standalone package and should not be split beyond the *salt-minion* and *salt-common* packages.

#### Name

- *salt-minion*

#### Files

- *scripts/salt-minion*
- *pkg/<minion init data>*
- *man/salt-minion.1*
- *conf/minion*

**Depends**

- *Salt Common*
- *ZeroMQ* >= 3.2
- *PyZMQ* >= 2.10
- *PyCrypto*
- *M2Crypto*
- *Python MessagePack* (Messagepack C lib, or msgpack-pure)

**Salt SSH**

Since Salt SSH does not require the same dependencies as the minion and master, it should be split out.

**Name**

- *salt-ssh*

**Files**

- *scripts/salt-ssh*
- *man/salt-ssh.1*
- *conf/cloud\**

**Depends**

- *Salt Common*
- *Python MessagePack* (Messagepack C lib, or msgpack-pure)

**Salt Cloud**

As of Salt 2014.1.0 Salt Cloud is included in the same repo as Salt. This can be split out into a separate package or it can be included in the salt-master package.

**Name**

- *salt-cloud*

**Files**

- *scripts/salt-cloud*
- *man/salt-cloud.1*

**Depends**

- *Salt Common*
- *apache libcloud* >= 0.14.0

## Salt Doc

The documentation package is very distribution optional. A completely split package will split out the documentation, but some platform conventions do not prefer this. If the documentation is not split out, it should be included with the *Salt Common* package.

### Name

- *salt-doc*

### Files

- *doc/\**

### Optional Depends

- *Salt Common*
- *Python Sphinx*
- *Make*

## 34.23.4 Salt Release Process

The goal for Salt projects is to cut a new feature release every four to six weeks. This document outlines the process for these releases, and the subsequent bug fix releases which follow.

### Feature Release Process

When a new release is ready to be cut, the person responsible for cutting the release will follow the following steps (written using the 0.16 release as an example):

1. All open issues on the release milestone should be moved to the next release milestone. (e.g. from the 0.16 milestone to the 0.17 milestone)
2. Release notes should be created documenting the major new features and bugfixes in the release.
3. Create an annotated tag with only the major and minor version numbers, preceded by the letter v. (e.g. v0.16) This tag will reside on the `develop` branch.
4. Create a branch for the new release, using only the major and minor version numbers. (e.g. 0.16)
5. On this new branch, create an annotated tag for the first revision release, which is generally a release candidate. It should be preceded by the letter v. (e.g. v0.16.0RC)
6. The release should be packaged from this annotated tag and uploaded to PyPI as well as the GitHub releases page for this tag.
7. The packagers should be notified on the [salt-packagers](#) mailing list so they can create packages for all the major operating systems. (note that release candidates should go in the testing repositories)
8. After the packagers have been given a few days to compile the packages, the release is announced on the [salt-users](#) mailing list.
9. Log into RTD and add the new release there. (Have to do it manually)

## Maintenance and Bugfix Releases

Once a release has been cut, regular cherry-picking sessions should begin to cherry-pick any bugfixes from the `develop` branch to the release branch (e.g. `0.16`). Once major bugs have been fixed and cherry-picked, a bugfix release can be cut:

1. On the release branch (i.e. `0.16`), create an annotated tag for the revision release. It should be preceded by the letter `v`. (e.g. `v0.16.2`) Release candidates are unnecessary for bugfix releases.
2. The release should be packaged from this annotated tag and uploaded to PyPI.
3. The packagers should be notified on the [salt-packagers](#) mailing list so they can create packages for all the major operating systems.
4. After the packagers have been given a few days to compile the packages, the release is announced on the [salt-users](#) mailing list.

## Cherry-Picking Process for Bugfixes

Bugfixes should be made on the `develop` branch. If the bug also applies to the current release branch, then on the pull request against `develop`, the user should mention `@basepi` and ask for the pull request to be cherry-picked. If it is verified that the fix is a bugfix, then the `Bugfix -- Cherry-Pick` label will be applied to the pull request. When those commits are cherry-picked, the label will be switched to the `Bugfix -- [Done] Cherry-Pick` label. This allows easy recognition of which pull requests have been cherry-picked, and which are still pending to be cherry-picked. All cherry-picked commits will be present in the next release.

Features will not be cherry-picked, and will be present in the next feature release.

### 34.23.5 Salt Coding Style

Salt is developed with a certain coding style, while the style is dominantly PEP 8 it is not completely PEP 8. It is also noteworthy that a few development techniques are also employed which should be adhered to. In the end, the code is made to be ``Salty``.

Most importantly though, we will accept code that violates the coding style and KINDLY ask the contributor to fix it, or go ahead and fix the code on behalf of the contributor. Coding style is NEVER grounds to reject code contributions, and is never grounds to talk down to another member of the community (There are no grounds to treat others without respect, especially people working to improve Salt)!!

## Linting

Most Salt style conventions are codified in Salt's `.pylintrc` file. Salt's `pylint` file has two dependencies: [pylint](#) and [saltpylint](#). You can install these dependencies with `pip`:

```
pip install pylint
pip install saltpylint
```

The `.pylintrc` file is found in the root of the Salt project and can be passed as an argument to the [pylint](#) program as follows:

```
pylint --rcfile=/path/to/salt/.pylintrc salt/dir/to/lint
```

## Variables

Variables should be a minimum of three characters and should provide an easy-to-understand name of the object being represented.

When keys and values are iterated over, descriptive names should be used to represent the temporary variables.

Multi-word variables should be separated by an underscore.

Variables which are two-letter words should have an underscore appended to them to pad them to three characters.

## Strings

Salt follows a few rules when formatting strings:

### Single Quotes

In Salt, all strings use single quotes unless there is a good reason not to. This means that docstrings use single quotes, standard strings use single quotes etc.:

```
def foo():  
    '''  
    A function that does things  
    '''  
    name = 'A name'  
    return name
```

### Formatting Strings

All strings which require formatting should use the `.format` string method:

```
data = 'some text'  
more = '{0} and then some'.format(data)
```

Make sure to use indices or identifiers in the format brackets, since empty brackets are not supported by python 2.6.

Please do NOT use `printf` formatting.

### Docstring Conventions

Docstrings should always add a newline, `docutils` takes care of the new line and it makes the code cleaner and more vertical:

GOOD:

```
def bar():  
    '''  
    Here lies a docstring with a newline after the quotes and is the salty  
    way to handle it! Vertical code is the way to go!  
    '''  
    return
```

BAD:

```
def baz():
    '''This is not ok!'''
    return
```

When adding a new function or state, where possible try to use a `versionadded` directive to denote when the function or state was added.

```
def new_func(msg=''):
    '''
    .. versionadded:: 0.16.0

    Prints what was passed to the function.

    msg : None
        The string to be printed.
    '''
    print msg
```

If you are uncertain what version should be used, either consult a core developer in IRC or bring this up when opening your [pull request](#) and a core developer will add the proper version once your pull request has been merged. Bugfixes will be available in a bugfix release (i.e. 0.17.1, the first bugfix release for 0.17.0), while new features are held for feature releases, and this will affect what version number should be used in the `versionadded` directive.

Similar to the above, when an existing function or state is modified (for example, when an argument is added), then under the explanation of that new argument a `versionadded` directive should be used to note the version in which the new argument was added. If an argument's function changes significantly, the `versionchanged` directive can be used to clarify this:

```
def new_func(msg='', signature=''):
    '''
    .. versionadded:: 0.16.0

    Prints what was passed to the function.

    msg : None
        The string to be printed. Will be prepended with 'Greetings! '.

    .. versionchanged:: 0.17.1

    signature : None
        An optional signature.

    .. versionadded 0.17.0
    '''
    print 'Greetings! {0}\n\n{1}'.format(msg, signature)
```

## Dictionaries

Dictionaries should be initialized using `{}` instead of `dict()`.

See [here](#) for an in-depth discussion of this topic.

## Imports

Salt code prefers importing modules and not explicit functions. This is both a style and functional preference. The functional preference originates around the fact that the module import system used by pluggable modules will include callable objects (functions) that exist in the direct module namespace. This is not only messy, but may unintentionally expose code python libs to the Salt interface and pose a security problem.

To say this more directly with an example, this is *GOOD*:

```
import os

def minion_path():
    path = os.path.join(self.opts['cachedir'], 'minions')
    return path
```

This on the other hand is *DISCOURAGED*:

```
from os.path import join

def minion_path():
    path = join(self.opts['cachedir'], 'minions')
    return path
```

The time when this is changed is for importing exceptions, generally directly importing exceptions is preferred:

This is a good way to import exceptions:

```
from salt.exceptions import CommandExecutionError
```

## Absolute Imports

Although `absolute imports` seems like an awesome idea, please do not use it. Extra care would be necessary all over salt's code in order for absolute imports to work as supposed. Believe it, it has been tried before and, as a tried example, by renaming `salt.modules.sysmod` to `salt.modules.sys`, all other salt modules which needed to import `sys` would have to also import `absolute_import`, which should be avoided.

## Vertical is Better

When writing Salt code, vertical code is generally preferred. This is not a hard rule but more of a guideline. As PEP 8 specifies, Salt code should not exceed 79 characters on a line, but it is preferred to separate code out into more newlines in some cases for better readability:

```
import os

os.chmod(
    os.path.join(self.opts['sock_dir'],
                 'minion_event_pub.ipc'),
    448
)
```

Where there are more line breaks, this is also apparent when constructing a function with many arguments, something very common in state functions for instance:

```
def managed(name,
            source=None,
            source_hash='',
            user=None,
            group=None,
            mode=None,
            template=None,
            makedirs=False,
            context=None,
            replace=True,
            defaults=None,
            env=None,
            backup='',
            **kwargs):
```

**Note:** Making function and class definitions vertical is only required if the arguments are longer than 80 characters. Otherwise, the formatting is optional and both are acceptable.

### Line Length

For function definitions and function calls, Salt adheres to the PEP-8 specification of at most 80 characters per line.

Non function definitions or function calls, please adopt a soft limit of 120 characters per line. If breaking the line reduces the code readability, don't break it. Still, try to avoid passing that 120 characters limit and remember, **vertical is better... unless it isn't**

### Indenting

Some confusion exists in the python world about indenting things like function calls, the above examples use 8 spaces when indenting comma-delimited constructs.

The confusion arises because the pep8 program INCORRECTLY flags this as wrong, where PEP 8, the document, cites only using 4 spaces here as wrong, as it doesn't differentiate from a new indent level.

Right:

```
def managed(name,
            source=None,
            source_hash='',
            user=None)
```

WRONG:

```
def managed(name,
            source=None,
            source_hash='',
            user=None)
```

Lining up the indent is also correct:

```
def managed(name,
            source=None,
            source_hash='',
            user=None)
```

This also applies to function calls and other hanging indents.

pep8 and Flake8 (and, by extension, the vim plugin Syntastic) will complain about the double indent for hanging indents. This is a **known conflict** between pep8 (the script) and the actual PEP 8 standard. It is recommended that this particular warning be ignored with the following lines in `~/.config/flake8`:

```
[flake8]
ignore = E226,E241,E242,E126
```

Make sure your Flake8/pep8 are up to date. The first three errors are ignored by default and are present here to keep the behavior the same. This will also work for pep8 without the Flake8 wrapper -- just replace all instances of `'flake8'` with `'pep8'`, including the filename.

### Code Churn

Many pull requests have been submitted that only churn code in the name of PEP 8. Code churn is a leading source of bugs and is strongly discouraged. While style fixes are encouraged they should be isolated to a single file per commit, and the changes should be legitimate, if there are any questions about whether a style change is legitimate please reference this document and the official PEP 8 (<http://legacy.python.org/dev/peps/pep-0008/>) document before changing code. Many claims that a change is PEP 8 have been invalid, please double check before committing fixes.

---

## Release notes

---

See the `version numbers` page for more information about the version numbering scheme.

### 35.1 Latest Branch Release

Salt 2015.5.10 Release Notes

### 35.2 Previous Releases

#### 35.2.1 Salt 2015.5.0 Release Notes - Codename Lithium

The 2015.5.0 feature release of Salt is focused on hardening Salt and mostly on improving existing systems. A few major additions are present, primarily the new Beacon system. Most enhancements have been focused around improving existing features and interfaces.

As usual the release notes are not exhaustive and primarily include the most notable additions and improvements. Hundreds of bugs have been fixed and many modules have been substantially updated and added.

**Warning:** In order to fix potential shell injection vulnerabilities in salt modules, a change has been made to the various `cmd` module functions. These functions now default to `python_shell=False`, which means that the commands will not be sent to an actual shell.

The largest side effect of this change is that `shellisms`, such as pipes, will not work by default. The modules shipped with salt have been audited to fix any issues that might have arisen from this change. Additionally, the `cmd` state module has been unaffected, and use of `cmd.run` in jinja is also unaffected. `cmd.run` calls on the CLI will also allow shellisms.

However, custom execution modules which use shellisms in `cmd` calls will break, unless you pass `python_shell=True` to these calls.

As a temporary workaround, you can set `cmd_safe: False` in your minion and master configs. This will revert the default, but is also less secure, as it will allow shell injection vulnerabilities to be written in custom code. We recommend you only set this setting for as long as it takes to resolve these issues in your custom code, then remove the override.

---

**Note:** Starting in this version of salt, `pillar_opts` defaults to `False` instead of `True`. This means that master opts will not be present in minion pillar, and as a result, `config.get` calls will not include master opts.

We recommend pillar is used for configuration options which need to make it to the minion.

---

## Beacons

The beacon system allows the minion to hook into system processes and continually translate external events into the salt event bus. The primary example of this is the *inotify* beacon. This beacon uses inotify to watch configured files or directories on the minion for changes, creation, deletion etc.

This allows for the changes to be sent up to the master where the reactor can respond to changes.

## Sudo Minion Settings

It is now possible to run the minion as a non-root user and for the minion to execute commands via sudo. Simply add *sudo\_user: root* to the minion config, run the minion as a non-root user and grant that user sudo rights to execute salt-call.

## Lazy Loader

The Lazy Loader is a significant overhaul of Salt's module loader system. The Lazy Loader will lazily load modules on access instead of all on start. In addition to a major performance improvement, this ``sandboxes" modules so a bad/broken import of a single module will only affect jobs that require accessing the broken module. (:issue: 20274)

## Enhanced Active Directory Support

The eauth system for LDAP has been extended to support Microsoft Active Directory out of the box. This includes Active Directory and LDAP group support for eauth.

## Salt LXC Enhancements

The LXC systems have been overhauled to be more consistent and to fix many bugs.

This overhaul makes using LXC with Salt much easier and substantially improves the underlying capabilities of Salt's LXC integration.

## Salt SSH

- Additional configuration options and command line flags have been added to configure the scan roster on the fly
- Added support for `state.single` in `salt-ssh`
- Added support for `publish.publish`, `publish.full_data`, and `publish.runner` in `salt-ssh`
- Added support for `mine.get` in `salt-ssh`

## New Windows Installer

The new Windows installer changes how Salt is installed on Windows. The old installer used bbfreeze to create an isolated python environment to execute in. This made adding modules and python libraries difficult. The new installer sets up a more flexible python environment making it easy to manage the python install and add python modules.

Instead of frozen packages, a full python implementation resides in the bin directory (`C:\salt\bin`). By executing `pip` or `easy_install` from within the Scripts directory (`C:\salt\bin\Scripts`) you can install any additional python modules you may need for your custom environment.

The .exe's that once resided at the root of the salt directory (C:\salt) have been replaced by .bat files and should function the same way as the .exe's in previous versions.

The new Windows Installer will not replace the minion config file and key if they already exist on the target system. Only the salt program files will be replaced. C:\salt\conf and C:\salt\var will remain unchanged.

### Removed Requests Dependency

The hard dependency on the requests library has been removed. Requests is still required by a number of cloud modules but is no longer required for normal Salt operations.

This removal fixes issues that were introduced with requests and salt-ssh, as well as issues users experienced from the many different packaging methods used by requests package maintainers.

### Python 3 Updates

While Salt does not YET run on Python 3 it has been updated to INSTALL on Python 3, taking us one step closer. What remains is getting the test suite to the point where it can run on Python 3 so that we can verify compatibility.

### RAET Additions

The RAET support continues to improve. RAET now supports multi-master and many bugs and performance issues have been fixed. RAET is much closer to being a first class citizen.

### Modified File Detection

A number of functions have been added to the RPM-based package managers to detect and diff files that are modified from the original package installs. This can be found in the new pkg.modified functions.

### Reactor Update

Fix an infinite recursion problem for runner/wheel reactor jobs by passing a ``user" (Reactor) to all jobs that the reactor starts. The reactor skips all events created by that username -- thereby only reacting to events not caused by itself. Because of this, runner and wheel executions from the runner will have user ``Reactor" in the job cache.

### Misc Fixes/Additions

- SDB driver for etcd. (:issue: 22043)
- Add `only_upgrade` argument to `apt-based pkg.install` to only install a package version if the package is already installed. (Great for security updates!)
- Joyent now requires a `keyname` to be specified in the provider configuration. This change was necessitated upstream by the 7.0+ API.
- Add `args` argument to `cmd.script_retcodes` to match `cmd.script` in the `cmd` module. (:issue: 21122)
- Fixed bug where TCP keepalive was not being sent on the defined interval on the return port (4506) from minion to master. (:issue: 21465)
- `LocalClient` may now optionally raise `SaltClientError` exceptions. If using this class directly, checking for and handling this exception is recommended. (:issue: 21501)

- The SAuth object is now a singleton, meaning authentication state is global (per master) on each minion. This reduces sign-ins of minions from 3->1 per startup.
- Nested outputter has been optimized, it is now much faster.
- Extensive fileserver backend updates.

## Deprecations

- Removed parameter keyword argument from `eselect.exec_action` execution module.
- Removed `runas` parameter from the following `pip`` execution module functions: `install`, `uninstall`, `freeze`, `list_`, `list_upgrades`, `upgrade_available`, `upgrade`. Please migrate to `user`.
- Removed `runas` parameter from the following `pip` state module functions: `installed`, `removed`, `update`. Please migrate to `user`.
- Removed `quiet` option from all functions in `cmdmod` execution module. Please use `output_loglevel=quiet` instead.
- Removed `parameter` argument from `eselect.set_state`. Please migrate to `module_parameter` or `action_parameter`.
- The `salt_events` table schema has changed to include an additional field called `master_id` to distinguish between events flowing into a database from multiple masters. If `event_return` is enabled in the master config, the database schema must first be updated to add the `master_id` field. This alteration can be accomplished as follows:

```
ALTER TABLE salt_events ADD master_id VARCHAR(255) NOT NULL;
```

## Known Issues

- In multi-master mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting ``auth_timeout`` and ``auth_tries`` down to shorter periods.

## 35.2.2 Salt 2015.5.1 Release Notes

release 2015-05-20

Version 2015.5.1 is a bugfix release for 2015.5.0.

Changes:

- `salt.runners.cloud.action()` has changed the `fun` keyword argument to `func`. Please update any calls to this function in the cloud runner.

Extended Changelog Courtesy of Todd Stansell (<https://github.com/tjstansell/salt-changelogs>):

**PR #23989: (rallytime) Backport #23980 to 2015.5 @ 2015-05-20T19:33:41Z**

- **PR #23980:** (*iggy*) template: `jinja2` -> `jinja` | refs: #23989
- 117ecb1 Merge pull request #23989 from rallytime/bp-23980
- 8f8557c template: `jinja2` -> `jinja`

**PR #23988: (rallytime) Backport #23977 to 2015.5 @ 2015-05-20T19:13:36Z**

- **PR #23977:** (*ionutbalutoiu*) Fixed glance `image_create` | refs: #23988

- d4f1ba0 Merge pull request #23988 from rallytime/bp-23977
- 46fc7c6 Fixed glance image\_create

**PR #23986: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-20T18:41:33Z**

- PR #23965: (hvnsweeting) handle all exceptions gitpython can raise
- 9566e7d Merge pull request #23986 from basepi/merge-forward-2015.5
- 0b78156 Merge remote-tracking branch `upstream/2014.7' into merge-forward-2015.5
- 314e4db Merge pull request #23965 from hvnsweeting/20147-fix-gitfs-gitpython-exception
- 2576301 handle all exception gitpython can raise

**PR #23985: (UtahDave) Add 2014.7.5-2 and 2015.5.0-2 Windows installer download links @ 2015-05-20T18:32:44Z**

- 9d1130e Merge pull request #23985 from UtahDave/2015.5local
- 10338d0 Add links to Windows 2015.5.0-2 install downloads
- b84f975 updated Windows 2014.7.5-2 installer download link

**PR #23983: (rallytime) Versionadded tags for https\_user and https\_pass args new in 2015.5.0 @ 2015-05-20T18:05:27Z**

- ca7729d Merge pull request #23983 from rallytime/versionadded\_git\_options
- 14eae22 Versionadded tags for https\_user and https\_pass args new in 2015.5.0

**PR #23970: (jayeshka) adding system unit test case @ 2015-05-20T17:12:57Z**

- b06df57 Merge pull request #23970 from jayeshka/system-unit-test
- 89eb008 adding system unit test case

**PR #23967: (jayeshka) adding states/memcached unit test case @ 2015-05-20T17:12:26Z**

- 38d5f75 Merge pull request #23967 from jayeshka/memcached-states-unit-test
- 8ef9240 adding states/memcached unit test case

**PR #23966: (jayeshka) adding states/modjk unit test case @ 2015-05-20T17:11:48Z**

- 868e807 Merge pull request #23966 from jayeshka/modjk-states-unit-test
- 422a964 adding states/modjk unit test case

**PR #23942: (jacobhammons) Updates to sphinx saltstack2 doc theme @ 2015-05-20T15:43:54Z**

- 6316490 Merge pull request #23942 from jacobhammons/2015.5
- 31023c8 Updates to sphinx saltstack2 doc theme

**PR #23874: (joejulian) Validate keyword arguments to be valid @ 2015-05-20T04:53:40Z**

- ISSUE #23872: (joejulian) create\_ca\_signed\_cert can error if dereferenced dict is used for args | refs: #23874
- 587957b Merge pull request #23874 from joejulian/2015.5\_tls\_validate\_kwargs
- 30102ac Fix py3 and ordering inconsistency problems.
- 493f7ad Validate keyword arguments to be valid

**PR #23960: (rallytime) Backport #22114 to 2015.5 @ 2015-05-20T04:37:09Z**

- PR #22114: (dmyerscough) Fixing KeyError when there are no additional pages | refs: #23960

- 00c5c22 Merge pull request #23960 from rallytime/bp-22114
- f3e1d63 Catch KeyError
- 306b1ea Fixing KeyError
- 6b2cda2 Fix PEP8 complaint
- 239e50f Fixing KeyError when there are no additional pages

**PR #23961: (rallytime) Backport #23944 to 2015.5 @ 2015-05-20T04:35:41Z**

- PR #23944: (ryan-lane) Add missing loginclass argument to \_changes call | refs: #23961
- 4648b46 Merge pull request #23961 from rallytime/bp-23944
- 970d19a Add missing loginclass argument to \_changes call

**PR #23948: (jfindlay) augeas.change state now returns changes as a dict @ 2015-05-20T04:00:10Z**

- 0cb5cd3 Merge pull request #23948 from jfindlay/augeas\_changes
- f09b80a augeas.change state now returns changes as a dict

**PR #23957: (rallytime) Backport #23951 to 2015.5 @ 2015-05-20T03:04:24Z**

- PR #23951: (ryan-lane) Do not check perms in file.copy if preserve | refs: #23957
- 2d185f7 Merge pull request #23957 from rallytime/bp-23951
- 996b431 Update file.py
- 85d461f Do not check perms in file.copy if preserve

• **PR #23956: (rallytime) Backport #23906 to 2015.5 @ 2015-05-20T03:04:14Z**

- ISSUE #23839: (gladiatr72) wonky loader syndrome | refs: #23906
- ISSUE #23373: (tnypex) reactor/orchestrator race condition on salt['pillar.get'] | refs: #23906
- PR #23906: (gladiatr72) Added exception handler to trap the RuntimeError raised when | refs: #23956
- ebf1ff Merge pull request #23956 from rallytime/bp-23906
- 9d87fd3 add proper marker for format argument
- 197688e Added exception handler to trap the RuntimeError raised when Depends.enforce\_dependency() class method fires unsuccessfully. There appears to be no synchronization within the Depends decorator class wrt the class global\_dependency\_dict which results in incomplete population of any loader instantiation occurring at the time of one of these exceptions.

• **PR #23955: (rallytime) Backport #19305 to 2015.5 @ 2015-05-20T03:03:55Z**

- ISSUE #19852: (TaiSHiNet) DigitalOcean APIv2 can't delete machines when there is only 1 page | refs: #23955
- ISSUE #19304: (TaiSHiNet) DigitalOcean API v2 cannot delete VMs on 2nd page | refs: #19305
- PR #19305: (TaiSHiNet) Fixes droplet listing past page 1 | refs: #23955
- da3f919 Merge pull request #23955 from rallytime/bp-19305
- bb2429 Fixes droplet listing past page 1

• **PR #23940: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-19T22:37:58Z**

- ISSUE #23820: (UtahDave) 2014.7.5 schedule error | refs: #23881
- ISSUE #22131: (quixoten) ``unexpected keyword argument `merge'' on 2014.7.2 (salt-ssh) | refs: #23887

- PR #23939: (*basepi*) Add extended changelog to 2014.7.6 release notes
- PR #23887: (*basepi*) [2014.7] Bring salt-ssh pillar.get in line with mainline pillar.get
- PR #23881: (*garethgreenaway*) Fixes to schedule module in 2014.7
- 02a78fc Merge pull request #23940 from basepi/merge-forward-2015.5
- 36f0065 Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
  - \* 9133912 Merge pull request #23939 from basepi/v2014.7.6release
    - 32b65dc Add extended changelog to 2014.7.6 release notes
  - \* 0031ca2 Merge pull request #23881 from garethgreenaway/23820\_2014\_7\_schedule\_list\_issue
    - b207f2a Missing continue in the list function when deleting unused attributes.
  - \* 63bd21e Merge pull request #23887 from basepi/salt-ssh.pillar.get.22131
    - bc84502 Bring salt-ssh pillar.get in line with mainline pillar.get
- PR #23932: (*rallytime*) Backport #23908 to 2015.5 @ 2015-05-19T21:41:28Z
  - PR #23908: (*nleib*) fix connection function to mongo | refs: #23932
  - ee4c01b Merge pull request #23932 from rallytime/bp-23908
  - 5d520c9 fix connection function to mongo
- PR #23931: (*rallytime*) Backport #23880 to 2015.5 @ 2015-05-19T21:41:18Z
  - PR #23880: (*bastiaanb*) if setting client\_config\_dir to '~', expand path | refs: #23931
  - 70bd407 Merge pull request #23931 from rallytime/bp-23880
  - 8ce59a2 if setting client\_config\_dir to '~', expand path
- PR #23898: (*kiorky*) Lxc profiles | refs: #23897 @ 2015-05-19T21:08:28Z
  - ISSUE #23847: (*kiorky*) lxc: systemd containers cant be seeded | refs: #23806 #23898 #23897 #23808
  - ISSUE #23833: (*kiorky*) lxc.set\_dns fails intermittently | refs: #23898 #23807 #23897 #23808
  - ISSUE #23772: (*cheuschober*) lxc.init fails to bootstrap container | refs: #23806 #23898 #23807 #23897 #23808
  - ISSUE #23658: (*arthurlogilab*) [salt-cloud lxc] too verbose, shows host: True multiple times when starting | refs: #23898 #23897
  - ISSUE #23657: (*arthurlogilab*) [salt-cloud lxc] NameError: global name '\_\_salt\_\_' is not defined | refs: #23727 #23898 #23897
  - PR #23897: (*kiorky*) Lxc seed and prof ports | refs: #23898
  - PR #23808: (*kiorky*) Lxc seed and prof ports | refs: #23807 #23897
  - PR #23807: (*kiorky*) Lxc profiles | refs: #23898
  - PR #23806: (*kiorky*) Lxc seeding | refs: #23807
  - 5bdbf0a Merge pull request #23898 from makinacorp/lxc\_profiles
  - d9051a0 lxc: systemd support
  - e8d674f lxc: chroot fallback toggle
  - e2887a0 lxc: sync func name with develop
  - e96e345 lxc more fixes (lxc.set\_dns)

- fdb6424 lxc: Fix salt config (no more a kwarg)
- 63e63fa repair salt cloud lxc api on develop
- 80eabe2 lxc salt cloud doc
- 73f229d lxc: unificate saltconfig/master/master\_port
- 0bc1f08 lxc: refactor a bit saltcloud/lxc interface
- 7a80370 lxc: get networkprofile from saltcloud
- 47acb2e lxc: default net profile has now correct options
- 7eadf48 lxc: select the appropriate default bridge
- **PR #23922:** (*garethgreenaway*) Fixes to debian\_ip.py @ 2015-05-19T18:50:53Z
  - **ISSUE #23900:** (*hashi825*) salt ubuntu network building issue 2015.5.0 | refs: #23922
  - b818f72 Merge pull request #23922 from garethgreenaway/23900\_2015\_5\_bonding\_interface\_fixes
  - 0bba536 Fixing issue reported when using bonded interfaces on Ubuntu. Attributes should be bond-, but the code was attempting to split just on **bond\_**. Fix accounts for both, but the debian\_ip.py module will write out bond attributes with bond-
- **PR #23925:** (*jplic*) Fixed wrong path in LXC cloud documentation @ 2015-05-19T18:23:56Z
  - **PR #23924:** (*jplic*) Fixed wrong path in LXC cloud documentation | refs: #23925
  - b1c98a3 Merge pull request #23925 from jplic/fix/wrong\_lxc\_path
  - a4bcd75 Fixed wrong path in LXC cloud documentation
- **PR #23894:** (*whiteinge*) Add \_\_all\_\_ attribute to Mock class for docs @ 2015-05-19T17:17:35Z
  - 7f6a716 Merge pull request #23894 from whiteinge/doc-mock\_\_all\_\_
  - 6eeca46 Add \_\_all\_\_ attribute to Mock class for docs
- **PR #23884:** (*jfindlay*) Fix locale.set\_locale on debian @ 2015-05-19T15:51:22Z
  - **ISSUE #23767:** (*chrimi*) Salt system.locale fails on non existent default locale | refs: #23884
  - 8108a9b Merge pull request #23884 from jfindlay/fix\_locale
  - 91c2d51 use append\_if\_not\_found in locale.set\_locale
  - e632603 (re)generate /etc/default/locale
- **PR #23866:** (*jfindlay*) backport #23834, change portage.dep.strip\_empty to list comprehension @ 2015-05-19T15:50:43Z
  - **PR #23834:** (*Arabus*) Avoid deprecation warning from portage.dep.strip\_empty() | refs: #23866
  - 6bae12f Merge pull request #23866 from jfindlay/flag\_strip
  - aa032cc replace portage.dep.strip\_empty() with list comprehension
  - 7576872 Proper replacement for portage.dep.strip\_empty() with list comprehension, pep8fix
  - 2851a5c Switch portage.dep.strip\_empty(...) to filter(None,...) to avoid deprecation warning and do essentially the same
- **PR #23917:** (*corywright*) Split debian bonding options on dash instead of underscore @ 2015-05-19T15:44:35Z
  - **ISSUE #23904:** (*mbrgm*) Network config bonding section cannot be parsed when attribute names use dashes | refs: #23917
  - a67a008 Merge pull request #23917 from corywright/issue23904

- c06f8cf Split debian bonding options on dash instead of underscore
- PR #23909: (*jayeshka*) `str` object has no attribute `capitalized` @ 2015-05-19T15:41:53Z
  - e8fcd09 Merge pull request #23909 from jayeshka/file-exe-module
  - e422d9d `str` object has no attribute `capitalized`
- PR #23903: (*garethgreenaway*) Adding docs for missing schedule state module parameters. @ 2015-05-19T06:29:34Z
  - c73bf38 Merge pull request #23903 from garethgreenaway/missing\_docs\_schedule\_state
  - acd8ab9 Adding docs for missing schedule state module parameters.
- f7eb70c changed previous release to 2014.7.6
- 608059f Merge branch `2015.5' of <https://github.com/jacobhammons/salt> into 2015.5
  - a56697b Merge branch `2015.5' of <https://github.com/saltstack/salt> into 2015.5
  - 1c2af5c Merge branch `2015.5' of <https://github.com/saltstack/salt> into 2015.5
  - ef58128 Merge branch `2015.5' of <https://github.com/saltstack/salt> into 2015.5
  - 8664e8b Merge branch `2015.5' of <https://github.com/saltstack/salt> into 2015.5-2
  - 46eb265 saltstack2 sphinx theme updates
  - e7442d3 Merge branch `2015.5' of <https://github.com/saltstack/salt> into 2015.5
  - ee3c1bd missed one
  - 3872921 More updates to sphinx2 theme
  - fcd4865 Merge branch `2015.5' of <https://github.com/saltstack/salt> into 2015.5
  - 8c32152 removed TOC numbering, additional tweaks to layout.html
  - 73dfaef Merge branch `2015.5' of <https://github.com/saltstack/salt> into 2015.5
  - 16d8a75 saltstack2 sphinx theme and build settings
- PR #23806: (*kiorky*) Lxc seeding | refs: #23807 @ 2015-05-18T23:18:33Z
  - ISSUE #23847: (*kiorky*) lxc: systemd containers cant be seeded | refs: #23806 #23898 #23897 #23808
  - ISSUE #23772: (*cheuschober*) lxc.init fails to bootstrap container | refs: #23806 #23898 #23807 #23897 #23808
  - ff3cc7d Merge pull request #23806 from makinacorpus/lxc\_seeding
  - 61b7aad runners/lxc: optim
- PR #23892: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-18T23:07:57Z
  - PR #23891: (*basepi*) Update the release notes index page
  - PR #23888: (*basepi*) Update the 2014.7.6 release notes with CVE details
  - PR #23871: (*rallytime*) Backport #23848 to 2014.7
  - PR #23848: (*dumol*) Updated installation docs for SLES 12. | refs: #23871
  - 5f1a93d Merge pull request #23892 from basepi/merge-forward-2015.5
  - c2eed77 Merge remote-tracking branch `upstream/2014.7' into merge-forward-2015.5
  - 17c5810 Merge pull request #23891 from basepi/releasenotes
    - \* dec153b Update the release notes index page

- a93e58f Merge pull request #23888 from basepi/v2014.7.6release
  - \* 49921b6 Update the 2014.7.6 release notes with CVE details
- 5073028 Merge pull request #23871 from rallytime/bp-23848
  - \* 379c09c Updated for SLES 12.
- PR #23875: (*rallytime*) Backport #23838 to 2015.5 @ 2015-05-18T22:28:55Z
  - PR #23838: (*gtmanfred*) add refresh\_beacons and sync\_beacons | refs: #23875
  - 66d1335 Merge pull request #23875 from rallytime/bp-23838
  - 3174227 Add versionadded directives to new beacon saltutil functions
  - 4a94b2c add refresh\_beacons and sync\_beacons
- PR #23876: (*rallytime*) Switch digital ocean tests to v2 driver @ 2015-05-18T22:17:13Z
  - d294cf2 Merge pull request #23876 from rallytime/switch\_digital\_ocean\_tests\_v2
  - dce9b54 Remove extra line
  - 4acf58e Switch digital ocean tests to v2 driver
- PR #23882: (*garethgreenaway*) Fixes to scheduler in 2015.5 @ 2015-05-18T22:09:24Z
  - ISSUE #23792: (*neogenix*) Salt Scheduler Incorrect Response (True, should be False) | refs: #23882
  - b97a48c Merge pull request #23882 from garethgreenaway/23792\_2015\_5\_wrong\_return\_code
  - 37dbde6 Job already exists in schedule, should return False.
- PR #23868: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-18T18:35:54Z
  - ISSUE #20198: (*jcftang*) virt.get\_graphics, virt.get\_nics are broken, in turn breaking other things | refs: #23809
  - PR #23823: (*gtmanfred*) add link local for ipv6
  - PR #23810: (*rallytime*) Backport #23757 to 2014.7
  - PR #23809: (*rallytime*) Fix virtualport section of virt.get\_nics loop
  - PR #23802: (*gtmanfred*) if it is ipv6 ip\_to\_int will fail
  - PR #23757: (*clan*) use abspath, do not eliminating symlinks | refs: #23810
  - PR #23573: (*techhat*) Scan all available networks for public and private IPs | refs: #23802
  - PR #21487: (*rallytime*) Backport #21469 to 2014.7 | refs: #23809
  - PR #21469: (*vdesjardins*) fixes #20198: virt.get\_graphics and virt.get\_nics calls in module virt | refs: #21487
  - 61c922e Merge pull request #23868 from basepi/merge-forward-2015.5
  - c9ed233 Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
  - aee00c8 Merge pull request #23810 from rallytime/bp-23757
    - \* fb32c32 use abspath, do not eliminating symlinks
  - 6b3352b Merge pull request #23809 from rallytime/virt\_get\_nics\_fix
    - \* 0616fb7 Fix virtualport section of virt.get\_nics loop
  - 188f03f Merge pull request #23823 from gtmanfred/2014.7
    - \* 5ef006d add link local for ipv6

- f3ca682 Merge pull request #23802 from gtmanfred/2014.7
  - \* 2da98b5 if it is ipv6 ip\_to\_int will fail
- PR #23863: (*rahulhan*) Adding states/timezone.py unit test @ 2015-05-18T17:02:19Z
  - 433f873 Merge pull request #23863 from rahulhan/states\_timezone\_unit\_test
  - 72fcabc Adding states/timezone.py unit test
- PR #23862: (*rahulhan*) Adding states/tomcat.py unit tests @ 2015-05-18T17:02:10Z
  - 37b3ee5 Merge pull request #23862 from rahulhan/states\_tomcat\_unit\_test
  - 65d7752 Adding states/tomcat.py unit tests
- PR #23860: (*rahulhan*) Adding states/test.py unit tests @ 2015-05-18T17:01:49Z
  - dde7207 Merge pull request #23860 from rahulhan/states\_test\_unit\_test
  - 1f4cf86 Adding states/test.py unit tests
- PR #23859: (*rahulhan*) Adding states/sysrc.py unit tests @ 2015-05-18T17:01:46Z
  - 3c9b813 Merge pull request #23859 from rahulhan/states\_sysrc\_unit\_test
  - 6a903b0 Adding states/sysrc.py unit tests
- PR #23812: (*rallytime*) Backport #23790 to 2015.5 @ 2015-05-18T15:30:34Z
  - PR #23790: (*aboe76*) updated suse spec file to version 2015.5.0 | refs: #23812
  - 4cf30a7 Merge pull request #23812 from rallytime/bp-23790
  - 3f65631 updated suse spec file to version 2015.5.0
- PR #23811: (*rallytime*) Backport #23786 to 2015.5 @ 2015-05-18T15:30:27Z
  - PR #23786: (*kaithar*) Log the error generated that causes returns.mysql.returner to except. | refs: #23811
  - c6f939a Merge pull request #23811 from rallytime/bp-23786
  - 346f30b Log the error generated that causes returns.mysql.returner to except.
- PR #23850: (*jayeshka*) adding sysbench unit test case @ 2015-05-18T15:28:04Z
  - ce60582 Merge pull request #23850 from jayeshka/sysbench-unit-test
  - 280abde adding sysbench unit test case
- PR #23843: (*The-Loeki*) Fix erroneous virtual:physical core grain detection @ 2015-05-18T15:24:22Z
  - 060902f Merge pull request #23843 from The-Loeki/patch-1
  - 9e2cf60 Fix erroneous virtual:physical core grain detection
- PR #23816: (*Snergster*) Doc for #23685 Added prereq, caution, and additional mask information @ 2015-05-18T15:18:03Z
  - ISSUE #23815: (*Snergster*) [beacons] inotify errors on subdir creation | refs: #23816
  - 3257a9b Merge pull request #23816 from Snergster/23685-doc-fix
  - 0fca49d Added prereq, caution, and additional mask information
- PR #23832: (*ahus1*) make saltify provider use standard bootstrap procedure @ 2015-05-18T02:18:29Z
  - PR #23829: (*ahus1*) make saltify provider use standard bootstrap procedure | refs: #23832
  - 3df3b85 Merge pull request #23832 from ahus1/ahus1\_saltify\_bootstrap\_2015.5

- f5b1734 fixing problem in unit test
- cba47f6 make saltify to use standard bootstrap procedure, therefore providing all options like master\_sign\_pub\_file
- PR #23791: (*optix2000*) Psutil compat @ 2015-05-16T04:05:54Z
  - 8ec4fb2 Merge pull request #23791 from optix2000/psutil\_compat
  - 5470cf5 Fix pylint errors and sloppy inline comments
  - 64634b6 Update psutil.pid\_list to use psutil.pids
  - 5dd6d69 Fix imports that aren't in \_\_all\_\_
  - 8a1da33 Fix test cases by mocking psutil\_compat
  - 558798d Fix net\_io\_counters deprecation issue
  - 8140f92 Override unnecessary pylint errors
  - 7d02ad4 Fix some of the mock names for the new API
  - 9b3023e Fix overloaded getters/setters. Fix line lengths
  - 180eb87 Fix whitespace
  - f8edf72 Use new psutil API in ps module
  - e48982f Fix version checking in psutil\_compat
  - 93ee411 Create compatibility psutil. psutil 3.0 drops 1.0 API, but we still support old psutil versions.
- PR #23782: (*terminalmage*) Replace ``command -v`` with ``which`` and get rid of spurious log messages @ 2015-05-16T04:03:10Z
  - 405517b Merge pull request #23782 from terminalmage/issue23772
  - 0f6f239 More ignore\_retcode to suppress spurious log msgs
  - b4c48e6 Ignore return code in lxc.attachable
  - 08658c0 Replace ``command -v`` with ``which``
- PR #23783: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-15T21:38:51Z
  - ISSUE #22959: (*highlyunavailable*) Windows Salt hangs if file.directory is trying to write to a drive that doesn't exist
  - ISSUE #22332: (*rallytime*) [salt-ssh] Add a check for host in /etc/salt/roster | refs: #23748
  - ISSUE #16424: (*stanvit*) salt-run cloud.create fails with saltify
  - PR #23748: (*basepi*) [2014.7] Log salt-ssh roster render errors more assertively and verbosely
  - PR #23731: (*twangboy*) Fixes #22959: Trying to add a directory to an unmapped drive in windows
  - PR #23730: (*rallytime*) Backport #23729 to 2014.7
  - PR #23729: (*rallytime*) Partially merge #23437 (grains fix) | refs: #23730
  - PR #23688: (*twangboy*) Added inet\_pton to utils/validate/net.py for ip.set\_static\_ip in windows
  - PR #23488: (*cellscape*) LXC cloud fixes
  - PR #23437: (*cedwards*) Grains item patch | refs: #23729
  - cb2eb40 Merge pull request #23783 from basepi/merge-forward-2015.5
  - 9df51ca \_\_opts\_\_.get

- 51d23ed Merge remote-tracking branch `upstream/2014.7' into merge-forward-2015.5
  - \* d9af0c3 Merge pull request #23488 from cellscape/lxc-cloud-fixes
    - 64250a6 Remove profile from opts after creating LXC container
    - c4047d2 Set destroy=True in opts when destroying cloud instance
    - 9e1311a Store instance names in opts when performing cloud action
    - 934bc57 Correctly pass custom env to lxc-attach
    - 7fb85f7 Preserve test=True option in cloud states
    - 9771b5a Fix detection of absent LXC container in cloud state
    - fb24f0c Report failure when failed to create/clone LXC container
    - 2d9aa2b Avoid shadowing variables in lxc module
    - 792e102 Allow to override profile options in lxc.cloud\_init\_interface
    - 42bd64b Return changes on successful lxc.create from salt-cloud
    - 4409eab Return correct result when creating cloud LXC container
    - 377015c Issue #16424: List all providers when creating salt-cloud instance without profile
  - \* 808bbe1 Merge pull request #23748 from basepi/salt-ssh.roster.host.check
    - bc53e04 Log entire exception for render errors in roster
    - 753de6a Log render errors in roster to error level
    - e01a7a9 Always let the real YAML error through
  - \* 72cf360 Merge pull request #23731 from twangboy/fix\_22959
    - 88e5495 Fixes #22959: Trying to add a directory to an unmapped drive in windows
  - \* 2610195 Merge pull request #23730 from rallytime/bp-23729
    - 1877cae adding support for nested grains to grains.item
  - \* 3e9df88 Merge pull request #23688 from twangboy/fix\_23415
    - 6a91169 Fixed unused-import pylint error
    - 5e25b3f fixed pylint errors
    - 1a96766 Added inet\_pton to utils/validate/net.py for ip.set\_static\_ip in windows
- **PR #23781:** (*jfindlay*) fix unit test mock errors on arch @ 2015-05-15T19:40:07Z
  - 982f873 Merge pull request #23781 from jfindlay/fix\_locale\_tests
  - 14c711e fix unit test mock errors on arch
- **PR #23740:** (*jfindlay*) Binary write @ 2015-05-15T18:10:44Z
  - **ISSUE #23566:** (*rks2286*) Salt-cp corrupting the file after transfer to minion | refs: #23740
  - 916b1c4 Merge pull request #23740 from jfindlay/binary\_write
  - 626930a update incorrect comment wording
  - a978f5c always use binary file write mode on windows
- **PR #23736:** (*jfindlay*) always load pip execution module @ 2015-05-15T18:10:16Z

- ISSUE #23682: (*chrish42*) Pip module requires system pip, even when not used (with `env_bin`) | refs: #23736
- 348645e Merge pull request #23736 from *jfindlay/fix\_pip*
- b8867a8 update pip tests
- 040bbc4 only check pip version in one place
- 6c453a5 check for executable status of `bin_env`
- 3337257 always load the pip module as pip could be anywhere
- PR #23770: (*cellscape*) Fix cloud LXC container destruction @ 2015-05-15T17:38:59Z
  - 10cedfb Merge pull request #23770 from *cellscape/fix-cloud-lxc-destruction*
  - 4f6021c Fix cloud LXC container destruction
- PR #23759: (*lisa2lisa*) fixed the problem for not beable to revoke `.`, for more detail <https://github.com/saltstack/salt/issues/23201>, fixed mysql cannot create user with pure digit password, for more info <https://github.com/saltstack/salt/issues/23664> @ 2015-05-15T17:38:38Z

  - 297b055 adding states/layman unit test case
- **PR #23580:** (*jayeshka*) adding smf unit test case @ 2015-05-12T16:29:58Z
  - cbe3282 Merge pull request #23580 from jayeshka/smf-unit-test
  - 4f97191 adding smf unit test case
- **PR #23572:** (*The-Loeki*) Fix regression of #21355 introduced by #21603 @ 2015-05-12T16:28:05Z
  - **ISSUE #21603:** (*ipmb*) ssh\_auth.present fails on key without comment | refs: #23572 #23572
  - **PR #21355:** (*The-Loeki*) Fix for comments containing whitespaces
  - 16a3338 Merge pull request #23572 from The-Loeki/ssh\_auth\_fix
  - d8248dd Fix regression of #21355 introduced by #21603
- **PR #23565:** (*garethgreenaway*) fix to aptpkg module @ 2015-05-12T16:25:46Z
  - **ISSUE #23490:** (*lichtamberg*) salt.modules.aptpkg.upgrade should have default ``dist\_upgrade=False" | refs: #23565
  - f843f89 Merge pull request #23565 from garethgreenaway/2015\_2\_aptpkg\_upgrade\_default\_to\_upgrade
  - 97ae514 aptpkg.upgrade should default to upgrade instead of dist\_upgrade.
- **PR #23550:** (*jfindlay*) additional mock for rh\_ip\_test test\_build\_bond @ 2015-05-12T15:17:16Z

- ISSUE #23473: (*terminalmage*) unit.modules.rh\_ip\_test.RhipTestCase.test\_build\_bond is not properly mocked | refs: #23550
- c1157cd Merge pull request #23550 from jfindlay/fix\_rh\_ip\_test
- e9b94d3 additional mock for rh\_ip\_test test\_build\_bond
- PR #23552: (*garethgreenaway*) Fix for an issue caused by a previous pull request @ 2015-05-11T21:54:59Z
  - b593328 Merge pull request #23552 from garethgreenaway/2015\_5\_returner\_fix\_broken\_previous\_pr
  - 7d70e2b Passed argumentes in the call \_fetch\_profile\_opts to were in the wrong order
- PR #23547: (*slinu3d*) Added AWS v4 signature support for 2015.5 @ 2015-05-11T21:52:24Z
  - d0f9682 Merge pull request #23547 from slinu3d/2015.5
  - f3bfbdb Fixed urlparse and urlencode calls
  - 802dbdb Added AWS v4 signature support for 2015.5
- PR #23544: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-11T18:02:06Z
  - ISSUE #23159: (*aneeshusa*) Unused validator
  - ISSUE #20518: (*ekle*) module s3.get does not support eu-central-1 | refs: #23467
  - ISSUE #563: (*chutz*) pidfile support for minion and master daemons | refs: #23460 #23461
  - PR #23538: (*cro*) Update date in LICENSE file
  - PR #23505: (*aneeshusa*) Remove unused ssh config validator. Fixes #23159.
  - PR #23467: (*slinu3d*) Added AWS v4 signature support
  - PR #23460: (*s0undt3ch*) [2014.7] Update to latest stable bootstrap script v2015.05.07
  - PR #23444: (*techhat*) Add create\_attach\_volume to nova driver
  - PR #23439: (*techhat*) Add wait\_for\_passwd\_maxtries variable
  - 06c6a1f Merge pull request #23544 from basepi/merge-forward-2015.5
  - f8a36bc Merge remote-tracking branch `upstream/2014.7' into merge-forward-2015.5
    - \* b79fed3 Merge pull request #23538 from cro/licupdate
      - 345efe2 Update date in LICENSE file
    - \* a123a36 Merge pull request #23505 from aneeshusa/remove-unused-ssh-config-validator
      - 90af167 Remove unused ssh config validator. Fixes #23159.
    - \* ca2c21a Merge pull request #23467 from slinu3d/2014.7
      - 0b4081d Fixed pylint error at line 363
      - 5be5eb5 Fixed pylink errors
      - e64f374 Fixed lint errors
      - b9d1ac4 Added AWS v4 signature support
    - \* e6f9eec Merge pull request #23444 from techhat/novacreateattach
      - ebdb7ea Add create\_attach\_volume to nova driver
    - \* e331463 Merge pull request #23460 from s0undt3ch/hotfix/bootstrap-script-2014.7
      - edcd0c4 Update to latest stable bootstrap script v2015.05.07

- \* 7a8ce1a Merge pull request #23439 from techhat/maxtries
  - 0ad3ff2 Add wait\_for\_passwd\_maxtries variable
- PR #23470: (*twangboy*) Fixed service.restart for salt-minion @ 2015-05-11T17:54:47Z
  - ISSUE #23426: (*twangboy*) Can't restart salt-minion on 64 bit windows (2015.5.0) | refs: #23470
  - aa5b896 Merge pull request #23470 from twangboy/fix\_svc\_restart
  - b3f284c Fixed tests
  - ad44d79 Fixed service.restart for salt-minion
- PR #23539: (*rahulhan*) Adding states/virtualenv\_mod.py unit tests @ 2015-05-11T17:02:31Z
  - 67988b2 Merge pull request #23539 from rahulhan/states\_virtualenv\_mod\_unit\_test
  - 750bb07 Adding states/virtualenv\_mod.py unit tests
- 6f0cf2e Merge remote-tracking branch `upstream/2015.2' into 2015.5
  - ISSUE #23244: (*freimer*) Caller not available in reactors | refs: #23245
  - PR #23509: (*keesbos*) Catch the unset (empty/None) environment case
  - PR #23423: (*cachedout*) Remove jid\_event from state.orch
  - PR #23245: (*freimer*) Add Caller functionality to reactors.
  - c966196 Merge pull request #23423 from cachedout/remove\_jid\_event\_from\_orch
    - \* f81aab7 Remove jid\_event from state.orch
  - 2bb09b7 Merge pull request #23509 from keesbos/Catch\_empty\_environment
    - \* 6dedeac Catch the unset (empty/None) environment case
  - 6d42f30 Merge pull request #23245 from freimer/issue\_23244
    - \* 24cf6eb Add Caller functionality to reactors.
- PR #23513: (*gladiatr72*) short-circuit auto-failure of iptables.delete state @ 2015-05-11T15:18:33Z
  - c3f03d8 Merge pull request #23513 from gladiatr72/RFC\_stop\_iptables.check\_from\_short-circuiting\_position-only\_delete\_rule
  - c71714c short-circuit auto-failure of iptables.delete state if position argument is set without the other accoutrements that check\_rule requires.
- PR #23534: (*jayeshka*) adding states/ini\_manage unit test case @ 2015-05-11T14:32:06Z
  - 4e77f6f Merge pull request #23534 from jayeshka/ini\_manage\_states-unit-test
  - 831223c adding states/ini\_manage unit test case
- PR #23533: (*jayeshka*) adding states/hipchat unit test case @ 2015-05-11T14:30:22Z
  - 11ba9ed Merge pull request #23533 from jayeshka/hipchat-states-unit-test
  - 41d14b3 adding states/hipchat unit test case
- PR #23532: (*jayeshka*) adding states/ipmi unit test case @ 2015-05-11T14:28:15Z
  - e542113 Merge pull request #23532 from jayeshka/ipmi-states-unit-test
  - fc3e64a adding states/ipmi unit test case
- PR #23531: (*jayeshka*) adding service unit test case @ 2015-05-11T14:27:12Z
  - 9ba85fd Merge pull request #23531 from jayeshka/service-unit-test

- 3ad5314 adding service unit test case
- PR #23517: (*garethgreenaway*) fix to returners @ 2015-05-11T14:20:51Z
  - ISSUE #23512: (*Code-Vortex*) hipchat\_returner / slack\_returner not work correctly | refs: #23517
  - 32838cd Merge pull request #23517 from garethgreenaway/23512\_2015\_5\_returners\_with\_profiles
  - 81e31e2 fix for returners that utilize profile attributes. code in the if else statement was backwards. #23512
- PR #23502: (*rahulhan*) Adding states/win\_servermanager.py unit tests @ 2015-05-08T19:47:18Z
  - 6be7d8d Merge pull request #23502 from rahulhan/states\_win\_servermanager\_unit\_test
  - 2490074 Adding states/win\_servermanager.py unit tests
- PR #23495: (*jayeshka*) adding seed unit test case @ 2015-05-08T17:30:38Z
  - 6048578 Merge pull request #23495 from jayeshka/seed-unit-test
  - 3f134bc adding seed unit test case
- PR #23494: (*jayeshka*) adding sensors unit test case @ 2015-05-08T17:30:18Z
  - 70bc3c1 Merge pull request #23494 from jayeshka/sensors-unit-test
  - 1fb48a3 adding sensors unit test case

  - b261c95 Add note to 2015.2.0 release notes about master opts in pillar

- **PR #23393:** (*basepi*) [2015.2] Add warning about python\_shell changes to 2015.2.0 release notes @ 2015-05-05T22:12:46Z
  - f79aed5 Merge pull request #23393 from basepi/2015.2.0python\_shell
  - b2f033f Add CLI note
  - 48e7b3e Add warning about python\_shell changes to 2015.2.0 release notes
- **PR #23380:** (*gladiatr72*) Fix for double output with static salt cli/v2015.2 @ 2015-05-05T21:44:28Z
  - a977776 Merge pull request #23380 from gladiatr72/fix\_for\_double\_output\_with\_static\_\_salt\_CLI/v2015.2
  - c47fdd7 Actually removed the `static` bits from below the else: fold this time.
  - 4ee3679 Fix for incorrect output with salt CLI `--static` option
- **PR #23379:** (*rahulhan*) Adding states/rabbitmq\_cluster.py @ 2015-05-05T21:44:06Z
  - 5c9543c Merge pull request #23379 from rahulhan/states\_rabbitmq\_cluster\_test
  - 04c22d1 Adding states/rabbitmq\_cluster.py
- **PR #23377:** (*rahulhan*) Adding states/xmpp.py unit tests @ 2015-05-05T21:43:35Z
  - 430f080 Merge pull request #23377 from rahulhan/states\_xmpp\_test
  - 32923b5 Adding states/xmpp.py unit tests
- **PR #23335:** (*steverweber*) 2015.2: include doc in master config for module\_dirs @ 2015-05-05T21:28:58Z
  - 8c057e6 Merge pull request #23335 from steverweber/2015.2
  - 5e3bae9 help installing python pysphere lib
  - 97513b0 include module\_dirs
  - 36b1c87 include module\_dirs
- **PR #23362:** (*jayeshka*) adding states/zk\_concurrency unit test case @ 2015-05-05T15:50:06Z
  - 1648253 Merge pull request #23362 from jayeshka/zk\_concurrency-states-unit-test
  - f60dda4 adding states/zk\_concurrency unit test case
- **PR #23363:** (*jayeshka*) adding riak unit test case @ 2015-05-05T14:23:05Z
  - 1cdaeed Merge pull request #23363 from jayeshka/riak-unit-test
  - f9da6db adding riak unit test case

### 35.2.3 Salt 2015.5.10 Release Notes

#### Security Fix

CVE-2016-3176: Insecure configuration of PAM external authentication service

This issue affects all Salt versions prior to 2015.8.8/2015.5.10 when PAM *external authentication* is enabled. This issue involves passing an alternative PAM authentication service with a command that is sent to LocalClient, enabling the attacker to bypass the configured authentication service. Thank you to Dylan Frese <dmfrese@gmail.com> for bringing this issue to our attention.

This update defines the PAM `eAuth service` that users authenticate against in the Salt Master configuration.

(No additional fixes are contained in this release).

## Read Before Upgrading Debian 8 (Jessie) from Salt Versions Earlier than 2015.5.9

Salt systemd service files are missing the following statement in these versions:

```
[Service]
KillMode=process
```

This statement must be added to successfully upgrade on these earlier versions of Salt.

### 35.2.4 Salt 2015.5.11 Release Notes (In Progress)

In progress, not yet released.

### 35.2.5 Salt 2015.5.2 Release Notes

release 2015-06-10

Version 2015.5.2 is a bugfix release for 2015.5.0.

Extended Changelog Courtesy of Todd Stansell (<https://github.com/tjstansell/salt-changelogs>):

**PR #24346: (rallytime) Backport #24271 to 2015.5 @ 2015-06-03T18:44:31Z**

**PR #24271: (randybias) Fixed the setup instructions**

refs: #24346

- 76927c9 Merge pull request #24346 from rallytime/bp-24271
- 04067b6 Fixed the setup instructions

**PR #24345: (rallytime) Backport #24013 to 2015.5 @ 2015-06-03T18:39:41Z**

**ISSUE #24012: (jbq) Enabling a service does not create the appropriate rc.d symlinks on Ubuntu**

refs: #24013

**PR #24013: (jbq) Fix enabling a service on Ubuntu #24012**

refs: #24345

- 4afa03d Merge pull request #24345 from rallytime/bp-24013
- 16e0732 Fix enabling a service on Ubuntu #24012

**PR #24365: (jacobhammons) Fixes for PDF build errors @ 2015-06-03T17:50:02Z**

- c3392c2 Merge pull request #24365 from jacobhammons/DocFixes
- 0fc1902 Fixes for PDF build errors

**PR #24313: (nicholascapo) Fix #22991 Correctly set result when test=True @ 2015-06-03T14:49:18Z**

**ISSUE #22991: (nicholascapo) npm.installed ignores test=True \* ae681a4 Merge pull request #24313 from nicholascapo/fix-22991-npm.installed-test-true \* ac9644c Fix #22991 npm.installed correctly set result on test=True**

**PR #24312: (nicholascapo) Fix #18966: file.serialize supports test=True @ 2015-06-03T14:49:06Z**

**ISSUE #18966: (bechtoldt) file.serialize ignores test=True \* d57a9a2 Merge pull request #24312 from nicholascapo/fix-18966-file.serialize-test-true \* e7328e7 Fix #18966 file.serialize correctly set result on test=True**

**PR #24302: (jfindlay) fix pkg hold/unhold integration test @ 2015-06-03T03:27:43Z**

- 6b694e3 Merge pull request #24302 from jfindlay/pkg\_tests
- c2db0b1 fix pkg hold/unhold integration test

PR #24349: (**rallytime**) Remove references to mount\_points in ec2 docs @ 2015-06-03T01:54:09Z

ISSUE #14021: (**mathrawka**) EC2 doc mentions mount\_point, but unable to use properly

refs: #24349

- aca8447 Merge pull request #24349 from rallytime/fix-14021
- a235b11 Remove references to mount\_points in ec2 docs

PR #24328: (**dr4Ke**) Fix state grains silently fails 2015.5 @ 2015-06-02T15:18:46Z

ISSUE #24319: (**dr4Ke**) grains state shouldn't fail silently \* 88a997e Merge pull request #24328 from dr4Ke/fix\_state\_grains\_silently\_fails\_2015.5 \* 8a63d1e fix state grains silently fails #24319

- ca1af20 grains state: add some tests

PR #24310: (**techhat**) Add warning about destroying maps @ 2015-06-02T03:01:28Z

ISSUE #24036: (**arthurlogilab**) [salt-cloud] Protect against passing command line arguments as names for the --destroy command

refs: #24310

ISSUE #9772: (**s0undt3ch**) Delete VM's in a map does not delete them all

refs: #24310

- 7dcd9bb Merge pull request #24310 from techhat/mapwarning
- ca535a6 Add warning about destroying maps

PR #24281: (**steverweber**) Ipmi docfix @ 2015-06-01T17:45:36Z

- 02bfb25 Merge pull request #24281 from steverweber/ipmi\_docfix
- dd36f2c yaml formatting
- f6deef3 include api\_key kwarg in ipmi state
- a7d4e97 doc cleanup
- 0ded2fd save more cleanup to doc
- 08872f2 fix name api\_key to api\_key
- 165a387 doc fix add api\_key kwargs
- 1ec7888 cleanup docs

PR #24287: (**jfindlay**) fix pkg test on ubuntu 12.04 for realz @ 2015-06-01T14:16:37Z

- 73cd2cb Merge pull request #24287 from jfindlay/pkg\_test
- 98944d8 fix pkg test on ubuntu 12.04 for realz

PR #24279: (**rallytime**) Backport #24263 to 2015.5 @ 2015-06-01T04:29:34Z

PR #24263: (**cdarwin**) Correct usage of import\_yaml in formula documentation

refs: #24279

- 02017a0 Merge pull request #24279 from rallytime/bp-24263
- beff7c7 Correct usage of import\_yaml in formula documentation

PR #24277: (**rallytime**) Put a space between after\_jump commands @ 2015-06-01T04:28:26Z

ISSUE #24226: (*c4urself*) iptables state needs to keep ordering of flags

refs: #24277

- 2ba696d Merge pull request #24277 from rallytime/fix\_iptables\_jump
- e2d1606 Move after\_jump split out of loop
- d14f130 Remove extra loop
- 42ed532 Put a space between after\_jump commands

PR #24262: (*basepi*) More dictupdate after #24142 @ 2015-05-31T04:09:37Z

PR #24142: (*basepi*) Optimize dictupdate.update and add #24097 functionality

refs: #24262

PR #24097: (*kiorky*) Optimize dictupdate

refs: #24142 #24142

- 113eba3 Merge pull request #24262 from basepi/dictupdatefix
- 0c4832c Raise a typeerror if non-dict types
- be21aaa Pylint
- bb8a6c6 More optimization
- c933249 py3 compat
- ff6b2a7 Further optimize dictupdate.update()
- c73f5ba Remove unused valtype

PR #24269: (*kiorky*) zfs: Fix spurious retcode hijacking in virtual @ 2015-05-30T17:47:49Z

- 785d5a1 Merge pull request #24269 from makinacorpuz/zfs
- 0bf23ce zfs: Fix spurious retcode hijacking in virtual

PR #24257: (*jfindlay*) fix pkg mod integration test on ubuntu 12.04 @ 2015-05-29T23:09:00Z

- 3d885c0 Merge pull request #24257 from jfindlay/pkg\_tests
- 9508924 fix pkg mod integration test on ubuntu 12.04

PR #24260: (*basepi*) Fix some typos from #24080 @ 2015-05-29T22:54:58Z

ISSUE #23657: (*arthurlogilab*) [salt-cloud lxc] NameError: global name `\_\_salt\_\_' is not defined

refs: #24080 #23982

PR #24080: (*kiorky*) Lxc consistency2

refs: #24260 #23982 #24066

PR #24066: (*kiorky*) Merge forward 2015.5 -> develop

refs: #23982

PR #24065: (*kiorky*) continue to fix #23883

refs: #24080 #24066

PR #23982: (*kiorky*) lxc: path support

refs: #24080

- 08a1075 Merge pull request #24260 from basepi/lxctypos24080

- 0fa1ad3 Fix another lxc typo
- 669938f s/you ll/you'll/

**PR #24080: (kiorky) Lxc consistency2**

refs: #24260 #23982 #24066

@ 2015-05-29T22:51:54Z

**ISSUE #23657: (arthurlogilab) [salt-cloud lxc] NameError: global name `__salt__` is not defined**

refs: #24080 #23982

**PR #24066: (kiorky) Merge forward 2015.5 -> develop**

refs: #23982

**PR #24065: (kiorky) continue to fix #23883**

refs: #24080 #24066

**PR #23982: (kiorky) lxc: path support**

refs: #24080

- 75590cf Merge pull request #24080 from makinacorp/lxc\_consistency2
- 81f8067 lxc: fix old lxc test
- 458f506 seed: lint
- 96b8d55 Fix seed.mkconfig yamldump
- 76ddb68 lxc/applynet: conservative
- ce7096f variable collision
- 8a8b28d lxc: lint
- 458b18b more lxc docs
- ef1f952 lxc docs: typos
- d67a43d more lxc docs
- 608da5e modules/lxc: merge resolution
- 27c4689 modules/lxc: more consistent comparision
- 07c365a lxc: merge conflict spotted
- 9993915 modules/lxc: rework settings for consistency
- ce11d83 lxc: Global doc refresh
- 61ed2f5 clouds/lxc: profile key is conflicting

**PR #24247: (rallytime) Backport #24220 to 2015.5 @ 2015-05-29T21:40:01Z**

**ISSUE #24210: (damonnk) salt-cloud vsphere.py should allow `key_filename` param**

refs: #24220

**PR #24220: (djcrabhat) adding `key_filename` param to vsphere provider**

refs: #24247

- da14f3b Merge pull request #24247 from rallytime/bp-24220
- 0b1041d adding `key_filename` param to vsphere provider

PR #24254: (*rallytime*) Add deprecation warning to Digital Ocean v1 Driver @ 2015-05-29T21:39:25Z

PR #22731: (*dmyerscough*) Decommission DigitalOcean APIv1 and have users use the new DigitalOcean APIv2

refs: #24254

- 21d6126 Merge pull request #24254 from rallytime/add\_deprecation\_warning\_digitalocean
- cafe37b Add note to docs about deprecation
- ea0f1e0 Add deprecation warning to digital ocean driver to move to digital\_ocean\_v2

PR #24252: (*aboe76*) Updated suse spec to 2015.5.1 @ 2015-05-29T21:38:45Z

- dac055d Merge pull request #24252 from aboe76/opensuse\_package
- 0ad617d Updated suse spec to 2015.5.1

PR #24251: (*garethgreenaway*) Returners broken in 2015.5 @ 2015-05-29T21:37:52Z

- 49e7fe8 Merge pull request #24251 from garethgreenaway/2015\_5\_returner\_brokenness
- 5df6b52 The code calling cfg as a function vs treating it as a dictionary and using get is currently backwards causing returners to fail when used from the CLI and in scheduled jobs.

PR #24255: (*rallytime*) Clarify digital ocean documentation and mention v1 driver deprecation @ 2015-05-29T21:37:07Z

ISSUE #21498: (*rallytime*) Clarify Digital Ocean Documentation

refs: #24255

- bfb9461 Merge pull request #24255 from rallytime/clarify\_digital\_ocean\_driver\_docs
- 8d51f75 Clarify digital ocean documentation and mention v1 driver deprecation

PR #24232: (*rallytime*) Backport #23308 to 2015.5 @ 2015-05-29T21:36:46Z

PR #23308: (*thusoy*) Don't merge: Add missing jump arguments to iptables module

refs: #24232

- 41f5756 Merge pull request #24232 from rallytime/bp-23308
- 2733f66 Import string
- 9097cca Add missing jump arguments to iptables module

PR #24245: (*Sacro*) Unset PYTHONHOME when starting the service @ 2015-05-29T20:00:31Z

- a95982c Merge pull request #24245 from Sacro/patch-2
- 6632d06 Unset PYTHONHOME when starting the service

PR #24121: (*hvnsweeting*) deprecate setting user permission in rabbitmq\_vhost.present @ 2015-05-29T15:55:40Z

- 1504c76 Merge pull request #24121 from hvnsweeting/rabbitmq-host-deprecate-set-permission
- 2223158 deprecate setting user permission in rabbitmq\_host.present

PR #24179: (*merll*) Changing user and group only possible for existing ids. @ 2015-05-29T15:52:43Z

PR #24169: (*merll*) Changing user and group only possible for existing ids.

refs: #24179

- ba02f65 Merge pull request #24179 from Precis/fix-file-uid-gid-2015.0

- ee4c9d5 Use ids if user or group is not present.

PR #24229: (**msteed**) Fix auth failure on syndic with external\_auth @ 2015-05-29T15:04:06Z

ISSUE #24147: (**paclat**) Syndication issues when using authentication on master of masters.

refs: #24229

- 9bf066 Merge pull request #24229 from msteed/issue-24147
- 482d1cf Fix auth failure on syndic with external\_auth

PR #24234: (**jayeshka**) adding states/quota unit test case. @ 2015-05-29T14:14:27Z

- 19fa43c Merge pull request #24234 from jayeshka/quota-states-unit-test
- c233565 adding states/quota unit test case.

PR #24217: (**jfindlay**) disable intermittently failing tests @ 2015-05-29T03:08:39Z

ISSUE #40: (**thatch45**) Clean up timeouts

refs: #22857

PR #23623: (**jfindlay**) Fix /jobs endpoint's return

refs: #24217

PR #22857: (**jackson tj**) Fix /jobs endpoint's return

refs: #23623

- e15142c Merge pull request #24217 from jfindlay/disable\_bad\_tests
- 6b62804 disable intermittently failing tests

PR #24199: (**ryan-lane**) Various fixes for boto\_route53 and boto\_elb @ 2015-05-29T03:02:41Z

- ce8e43b Merge pull request #24199 from lyft/route53-fix-elb
- d8dc9a7 Better unit tests for boto\_elb state
- 62f214b Remove cnames\_present test
- 7b9ae82 Lint fix
- b74b0d1 Various fixes for boto\_route53 and boto\_elb

PR #24142: (**basepi**) Optimize dictupdate.update and add #24097 functionality

refs: #24262

@ 2015-05-29T03:00:56Z

PR #24097: (**kiorky**) Optimize dictupdate

refs: #24142 #24142

PR #21968: (**ryanwohara**) Verifying the key has a value before using it. \* a43465d Merge pull request #24142 from basepi/dictupdate24097 \* 5c6e210 Deepcopy on merge\_recurse

- a13c84a Fix None check from #21968
- 9ef2c64 Add docstring
- 8579429 Add in recursive\_update from #24097
- 8599143 if key not in dest, don't recurse
- d8a84b3 Rename klass to valtype

**PR #24208: (jayeshka)** adding states/ports unit test case. @ 2015-05-28T23:06:33Z

- 526698b Merge pull request #24208 from jayeshka/ports-states-unit-test
- 657b709 adding states/ports unit test case.

**PR #24219: (jfindlay)** find zfs without modinfo @ 2015-05-28T21:07:26Z

**ISSUE #20635: (dennisjac)** 2015.2.0rc1: zfs errors in log after update

refs: #24219

- d00945f Merge pull request #24219 from jfindlay/zfs\_check
- 15d4019 use the salt loader in the zfs mod
- 5599b67 try to search for zfs if modinfo is unavailable

**PR #24190: (msteed)** Fix issue 23815 @ 2015-05-28T20:10:34Z

**ISSUE #23815: (Snergster)** [beacons] inotify errors on subdir creation \* 3dc4b85 Merge pull request #24190 from msteed/issue-23815 \* 086a1a9 lint

- 65de62f fix #23815
- d04e916 spelling
- db9f682 add inotify beacon unit tests

**PR #24211: (rallytime)** Backport #24205 to 2015.5 @ 2015-05-28T18:28:15Z

**PR #24205: (hazelesque)** Docstring fix in salt.modules.yumpkg.hold

refs: #24211

- 436634b Merge pull request #24211 from rallytime/bp-24205
- 23284b5 Docstring fix in salt.modules.yumpkg.hold

**PR #24212: (terminalmage)** Clarify error in rendering template for top file @ 2015-05-28T18:26:20Z

- cc58624 Merge pull request #24212 from terminalmage/clarify-error-msg
- ca807fb Clarify error in rendering template for top file

**PR #24213: (The-Loeki)** ShouldFix \_- troubles in debian\_ip @ 2015-05-28T18:24:39Z

**ISSUE #23904: (mbrgm)** Network config bonding section cannot be parsed when attribute names use dashes

refs: #23917

**ISSUE #23900: (hashi825)** salt ubuntu network building issue 2015.5.0

refs: #23922

**PR #23922: (garethgreenaway)** Fixes to debian\_ip.py

refs: #24213

**PR #23917: (corywright)** Split debian bonding options on dash instead of underscore

refs: #24213

- 9825160 Merge pull request #24213 from The-Loeki/patch-3
- a68d515 ShouldFix \_- troubles in debian\_ip

**PR #24214: (basepi)** 2015.5.1release @ 2015-05-28T16:23:57Z

- 071751d Merge pull request #24214 from basepi/2015.5.1release

- e5ba31b 2015.5.1 release date
- 768494c Update latest release in docs

**PR #24202: (rallytime) Backport #24186 to 2015.5 @ 2015-05-28T05:16:48Z**

**PR #24186: (thcipriani) Update salt vagrant provisioner info**

refs: #24202

- c2f1fdb Merge pull request #24202 from rallytime/bp-24186
- db793dd Update salt vagrant provisioner info

**PR #24192: (rallytime) Backport #20474 to 2015.5 @ 2015-05-28T05:16:18Z**

**PR #20474: (djcrabhat) add sudo, sudo\_password params to vsphere deploy to allow for non-root deploys**

refs: #24192

- 8a085a2 Merge pull request #24192 from rallytime/bp-20474
- fd3c783 add sudo, sudo\_password params to deploy to allow for non-root deploys

**PR #24184: (rallytime) Backport #24129 to 2015.5 @ 2015-05-28T05:15:08Z**

**PR #24129: (pengyao) Wheel client doc**

refs: #24184

- 7cc535b Merge pull request #24184 from rallytime/bp-24129
- 722a662 fixed a typo
- 565eb46 Add cmd doc for WheelClient

**PR #24183: (rallytime) Backport #19320 to 2015.5 @ 2015-05-28T05:14:36Z**

**PR #19320: (clan) add `state\_output\_profile` option for profile output**

refs: #24183

- eb0af70 Merge pull request #24183 from rallytime/bp-19320
- 55db1bf sate\_output\_profile default to True
- 9919227 fix type: statei -> state
- 0549ca6 add `state\_output\_profile` option for profile output

**PR #24201: (whiteinge) Add list of client libraries for the rest\_cherrypy module to the top-level documentation @ 2015-05-28T02:12:09Z**

- 1b5bf23 Merge pull request #24201 from whiteinge/rest\_cherrypy-client-libs
- 5f71802 Add list of client libraries for the rest\_cherrypy module
- 28fc77f Fix rest\_cherrypy config example indentation

**PR #24195: (rallytime) Merge #24185 with a couple of fixes @ 2015-05-27T22:18:37Z**

**PR #24185: (jacobhammons) Fixes for doc build errors**

refs: #24195

- 3307ec2 Merge pull request #24195 from rallytime/merge-24185
- d8daa9d Merge #24185 with a couple of fixes
- 634d56b Fixed pylon error

- 0689815 Fixes for doc build errors

**PR #24166: (jayeshka) adding states/pkgng unit test case.** @ 2015-05-27T20:27:49Z

- 7e400bc Merge pull request #24166 from jayeshka/pkgng-states-unit-test
- 2234bb0 adding states/pkgng unit test case.

**PR #24189: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5** @ 2015-05-27T20:26:31Z

**PR #24178: (rallytime) Backport #24118 to 2014.7, too.** **PR #24159: (rallytime) Fill out modules/keystone.py CLI Examples** **PR #24158: (rallytime) Fix test\_valid\_docs test for tls module** **PR #24118: (trevor-h) removed deprecated pymongo usage**

refs: #24139 #24178

- 9fcd479 Merge pull request #24189 from basepi/merge-forward-2015.5
- 8839e9c Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
- 9d7331c Merge pull request #24178 from rallytime/bp-24118
  - e2217a0 removed deprecated pymongo usage as no longer functional with pymongo > 3.x

- Total PR references: 231

Changes:

- **PR #25096:** (*jfindlay*) Postgres group test @ 2015-07-01T18:48:26Z
  - **PR #24330:** (*jayeshka*) adding states/postgres\_group unit test case. | refs: #25096
  - 21709aa Merge pull request #25096 from jfindlay/postgres\_group\_test
  - 3c379dc declobber postgres state unit test mocking
  - a162ffa adding states/postgres\_group unit test case.
- **PR #25085:** (*jfindlay*) accept all sources in the file state @ 2015-07-01T18:23:45Z
  - **ISSUE #25041:** (*wt*) REGRESSION: pillar.get of integer fails to render in sls | refs: #25085
  - 0a84640 Merge pull request #25085 from jfindlay/fix\_file
  - 937a252 remove unnecessary file state tests
  - 6f238e9 integration test file.managed sources
  - a5978d3 iterate an iterable source othwerise list+str it
- **PR #25095:** (*jfindlay*) Win groupadd unit tests @ 2015-07-01T18:18:53Z
  - **PR #24207:** (*jayeshka*) adding win\_groupadd unit test case. | refs: #25095
  - a983942 Merge pull request #25095 from jfindlay/win\_groupadd\_test
  - 564dff9 depend on win libs rather than mocking them
  - 9b9aeb8 resolved all errors.
  - aaf8935 adding win\_groupadd unit test case.
- **PR #25089:** (*jfindlay*) fix minion sudo @ 2015-07-01T15:53:16Z
  - **ISSUE #21520:** (*jfindlay*) sudo.salt\_call is broken | refs: #25089
  - **PR #20226:** (*thatch45*) Allow sudo priv escalation | refs: #25089
  - 7c8d2a8 Merge pull request #25089 from jfindlay/fix\_sudo
  - d8f91d4 add some apprehension to the sudo exec module
  - a9269c0 adding sudo exec module docs
  - e4a40b7 comment whitespace in minion config
  - 44cb167 adding sudo\_user minion config docs
  - d461060 adding sudo\_user minion config to default
- **PR #25099:** (*driskell*) Fix broken batch results @ 2015-07-01T15:51:29Z

- ISSUE #24875: (*ahammond*) ValueError: list.remove(x): x not in list in File ``/usr/lib/python2.6/site-packages/salt/cli/batch.py``, line 179, in run active.remove(minion) | refs: #25099
- 4d6078e Merge pull request #25099 from driskell/patch-1
- 59b23e5 Fix broken batch results
- PR #25083: (*steverweber*) ipmi: get\_sensor\_data would always fail @ 2015-06-30T20:57:21Z
  - 4635079 Merge pull request #25083 from steverweber/fix\_ipmi\_stat
  - 836f48c include \_ in IpmiCommand
  - 817e434 get\_sensor\_data would always fail
- PR #25067: (*The-Loeki*) Fix for maxdepth=0 in find @ 2015-06-30T20:54:06Z
  - 15f2a40 Merge pull request #25067 from The-Loeki/patch-1
  - 61edad3 Fix for maxdepth=0 in find
- PR #25078: (*terminalmage*) Use smaller number for upper limit of mac\_user's \_first\_avail\_uid helper function @ 2015-06-30T20:53:24Z
  - 58d933c Merge pull request #25078 from terminalmage/fix-mac-uid
  - df2ab7e Use smaller number for upper limit of mac\_user's \_first\_avail\_uid helper function
- PR #25045: (*garethgreenaway*) Fixes to debian\_ip.py in 2015.5 @ 2015-06-30T17:36:43Z
  - ISSUE #24521: (*multani*) State network.managed fails on Debian (Jessie) | refs: #25045
  - ebd6cdc Merge pull request #25045 from garethgreenaway/24521\_debian\_networking
  - 6f2a6c9 having proto default to static since it's needed to build the template.
- PR #25065: (*loregordon*) Add download links for 2015.5.1-3 and 2015.5.2 Windows installers @ 2015-06-30T15:29:31Z
  - ISSUE #25057: (*TheBigBear*) why is there still no newer salt-minion for windows than ver. 2015.5.0-2? no 2015.5.1 or 2015.5.2?
  - ae31b27 Merge pull request #25065 from loregordon/update-windows-installer-links
  - 40a0c13 Add download links for 2015.5.1-3 and 2015.5.2, Fixes #25057
- PR #25052: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-30T01:05:00Z
  - ISSUE #15209: (*hubez*) file.manage: source\_hash not working with s3:// (2014.7.0rc1) | refs: #25011
  - PR #25011: (*notpeter*) Add s3 to protocols for remote source\_hash (2014.7 backport)
  - ddaeb0f Merge pull request #25052 from basepi/merge-forward-2015.5
  - 2c5e664 Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
  - a7154e7 Merge pull request #25011 from notpeter/s3\_2014.7\_backport
    - \* 8b8af64 Add s3 to protocols for remote source\_hash
- PR #25038: (*jfindlay*) versionadded @ 2015-06-29T19:49:27Z
  - PR #24747: (*msciciel*) add get\_route function to network module | refs: #25038
  - c7003d4 Merge pull request #25038 from jfindlay/versionadded
  - d6dc6f9 versionadded
- PR #24747: (*msciciel*) add get\_route function to network module | refs: #25038 @ 2015-06-29T16:51:43Z

- 28c87ca Merge pull request #24747 from msciciel/2015.5
- 79b4ec2 network module lint fix
- 0b6ef78 network module: fix for ipv6
- f3d184c add get\_route function to network module
- PR #24975: (ryan-lane) Fix update of undefined env var in npm module @ 2015-06-29T16:45:05Z
  - 46a9677 Merge pull request #24975 from lyft/npm-module-fix
  - 6fde581 Try byte literals rather than unicode strings in the env
  - c8514de Fix update of undefined env var in npm module
- PR #24986: (heewa) Don't modify empty change @ 2015-06-29T16:44:17Z
  - 9cf8550 Merge pull request #24986 from heewa/fix-pkg-hold-when-errored
  - d47a448 Don't modify empty change
- PR #24999: (rallytime) Provide a less confusing error when cloud provider is misconfigured @ 2015-06-29T16:43:31Z
  - ISSUE #24969: (bradthurber) salt-cloud 2015.5.0: missing azure dependency results in misleading error | refs: #24999
  - ece897d Merge pull request #24999 from rallytime/cloud\_error\_help
  - 1e81a88 Clean up
  - be19a67 Provide a less confusing error when cloud provider is misconfigured
- PR #24987: (heewa) Don't try to cache a template when it's not a file @ 2015-06-29T14:02:59Z
  - 4af15cf Merge pull request #24987 from heewa/fix-trying-to-cache-no-file
  - 9ae0c78 Don't try to cache a template when it's not a file
- PR #25022: (jfindlay) revise label and milestone documentation @ 2015-06-29T13:51:24Z
  - 8eeaddb Merge pull request #25022 from jfindlay/label\_docs
  - 8575192 revise label and milestone documentation
- PR #25029: (jayeshka) adding redismod unit test case. @ 2015-06-29T13:50:33Z
  - 89c2e01 Merge pull request #25029 from jayeshka/redismod-unit-test
  - e3045be adding redismod unit test case.
- PR #24995: (rallytime) Fix deprecated pymongo usage causing errors in latest pymongo @ 2015-06-27T22:28:56Z
  - PR #24175: (trevor-h) fix deprecated pymongo usage causing errors in latest pymongo | refs: #24995
  - 6425252 Merge pull request #24995 from rallytime/tops\_mongo
  - a3c1063 fix deprecated pymongo usage causing errors in latest pymongo
- PR #24994: (garethgreenaway) Another Fix to gpg.py in 2015.5 @ 2015-06-27T22:28:15Z
  - ISSUE #24862: (dkatsanikakis) gpg.import\_key returns error after succesfully completed | refs: #24966 #24994
  - e9aaa11 Merge pull request #24994 from garethgreenaway/2015\_5\_24862\_gpg\_import\_key
  - d2f0d8f variable was referenced before assignment. Just removing the variable and checking the return from distutils.version.LooseVersion directly.

- **PR #24988:** (*jayeshka*) adding states/supervisord unit test case. @ 2015-06-27T22:24:42Z
  - ebd666e Merge pull request #24988 from jayeshka/supervisord-states-unit-test
  - bb0a6d5 adding states/supervisord unit test case.
- **PR #25007:** (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-26T21:28:57Z
  - **ISSUE #24915:** (*jtand*) Salt-cloud not working in 2014.7.6 | refs: #24944
  - **PR #24944:** (*techhat*) Double-check main\_cloud\_config
  - **PR #24936:** (*jtand*) Fixed ps module to not use deprecated psutil commands
  - 0487c3c Merge pull request #25007 from basepi/merge-forward-2015.5
  - 4980fd5 Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
  - a11e4c6 Merge pull request #24944 from techhat/issue24915
    - \* 59c3081 Double-check main\_cloud\_config
  - d26a544 Merge pull request #24936 from jtand/psutil
    - \* bdb7a19 Fixed ps module to not use deprecated psutil commands
- **PR #25003:** (*jacobhammons*) Updated man pages @ 2015-06-26T19:13:41Z
  - 91a60e1 Merge pull request #25003 from jacobhammons/man-pages
  - cf97a4a Updated man pages
- **PR #25002:** (*jacobhammons*) sphinx html theme updates @ 2015-06-26T18:39:14Z
  - a60a2c4 Merge pull request #25002 from jacobhammons/doc-announcements
  - f88f344 sphinx html theme updates
- **PR #24977:** (*rallytime*) Only warn about digital ocean deprecation if digital ocean is configured @ 2015-06-25T23:54:46Z
  - a791b23 Merge pull request #24977 from rallytime/do\_move\_warning
  - 6b54422 Only warn about digital ocean deprecation if digital ocean is configured
- **PR #24966:** (*garethgreenaway*) Fixes to gpg.py in 2015.5 @ 2015-06-25T19:58:49Z
  - **ISSUE #24862:** (*dkatsanikakis*) gpg.import\_key returns error after succesfully completed | refs: #24966 #24994
  - a71c1b7 Merge pull request #24966 from garethgreenaway/2015\_5\_24862\_gpg\_import\_key
  - 55eb73b fixing unit tests.
  - 80c24be Fixing an issue with the import\_key method. Different results depending on which gnupg python module is installed.
- **PR #24965:** (*jacksontj*) Fix memory leak in saltnado @ 2015-06-25T18:48:03Z
  - **ISSUE #24846:** (*mavenAtHouzz*) Memory leak issue in rest\_tornado EventListener | refs: #24965
  - 8622184 Merge pull request #24965 from jacksontj/2015.5
  - 48b5e16 pylint
  - 87adca4 Fix memory leak in saltnado
- **PR #24948:** (*jfindlay*) fix some malformed doc links and anchors @ 2015-06-25T15:51:38Z
  - 773c4cf Merge pull request #24948 from jfindlay/doc\_links

- 152a9b2 fix some malformed doc links and anchors
- **PR #24886:** (*anlutro*) Be more careful about stripping away root\_dir from directory options @ 2015-06-25T15:50:11Z
  - **ISSUE #24885:** (*anlutro*) Master config - Directories starting with a dot have the dot stripped when root\_dir is . | refs: #24886
  - 4ebc01e Merge pull request #24886 from alprs/fix-root\_dir\_bug
  - 52ccafd os.sep is the correct directory separator constant
  - 0ecbf26 Be more careful about stripping away root\_dir from directory options
- **PR #24930:** (*jacksonjtj*) Don't refetch file templates 100% of the time-- Performance optimization for templated files @ 2015-06-24T21:22:47Z
  - f52f7e1 Merge pull request #24930 from jacksonjtj/2015.5
  - 5fb7534 Only parse the source if we have one
  - c03a6fa Add support for sources of managed files to be local
  - 4cf78a0 pylint
  - d70914e Don't refetch the template 100% of the time-- Performance optimization for templated files
- **PR #24935:** (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-24T18:17:54Z
  - **PR #24918:** (*BretFisher*) SmartOS SMF minion startup fix
  - **PR #473:** (*whiteinge*) Added a couple functions to work with the minion file cache | refs: #24918
  - 925a4d9 Merge pull request #24935 from basepi/merge-forward-2015.5
  - 8d8bf34 Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
  - eeb05a1 Merge pull request #24918 from BretFisher/minion-start-smartos-smf-fix
    - \* d7bfb0c Smartos smf minion fix
- **PR #24873:** (*jfindlay*) convert osrelease grain to str before str op @ 2015-06-24T16:43:08Z
  - **ISSUE #24826:** (*rakai93*) rh\_service.py: `int` object has no attribute `startswith` | refs: #24873
  - 4e8ed0d Merge pull request #24873 from jfindlay/rh\_service
  - febe6ef convert osrelease grain to str before str op
- **PR #24923:** (*jayeshka*) adding states/status unit test case. @ 2015-06-24T15:50:07Z
  - 90819f9 Merge pull request #24923 from jayeshka/status-states-unit-test
  - baec650 adding states/status unit test case.
- **PR #24902:** (*cro*) Fix minion failover, document same @ 2015-06-24T15:20:43Z
  - 2dd24ec Merge pull request #24902 from cro/fixfo2
  - 90c73ff References to documentation.
  - f0c9204 Add references to failover parameters in conf
  - 9da96a8 Docs
  - e2314f0 Move comment.
  - b9a756f Fix master failover and add documentation for same. Factor in syndics. Syndics will not failover (yet).

- **PR #24926:** (*rallytime*) Back-port #22263 to 2015.5 @ 2015-06-24T15:09:40Z
  - **PR #22263:** (*cachedout*) Prevent a load from being written if one already exists | refs: #24926
  - 087ee09 Merge pull request #24926 from rallytime/bp-22263
  - 8c92d9c Prevent a load from being written if one already exists
- **PR #24900:** (*rallytime*) Back-port #24848 to 2015.5 @ 2015-06-24T15:09:18Z
  - **PR #24848:** (*nmadhok*) Correcting bash code blocks | refs: #24900
  - b34a74f Merge pull request #24900 from rallytime/bp-24848
  - d2b5456 Correcting bash code blocks
- **PR #24899:** (*rallytime*) Back-port #24847 to 2015.5 @ 2015-06-24T15:09:01Z
  - **PR #24847:** (*borutmrak*) unset size parameter for lxc.create when backing=zfs | refs: #24899
  - a546e8e Merge pull request #24899 from rallytime/bp-24847
  - 1e4ec7a unset size parameter for lxc.create when backing=zfs
- **PR #24898:** (*rallytime*) Back-port #24845 to 2015.5 @ 2015-06-24T15:06:09Z
  - **PR #24845:** (*porterjamesj*) fix bug in docker.loaded | refs: #24898
  - d4dd8d2 Merge pull request #24898 from rallytime/bp-24845
  - 071049a fix bug in docker.loaded
- **PR #24897:** (*rallytime*) Back-port #24839 to 2015.5 @ 2015-06-24T15:05:35Z
  - **ISSUE #24799:** (*infestdead*) Forced remount because options changed when no options changed (glusterfs)
  - **PR #24839:** (*infestdead*) fix for issue #24799 | refs: #24897
  - 6930855 Merge pull request #24897 from rallytime/bp-24839
  - f3b20d5 fix for issue #24799
- **PR #24891:** (*jayeshka*) adding states/ssh\_known\_hosts unit test case. @ 2015-06-23T16:46:58Z
  - 1650233 Merge pull request #24891 from jayeshka/ssh\_known\_hosts-states-unit-test
  - ef1347f adding states/ssh\_known\_hosts unit test case.
- **PR #24874:** (*dkiser*) Fix for salt-cloud when ssh key used to auth and using sudo. @ 2015-06-22T23:46:08Z
  - **ISSUE #24870:** (*dkiser*) salt-cloud fails on sudo password prompt when using ssh key to auth | refs: #24874
  - c32aae9 Merge pull request #24874 from dkiser/salt-cloud-24870
  - 6c31143 Fix key error for the PR to fix #24870.
  - bdcf7d8 Fix pylint for #24874.
  - 8f66d19 Fix for salt-cloud when ssh key used to auth and using sudo.
- **PR #24880:** (*dkiser*) Fix to allow password for salt-cloud to be set outside of a vm specif... @ 2015-06-22T23:44:59Z
  - **ISSUE #24871:** (*dkiser*) salt-cloud fails to honor 'password' in cloud options before raising an exception | refs: #24880
  - ddaa21c Merge pull request #24880 from dkiser/salt-cloud-24871

- 4f6c035 Fix to allow password for salt-cloud to be set outside of a vm specific context.
- **PR #24852:** (*pruiz*) Fix issue 24851: regular expression so it now matches packages with `!` or `-'` at pkg name @ 2015-06-22T20:37:13Z
  - 3902b16 Merge pull request #24852 from pruiz/issue-24851
  - 73adb1d Fix regular expression so it now matches packages with `!` or `-'` at pkg name.
- **PR #24861:** (*jayeshka*) adding states/ssh\_auth unit test case. @ 2015-06-22T16:20:01Z
  - 6c5b788 Merge pull request #24861 from jayeshka/ssh\_auth-states-unit-test
  - e5d7b0d adding states/ssh\_auth unit test case.
- **PR #24824:** (*kev009*) Detect bhyve virtual type for FreeBSD guests @ 2015-06-22T15:24:35Z
  - **ISSUE #23478:** (*calvinhp*) grains.get virtual reports ``physical" on bhyve FreeBSD VM | refs: #24824
  - 9e3321c Merge pull request #24824 from kev009/grains-bhyve-bsd
  - a226209 Detect bhyve virtual type for freebsd guests
- **PR #24795:** (*anlutro*) Fix state.apply for salt-ssh @ 2015-06-22T15:23:57Z
  - **ISSUE #24746:** (*anlutro*) state.apply doesn't seem to work | refs: #24795
  - 7b07ef9 Merge pull request #24795 from alprs/fix-salt\_ssh\_state\_apply
  - 905840b Fix state.apply for salt-ssh
- **PR #24832:** (*jacksontj*) Don't incur a ``\_load\_all" of the lazy\_loader while looking for mod\_init. @ 2015-06-22T15:17:10Z
  - **PR #20540:** (*jacksontj*) Loader nomerge: Don't allow modules to ``merge" | refs: #24832
  - **PR #20481:** (*jacksontj*) Add submodule support to LazyLoader | refs: #20540
  - **PR #20473:** (*jacksontj*) Add ``disabled" support | refs: #20481
  - **PR #20274:** (*jacksontj*) Loader overhaul to LazyLoader | refs: #20473
  - **PR #12327:** (*jacksontj*) Add a LazyLoader class which will lazily load modules (with the given lo... | refs: #20274
  - 31d4c13 Merge pull request #24832 from jacksontj/2015.5
  - cfa7c0a pylint
  - be18439 Don't incur a ``\_load\_all" of the lazy\_loader while looking for mod\_init.
- **PR #24834:** (*rallytime*) Back-port #24811 to 2015.5 @ 2015-06-19T18:43:49Z
  - **ISSUE #14666:** (*luciddr34m3r*) salt-cloud GoGrid exception when using map file | refs: #24811
  - **PR #24811:** (*rallytime*) Add notes to map and gogrid docs -- don't use -P with map files | refs: #24834
  - 2d8148f Merge pull request #24834 from rallytime/bp-24811
  - e2684ec Add notes to map and gogrid docs -- don't use -P with map files
- **PR #24790:** (*rallytime*) Back-port #24741 to 2015.5 @ 2015-06-19T17:25:58Z
  - **PR #24741:** (*CameronNemo*) Improve Upstart enable/disable handling | refs: #24790
  - d2edb63 Merge pull request #24790 from rallytime/bp-24741
  - a54245f Add missing import
  - 4ce6370 salt.modules.upstart: fix lint errors

- aec53ec Improve Upstart enable/disable handling
- PR #24789: (*rallytime*) Back-port #24717 to 2015.5 @ 2015-06-19T17:17:00Z
  - PR #24717: (*gthb*) virtualenv.managed: document user and no\_chown | refs: #24789
  - 645e62a Merge pull request #24789 from rallytime/bp-24717
  - 95ac4eb virtualenv.managed: document user and no\_chown
- PR #24823: (*jayeshka*) adding states/splunk\_search unit test case. @ 2015-06-19T17:14:12Z
  - 0a6c70f Merge pull request #24823 from jayeshka/splunk\_search-states-unit-test
  - 98831a8 adding states/splunk\_search unit test case.
- PR #24809: (*jodv*) Correctly create single item list for failover master type with string value for master opt @ 2015-06-19T15:22:20Z
  - 4c5a708 Merge pull request #24809 from jodv/single\_item\_master\_list
  - 18ceebe single item list vs. list of characters
- PR #24802: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-18T20:11:58Z
  - ISSUE #24776: (*nmadhok*) --static option in salt raises ValueError and has been broken for a very long time | refs: #24777
  - ISSUE #21318: (*thanatos*) get\_full\_returns raises KeyError | refs: #24769
  - ISSUE #18994: (*njhartwell*) salt.client.get\_cli\_returns errors when called immediately after run\_job | refs: #24769

  - 3ff6eff Merge pull request #24632 from jacobhammons/bug-fixes
  - 7c52012 Fixed typos
  - c7cdd41 Doc bug fixes Refs #24547 Refs #24275 Refs #24375 Refs #24560 Refs #24163
- PR #24607: (*garethgreenaway*) fixes to minion.py @ 2015-06-17T18:16:42Z
  - ISSUE #24198: (*ahammond*) salt-call event.send doesn't send events from minion | refs: #24607
  - 9995f64 Merge pull request #24607 from garethgreenaway/2015\_5\_sending\_events\_multi\_master
  - 8abd3f0 A fix if you have multiple masters configured and try to fire events to the minion. Currently they fail silently. Might be the cause of #24198.
- PR #24755: (*rallytime*) Remove SALT\_CLOUD\_REQS from setup.py @ 2015-06-17T17:42:25Z
  - bf2dd94 Merge pull request #24755 from rallytime/fix\_setup\_15
  - 48769a5 Remove SALT\_CLOUD\_REQS from setup.py
- PR #24740: (*rallytime*) Backport #24720 to 2015.5 @ 2015-06-17T16:43:37Z
  - PR #24720: (*TheScriptSage*) Issue 24621 - AD/LDAP Group Auth Issue | refs: #24740
  - 3d53d79 Merge pull request #24740 from rallytime/bp-24720
  - a9bcdb5 Updating master.py to properly check against groups when user is only authed against group. Tested against unit.auth\_test.
- PR #24723: (*rallytime*) Back-port #20124 to 2015.5 @ 2015-06-17T16:43:20Z
  - PR #20124: (*cgtx*) add init system to default grains | refs: #24723
  - ac2851b Merge pull request #24723 from rallytime/bp-20124
  - 4d0061b fix infinite loop introduced by #20124 when the init system is not in the supported\_inits list

- 0c7fa0f Optimizations for #20124
- f353454 add init system to default grains (resolve #20124)
- PR #24754: (*anlutro*) salt-cloud documentation - Add information about linode location @ 2015-06-17T16:04:48Z
  - 78cd09b Merge pull request #24754 from alprs/docs-add\_linode\_location\_option
  - d88e071 add information about linode location
- PR #24748: (*jayeshka*) adding states/serverdensity\_device unit test case. @ 2015-06-17T15:39:07Z
  - d5554f7 Merge pull request #24748 from jayeshka/serverdensity\_device-states-unit-test
  - 1a4c241 adding states/serverdensity\_device unit test case.
- PR #24739: (*rallytime*) Back-port #24735 to 2015.5 @ 2015-06-17T15:16:47Z
  - PR #24735: (*notpeter*) Add 2015.5 codename to version numbers docs | refs: #24739
  - 0b7e7ef Merge pull request #24739 from rallytime/bp-24735
  - 64c565d Add .0 to version number
  - 5ed801b Add codenames for 2015.5 and future versions. Trailing newline.
- PR #24732: (*msteed*) Fix stacktrace when --summary is used @ 2015-06-17T03:27:57Z
  - ISSUE #24111: (*yermulnik*) cli option '--summary' got broken after upgrade to 2015.5.1 | refs: #24732
  - c8713f2 Merge pull request #24732 from msteed/issue-24111
  - 54b33dd Fix stacktrace when --summary is used
- PR #24721: (*rallytime*) Back-port #24668 to 2015.5 @ 2015-06-17T03:23:47Z
  - PR #24668: (*grischa*) enable virtual package names in pyobjects renderer | refs: #24721 #24757
  - 70d3781 Merge pull request #24721 from rallytime/bp-24668
  - 68fb5af fixing other test
  - ba4f262 fixing text for virtual support in pyobjects
  - b349d91 enable virtual package names in pyobjects renderer
- PR #24718: (*rallytime*) Added some missing config documentation to the vsphere driver @ 2015-06-17T03:19:35Z
  - ISSUE #21923: (*Fluro*) Salt cloud not running provisioning script as root | refs: #24718
  - ISSUE #17241: (*hasues*) Salt-Cloud for vSphere needs additional documentation | refs: #24718
  - 1b9d689 Merge pull request #24718 from rallytime/update\_vsphere\_docs
  - bfdebb6 Added some missing config documentation to the vsphere driver
- PR #24714: (*rallytime*) Remove cloud-requirements.txt @ 2015-06-17T03:17:04Z
  - 64857c7 Merge pull request #24714 from rallytime/remove\_cloud\_reqs\_15
  - 67b796d Remove cloud-requirements.txt
- PR #24733: (*msteed*) Include Tornado in versions report @ 2015-06-17T03:13:53Z
  - ISSUE #24439: (*bechtoldt*) Add tornado version to versions report | refs: #24733
  - f96b1d6 Merge pull request #24733 from msteed/issue-24439
  - 76cfef0 Include Tornado in versions report

- **PR #24737:** (*jacksontj*) Move AES command logging to trace @ 2015-06-17T01:48:11Z
  - a861fe0 Merge pull request #24737 from jacksontj/2015.5
  - a4ed41a Move AES command logging to trace
- **PR #24724:** (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-16T22:46:27Z
  - **ISSUE #24196:** (*johnccfm*) Exception when using user.present with Windows | refs: #24646
  - **PR #24646:** (*twangboy*) Fixed user.present on existing user
  - 0d2dc46 Merge pull request #24724 from basepi/merge-forward-2015.5
  - 4641028 Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
  - a18dada Merge pull request #24646 from twangboy/fix\_24196
    - \* a208e1d Fixed user.present on existing user
- **PR #24701:** (*jayeshka*) adding states/selinux unit test case. @ 2015-06-16T15:27:29Z
  - 3d33fe7 Merge pull request #24701 from jayeshka/selinux-states-unit-test
  - 0c136fd adding states/selinux unit test case.
- **PR #24687:** (*cachedout*) Note about minimum worker\_threads @ 2015-06-15T20:46:23Z
  - 2e287a9 Merge pull request #24687 from cachedout/min\_worker\_threads
  - b7bb7ea Note about minimum worker\_threads
- **PR #24688:** (*cachedout*) Update AUTHORS @ 2015-06-15T20:46:03Z
  - 432478c Merge pull request #24688 from cachedout/update\_authors
  - 3f6880e Better email
  - 6c7b773 Update AUTHORS
- **PR #24649:** (*cachedout*) Improved error reporting for failed states @ 2015-06-15T16:04:20Z
  - **ISSUE #22385:** (*cachedout*) States which require unavailable modules should display the reason | refs: #24649
  - 9a2b50d Merge pull request #24649 from cachedout/issue\_22385
  - b9fe792 States will now return the reason behind failure if a module could not be loaded
- **PR #24673:** (*jayeshka*) adding states/schedule unit test case. @ 2015-06-15T15:24:52Z
  - 66e9e16 Merge pull request #24673 from jayeshka/schedule-states-unit-test
  - 54aaaa5 adding states/schedule unit test case.
- **PR #24663:** (*kartiksubbarao*) Update augeas\_cfg.py @ 2015-06-15T15:18:48Z
  - **ISSUE #24661:** (*kartiksubbarao*) augeas.change doesn't support setting empty values | refs: #24663
  - 5eb19c4 Merge pull request #24663 from kartiksubbarao/patch-2
  - e18db50 Update augeas\_cfg.py
- **PR #24667:** (*dkiser*) fix for #24583 clouds/openstack.py keyring first time succeeds @ 2015-06-14T21:58:58Z
  - **ISSUE #24583:** (*dkiser*) salt-cloud keyring password referenced before assignment | refs: #24667
  - 4450432 Merge pull request #24667 from dkiser/fix-cloud-keyring
  - c92c05f fix for #24583 clouds/openstack.py keyring first time succeeds

- **PR #24659:** (*kartiksubbarao*) Update aliases.py @ 2015-06-13T17:31:42Z
  - **ISSUE #24537:** (*kartiksubbarao*) alias.present doesn't update alias values that are substrings of the existing value | refs: #24659
  - 4c64ee9 Merge pull request #24659 from kartiksubbarao/patch-1
  - d683474 Update aliases.py
- **PR #24644:** (*cro*) Merge forward 2014.7->2015.5 @ 2015-06-12T21:31:41Z
  - **PR #24643:** (*cro*) Add reference to salt-announce mailing list
  - **PR #24620:** (*twangboy*) Fixed comment and uncomment functions in file.py
  - 89eb616 Merge pull request #24644 from cro/2014.7-2015.5-20150612
  - 4136dc3 Merge forward from 2014.7 to 2015.5
  - b99484f Merge pull request #24643 from cro/saltannounce
    - \* ecb0623 Add salt-announce mailing list.
  - 635121e Merge pull request #24620 from twangboy/fix\_24215
    - \* d7a9999 Fixed comment and uncomment functions in file.py
- **PR #24642:** (*basepi*) Revert ``fix target rule, remove unneeded quotation mark" @ 2015-06-12T20:14:26Z
  - **PR #24595:** (*tankywoo*) fix target rule, remove unneeded quotation mark | refs: #24642
  - b896a0d Merge pull request #24642 from saltstack/revert-24595-fix-iptables-target
  - 5ff3224 Revert ``fix target rule, remove unneeded quotation mark"
- **PR #24628:** (*jayeshka*) adding states/reg unit test case. @ 2015-06-12T17:29:11Z
  - 01092c2 Merge pull request #24628 from jayeshka/reg\_states-unit-test
  - af1bd8f adding states/reg unit test case.
- **PR #24631:** (*rallytime*) Back-port #24591 to 2015.5 @ 2015-06-12T16:54:32Z
  - **ISSUE #24494:** (*arnoutpierre*) Computed comments in jinja states | refs: #24591
  - **ISSUE #24073:** (*primechuck*) State.highstate uses stale grain data. | refs: #24492
  - **ISSUE #23359:** (*BalintSzigeti*) init.sls parsing issue | refs: #24591
  - **ISSUE #21217:** (*Colstuwjx*) Maybe a bug for jinja render? | refs: #24591
  - **PR #24591:** (*tbaker57*) Add some documentation surrounding Jinja vs yaml comments - | refs: #24631
  - **PR #24492:** (*DmitryKuzmenko*) Don't remove grains from opts
  - 5f491f9 Merge pull request #24631 from rallytime/bp-24591
  - f13cd41 Add extra clarification why jinja comments are needed.
  - 2374971 Fix typo
  - 6a91747 Add some documentation surrounding Jinja comments - refs #24492, #21217, #23359
- **PR #24616:** (*garethgreenaway*) additional logging in state.py module @ 2015-06-12T16:25:39Z
  - f23f99e Merge pull request #24616 from garethgreenaway/2015\_5\_logging\_disabled\_states
  - 4dbf0ef Adding some logging statement to give feedback when states, including highstate, are disabled. Useful when running from scheduler.
- **PR #24595:** (*tankywoo*) fix target rule, remove unneeded quotation mark | refs: #24642 @ 2015-06-12T16:23:22Z

- 6dccb0 Merge pull request #24595 from tankywoo/fix-iptables-target
- 10a5160 fix target rule, remove unneeded quotation mark
- PR #24604: (*jfindlay*) fix pkg module integration tests @ 2015-06-12T16:04:26Z
  - 8ac3d94 Merge pull request #24604 from jfindlay/pkg\_tests
  - d88fb22 fix pkg module integration tests on CentOS 5
  - fb91b40 fix pkg module integration tests on ubuntu 12
- PR #24600: (*basepi*) [2015.5] Remove \_\_kwarg\_\_ from salt-ssh keyword args @ 2015-06-12T04:21:29Z
  - 0ff545c Merge pull request #24600 from basepi/salt-ssh.orchestrate.20615
  - 9b55683 Remove \_\_kwarg\_\_ from salt-ssh keyword args
- PR #24608: (*basepi*) [2015.5] Normalize salt-ssh flat roster minion IDs to strings @ 2015-06-11T21:35:07Z
  - ISSUE #22843: (*Xiol*) salt-ssh roster doesn't support integers as host keys | refs: #24608
  - 832916f Merge pull request #24608 from basepi/salt-ssh.flat.roster.integers.22843
  - 381820f Normalize salt-ssh flat roster minion IDs to strings
- PR #24605: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-11T19:15:21Z
  - PR #24589: (*BretFisher*) Fixed Mine example for jinja code block
  - 4eb5bb2 Merge pull request #24605 from basepi/merge-forward-2015.5
  - f96c502 Merge remote-tracking branch `upstream/2014.7' into merge-forward-2015.5
  - d83928a Merge pull request #24589 from BretFisher/patch-1
    - \* 65a1133 Fixed Mine example for jinja code block
- PR #24598: (*jacobhammons*) 2015.5.2 release changes @ 2015-06-11T17:24:11Z
  - ISSUE #24457: (*ryan-lane*) When selecting the version of docs on the docs site, it brings you to the homepage | refs: #24598
  - ISSUE #24250: (*jfindlay*) have version links on docs page link to that version of the current page | refs: #24598
  - e0bb177 Merge pull request #24598 from jacobhammons/doc-fixes
  - f3f34dd 2015.5.2 release changes Refs #24250 Refs #24457
- PR #24588: (*basepi*) Fixes for saltmod.function for salt-ssh @ 2015-06-11T16:15:21Z
  - ISSUE #20615: (*aurynn*) 2014.7.1: salt/states/saltmod using incorrect return dict for orchestrate | refs: #24588
  - 26930b4 Merge pull request #24588 from basepi/salt-ssh.orchestrate.20615
  - 826936c Move documentation into docstring instead of comments
  - de052e7 Assign `return' to `ret' if necessary in saltmod.function
  - 34ff989 Convert keyword args to key=value strings in salt-ssh
- PR #24593: (*jayeshka*) adding states/redismod unit test case. @ 2015-06-11T15:55:27Z
  - 5a21ad1 Merge pull request #24593 from jayeshka/redismod\_states-unit-test
  - 3b95744 adding states/redismod unit test case.

- **PR #24581:** (*rallytime*) Disabled some flaky tests until we can figure out how to make them more reliable @ 2015-06-11T15:51:41Z
  - **ISSUE #40:** (*thatch45*) Clean up timeouts | refs: #22857
  - **PR #24217:** (*jfindlay*) disable intermittently failing tests | refs: #24581
  - **PR #23623:** (*jfindlay*) Fix /jobs endpoint's return | refs: #24217
  - **PR #22857:** (*jackson tj*) Fix /jobs endpoint's return | refs: #23623
  - 8ffb86e Merge pull request #24581 from rallytime/disable\_some\_flaky\_tests
  - c82f135 Disabled some flaky tests until we can figure out how to make them more reliable
- **PR #24566:** (*jayeshka*) adding states/rdp unit test case. @ 2015-06-11T02:14:39Z
  - a570d7f Merge pull request #24566 from jayeshka/rdp\_states-unit-test
  - 273b994 adding states/rdp unit test case.
- **PR #24551:** (*joejulian*) 2015.5 dont pollute environment @ 2015-06-11T02:13:06Z
  - **ISSUE #24480:** (*kiorky*) [CRITICAL] [2015.5] tls breaks tzinfo | refs: #24551
  - 20ada1f Merge pull request #24551 from joejulian/2015.5\_dont\_pollute\_environment
  - cfc3b43 Don't pollute the TZ environment variable
  - cba8d3f pep8
  - 9cb7015 Mark keyword version adds
  - 76e2583 Merge tls changes from develop
- **PR #24574:** (*jacobhammons*) Refs #19901 @ 2015-06-10T20:09:23Z
  - **ISSUE #19901:** (*clinta*) State cache is not documented | refs: #24468
  - bb2fd6a Merge pull request #24574 from jacobhammons/19901
  - e2a2946 Refs #19901
- **PR #24577:** (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-10T19:46:22Z
  - **ISSUE #24427:** (*fayted*) 2015.5.1-3 Windows 64Bit Minion fails to start after install | refs: #24530
  - **PR #24530:** (*twangboy*) Start Minion Service on Silent Install
  - b03166c Merge pull request #24577 from basepi/merge-forward-2015.5
  - e1d45cc Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
  - d376390 Merge pull request #24530 from twangboy/fix\_24427
    - \* 673e1d8 Added missing panel.bmp for installer
    - \* cc50218 Start Minion Service on Silent Install
- **PR #24571:** (*jacobhammons*) Refs #24235 @ 2015-06-10T17:02:18Z
  - **ISSUE #24235:** (*tomasfejfar*) Difference between running from minion and from master | refs: #24468
  - 3ec457b Merge pull request #24571 from jacobhammons/24235
  - 8df5d53 Refs #24235
- **PR #24565:** (*pille*) fix backtrace, when listing plugins @ 2015-06-10T16:33:11Z
  - fe07eb5 Merge pull request #24565 from pille/munin-ignore-broken-symlinks

- 8511a6c fix backtrace, when listing plugins
- **PR #24554:** (*ryan-lane*) Fix yes usage for pecl defaults @ 2015-06-09T23:59:49Z
  - 251c8f9 Merge pull request #24554 from lyft/pecl-module-fix
  - 56a9cfc Fix yes usage for pecl defaults
- **PR #24535:** (*rallytime*) Back-port #24518 to 2015.5 @ 2015-06-09T20:06:18Z
  - **PR #24518:** (*rallytime*) Merge #24448 with Pylint Fixes | refs: #24535
  - **PR #24448:** (*codertux*) Update modules path for operating systems using systemd | refs: #24518
  - dbd49b4 Merge pull request #24535 from rallytime/bp-24518
  - fc75197 Pylint fix
  - 3e08840 Update modules path for operating systems using systemd
- **PR #24538:** (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-09T17:27:20Z
  - **PR #24513:** (*jquast*) bugfix use of `iteritem` in 2014.7 branch
  - **PR #24511:** (*jquast*) bugfix: trailing "...done" in rabbitmq output | refs: #24513
  - 485ed3c Merge pull request #24538 from basepi/merge-forward-2015.5
  - 6a8039d Merge remote-tracking branch `upstream/2014.7' into merge-forward-2015.5
  - 6ebc476 Merge pull request #24513 from jquast/2014.7-bugfix-iteritem
    - \* 2be0180 bugfix use of `iteritem` in 2014.7 branch
- **PR #24495:** (*jayeshka*) adding states/rabbitmq\_vhost unit test case. @ 2015-06-09T15:33:23Z
  - 73e6388 Merge pull request #24495 from jayeshka/rabbitmq\_vhost\_states-unit-test
  - 31889e3 cosmetic change.
  - cf501cf resolved error.
  - 4bb6087 Merge branch `2015.5' of <https://github.com/saltstack/salt> into rabbitmq\_vhost\_states-unit-test
  - 3ad7714 adding states/rabbitmq\_vhost unit test case.
- **PR #24445:** (*jayeshka*) adding states/pyrax\_queues unit test case. @ 2015-06-09T15:28:45Z
  - bf1abcc Merge pull request #24445 from jayeshka/pyrax\_queues\_states-unit-test
  - ea27cef adding states/pyrax\_queues unit test case.
- **PR #24490:** (*aneeshusa*) Fix pacman.list\_upgrades for new python\_shell default. @ 2015-06-09T15:13:16Z
  - 0247e8d Merge pull request #24490 from aneeshusa/fix-pacman-list-upgrades
  - 980e1cb Lint fix.
  - dca33f1 Fix pacman.list\_upgrades for new python\_shell default.
- **PR #24517:** (*steverweber*) small fixes to the ipmi docs @ 2015-06-09T15:10:14Z
  - 6268ddb Merge pull request #24517 from steverweber/ipmi\_doc
  - 6413712 lint
  - e78aea9 more small fixes to the ipmi docs
- **PR #24524:** (*jayeshka*) any() takes list oy tuple. @ 2015-06-09T13:49:42Z
  - 3728b3f Merge pull request #24524 from jayeshka/rabbitmq\_vhost\_states-module

- 01c99ad any() takes list oy tuple.
- **PR #24482:** (*eliasp*) `docker.running` needs now the `image` param. @ 2015-06-09T04:43:04Z
  - dd23de8 Merge pull request #24482 from eliasp/2015.5-states.dockerio-docker.running-doc
  - 5de741d `docker.running` needs now the `image` param.
- **PR #24515:** (*basepi*) [2015.5] Add xml library to the salt-thin @ 2015-06-09T04:10:06Z
  - **ISSUE #23503:** (*jfindlay*) salt-ssh fails on CentOS 7 when python-zmq is not installed | refs: #24515
  - 2a727c3 Merge pull request #24515 from basepi/susexml23503
  - 078b33e Add xml library to the thin
- **PR #24497:** (*jayeshka*) adding states/rbenv unit test case. @ 2015-06-09T03:56:10Z
  - fce998a Merge pull request #24497 from jayeshka/rbenv\_states-unit-test
  - 79d343a adding states/rbenv unit test case.
- **PR #24496:** (*jayeshka*) adding states/rabbitmq\_user unit test case. @ 2015-06-09T03:55:23Z
  - 2bc4b1 Merge pull request #24496 from jayeshka/rabbitmq\_user\_states-unit-test
  - 7d96f27 adding states/rabbitmq\_user unit test case.
- **PR #24481:** (*eliasp*) Fix typo (licnese → license). @ 2015-06-09T03:30:25Z
  - 02a597b Merge pull request #24481 from eliasp/2015.5-salt.states.powerpath-license\_typo
  - 1280054 Fix typo (licnese → license).
- **PR #24467:** (*thenewwazoo*) Fix dockerio bound volumes @ 2015-06-09T01:40:23Z
  - 5ad3db5 Merge pull request #24467 from thenewwazoo/fix-dockerio-bound-volumes
  - db4e3dc Let's raise an exception if create fails
  - d1d85dd Add logging
  - ddc63f0 Fix volume handling when creating containers
- **PR #24504:** (*rallytime*) Move vsphere deprecation to 2015.5 @ 2015-06-08T22:43:05Z
  - **PR #24487:** (*nmadhok*) Deprecating vsphere cloud driver in favor of vmware cloud driver | refs: #24504
  - d236fbd Merge pull request #24504 from rallytime/move\_vsphere\_deprecation\_2015.5
  - d876535 Add Getting Started with VSphere doc to 2015.5
  - b685ebc Add vSphere deprecation warnings to 2015.5
- **PR #24506:** (*rallytime*) Backport #24450 to 2015.5 @ 2015-06-08T22:42:14Z
  - **PR #24450:** (*ruzarowski*) Fix salt cli runs with batch-size set | refs: #24506
  - cb55460 Merge pull request #24506 from rallytime/bp-24450
  - 1c0fca2 Backport #24450 to 2015.5
- **PR #24498:** (*rallytime*) Added ``CLI Example" to make failing test happy on 2015.5 @ 2015-06-08T15:48:40Z
  - 3173fd1 Merge pull request #24498 from rallytime/fix\_doc\_failure\_fifteen
  - d992ef4 Added ``CLI Example" to make failing test happy on 2015.5
- **PR #24471:** (*anlutro*) Set up salt-ssh file logging @ 2015-06-08T15:26:49Z
  - 3639e41 Merge pull request #24471 from alprs/fix-salt\_ssh\_logging

- 6a11ec8 set up salt-ssh file logging
- PR #24469: (*jfindlay*) correctly handle user environment info for npm @ 2015-06-08T15:26:02Z
  - ISSUE #24231: (*tarwich*) npm.bootstrap | refs: #24469
  - 551e70f Merge pull request #24469 from jfindlay/npm\_env
  - 8140c96 update npm's user info envs
  - cb572f8 add *env* parameter to npm.uninstall
- PR #24468: (*jacobhammons*) Bug fixes and build errors @ 2015-06-08T15:25:40Z
  - ISSUE #24268: (*tkent-xetus*) Ability to specify revision for win\_gitrepos undocumented | refs: #24468
  - ISSUE #24235: (*tomasfejfar*) Difference between running from minion and from master | refs: #24468
  - ISSUE #24193: (*abng88*) Update ext\_pillar docs to mention that this feature is supported masterless as well | refs: #24468
  - ISSUE #24172: (*zhujinhe*) Can lists be passed in the pillar on the command line on version 2015.5.0? | refs: #24468
  - ISSUE #23211: (*lloesche*) Document that salt:// escapes special characters in filenames | refs: #24468
  - ISSUE #19901: (*clinta*) State cache is not documented | refs: #24468
  - ISSUE #19801: (*ksalman*) How are grains static? | refs: #24468
  - 0d9e0c2 Merge pull request #24468 from jacobhammons/doc-fixes
  - 1035959 Appended .0 to version added
  - d45c4ed Bug fixes and build errors Refs #23211 Refs #24268 Refs #24235 Refs #24193 Refs #24172 Refs #19901 Refs #19801
- PR #24465: (*jfindlay*) catch exception from softwarerepositories @ 2015-06-08T15:25:19Z
  - ISSUE #24318: (*favadi*) uncaught exception for pkgrepo.absent for invalid PPA | refs: #24465
  - be6905a Merge pull request #24465 from jfindlay/unknown\_ppa
  - 19c9128 catch exception from softwarerepositories
- PR #24464: (*jfindlay*) fix typo in modules/mount.py @ 2015-06-08T15:25:07Z
  - ISSUE #24296: (*objectx*) mount.mount calls file.mkdir with incorrect named argument | refs: #24464
  - 58d1ea8 Merge pull request #24464 from jfindlay/file\_mkdir
  - 6e8cd44 fix typo in modules/mount.py
- PR #24461: (*dkiser*) fix for #24434 @ 2015-06-08T15:24:53Z
  - ISSUE #24434: (*dkiser*) multimaster failover fails due to logic from issue #23611
  - 4f332a7 Merge pull request #24461 from dkiser/multimaster\_minion\_fix
  - 1944a74 fix for #24434
- PR #24479: (*ahus1*) change ``path`` to ``name`` for ``file`` operations @ 2015-06-07T17:56:11Z
  - 8917416 Merge pull request #24479 from ahus1/patch-1
  - 7d6b60c change ``path`` to ``name`` for ``file`` operations
- PR #24475: (*rallytime*) Back-port #24454 to 2015.5 @ 2015-06-07T01:29:32Z

- PR #24454: (*rhertzog*) Strip extraneous newline character added in last environment variable | refs: #24475
- 8618d5b Merge pull request #24475 from rallytime/bp-24454
- a793c19 Avoid extraneous newline character added in last environment variable
- PR #24474: (*rallytime*) Back-port #24420 to 2015.5 @ 2015-06-07T01:29:11Z
  - ISSUE #24407: (*aboe76*) Please expand salt module random | refs: #24420
  - PR #24420: (*aboe76*) added random integer module to mod\_random.py | refs: #24474
  - 61658ff Merge pull request #24474 from rallytime/bp-24420
  - 4219b40 Fix lint error and update versionadded to 2015.5.3
  - 3613cc9 added random integer module to mod\_random.py
- PR #24472: (*variia*) ensure {} output is not treated as change in module.py state, fixes #... @ 2015-06-06T14:45:44Z
  - ISSUE #24233: (*variia*) yumpkg.group\_install keeps returning state change
  - 508d7dd Merge pull request #24472 from variia/Fix-yumpkg\_group\_install-return-change-#24233
  - 37e8827 ensure {} output is not treated as change in module.py state, fixes #24233
- PR #24466: (*basepi*) [2015.5] Fix for # in inner strings in yaml arguments @ 2015-06-06T14:35:56Z
  - ISSUE #18045: (*dstokes*) Pillar kwargs parse error with # | refs: #24466
  - ISSUE #8585: (*UtahDave*) '#' in single quoted option on cli not making it into the execution module | refs: #24466
  - 0292e67 Merge pull request #24466 from basepi/fixhashinargs18045
  - 2e0609f Fix for # in inner strings in yaml arguments
- PR #24456: (*rallytime*) Back-port #24441 to 2015.5 @ 2015-06-05T22:32:25Z
  - PR #24441: (*arthurlogilab*) [doc] Aligment fix on external\_auth documentation | refs: #24456
  - ced558a Merge pull request #24456 from rallytime/bp-24441
  - 7002855 yaml indentations should be 2 spaces
  - 21b51ab [doc] Aligment fix on external\_auth documentation
- PR #24398: (*kiorky*) VirtualName for states.apk | refs: #24399 @ 2015-06-05T17:40:04Z
  - ISSUE #24397: (*kiorky*) on debian: states.apk should use virtualname as it shadows system apk module | refs: #24398 #24398 #24399 #24399 #24400

- PR #24388: (*pengyao*) fixes #24358 @ 2015-06-04T20:07:40Z
  - ISSUE #24358: (*pengyao*) Netapi SSH client don't support ssh\_user and ssh\_passwd arguments | refs: #24388
  - 86ce9db Merge pull request #24388 from pengyao/sshclient-kwarg
  - 5c08ca4 fixes #24358
- PR #24367: (*terminalmage*) Improve error message when module does not exist @ 2015-06-04T20:07:12Z
  - ISSUE #22958: (*highlyunavailable*) Weird error when typoing a command | refs: #24367
  - 72d2eae Merge pull request #24367 from terminalmage/issue22958

- d0d7a54 Improve error message when module does not exist
- **PR #24412:** (*jfindlay*) backport #23387 @ 2015-06-04T20:06:03Z
  - **ISSUE #23101:** (*gravyboat*) Create a docs page for labels | refs: #23387
  - **PR #23387:** (*rallytime*) Add some ``What are all these labels for?" documentation | refs: #24412
  - a628778 Merge pull request #24412 from jfindlay/bp-23387
  - bf85772 Make sure the parameters are in the correct order
  - 9f53809 Add ``\* Change" label parameters
  - b27a15e Remove ``workaround" wording
  - 9ff35a Some small fixes
  - 54a7089 Link the new labels doc in contributing and hacking docs
  - 375695e Add pull request label definitions
  - de94563 Add Feature Request label definition
  - 684f291 Add issue definition and augment functional areas section
  - 2da13dd Start a ``what are all of these labels for?" doc
- **PR #24336:** (*twangboy*) Added line to give more descriptive error @ 2015-06-04T19:56:00Z
  - **ISSUE #24154:** (*ssguard*) Exception when running cp.get\_url | refs: #24336
  - 485116c Merge pull request #24336 from twangboy/fix\_cp\_get\_url
  - 37b11f9 Added line to give more descriptive error
- **PR #24413:** (*techhat*) Add more namespaced functions to GoGrid driver @ 2015-06-04T19:51:22Z
  - b3d39cc Merge pull request #24413 from techhat/gogridnamespace
  - 1b397cb Adding blank line
  - da08cc9 Add more namespaced functions to GoGrid driver
- **PR #24399:** (*kiorky*) Versionvirtual | refs: #24398 @ 2015-06-04T18:02:22Z
  - **ISSUE #24397:** (*kiorky*) on debian: states.apt should use virtualname as it shadows system apt module | refs: #24398 #24398 #24399 #24399 #24400
  - **PR #24398:** (*kiorky*) VirtualName for states.apt | refs: #24399
  - 27f109b Merge pull request #24399 from makinacorpus/versionvirtual
  - 235c78d Use apt\_pkg.version\_compare if available
  - 1c0cd45 reindent block to isolate conflict on merge forward
  - 699ecea use var to isolate conflict on merge forward
- **PR #24371:** (*joejulian*) 2015.5 tls module tests @ 2015-06-04T15:20:16Z
  - deaee68 Merge pull request #24371 from joejulian/2015.5\_tls\_module\_tests
  - 4c5dee1 Add @destructiveTest decorator to destructive tests
  - 274bbd4 Accept results from older pyOpenSSL
  - 161f913 All cert info should be in UTC always
  - 9affcca See the whole diff if dict compare fails

- 94f6208 Ignore extensions for now. Resolve this as part of fixing issue 24338.
- 84904d3 Mask lint warning for unused imported module
- 5675b78 Do not test if PyOpenSSL is not installed
- 563cc66 Add tls tests
- **PR #24403:** (*jayeshka*) adding states/process unit test case. @ 2015-06-04T15:19:01Z
  - 84686ee Merge pull request #24403 from jayeshka/process\_states-unit-test
  - fcb71fb adding states/process unit test case.
- **PR #24402:** (*jayeshka*) adding states/pyenv unit test case. @ 2015-06-04T15:18:11Z
  - 35de8d7 Merge pull request #24402 from jayeshka/pyenv\_states-unit-test
  - 5f263ab adding states/pyenc unit test case.
- **PR #24401:** (*jayeshka*) adding states/powerpath unit test case. @ 2015-06-04T15:17:46Z
  - 632f838 Merge pull request #24401 from jayeshka/powerpath-states-unit-test
  - 49ff927 adding states/powerpath unit test case.
- **PR #24400:** (*kiorky*) Aptversion @ 2015-06-04T15:17:19Z
  - **ISSUE #24397:** (*kiorky*) on debian: states.apt should use virtualname as it shadows system apt module | refs: #24398 #24398 #24399 #24399 #24400
  - 0a6e5e0 Merge pull request #24400 from makinacorpus/aptversion
  - e15cb93 Use apt\_pkg.version\_compare if available
  - 953725a Fix too much quoting in apt.version\_cmp
- **PR #24385:** (*jeanpralo*) Fix salt.modules.dockerio.start method @ 2015-06-04T15:00:22Z
  - a904055 Merge pull request #24385 from jeanpralo/Fix-binds-dockerio.start
  - a0fed31 binds dict if not specified should remain to none otherwise docker-py will try to create a new host config and all volume and ports binds are lost. config should be done at the creation of the container not when we start it
- **PR #24381:** (*jtand*) Disabled flaky test to review later @ 2015-06-04T14:57:43Z
  - 9890bc4 Merge pull request #24381 from jtand/seed\_test
  - 7570ae9 Disabled flaky test to review later
- **PR #24382:** (*basepi*) [2015.5] Handle CommandExecutionError in grains commands, Fixes #23342 @ 2015-06-04T12:44:04Z
  - **ISSUE #23342:** (*philipsd6*) salt-ssh 2015.2.0rc2 fails when target doesn't have lspci available | refs: #24382
  - b3fa8fe Merge pull request #24382 from basepi/grainscommandnotfound23342
  - 85b91d6 Handle CommandExecutionError in grains commands
- **PR #24379:** (*Starblade42*) Fixes an issue where Pagerduty states/modules couldn't find their profile in the Pillar @ 2015-06-04T12:41:13Z
  - 52587a4 Merge pull request #24379 from Starblade42/2015.5
  - b93dc5e Linting!
  - 2dd5904 Fixes an issue where Pagerduty states/modules couldn't find it's profile in the Pillar
- **PR #24366:** (*terminalmage*) Use yes \$'\n' instead of printf '\n' for pecl commands @ 2015-06-03T21:28:58Z

- 3ca35d1 Merge pull request #24366 from terminalmage/pecl-yes
- dcd9ad8 Use yes '\$\n' instead of printf '\n' for pecl commands
- PR #24348: (*kiorky*) Try to close input pipes before calling lxc-start @ 2015-06-03T19:38:07Z
  - ISSUE #24284: (*kiorky*) systemd lxc containers need use\_vt=True at lxc-start stage | refs: #24348
  - PR #548: (*Lanzaa*) Salt is now platform dependent. Use get\_python\_lib(1) | refs: #24348
  - 86a3b31 Merge pull request #24348 from makinacorpus/lxcpre
  - 0cb11a2 lxc: typo
  - d71efa6 Try to close input pipes before calling lxc-start

### 35.2.7 Salt 2015.5.4 Release Notes

Version 2015.5.4 is a bugfix release for 2015.5.0.

Changes:

- The `cron.present` state now correctly defaults to state ID as identifier.
- When querying for VMs in `digital_ocean_v2.py`, the number of VMs to include in a page was changed from 20 (default) to 200 to reduce the number of API calls to Digital Ocean.
- The `vmware` Salt-Cloud driver was back-ported from the `develop` branch in order for installations of Salt that are older than 2015.8.0 to be able to use the `vmware` driver without stack-tracing on various deprecation paths that were implemented in the 2015.8.0 release.

#### Changes for v2015.5.3..v2015.5.4

Changes:

- PR #26292: (*iquast*) Rabbitmq 3.2.4 on Ubuntu has "...done.", not "...done" @ 2015-08-13T19:53:29Z
- PR #26296: (*iquast*) bugfix missing `'runas=None'` for `rabbitmqctl` cmds (backport to 2015.5) @ 2015-08-13T19:52:40Z
- PR #26293: (*jfindlay*) Fix #26268 @ 2015-08-13T19:48:06Z
  - ISSUE #25618: (*twangboy*) Fix `reg.py` to work with the registry properly | refs: #26268
  - PR #26268: (*twangboy*) Multiple improvements to `reg` executionmod and `state` mod | refs: #26293
- PR #26290: (*rallytime*) Only call `convert_to_arn` when action name is provided @ 2015-08-13T18:48:58Z
  - ISSUE #25192: (*deuscapturus*) 2015.5.2 `boto_cloudwatch_alarm.present` not working. | refs: #26290
- PR #26288: (*bbinet*) allow to delete grains which value is `False` @ 2015-08-13T18:24:36Z

- PR #26263: (*rallytime*) Don't make changes when test=True for openstack present/absent funcs @ 2015-08-13T16:30:31Z
  - ISSUE #24882: (*nmadhok*) salt.states.openstack\_config.present and salt.states.openstack\_config.absent make changes when test=True | refs: #26263
- PR #26265: (*rallytime*) Don't stacktrace on query return in ec2.create\_snapshot @ 2015-08-13T16:28:48Z
  - ISSUE #24484: (*codehotter*) clouds/ec2.py: create\_snapshot throws exception | refs: #26265
- PR #26285: (*stanislavb*) Remove explicit version from instance identity URL @ 2015-08-13T16:25:32Z
- PR #26275: (*cachedout*) Re-init modules on multi-master reconnect @ 2015-08-13T15:52:50Z
- PR #26273: (*garethgreenaway*) Fixes to schedule module in 2015.5 @ 2015-08-13T15:34:43Z
- PR #26271: (*rallytime*) Fix del\_root\_vol\_on\_destroy and del\_all\_vols\_on\_destroy functionality on ec2 @ 2015-08-12T23:22:47Z
  - ISSUE #24483: (*codehotter*) clouds/ec2.py: del\_root\_vol\_on\_destroy and del\_all\_vols\_on\_destroy not working | refs: #26271
- PR #26219: (*anlutro*) cron: make identifier default to state ID @ 2015-08-12T18:42:33Z
  - ISSUE #25958: (*anlutro*) Cron identifier does not default to state ID as documented | refs: #26219
- PR #26257: (*rallytime*) Back-port #26237 to 2015.5 @ 2015-08-12T18:40:35Z
  - ISSUE #26207: (*fullermd*) group members setting fails with obscure error message on FreeBSD | refs: #26237
  - PR #26237: (*silenius*) fix issue #26207 | refs: #26257
- PR #26258: (*nmadhok*) Fix permission on tests/runtests.py on 2015.5 branch @ 2015-08-12T18:40:04Z
- PR #26261: (*nmadhok*) Correct spelling of integration in docs @ 2015-08-12T18:14:48Z
  - PR #2015: (*thekuffs*) Esky / bbfreeze support
- PR #26247: (*nmadhok*) Initial commit of unit tests for vmware cloud driver @ 2015-08-12T16:58:24Z
- PR #26246: (*nmadhok*) Backport additions to VMware cloud driver from develop to 2015.5 branch @ 2015-08-12T15:11:26Z
- PR #26239: (*opdude*) Fixed documentation to match function name @ 2015-08-12T14:48:52Z
- PR #26232: (*garethgreenaway*) Fix to trust\_key in gpg module for 2015.5. @ 2015-08-12T04:48:27Z
- PR #26084: (*twangboy*) Added python\_shell=True, quoted user input @ 2015-08-10T21:29:35Z
  - ISSUE #25802: (*jefftucker*) Running module ``npm.list" fails on Windows for masterless minion | refs: #26084
- PR #26183: (*cro*) Fix LDAP configuration issue. @ 2015-08-10T19:09:41Z
- PR #26186: (*jacobhammons*) regenerated man pages @ 2015-08-10T19:07:44Z
- PR #26182: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-08-10T19:00:10Z
  - ISSUE #25961: (*getabc*) [2015.5.3-2] salt-winrepo.git/salt-minion.sls fails certificate `\*.wpengine.com' or `wpengine.com' | refs: #26047
  - ISSUE #25751: (*basepi*) Document *master\_finger* more prominently | refs: #26088
  - PR #26116: (*corux*) file.replace fails if repl string is an invalid regex and append/prepend is used
  - PR #26088: (*jacobhammons*) Master finger
  - PR #26047: (*jacobhammons*) Updated windows download links in the docs to <https://repo.saltstack.com>

- PR #26000: (*driskell*) Implement full event caching for subscribed tags @ 2015-08-10T18:57:17Z
  - ISSUE #25998: (*driskell*) Event subsystem discarding required events during --batch breaking it for slow running commands | refs: #26000
- PR #26175: (*rallytime*) Back-port #26153 to 2015.5 @ 2015-08-10T18:22:32Z
  - PR #26153: (*loa*) Fix dockerio state documentation typo | refs: #26175
- PR #26177: (*rallytime*) Back-port #26147 to 2015.5 @ 2015-08-10T18:22:01Z
  - ISSUE #26024: (*jpgic*) lxc\_conf\_unset in cloud.profile is ignored
  - PR #26147: (*martinhoefling*) Fixes #26024 | refs: #26177
- PR #26179: (*rallytime*) Back-port #25404 to 2015.5 @ 2015-08-10T18:21:50Z
  - ISSUE #21082: (*clinta*) master\_type failover does not failover on DNS errors | refs: #25404
  - PR #25404: (*DmitryKuzmenko*) Fixed minion failover to next master on DNS errors. | refs: #26179
- PR #26180: (*jfindlay*) fix processing of state.template @ 2015-08-10T18:21:38Z
  - ISSUE #26112: (*wt*) state.template fails with unclear error with template with only an include | refs: #26180
- PR #26172: (*nmadhok*) [Backport] Make sure variable is a dictionary before popping something from it. @ 2015-08-10T16:42:50Z
  - ISSUE #26162: (*nmadhok*) VMware cloud driver create function failing with traceback on latest develop | refs: #26163 #26172
  - PR #26163: (*nmadhok*) Make sure variable is a dictionary before popping something from it.
- PR #26168: (*cachedout*) Fix slack docs @ 2015-08-10T14:57:18Z
  - ISSUE #26098: (*rdinoff*) SALT.STATES.SLACK Doc update | refs: #26168
- PR #26127: (*garethgreenaway*) Fixes to salt.utils.http related to cp.get\_file\_str bug. @ 2015-08-10T14:38:25Z
  - ISSUE #24106: (*nvx*) fileclient.py#get\_url ignores HTTP Auth again (2015.5 regression) | refs: #26127
- PR #26140: (*nmadhok*) VMware cloud driver fixes @ 2015-08-10T13:15:58Z
  - ISSUE #26141: (*nmadhok*) salt-cloud VMware driver fails with error in parsing configuration file | refs: #26140
  - ISSUE #25809: (*o-sleep*) vmware cloud module error message | refs: #26140
  - ISSUE #25625: (*steverweber*) cloud vmware driver does not provide mac\_address unless vmware tools is running | refs: #26137 #26140
- PR #26137: (*steverweber*) use device mac address if vmttools not active @ 2015-08-09T03:05:36Z
  - ISSUE #25625: (*steverweber*) cloud vmware driver does not provide mac\_address unless vmware tools is running | refs: #26137 #26140
- PR #26119: (*jodv*) Backport eauth bugfix to 2015.5 @ 2015-08-09T02:19:52Z
- PR #26135: (*cro*) Fix proxy minions in 2015.5 and significantly update documentation. @ 2015-08-09T02:19:21Z
- PR #26132: (*TheBigBear*) minor edit @ 2015-08-08T21:05:34Z
- PR #26133: (*amontalban*) Fixed #25915 in salt/modules/pkgng.py and salt/states/pkg.py @ 2015-08-08T21:05:05Z
  - ISSUE #25915: (*ari*) FreeBSD pkg install fails
- PR #26111: (*anlutro*) Better error messages when virtualenv creation fails @ 2015-08-07T21:42:09Z

- PR #26110: (*jfindlay*) check for sources before adding them to cmd str @ 2015-08-07T21:33:23Z
  - ISSUE #26093: (*freedba*) archive.tar bug | refs: #26110
- PR #26106: (*vr-jack*) Update `__init__.py` @ 2015-08-07T21:15:55Z
- PR #26101: (*rallytime*) Back-port #25984 to 2015.5 @ 2015-08-07T18:56:26Z
  - ISSUE #25983: (*jmdcal*) Trying to get md5 of local zip | refs: #25984
  - PR #25984: (*jmdcal*) Support local files without md5sum | refs: #26101
- PR #26080: (*techhat*) Fix string checking in s3fs @ 2015-08-06T23:36:09Z
- PR #26079: (*cachedout*) Update docs to remove state.over @ 2015-08-06T23:35:26Z
  - ISSUE #26039: (*basepi*) Update scheduler docs to use orchestrate instead of overstate | refs: #26079
- PR #26058: (*opdude*) Fix choco version on chocolatey versions below 0.9.9 @ 2015-08-06T18:50:10Z
- PR #26068: (*jfindlay*) fix autoruns.list looking in wrong directory @ 2015-08-06T18:49:48Z
- PR #26065: (*s0undt3ch*) [2015.5] Update to latest bootstrap stable release v2015.06.08 @ 2015-08-06T17:09:35Z
  - ISSUE #634: (*loupgaroublond*) /srv/salt/\_grains/ not documented | refs: #26065
  - ISSUE #631: (*fatbox*) Can't extend the same item multiple times | refs: #26065
  - ISSUE #625: (*whiteinge*) `cmd.run` state `user` flag is not working | refs: #25506 #632
  - PR #640: (*terminalmage*) fix syntax errors introduced in 0f776c13 | refs: #26065
  - PR #638: (*blast-hardcheese*) Tightened up configuration documentation | refs: #26065
  - PR #633: (*epoelke*) Bug fix to salt-key | refs: #26065
  - PR #632: (*whiteinge*) Change the `cmd.run` state to use the new `runas` arg | refs: #26065
- PR #26061: (*gmcwhistler*) Patch for issue #25994 @ 2015-08-06T17:07:34Z
  - ISSUE #25994: (*gmcwhistler*) module.ilo tempfile creation in `__execute_cmd` results in `TypeError: cannot concatenate 'str' and 'int' objects`
- PR #26064: (*s0undt3ch*) Don't stacktrace when trying to get the default locale. @ 2015-08-06T16:11:05Z
  - ISSUE #26063: (*saltstack-bot*) not working with salt-cloud shows unknown locale error | refs: #26064
- PR #26048: (*jacobhammons*) Updated windows download links in the docs to <https://repo.saltstack.com> @ 2015-08-05T22:59:50Z
- PR #26044: (*rallytime*) Make sure the key we're comparing is also lowercase @ 2015-08-05T19:23:54Z

### 35.2.8 Salt 2015.5.5 Release Notes

Version 2015.5.5 is a bugfix release for 2015.5.0.

Changes:

- The `cron.present` state now correctly defaults to state ID as identifier.
- When querying for VMs in `digital_ocean_v2.py`, the number of VMs to include in a page was changed from 20 (default) to 200 to reduce the number of API calls to Digital Ocean.
- The `vmware` Salt-Cloud driver was back-ported from the develop branch in order for installations of Salt that are older than 2015.8.0 to be able to use the `vmware` driver without stack-tracing on various deprecation paths that were implemented in the 2015.8.0 release.

#### Changes for v2015.5.3..v2015.5.5

Changes:

- **PR #26292:** (*iquast*) Rabbitmq 3.2.4 on Ubuntu has "...done.", not "...done" @ 2015-08-13T19:53:29Z
- **PR #26296:** (*iquast*) bugfix missing `'runas=None'` for `rabbitmqctl` cmds (backport to 2015.5) @ 2015-08-13T19:52:40Z
- **PR #26293:** (*jfindlay*) Fix #26268 @ 2015-08-13T19:48:06Z
  - **ISSUE #25618:** (*twangboy*) Fix `reg.py` to work with the registry properly | refs: #26268
  - **PR #26268:** (*twangboy*) Multiple improvements to `reg` executionmod and `state` mod | refs: #26293
- **PR #26290:** (*rallytime*) Only call `convert_to_arn` when action name is provided @ 2015-08-13T18:48:58Z
  - **ISSUE #25192:** (*deuscapturus*) 2015.5.2 `boto_cloudwatch_alarm.present` not working. | refs: #26290
- **PR #26288:** (*bbinet*) allow to delete grains which value is False @ 2015-08-13T18:24:36Z
- **PR #26263:** (*rallytime*) Don't make changes when `test=True` for `openstack` present/absent funcs @ 2015-08-13T16:30:31Z

- ISSUE #24882: (*nmadhok*) salt.states.openstack\_config.present and salt.states.openstack\_config.absent make changes when test=True | refs: #26263
- PR #26265: (*rallytime*) Don't stacktrace on query return in ec2.create\_snapshot @ 2015-08-13T16:28:48Z
  - ISSUE #24484: (*codehotter*) clouds/ec2.py: create\_snapshot throws exception | refs: #26265
- PR #26285: (*stanislavb*) Remove explicit version from instance identity URL @ 2015-08-13T16:25:32Z
- PR #26275: (*cachedout*) Re-init modules on multi-master reconnect @ 2015-08-13T15:52:50Z
- PR #26273: (*garethgreenaway*) Fixes to schedule module in 2015.5 @ 2015-08-13T15:34:43Z
- PR #26271: (*rallytime*) Fix del\_root\_vol\_on\_destroy and del\_all\_vols\_on\_destroy functionality on ec2 @ 2015-08-12T23:22:47Z
  - ISSUE #24483: (*codehotter*) clouds/ec2.py: del\_root\_vol\_on\_destroy and del\_all\_vols\_on\_destroy not working | refs: #26271
- PR #26219: (*anlutro*) cron: make identifier default to state ID @ 2015-08-12T18:42:33Z
  - ISSUE #25958: (*anlutro*) Cron identifier does not default to state ID as documented | refs: #26219
- PR #26257: (*rallytime*) Back-port #26237 to 2015.5 @ 2015-08-12T18:40:35Z
  - ISSUE #26207: (*fullermd*) group members setting fails with obscure error message on FreeBSD | refs: #26237
  - PR #26237: (*silenius*) fix issue #26207 | refs: #26257
- PR #26258: (*nmadhok*) Fix permission on tests/runtests.py on 2015.5 branch @ 2015-08-12T18:40:04Z
- PR #26261: (*nmadhok*) Correct spelling of integration in docs @ 2015-08-12T18:14:48Z
  - PR #2015: (*thekuffs*) Esky / bbfreeze support
- PR #26247: (*nmadhok*) Initial commit of unit tests for vmware cloud driver @ 2015-08-12T16:58:24Z
- PR #26246: (*nmadhok*) Backport additions to VMware cloud driver from develop to 2015.5 branch @ 2015-08-12T15:11:26Z
- PR #26239: (*opdude*) Fixed documentation to match function name @ 2015-08-12T14:48:52Z
- PR #26232: (*garethgreenaway*) Fix to trust\_key in gpg module for 2015.5. @ 2015-08-12T04:48:27Z
- PR #26084: (*twangboy*) Added python\_shell=True, quoted user input @ 2015-08-10T21:29:35Z
  - ISSUE #25802: (*jefftucker*) Running module ``npm.list" fails on Windows for masterless minion | refs: #26084
- PR #26183: (*cro*) Fix LDAP configuration issue. @ 2015-08-10T19:09:41Z
- PR #26186: (*jacobhammons*) regenerated man pages @ 2015-08-10T19:07:44Z
- PR #26182: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-08-10T19:00:10Z
  - ISSUE #25961: (*getabc*) [2015.5.3-2] salt-winrepo.git/salt-minion.sls fails certificate ``\*.wpengine.com' or `wpengine.com' | refs: #26047
  - ISSUE #25751: (*basepi*) Document *master\_finger* more prominently | refs: #26088
  - PR #26116: (*corux*) file.replace fails if repl string is an invalid regex and append/prepend is used
  - PR #26088: (*jacobhammons*) Master finger
  - PR #26047: (*jacobhammons*) Updated windows download links in the docs to <https://repo.saltstack.com>
- PR #26000: (*driskell*) Implement full event caching for subscribed tags @ 2015-08-10T18:57:17Z

- ISSUE #25998: (*driskell*) Event subsystem discarding required events during --batch breaking it for slow running commands | refs: #26000
- PR #26175: (*rallytime*) Back-port #26153 to 2015.5 @ 2015-08-10T18:22:32Z
  - PR #26153: (*loa*) Fix dockerio state documentation typo | refs: #26175
- PR #26177: (*rallytime*) Back-port #26147 to 2015.5 @ 2015-08-10T18:22:01Z
  - ISSUE #26024: (*jpgic*) lxc\_conf\_unset in cloud.profile is ignored
  - PR #26147: (*martinhoefling*) Fixes #26024 | refs: #26177
- PR #26179: (*rallytime*) Back-port #25404 to 2015.5 @ 2015-08-10T18:21:50Z
  - ISSUE #21082: (*clinta*) master\_type failover does not failover on DNS errors | refs: #25404
  - PR #25404: (*DmitryKuzmenko*) Fixed minion failover to next master on DNS errors. | refs: #26179
- PR #26180: (*jfindlay*) fix processing of state.template @ 2015-08-10T18:21:38Z
  - ISSUE #26112: (*wt*) state.template fails with unclear error with template with only an include | refs: #26180
- PR #26172: (*nmadhok*) [Backport] Make sure variable is a dictionary before popping something from it. @ 2015-08-10T16:42:50Z
  - ISSUE #26162: (*nmadhok*) VMware cloud driver create function failing with traceback on latest develop | refs: #26163 #26172
  - PR #26163: (*nmadhok*) Make sure variable is a dictionary before popping something from it.
- PR #26168: (*cachedout*) Fix slack docs @ 2015-08-10T14:57:18Z
  - ISSUE #26098: (*rdinoff*) SALT.STATES.SLACK Doc update | refs: #26168
- PR #26127: (*garethgreenaway*) Fixes to salt.utils.http related to cp.get\_file\_str bug. @ 2015-08-10T14:38:25Z
  - ISSUE #24106: (*nvx*) fileclient.py#get\_url ignores HTTP Auth again (2015.5 regression) | refs: #26127
- PR #26140: (*nmadhok*) VMware cloud driver fixes @ 2015-08-10T13:15:58Z
  - ISSUE #26141: (*nmadhok*) salt-cloud VMware driver fails with error in parsing configuration file | refs: #26140
  - ISSUE #25809: (*o-sleep*) vmware cloud module error message | refs: #26140
  - ISSUE #25625: (*steverweber*) cloud vmware driver does not provide mac\_address unless vmware tools is running | refs: #26137 #26140
- PR #26137: (*steverweber*) use device mac address if vmttools not active @ 2015-08-09T03:05:36Z
  - ISSUE #25625: (*steverweber*) cloud vmware driver does not provide mac\_address unless vmware tools is running | refs: #26137 #26140
- PR #26119: (*jodv*) Backport eauth bugfix to 2015.5 @ 2015-08-09T02:19:52Z
- PR #26135: (*cro*) Fix proxy minions in 2015.5 and significantly update documentation. @ 2015-08-09T02:19:21Z
- PR #26132: (*TheBigBear*) minor edit @ 2015-08-08T21:05:34Z
- PR #26133: (*amontalban*) Fixed #25915 in salt/modules/pkgng.py and salt/states/pkg.py @ 2015-08-08T21:05:05Z
  - ISSUE #25915: (*ari*) FreeBSD pkg install fails
- PR #26111: (*anlutro*) Better error messages when virtualenv creation fails @ 2015-08-07T21:42:09Z
- PR #26110: (*jfindlay*) check for sources before adding them to cmd str @ 2015-08-07T21:33:23Z

- ISSUE #26093: (*freedba*) archive.tar bug | refs: #26110
- PR #26106: (*vr-jack*) Update `__init__.py` @ 2015-08-07T21:15:55Z
- PR #26101: (*rallytime*) Back-port #25984 to 2015.5 @ 2015-08-07T18:56:26Z
  - ISSUE #25983: (*jmdcal*) Trying to get md5 of local zip | refs: #25984
  - PR #25984: (*jmdcal*) Support local files without md5sum | refs: #26101
- PR #26080: (*techhat*) Fix string checking in `s3fs` @ 2015-08-06T23:36:09Z
- PR #26079: (*cachedout*) Update docs to remove `state.over` @ 2015-08-06T23:35:26Z
  - ISSUE #26039: (*basepi*) Update scheduler docs to use `orchestrate` instead of `overstate` | refs: #26079
- PR #26058: (*opdude*) Fix `choco` version on `chocolatey` versions below 0.9.9 @ 2015-08-06T18:50:10Z
- PR #26068: (*jfindlay*) fix `autoruns.list` looking in wrong directory @ 2015-08-06T18:49:48Z
- PR #26065: (*s0undt3ch*) [2015.5] Update to latest bootstrap stable release v2015.06.08 @ 2015-08-06T17:09:35Z
  - ISSUE #634: (*loupgaroublond*) `/srv/salt/_grains/` not documented | refs: #26065
  - ISSUE #631: (*fatbox*) Can't extend the same item multiple times | refs: #26065
  - ISSUE #625: (*whiteinge*) `cmd.run` state `user` flag is not working | refs: #25506 #632
  - PR #640: (*terminalmage*) fix syntax errors introduced in 0f776c13 | refs: #26065
  - PR #638: (*blast-hardcheese*) Tightened up configuration documentation | refs: #26065
  - PR #633: (*epoelke*) Bug fix to `salt-key` | refs: #26065
  - PR #632: (*whiteinge*) Change the `cmd.run` state to use the new `runas` arg | refs: #26065
- PR #26061: (*gmcwhistler*) Patch for issue #25994 @ 2015-08-06T17:07:34Z
  - ISSUE #25994: (*gmcwhistler*) `module.ilo` tempfile creation in `__execute_cmd` results in `TypeError: cannot concatenate 'str' and 'int' objects`
- PR #26064: (*s0undt3ch*) Don't stacktrace when trying to get the default locale. @ 2015-08-06T16:11:05Z
  - ISSUE #26063: (*saltstack-bot*) not working with `salt-cloud` shows unknown locale error | refs: #26064
- PR #26048: (*jacobhammons*) Updated windows download links in the docs to <https://repo.saltstack.com> @ 2015-08-05T22:59:50Z
- PR #26044: (*rallytime*) Make sure the key we're comparing is also lowercase @ 2015-08-05T19:23:54Z
  - ISSUE #25616: (*rallytime*) [2015.5] Provisioning Linodes Stacktraces | refs: #26044
- PR #26042: (*jfindlay*) fix test mode logic in state docs @ 2015-08-05T19:23:07Z
- PR #26036: (*nicholascapo*) `survey.hash`: Remove manually printed text @ 2015-08-05T19:21:59Z
  - ISSUE #24460: (*nicholascapo*) `Survey runner` does not follow `--out` flag | refs: #26036
- PR #26030: (*opdude*) Fix a bug in `choco` version that returned odd data @ 2015-08-05T16:30:25Z
- PR #26032: (*jfindlay*) add test logic to state `reult` doc @ 2015-08-05T16:28:32Z
- PR #26031: (*alekti*) Revert ``Add file as supported protocol for file source\_hash. Fixes #23764" @ 2015-08-05T15:32:01Z
  - ISSUE #23764: (*es1o*) `source_hash` from local file is not supported. | refs: #25750
- PR #26021: (*anlutro*) Documentation: Specify `versionadded` for `git.present` shared argument @ 2015-08-05T14:17:38Z

- PR #26020: (*alekti*) Correctly resolve conflict merging pull 25750 to 2015.5 @ 2015-08-05T14:16:58Z
  - ISSUE #23764: (*es1o*) source\_hash from local file is not supported. | refs: #25750
  - PR #25750: (*alekti*) Add file as supported protocol for file source\_hash. Fixes #25701. | refs: #26020
- PR #26016: (*basepi*) Revert ``Deep merge of pillar lists" @ 2015-08-05T04:59:52Z
  - ISSUE #22241: (*masterkorp*) Salt master not properly generating the map | refs: #25358
  - PR #25358: (*dkiser*) Deep merge of pillar lists | refs: #26016
- PR #25992: (*twangboy*) Refactor win\_system.py @ 2015-08-05T04:54:18Z
  - ISSUE #12255: (*eliasp*) `system.set\_computer\_desc' fails with non-ASCII chars | refs: #25992
  - ISSUE #3: (*thatch45*) libvirt module
- PR #26002: (*twangboy*) Fixed regex to account for comment character followed by whitespace @ 2015-08-04T22:28:11Z
  - ISSUE #25948: (*twangboy*) Fix uncomment function to handle spaces | refs: #26002
- PR #25970: (*jfindlay*) accept addition of layman overlay @ 2015-08-04T15:42:28Z
  - ISSUE #25949: (*godlike64*) layman.add does not work with unofficial overlays | refs: #25970
- PR #25971: (*basepi*) [2015.5] salt.modules.reg Add spaces for strings split across multiple lines @ 2015-08-04T15:39:48Z
- PR #25990: (*rallytime*) Back-port #25976 to 2015.5 @ 2015-08-04T14:36:53Z
  - PR #25976: (*fleaflicker*) Typo in help output | refs: #25990
- PR #25996: (*attiasr*) fix msixexec package remove @ 2015-08-04T14:36:31Z
- PR #25966: (*rallytime*) Back-port #25864 to 2015.5 @ 2015-08-03T18:48:26Z
  - ISSUE #25863: (*peterdemin*) pkg.installed fails on already installed package if it is in versionlock.list | refs: #25864
  - PR #25864: (*peterdemin*) #25863 state.pkg.installed fix | refs: #25966
- PR #25967: (*rallytime*) Back-port #25917 to 2015.5 @ 2015-08-03T18:48:02Z
  - PR #25917: (*jmdcal*) adding missing format string | refs: #25967
- PR #25895: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-08-03T17:12:37Z
  - ISSUE #23764: (*es1o*) source\_hash from local file is not supported. | refs: #25750
  - PR #25750: (*alekti*) Add file as supported protocol for file source\_hash. Fixes #25701. | refs: #26020
  - PR #25704: (*cachedout*) Ensure prior alignment with master\_type in 2014.7
  - PR #25657: (*MrCitron*) Add the ability to specify a base pattern for carbon returner
  - PR #25633: (*AkhterAli*) Update loader.py
- PR #25941: (*jfindlay*) add timelib to dependency versions @ 2015-08-03T12:23:42Z
  - ISSUE #25850: (*ssguard*) Need to add packages to --versions-report | refs: #25941
- PR #25951: (*garethgreenaway*) Log when event.fire and event.fire\_master fail. @ 2015-08-03T00:19:45Z
- PR #25942: (*jfindlay*) typo in minion doc @ 2015-07-31T23:34:55Z
  - ISSUE #25838: (*grep4linux*) docs disable\_modules documentation typo | refs: #25942
- PR #25938: (*jacobhammons*) Doc on using syndic with multimaster @ 2015-07-31T23:05:05Z

- PR #14690: (*jackson tj*) Multi syndic | refs: #25938
- PR #25848: (*twangboy*) Added allusers="1" when installing msi @ 2015-07-31T20:33:17Z
  - ISSUE #25839: (*twangboy*) ALLUSERS="1" should be a default when installing MSI's | refs: #25848
- PR #25898: (*jfindlay*) clarify and expand syndic docs @ 2015-07-31T20:01:23Z
- PR #25927: (*jackson tj*) Pass actual renderers to the Reactor's Compiler @ 2015-07-31T20:00:17Z
  - ISSUE #25852: (*UtahDave*) Salt loader is not loading Salt vars in reactor python renderer | refs: #25927
- PR #25921: (*cachedout*) Handle non-ascii in state log @ 2015-07-31T17:41:30Z

  - ISSUE #24484: (*codehotter*) clouds/ec2.py: create\_snapshot throws exception | refs: #26326
- PR #26306: (*rallytime*) Move VM creation details dict to log.trace @ 2015-08-14T17:39:52Z
  - ISSUE #16179: (*UtahDave*) Salt Cloud -l debug includes the entire bootstrap script twice in its output | refs: #26306

### 35.2.9 Salt 2015.5.6 Release Notes

Version 2015.5.6 is a bugfix release for 2015.5.0.

#### Security Fixes

CVE-2015-6941 - win\_useradd module and salt-cloud display passwords in debug log

Updated the win\_useradd module return data to no longer include the password of the newly created user. The password is now replaced with the string XXX-REDACTED-XXX. Updated the Salt Cloud debug output to no longer display win\_password and sudo\_password authentication credentials.

CVE-2015-6918 - Git modules leaking HTTPS auth credentials to debug log

Updated the Git state and execution modules to no longer display HTTPS basic authentication credentials in loglevel debug output on the Salt master. These credentials are now replaced with REDACTED in the debug output. Thanks to Andreas Stieger <[asteiger@suse.com](mailto:asteiger@suse.com)> for bringing this to our attention.

#### Changes for v2015.5.5..v2015.5.6

Total Merges: 144

Changes:

- PR #27557: (*jfindlay*) add doc motivating mine vs grains
- PR #27515: (*jfindlay*) save iptables rules on SuSE
- PR #27509: (*jfindlay*) tell the user why the gluster module does not work
- PR #27379: (*jfindlay*) document and check dict type for pip env\_vars
- PR #27516: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #27472: (*cachedout*) Change recommended schema for data field in mysql event table

- PR #27468: (*cachedout*) Fix 27351
- PR #27479: (*aboe76*) fix locale on opensuse and suse [`#27438`\\_](#)
- PR #27483: (*rallytime*) Outputters should sync to output, not outputters, on the minion.
- PR #27484: (*rallytime*) Back-port [#27434](#) and [#27470](#) to 2015.5
- PR #27469: (*twangboy*) Added quotes to version numbers example
- PR #27467: (*cachedout*) file.managed: check contents\_{pillar|grain} result
- PR #27419: (*rallytime*) Amend error log to include multiple tips for troubleshooting.
- PR #27426: (*rallytime*) Don't stacktrace if there are conflicting id errors in highstate
- PR #27408: (*rallytime*) Fix avail\_locations function for the softlayer\_hw driver in 2015.5
- PR #27410: (*jacobhammons*) Fix css layout Refs [`#27389`\\_](#)
- PR #27336: (*rallytime*) [2015.5] Fixup salt-cloud logging
- PR #27358: (*lorenegordon*) Escape search replacement text, fixes [`#27356`\\_](#)
- PR #27345: (*rallytime*) Allow use of rst header links by separating options out from yaml example
- PR #26903: (*bersace*) Review defaults.get
- PR #27317: (*efficks*) State unzip should use unzip command instead of unzip\_cmd.
- PR #27309: (*rallytime*) Change a value list to a comma-separated string in boto\_route53.present
- PR #27311: (*jfindlay*) discuss replacement occurrences in file doc
- PR #27310: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #27308: (*terminalmage*) Fix refresh\_db regression in yumpkg.py
- PR #27286: (*terminalmage*) Add a configurable timer for minion return retries
- PR #27278: (*rallytime*) Back-port [#27256](#) to 2015.5
- PR #27277: (*rallytime*) Back-port [#27230](#) to 2015.5
- PR #27253: (*jfindlay*) 2015.5 -> 2015.5.0
- PR #27244: (*garethgreenaway*) Exception in cloud.ec2.create\_snapshot
- PR #27231: (*jfindlay*) only write cron file if it is changed
- PR #27233: (*basepi*) [2015.5] Add stub release notes for 2015.5.6
- PR #27208: (*basepi*) [2015.5] Add test.nop state
- PR #27201: (*jfindlay*) rename hash\_hostname to hash\_known\_hosts
- PR #27214: (*jacksonjtj*) Correctly support https, port 443 is not a requirement
- PR #27172: (*rallytime*) Back-port [#27150](#) to 2015.5
- PR #27194: (*rallytime*) Back-port [#27180](#) to 2015.5
- PR #27176: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #27170: (*rallytime*) Update Getting Started with GCE docs to use cloud.profiles or cloud.profiles.d examples
- PR #27167: (*rallytime*) Back-port [#27148](#) to 2015.5
- PR #27168: (*techhat*) Add further gating of impacket library
- PR #27166: (*rallytime*) Allow a full-query for EC2, even if there are no profiles defined

- PR #27162: (*rallytime*) Be explicit in using ``SoftLayer" for service queries in SoftLayer drivers
- PR #27149: (*twangboy*) Fixed problem with add/remove path
- PR #27147: (*rallytime*) Enforce bounds in the GCE Regex
- PR #27128: (*egoven*) don't show diff for test run if show\_diff=False
- PR #27116: (*jacobhammons*) Update latest to 2015.8, 2015.5 is now previous
- PR #27033: (*jfindlay*) Merge #27019
- PR #26942: (*Arabus*) Fix docker.run
- PR #26977: (*abh*) Add support for PEERNTP network interface configuration
- PR #27023: (*jfindlay*) add test support for htpasswd state mod
- PR #27074: (*twangboy*) Replaced password with redacted when displayed
- PR #27073: (*rallytime*) Remove ``use develop branch" warning from LXC tutorial
- PR #27054: (*rallytime*) Back-port #27029 to 2015.5
- PR #27053: (*rallytime*) Back-port #26992 to 2015.5
- PR #27052: (*rallytime*) Back-port #26930 to 2015.5
- PR #27049: (*johanek*) Run repoquery less
- PR #27070: (*stanislavb*) Deprecate salt.utils.iam in Carbon
- PR #27030: (*jfindlay*) Backport #26938
- PR #27025: (*cachedout*) Better try and error handling for prep\_jid
- PR #27035: (*terminalmage*) useradd.py: Use contextmanager to prevent leaked filehandles
- PR #27034: (*rallytime*) Update softlayer docs for where to find apikey
- PR #27024: (*rallytime*) Back-port #27004 to 2015.5
- PR #27027: (*rallytime*) Back-port #27013 to 2015.5
- PR #27026: (*rallytime*) Back-port #27011 to 2015.5
- PR #26972: (*twangboy*) Catch the 404 error from fileclient
- PR #26951: (*terminalmage*) Fix timezone module for CentOS
- PR #26875: (*marccardinal*) LXC gateway provisioned only when IP is provided
- PR #26997: (*twangboy*) Fixed symlinks for windows (don't use user root)
- PR #27001: (*twangboy*) Added CLI Example for reg.delete\_key\_recursive
- PR #26996: (*jacobhammons*) Beacon doc updates
- PR #26868: (*joejulian*) Use the actual device name when checking vgdisplay
- PR #26955: (*dsumsky*) S3 ext\_pillar module has broken caching mechanism (backport to 2015.5)
- PR #26987: (*rallytime*) Back-port #26966 to 2015.5
- PR #26915: (*rallytime*) Update Joyent Cloud Tests
- PR #26971: (*rallytime*) Fix a couple of typos in reactor docs
- PR #26976: (*thatch45*) Revert ``file.symlink gets windows account instead of root"
- PR #26975: (*whiteinge*) Remove mocks from rest\_cherry.py integration tests; fix groups check bug

- PR #26899: (*twangboy*) file.symlink gets windows account instead of root
- PR #26960: (*rallytime*) Fix bash code block formatting in CherryPy netapi docs
- PR #26940: (*rallytime*) Fix minor doc typo in client api
- PR #26871: (*rallytime*) Back-port #26852 to 2015.5
- PR #26851: (*jacobhammons*) states/pkgrepo examples, suse installation updates
- PR #26817: (*jfindlay*) modify groupadd for rhel 5
- PR #26824: (*pravka*) [salt-cloud] Fix creating droplet from snapshot in digital\_ocean provider
- PR #26823: (*joejulian*) use dbus instead of localectl
- PR #26820: (*jfindlay*) add default param in `_parse_localectl` in locale mod
- PR #26821: (*twangboy*) Fixed user.rename function in windows
- PR #26803: (*twangboy*) Added check for PyMySQL if MySQLdb import fails
- PR #26815: (*jfindlay*) stringify linode id before performing str actions
- PR #26800: (*jacobhammons*) Doc bug fixes
- PR #26793: (*rallytime*) Don't stacktrace if ``name" is specified as a minion id in a map file
- PR #26790: (*rallytime*) Update Saltify docs to be more accurate and helpful
- PR #26787: (*jfindlay*) merge #26775
- PR #26759: (*terminalmage*) Backport PR #26726 to 2015.5 branch
- PR #26768: (*garethgreenaway*) Fixes to ipset in 2015.5 for ``#26628`_``
- PR #26753: (*jfindlay*) import elementtree from `_compat` in ilo exec mod
- PR #26736: (*twangboy*) Changed import from smbconnection to smb3
- PR #26714: (*jfindlay*) add exception placeholder for older msgpacks
- PR #26710: (*rallytime*) Update GCE driver to return True, False or a new name in `__virtual__()`
- PR #26709: (*rallytime*) Ensure VM name is valid before trying to create Linode VM
- PR #26617: (*terminalmage*) Fix Windows failures in pip module due to raw string formatting
- PR #26700: (*kev009*) Ignore the first element of kern.disks split, which is the sysctl name
- PR #26695: (*terminalmage*) Better HTTPS basic auth redaction for 2015.5 branch
- PR #26694: (*terminalmage*) Backport #26693 to 2015.5
- PR #26681: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #26676: (*rallytime*) Back-port #26648 to 2015.5
- PR #26677: (*rallytime*) Back-port #26653 to 2015.5
- PR #26675: (*rallytime*) Back-port #26631 to 2015.5
- PR #26655: (*cheng0919*) Update win\_dns\_client.py
- PR #26662: (*jacobhammons*) update version to 2015.5
- PR #26651: (*jfindlay*) add 2015.5.4 notes to 2015.5.5 notes
- PR #26525: (*jfindlay*) document check\_file\_meta args, remove unused arg
- PR #26561: (*stanislavb*) Leave salt.utils.s3 location fallback to salt.utils.aws

- PR #26573: (*rallytime*) Don't stacktrace if using private\_ips and delete\_sshkeys together
- PR #26563: (*rallytime*) Fix error detection when salt-cloud config is missing a master's address
- PR #26641: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #26620: (*rallytime*) Also add -Z to script args for cloud tests
- PR #26618: (*rallytime*) Add script\_args: '-P' to Ubuntu 14 profiles for nightly cloud tests
- PR #26612: (*rallytime*) Use an available image to test against
- PR #26576: (*rallytime*) Ensure GCE and EC2 configuration checks are correct
- PR #26580: (*rallytime*) Avoid race condition when assigning floating IPs to new VMs
- PR #26581: (*terminalmage*) Skip tests that don't work with older mock
- PR #26591: (*rallytime*) Back-port #26554 to 2015.5
- PR #26565: (*cachedout*) Fix many errors with \_\_virtual\_\_ in tests
- PR #26553: (*rallytime*) Back-port #26548 to 2015.5
- PR #26552: (*rallytime*) Back-port #26542 to 2015.5
- PR #26551: (*rallytime*) Back-port #26539 to 2015.5
- PR #26549: (*rallytime*) Back-port #26524 to 2015.5
- PR #26527: (*jfindlay*) check exists and values in boto\_elb listeners
- PR #26446: (*stanislavb*) Fetch AWS region from EC2 instance metadata
- PR #26546: (*nmadhok*) Do not raise KeyError when calling avail\_images if VM/template is in disconnected state
- PR #26537: (*jfindlay*) Merge #26481
- PR #26528: (*zmalone*) Fixing encrypt to instructions in the 2015.5 branch

### 35.2.10 Salt 2015.5.7 Release Notes

---

**Note:** A significant orchestrate issue #29110 was discovered during the release process of 2015.5.7, so it has not been officially released. Please use 2015.5.8 instead.

Total Merges: 102

Changes:

- PR #28731: (*garethgreenaway*) Fixes to salt scheduler in 2015.5, ensuring that return\_job is only used on minion scheduler
- PR #28857: (*rallytime*) Back-port #28851 to 2015.5
- PR #28856: (*rallytime*) Back-port #28853 to 2015.5
- PR #28832: (*basepi*) [2015.5] Backport #28826
- PR #28833: (*basepi*) [2015.5] Increase the default gather\_job\_timeout
- PR #28829: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5

- PR #28756: (*MrCitron*) Fix [`#25775`](#) \_
- PR #28786: (*chrigl*) closes [`#28783`](#) \_
- PR #28776: (*rallytime*) Back-port [#28740](#) to 2015.5
- PR #28760: (*dmyerscough*) Fixing CherryPy key bug
- PR #28746: (*rallytime*) Back-port [#28718](#) to 2015.5
- PR #28705: (*cachedout*) Account for new headers class in tornado 4.3
- PR #28699: (*rallytime*) Back-port [#28670](#) to 2015.5
- PR #28703: (*rallytime*) Back-port [#28690](#) to 2015.5
- PR #28694: (*s0undt3ch*) [2015.5] Update to latest bootstrap script v2015.11.09
- PR #28669: (*rallytime*) Use the -q argument to strip extraneous messages from rabbitmq
- PR #28645: (*jacksonjtj*) Rework minion return\_retry\_timer
- PR #28668: (*twangboy*) Fixed join\_domain and unjoin\_domain for Windows
- PR #28666: (*jfindlay*) define r\_data before using it in file module
- PR #28662: (*cachedout*) Add note about disabling master\_alive\_interval
- PR #28627: (*twangboy*) Backport win\_useradd
- PR #28617: (*cachedout*) Set restrictive umask on module sync
- PR #28622: (*gravyboat*) Update puppet module wording
- PR #28563: (*s0undt3ch*) [2015.5] Update to latest bootstrap script v2015.11.04
- PR #28541: (*twangboy*) Fixed problem with system.set\_computer\_name
- PR #28537: (*jfindlay*) decode filename to utf-8 in file.recurse state
- PR #28529: (*rallytime*) Update contributing and documentation pages to recommend submitting against branches
- PR #28548: (*nmadhok*) [Backport] [2015.5] Tasks can be in queued state instead of running
- PR #28531: (*rallytime*) Add versionadded directives to virtualenv\_mod state/module
- PR #28508: (*twangboy*) Fixed windows tests
- PR #28525: (*rallytime*) Fix spacing in doc examples for boto\_route53 state and module
- PR #28517: (*rallytime*) Add state\_auto\_order defaults to True note to ordering docs
- PR #28512: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #28448: (*gwaters*) added a note to the tutorial for redhat derivatives
- PR #28406: (*rallytime*) Back-port [#28381](#) to 2015.5
- PR #28413: (*rallytime*) Back-port [#28400](#) to 2015.5
- PR #28366: (*erchn*) mark repo not enabled when pkgrepo state passes in disable: True
- PR #28373: (*beverlcl*) Fixing bug [`#28372`](#) \_ for use\_carrier option on bonding network interfaces.
- PR #28359: (*rallytime*) Back-port [#28358](#) to 2015.5
- PR #28346: (*twangboy*) Fix installer
- PR #28315: (*gwaters*) Adding a working example of setting pillar data on the cli

- PR #28211: (*terminalmage*) Fix for ext\_pillar being compiled twice in legacy git\_pillar code (2015.5 branch)
- PR #28263: (*cachedout*) New channel for event.send
- PR #28293: (*cachedout*) Minor grammar changes
- PR #28271: (*gwaters*) Update tutorial documentation
- PR #28280: (*0xf10e*) Correct Jinja function load\_\* to import\_\*
- PR #28255: (*cachedout*) Add \_\_cli opt
- PR #28213: (*rallytime*) If record returned None, don't continue with the state. Something went wrong
- PR #28238: (*basepi*) [2015.5] Fix schedule.present always diffing
- PR #28174: (*loregordon*) Add support for multiline regex in file.replace
- PR #28175: (*twangboy*) Fixes ``#19673`_`
- PR #28140: (*rallytime*) Add OpenBSD installation documentation to 2015.5 branch
- PR #28138: (*rallytime*) Back-port #28130 EC2 Sizes Only portion to 2015.5
- PR #28097: (*jacksonjtj*) For all multi-part messages, check the headers. If the header is not ...
- PR #28117: (*rallytime*) Clean up stacktrace when master can't be reached in lxc cloud driver
- PR #28110: (*terminalmage*) Add explanation of file\_client: local setting masterless mode
- PR #28109: (*rallytime*) Add created reactor event to lxc cloud driver
- PR #27996: (*rallytime*) Don't fail if pip package is already present and pip1 is installed
- PR #28056: (*rallytime*) Back-port #28033 to 2015.5
- PR #28059: (*rallytime*) Back-port #28040 to 2015.5
- PR #28047: (*cachedout*) Restore FTP functionality to file client
- PR #28032: (*twangboy*) Fixed win\_path.py
- PR #28037: (*rallytime*) Back-port #28003 to 2015.5
- PR #28031: (*jacobhammons*) Updated release notes with additional CVE information
- PR #28008: (*jfindlay*) platform independent line endings in hosts mod
- PR #28012: (*rallytime*) Clean up stack trace when something goes wrong with minion output
- PR #27995: (*jacobhammons*) added link to grains security FAQ to targeting and pillar topics.
- PR #27986: (*jacobhammons*) Changed current release to 5.6 and added CVE to release notes
- PR #27913: (*pass-by-value*) Set default
- PR #27876: (*terminalmage*) 2015.5 branch: Fix traceback when 2015.8 git ext\_pillar config schema used
- PR #27726: (*jfindlay*) deprecate hash\_hostname in favor of hash\_known\_hosts
- PR #27776: (*jfindlay*) return message when local jobs\_cache not found
- PR #27766: (*jfindlay*) better check for debian userdel error
- PR #27758: (*iggy*) Remove redundant text from syslog returner
- PR #27841: (*terminalmage*) Detect Manjaro Linux as Arch derivative
- PR #27852: (*rallytime*) Back-port #27806 to 2015.5
- PR #27838: (*basepi*) [2015.5] Fix highstate outputter for jobs.lookup\_jid

- PR #27791: (*eguwen*) 2015.5 postgres\_user groups backport
- PR #27759: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #27732: (*jacobhammons*) update docs for `__virtual__` and `__virtualname__`
- PR #27747: (*Sacro*) Chocolatey doesn't have a help command.
- PR #27733: (*jacobhammons*) hardening topic - updates to docs.saltstack.com theme
- PR #27706: (*jacobhammons*) Assorted doc bugs
- PR #27695: (*rallytime*) Back-port #27671 to 2015.5
- PR #27524: (*jfindlay*) parse pkgng output in quiet mode for `>= 1.6.1`
- PR #27686: (*rallytime*) Back-port #27476 to 2015.5
- PR #27684: (*rallytime*) Back-port #27656 to 2015.5
- PR #27683: (*rallytime*) Back-port #27659 to 2015.5
- PR #27682: (*rallytime*) Back-port #27566 to 2015.5
- PR #27681: (*rallytime*) Back-port #25928 to 2015.5
- PR #27680: (*rallytime*) Back-port #27535 to 2015.5
- PR #27442: (*JaseFace*) Ensure we pass on the enable setting if present, or use the default of True if not in `build_schedule_item()`
- PR #27641: (*rallytime*) Gate the psutil import and add depends doc for diskusage beacon
- PR #27644: (*rallytime*) Back-port #27640 to 2015.5
- PR #27612: (*rallytime*) Fix GCE external\_ip stacktraces in 2015.5
- PR #27568: (*jacobhammons*) regenerated man pages

### 35.2.11 Salt 2015.5.8 Release Notes

#### Security Fix

CVE-2015-8034: Saving `state.sls` cache data to disk with insecure permissions

This affects users of the `state.sls` function. The state run cache on the minion was being created with incorrect permissions. This file could potentially contain sensitive data that was inserted via jinja into the state SLS files. The permissions for this file are now being set correctly. Thanks to @zmalone for bringing this issue to our attention.

#### Changes

Extended changelog courtesy of Todd Stansell (<https://github.com/tjstansell/salt-changelogs>):

*Generated at: 2015-11-23T23:16:23Z*

Total Merges: 118

Changes:

- PR #29128: (*cachedout*) Set a safer default value for `ret` in `saltmod`
- PR #29122: (*cachedout*) Fix broken state orchestration
- PR #29096: (*rallytime*) Back-port #29093 to 2015.5

- PR #29084: (*rallytime*) Back-port #29055 to 2015.5
- PR #29083: (*rallytime*) Back-port #29053 to 2015.5
- PR #28932: (*twangboy*) Fixed user.present / user.absent in windows
- PR #29011: (*rallytime*) Back-port #28630 to 2015.5
- PR #28982: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #28949: (*whiteinge*) Add sync\_sdb execution function
- PR #28930: (*twangboy*) Added missing import mmap required by file.py
- PR #28908: (*rallytime*) A couple of spelling fixes for doc conventions page.
- PR #28902: (*whiteinge*) Fix missing JSON support for /keys endpoint
- PR #28897: (*rallytime*) Back-port #28873 to 2015.5
- PR #28871: (*basepi*) [2015.5] Fix command generation for mdadm.assemble
- PR #28864: (*jfindlay*) add 2015.5.7 release notes
- PR #28731: (*garthgreenaway*) Fixes to salt scheduler in 2015.5, ensuring that return\_job is only used on minion scheduler
- PR #28857: (*rallytime*) Back-port #28851 to 2015.5
- PR #28856: (*rallytime*) Back-port #28853 to 2015.5
- PR #28832: (*basepi*) [2015.5] Backport #28826
- PR #28833: (*basepi*) [2015.5] Increase the default gather\_job\_timeout
- PR #28829: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #28756: (*MrCitron*) Fix [`#25775`](#)
- PR #28786: (*chrigl*) closes [`#28783`](#)
- PR #28776: (*rallytime*) Back-port #28740 to 2015.5
- PR #28760: (*dmyerscough*) Fixing CherryPy key bug
- PR #28746: (*rallytime*) Back-port #28718 to 2015.5
- PR #28705: (*cachedout*) Account for new headers class in tornado 4.3
- PR #28699: (*rallytime*) Back-port #28670 to 2015.5
- PR #28703: (*rallytime*) Back-port #28690 to 2015.5
- PR #28694: (*s0undt3ch*) [2015.5] Update to latest bootstrap script v2015.11.09
- PR #28669: (*rallytime*) Use the -q argument to strip extraneous messages from rabbitmq
- PR #28645: (*jacksonjtj*) Rework minion return\_retry\_timer
- PR #28668: (*twangboy*) Fixed join\_domain and unjoin\_domain for Windows
- PR #28666: (*jfindlay*) define r\_data before using it in file module
- PR #28662: (*cachedout*) Add note about disabling master\_alive\_interval
- PR #28627: (*twangboy*) Backport win\_useradd
- PR #28617: (*cachedout*) Set restrictive umask on module sync
- PR #28622: (*gravyboat*) Update puppet module wording

- PR #28563: (*s0undt3ch*) [2015.5] Update to latest bootstrap script v2015.11.04
- PR #28541: (*twangboy*) Fixed problem with `system.set_computer_name`
- PR #28537: (*jfindlay*) decode filename to utf-8 in `file.recurse` state
- PR #28529: (*rallytime*) Update contributing and documentation pages to recommend submitting against branches
- PR #28548: (*nmadhok*) [Backport] [2015.5] Tasks can be in queued state instead of running
- PR #28531: (*rallytime*) Add versionadded directives to `virtualenv_mod` state/module
- PR #28508: (*twangboy*) Fixed windows tests
- PR #28525: (*rallytime*) Fix spacing in doc examples for `boto_route53` state and module
- PR #28517: (*rallytime*) Add `state_auto_order` defaults to True note to ordering docs
- PR #28512: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #28448: (*gwaters*) added a note to the tutorial for redhat derivatives
- PR #28406: (*rallytime*) Back-port #28381 to 2015.5
- PR #28413: (*rallytime*) Back-port #28400 to 2015.5
- PR #28366: (*erchn*) mark repo not enabled when `pkgrepo` state passes in `disable: True`
- PR #28373: (*beverlcl*) Fixing bug ``#28372`_` for `use_carrier` option on bonding network interfaces.
- PR #28359: (*rallytime*) Back-port #28358 to 2015.5
- PR #28346: (*twangboy*) Fix installer
- PR #28315: (*gwaters*) Adding a working example of setting pillar data on the cli
- PR #28211: (*terminalmage*) Fix for `ext_pillar` being compiled twice in legacy `git_pillar` code (2015.5 branch)
- PR #28263: (*cachedout*) New channel for `event.send`
- PR #28293: (*cachedout*) Minor grammar changes
- PR #28271: (*gwaters*) Update tutorial documentation
- PR #28280: (*0xf10e*) Correct Jinja function `load_*` to `import_*`
- PR #28255: (*cachedout*) Add `__cli` opt
- PR #28213: (*rallytime*) If record returned None, don't continue with the state. Something went wrong
- PR #28238: (*basepi*) [2015.5] Fix `schedule.present` always diffing
- PR #28174: (*lorenegordon*) Add support for multiline regex in `file.replace`
- PR #28175: (*twangboy*) Fixes ``#19673`_`
- PR #28140: (*rallytime*) Add OpenBSD installation documentation to 2015.5 branch
- PR #28138: (*rallytime*) Back-port #28130 EC2 Sizes Only portion to 2015.5

- PR #27644: (*rallytime*) Back-port #27640 to 2015.5
- PR #27612: (*rallytime*) Fix GCE external\_ip stacktraces in 2015.5
- PR #27568: (*jacobhammons*) regenerated man pages

### 35.2.12 Salt 2015.5.9 Release Notes

Extended changelog courtesy of Todd Stansell (<https://github.com/tjstansell/salt-changelogs>):

Generated at: 2016-01-08T23:02:31Z

Total Merges: 44

Changes:

- PR #30237: (*jacobhammons*) Updated man pages and doc version for 2015.5.9
- PR #30207: (*rallytime*) Use correct spacing in rabbitmq state examples
- PR #30191: (*jacobhammons*) Updated doc site banners
- PR #30125: (*abednarik*) Update user home event when createhome is set to False
- PR #30127: (*jsutton*) Updating documentation and example minion config for random\_master/master\_shuffle.
- PR #30110: (*markckimball*) Fixed flag sent to salt.utils.http in order for verify\_ssl to work correctly
- PR #30093: (*zmalone*) Noting that file\_roots and ``state tree" should both be avoided
- PR #30097: (*cachedout*) Note concern about cleartext password in docs for shadow.gen\_password
- PR #30089: (*mpreziuso*) Fixes terminology and adds more accurate details about the algorithms
- PR #30086: (*cachedout*) Document that gitfs needs recent libs
- PR #30070: (*cachedout*) Add documentation on debugging salt-ssh
- PR #30059: (*mpreziuso*) Fixes wrong function scope
- PR #30025: (*jtand*) Skipping some Boto tests until resolved moto issue
- PR #29949: (*aletourneau*) Enhanced netScaler docstring
- PR #29941: (*cachedout*) Fix spelling error in boto\_vpc
- PR #29908: (*cachedout*) Allow kwargs to be passed to pacman provide for update func
- PR #29909: (*abednarik*) FreeBSD pkgng fix for non-interactive install.
- PR #29730: (*rallytime*) Update docker-py version requirement to 0.6.0 for dockerio.py files
- PR #29715: (*rallytime*) Install correct package version, if provided, for npm state.
- PR #29721: (*terminalmage*) Fix display of multiline strings when iterating over a list
- PR #29646: (*rallytime*) Don't stacktrace on kwargs.get if kwargs=None
- PR #29673: (*rallytime*) Default value should be False and not `False'
- PR #29527: (*jfindlay*) 2015.5.7 notes: add note about not being released
- PR #29539: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #29504: (*rallytime*) Document userdata\_file option for EC2 driver
- PR #29507: (*rallytime*) Switch volumes and del\_\*\_on\_destroy example ordering
- PR #29469: (*abednarik*) Added Documentation note in salt cloud.

- PR #29461: (*dmyerscough*) Fix resource limits, systemd sets the default too small
- PR #29439: (*rallytime*) Back-port #28656 to 2015.5
- PR #29418: (*jacobhammons*) Added CVE 2015-8034 to 2015.5.8 release notes
- PR #29389: (*jacobhammons*) updated version numbers in documentation
- PR #28501: (*twangboy*) Requested fixes for 26898
- PR #29348: (*jtand*) Fixes an file.search on python2.6
- PR #29336: (*rallytime*) Back-port #29276 to 2015.5
- PR #29333: (*rallytime*) Back-port #29280 to 2015.5
- PR #29316: (*basepi*) [2015.5] Merge forward from 2014.7 to 2015.5
- PR #29216: (*clan*) size is 0 doesn't mean no data, e.g. /proc/version
- PR #29261: (*attiasr*) fix incorrect reinstallation of windows pkg
- PR #29214: (*cro*) Doc for salt.utils.http should say verify\_ssl not ssl\_verify.
- PR #29204: (*loregordon*) Use os.path.join to return full path to ca bundle

### 35.2.13 Salt 2014.7.0 Release Notes - Codename Helium

This release is the largest Salt release ever, with more features and commits than any previous release of Salt. Everything from the new RAET transport to major updates in Salt Cloud and the merging of Salt API into the main project.

---

**Important:** The Fedora/RHEL/CentOS `salt-master` package has been modified for this release. The following components of Salt have been broken out and placed into their own packages:

- salt-syndic
- salt-cloud
- salt-ssh

When the `salt-master` package is upgraded, these components will be removed, and they will need to be manually installed.

---

**Important:** Compound/pillar matching have been temporarily disabled for the `mine` and `publish` modules for this release due to the possibility of inferring pillar data using pillar glob matching. A proper fix is now in the 2014.7 branch and scheduled for the 2014.7.1 release, and compound matching and non-globbering pillar matching will be re-enabled at that point.

Compound and pillar matching for normal salt commands are unaffected.

---

### New Transport!

#### RAET Transport Option

This has been a HUGE amount of work, but the beta release of Salt with RAET is ready to go. RAET is a reliable queuing transport system that has been developed in partnership with a number of large enterprises to give Salt an alternative to ZeroMQ and a way to get Salt to scale well beyond tens of thousands of servers. Unlike ZeroMQ, RAET

is completely asynchronous in every aspect of its operation and has been developed using the flow programming paradigm. This allows for many new capabilities to be added to Salt in the upcoming releases.

Please keep in mind that this is a beta release of RAET and we hope for bugs to be worked out, performance to be better realized and more in the 2015.5.0 release.

Simply stated, users running Salt with RAET should expect some hiccups as we hammer out the update. This is a BETA release of Salt RAET.

For information about how to use Salt with RAET please see the [tutorial](#).

## Salt SSH Enhancements

Salt SSH has just entered a new league, with substantial updates and improvements to make salt-ssh more reliable and easier than ever! From new features like the ansible roster and fileservers backends to the new pypi salt-ssh installer to lowered deps and a swath of bugfixes, salt-ssh is basically reborn!

### Install salt-ssh Using pip

Salt-ssh is now pip-installable!

<https://pypi.python.org/pypi/salt-ssh/>

Pip will bring in all of the required deps, and while some deps are compiled, they all include pure python implementations, meaning that any compile errors which may be seen can be safely ignored.

```
pip install salt-ssh
```

### Fileserver Backends

Salt-ssh can now use the salt fileserver backend system. This allows for the gitfs, hgfs, s3, and many more ways to centrally store states to be easily used with salt-ssh. This also allows for a distributed team to easily use a centralized source.

### Saltfile Support

The new saltfile system makes it easy to have a user specific custom extended configuration.

### Ext Pillar

Salt-ssh can now use the external pillar system. Making it easier than ever to use salt-ssh with teams.

### No More sshpass

Thanks to the enhancements in the salt vt system, salt-ssh no longer requires sshpass to send passwords to ssh. This also makes the manipulation of ssh calls substantially more flexible, allowing for intercepting ssh calls in a much more fluid way.

### Pure Python Shim

The `salt-ssh` call originally used a shell script to discover what version of python to execute with and determine the state of the `ssh` code deployment. This shell script has been replaced with a pure python version making it easy to increase the capability of the code deployment without causing platform inconsistency issues with different shell interpreters.

### Custom Module Delivery

Custom modules are now seamlessly delivered. This makes the deployment of custom grains, states, execution modules and returners a seamless process.

### CP Module Support

Salt-ssh now makes simple file transfers easier than ever! The `cp` module allows for files to be conveniently sent from the salt fileserver system down to systems.

### More Thin Directory Options

Salt `ssh` functions by copying a subset of the salt code, or `salt thin` down to the target system. In the past this was always transferred to `/tmp/.salt` and cached there for subsequent commands.

Now, `salt thin` can be sent to a random directory and removed when the call is complete with the `-W` option. The new `-W` option still uses a static location but will clean up that location when finished.

The default `salt thin` location is now user defined, allowing multiple users to cleanly access the same systems.

### State System Enhancements

#### New Imperative State Keyword ``Listen''

The new `listen` and `listen_in` keywords allow for completely imperative states by calling the `mod_watch()` routine after all states have run instead of re-ordering the states.

#### Mod Aggregate Runtime Manipulator

The new `mod_aggregate` system allows for the state system to rewrite the state data during execution. This allows for state definitions to be aggregated dynamically at runtime.

The best example is found in the `pkg` state. If `mod_aggregate` is turned on, then when the first `pkg` state is reached, the state system will scan all of the other running states for `pkg` states and take all other packages set for `install` and `install` them all at once in the first `pkg` state.

These runtime modifications make it easy to run groups of states together. In future versions, we hope to fill out the `mod_aggregate` system to build in more and more optimizations.

For more documentation on `mod_aggregate`, see [the documentation](#).

### New Requisites: `onchanges` and `onfail`

The new `onchanges` and `onchanges_in` requisites make a state apply only if there are changes in the required state. This is useful to execute post hooks after changes occur on a system.

The other new requisites, `onfail`, and `onfail_in`, allow for a state to run in reaction to the failure of another state.

For more information about these new requisites, see the [requisites documentation](#).

### Global `onlyif` and `unless`

The `onlyif` and `unless` options can now be used for any state declaration.

### Use `names` to expand and override values

The *names declaration* in Salt's state system can now override or add values to the expanded data structure. For example:

```
my_users:
  user.present:
    - names:
      - larry
      - curly
    - moe:
      - shell: /bin/zsh
      - groups:
        - wheel
    - shell: /bin/bash
```

## Major Features

### Scheduler Additions

The Salt scheduler system has received MAJOR enhancements, allowing for cron-like scheduling and much more granular timing routines. See [here](#) for more info.

### Red Hat 7 Family Support

All the needed additions have been made to run Salt on RHEL 7 and derived OSes like CentOS and Scientific.

### Fileserver Backends in `salt-call`

Fileserver backends like `gitfs` can now be used without a salt master! Just add the fileserver backend configuration to the minion config and execute `salt-call`. This has been a much-requested feature and we are happy to finally bring it to our users.

### Amazon Execution Modules

An entire family of execution modules further enhancing Salt's Amazon Cloud support. They include the following:

- *Autoscale Groups* (includes *state support*) -- related: *Launch Control* states
- *Cloud Watch* (includes *state support*)
- *Elastic Cache* (includes *state support*)
- *Elastic Load Balancer* (includes *state support*)
- *IAM Identity and Access Management* (includes *state support*)
- *Route53 DNS* (includes *state support*)
- *Security Groups* (includes *state support*)
- *Simple Queue Service* (includes *state support*)

### LXC Runner Enhancements

BETA The Salt LXC management system has received a number of enhancements which make running an LXC cloud entirely from Salt an easy proposition.

### Next Gen Docker Management

The Docker support in Salt has been increased at least ten fold. The Docker API is now completely exposed and Salt ships with Docker data tracking systems which make automating Docker deployments very easy.

### Peer System Performance Improvements

The peer system communication routines have been refined to make the peer system substantially faster.

### SDB

Encryption at rest for configs

### GPG Renderer

Encrypted pillar at rest

### OpenStack Expansion

Lots of new OpenStack stuff

### Queues System

Ran change external queue systems into Salt events

## Multi Master Failover Additions

Connecting to multiple masters is more dynamic than ever

## Chef Execution Module

Managing Chef with Salt just got even easier!

## salt-api Project Merge

The `salt-api` project has been merged into Salt core and is now available as part of the regular `salt-master` package install. No API changes were made, the **salt-api** script and init scripts remain intact.

`salt-api` has always provided Yet Another Pluggable Interface to Salt (TM) in the form of `netapi` modules. These are modules that bind to a port and start a service. Like many of Salt's other module types, `netapi` modules often have library and configuration dependencies. See the documentation for each module for instructions.

See also:

*The full list of netapi modules.*

**Synchronous and Asynchronous Execution of Runner and Wheel Modules** `salt.runner.RunnerClient` and `salt.wheel.WheelClient` have both gained complimentary `cmd_sync` and `cmd_async` methods allowing for synchronous and asynchronous execution of any Runner or Wheel module function, all protected using Salt's *external authentication* system. `salt-api` benefits from this addition as well.

**rest\_cherry.py Additions** The `rest_cherry.py` `netapi` module provides the main REST API for Salt.

**Web Hooks** This release of course includes the Web Hook additions from the most recent `salt-api` release, which allows external services to signal actions within a Salt infrastructure. External services such as Amazon SNS, Travis-CI, or GitHub, as well as internal services that cannot or should not run a Salt minion daemon can be used as first-class components in Salt's rich orchestration capabilities.

The raw HTTP request body is now available in the event data. This is sometimes required information for checking an HMAC signature in order to verify a HTTP request. As an example, Amazon or GitHub requests are signed this way.

**Generating and Accepting Minion Keys** The `/key` convenience URL generates a public and private key for a minion, automatically pre-accepts the public key on the Salt Master, and returns both keys as a tarball for download.

This allows for easily bootstrapping the key on a new minion with a single HTTP call, such as with a Kickstart script, all using regular shell tools.

```
curl -sS http://salt-api.example.com:8000/keys \  
  -d mid=jerry \  
  -d username=kickstart \  
  -d password=kickstart \  
  -d eauth=pam \  
  -o jerry-salt-keys.tar
```

## Fileserver Backend Enhancements

All of the fileserver backends have been overhauled to be faster, lighter, and more reliable. The VCS backends (*gitfs*, *hgfs*, and *svnfs*) have also received a **lot** of new features.

Additionally, most config parameters for the VCS backends can now be configured on a per-remote basis, allowing for global config parameters to be overridden for a specific *gitfs*/*hgfs*/*svnfs* remote.

## New **gitfs** Features

**Pygit2 and Dulwich** In addition to supporting GitPython, support for *pygit2* (0.20.3 and newer) and *dulwich* have been added. Provided a compatible version of *pygit2* is installed, it will now be the default provider. The config parameter *gitfs\_provider* has been added to allow one to choose a specific provider for *gitfs*.

**Mountpoints** Prior to this release, to serve a file from *gitfs* at a salt fileserver URL of `salt://foo/bar/baz.txt`, it was necessary to ensure that the parent directories existed in the repository. A new config parameter *gitfs\_mountpoint* allows *gitfs* remotes to be exposed starting at a user-defined `salt://` URL.

**Environment Whitelisting/Blacklisting** By default, *gitfs* will expose all branches and tags as Salt fileserver environments. Two new config parameters, *gitfs\_env\_whitelist*, and *gitfs\_env\_blacklist*, allow more control over which branches and tags are exposed. More detailed information on how these two options work can be found in the *Gitfs Walkthrough*.

**Expanded Authentication Support** As of *pygit2* 0.20.3, both http(s) and SSH key authentication are supported, and Salt now also supports both authentication methods when using *pygit2*. Keep in mind that *pygit2* 0.20.3 is not yet available on many platforms, so those who had been using authenticated git repositories with a passphraseless key should stick to GitPython if a new enough *pygit2* is not yet available for the platform on which the master is running.

A full explanation of how to use authentication can be found in the *Gitfs Walkthrough*.

## New **hgfs** Features

**Mountpoints** This feature works exactly like its *gitfs counterpart*. The new config parameter is called *hgfs\_mountpoint*.

**Environment Whitelisting/Blacklisting** This feature works exactly like its *gitfs counterpart*. The new config parameters are called *hgfs\_env\_whitelist* and *hgfs\_env\_blacklist*.

## New **svnfs** Features

**Mountpoints** This feature works exactly like its *gitfs counterpart*. The new config parameter is called *svnfs\_mountpoint*.

**Environment Whitelisting/Blacklisting** This feature works exactly like its *gitfs counterpart*. The new config parameters are called *svnfs\_env\_whitelist* and *svnfs\_env\_blacklist*.

**Configurable Trunk/Branches/Tags Paths** Prior to this release, the paths where trunk, branches, and tags were located could only be in directories named ```trunk```, ```branches```, and ```tags``` directly under the root of the repository. Three new config parameters (*svnfs\_trunk*, *svnfs\_branches*, and *svnfs\_tags*) allow SVN repositories which are laid out differently to be used with svnfs.

### New **minionfs** Features

**Mountpoint** This feature works exactly like its *gitfs counterpart*. The new config parameter is called *minionfs\_mountpoint*. The one major difference is that, as minionfs doesn't use multiple remotes (it just serves up files pushed to the master using *cp.push*) there is no such thing as a per-remote configuration for *minionfs\_mountpoint*.

**Changing the Saltenv from Which Files are Served** A new config parameter (*minionfs\_env*) allows minionfs files to be served from a Salt fileserver environment other than `base`.

**Minion Whitelisting/Blacklisting** By default, minionfs will expose the pushed files from all minions. Two new config parameters, *minionfs\_whitelist*, and *minionfs\_blacklist*, allow minionfs to be restricted to serve files from only the desired minions.

### Pyobjects Renderer

Salt now ships with with the *Pyobjects Renderer* that allows for construction of States using pure Python with an idiomatic object interface.

### New Modules

In addition to the Amazon modules mentioned above, there are also several other new execution modules:

- *Oracle*
- *Random*
- *Redis*
- *Amazon Simple Queue Service*
- *Block Device Management*
- *CoreOS etcd*
- *Genesis*
- *InfluxDB*
- *Server Density*
- *Twilio Notifications*
- *Varnish*
- *ZNC IRC Bouncer*
- *SMTP*

## New Runners

- *Map/Reduce Style*
- *Queue*

## New External Pillars

- *CoreOS etcd*

## New Salt-Cloud Providers

- *Aliyun ECS Cloud*
- *LXC Containers*
- *Proxmox (OpenVZ containers & KVM)*

## Salt Call Change

When used with a returner, salt-call now contacts a master if `--local` is not specified.

## Deprecations

### `salt.modules.virtualenv_mod`

- Removed deprecated memoize function from salt/utils/\_\_init\_\_.py (deprecated)
- Removed deprecated no\_site\_packages argument from create function (deprecated)
- Removed deprecated check\_dns argument from minion\_config and apply\_minion\_config functions (deprecated)
- Removed deprecated OutputOptionsWithTextMixin class from salt/utils/parsers.py (deprecated)
- Removed the following deprecated functions from salt/modules/ps.py: - physical\_memory\_usage (deprecated) - virtual\_memory\_usage (deprecated) - cached\_physical\_memory (deprecated) - physical\_memory\_buffers (deprecated)
- Removed deprecated cloud arguments from cloud\_config function in salt/config.py: - vm\_config (deprecated) - vm\_config\_path (deprecated)
- Removed deprecated libcloud\_version function from salt/cloud/libcloudfuncs.py (deprecated)
- Removed deprecated CloudConfigMixin class from salt/utils/parsers.py (deprecated)

## 35.2.14 Salt 2014.7.1 Release Notes

release 2015-01-12

Version 2014.7.1 is a bugfix release for 2014.7.0. The changes include:

- Fixed gitfs serving symlinks in `file.recurse` states (issue 17700)

- Fixed holding of multiple packages (YUM) when combined with version pinning ([issue 18468](#))
- Fixed use of Jinja templates in masterless mode with non-roots files server backend ([issue 17963](#))
- Re-enabled pillar and compound matching for mine and publish calls. Note that pillar globbing is still disabled for those modes, for security reasons. ([issue 17194](#))
- Fix for `tty: True` in salt-ssh ([issue 16847](#))
- Fix for supervisor states when supervisor not installed to system python ([issue 18044](#))
- Fix for logging when `log_level='quiet'` for `cmd.run` ([issue 19479](#))

### 35.2.15 Salt 2014.7.2 Release Notes

release TBA

Version 2014.7.2 is a bugfix release for 2014.7.0. The changes include:

- Fix erroneous warnings for systemd service enabled check ([issue 19606](#))
- Fix FreeBSD kernel module loading, listing, and persistence `kmod` ([issue 197151](#), [issue 19682](#))
- Allow case-sensitive npm package names in the `npm state`. This may break behavior for people expecting the state to lowercase their npm package names for them. The `npm module` was never affected by mandatory lowercasing. ([issue 20329](#))
- Deprecate the `activate` parameter for `pip.install` for both the `module` and the `state`. If `bin_env` is given and points to a virtualenv, there is no need to activate that virtualenv in a shell for pip to install to the virtualenv.
- Fix a file-locking bug in `gitfs` ([issue 18839](#))

### 35.2.16 Salt 2014.7.3 Release Notes

release TBA

Version 2014.7.3 is a bugfix release for 2014.7.0.

Changes:

- Multi-master minions mode no longer route fileclient operations asymmetrically. This fixes the source of many multi-master bugs where the minion would become unresponsive from one or more masters.
- Fix bug wherein `network.iface` could produce stack traces.
- `net.arp` will no longer be made available unless `arp` is installed on the system.
- Major performance improvements to Saltnado
- Allow KVM module to operate under KVM itself or VMWare Fusion
- Various fixes to the Windows installation scripts
- Fix issue where the syndic would not correctly propagate loads to the master job cache.
- Improve error handling on invalid `/etc/network/interfaces` file in salt networking modules
- Fix bug where a response status was not checked for in `fileclient.get_url`
- Enable `eauth` when running salt in batch mode
- Increase timeout in Boto Route53 module
- Fix bugs with Salt's `'tar'` module option parsing

- Fix parsing of NTP servers on Windows
- Fix issue with blockdev tuning not reporting changes correctly
- Update to the latest Salt bootstrap script
- Update Linode salt-cloud driver to use either linode-python or apache-libcloud
- Fix for s3.query function to return correct headers
- Fix for s3.head returning None for files that exist
- Fix the disable function in win\_service module so that the service is disabled correctly
- Fix race condition between master and minion when making a directory when both daemons are on the same host
- Fix an issue where file.recurse would fail at the root of an svn repo when the repo has a mountpoint
- Fix an issue where file.recurse would fail at the root of an hgfs repo when the repo has a mountpoint
- Fix an issue where file.recurse would fail at the root of an gitfs repo when the repo has a mountpoint
- Add status.master capability for Windows.
- Various fixes to ssh\_known\_hosts
- Various fixes to states.network bonding for Debian
- The debian\_ip.get\_interfaces module no longer removes nameservers.
- Better integration between grains.virtual and systemd-detect-virt and virt-what
- Fix traceback in sysctl.present state output
- Fix for issue where mount.mounted would fail when superopts were not a part of mount.active (extended=True). Also mount.mounted various fixes for Solaris and FreeBSD.
- Fix error where datetimes were not correctly safeguarded before being passed into msgpack.
- Fix file.replace regressions. If the pattern is not found, and if dry run is False, and if *backup* is False, and if a pre-existing file exists with extension *.bak*, then that backup file will be overwritten. This backup behavior is a result of how *fileinput* works. Fixing it requires either passing through the file twice (the first time only to search for content and set a flag), or rewriting *file.replace* so it doesn't use *fileinput*
- VCS filereserver fixes/optimizations
- Catch fileserver configuration errors on master start
- Raise errors on invalid gitfs configurations
- set\_locale when locale file does not exist (Redhat family)
- Fix to correctly count active devices when created mdadm array with spares
- Fix to correctly target minions in batch mode
- Support ssh:// urls using the gitfs dulwich backend
- New fileserver runner
- Fix various bugs with argument parsing to the publish module.
- Fix disk.usage for Synology OS
- Fix issue with tags occurring twice with docker.pulled
- Fix incorrect key error in SMTP returner
- Fix condition which would remount loopback filesystems on every state run

- Remove requisites from listens after they are called in the state system
- Make system implementation of service.running aware of legacy service calls
- Fix issue where publish.publish would not handle duplicate responses gracefully.
- Accept Kali Linux for aptpkg salt execution module
- Fix bug where cmd.which could not handle a dirname as an argument
- Fix issue in ps.pgrep where exceptions were thrown on Windows.

Known issues:

- In multimaster mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting ``auth_timeout'` and ``auth_tries'` down to shorter periods.

### 35.2.17 Salt 2014.7.4 Release Notes

`release` TBA

Version 2014.7.4 is a bugfix release for 2014.7.0.

Changes:

- Multi-master minions mode no longer route fileclient operations asymmetrically. This fixes the source of many multi-master bugs where the minion would become unresponsive from one or more masters.
- Fix bug wherein network.iface could produce stack traces.
- net.arp will no longer be made available unless arp is installed on the system.
- Major performance improvements to Saltnado
- Allow KVM module to operate under KVM itself or VMWare Fusion
- Various fixes to the Windows installation scripts
- Fix issue where the syndic would not correctly propagate loads to the master job cache.
- Improve error handling on invalid `/etc/network/interfaces` file in salt networking modules
- Fix bug where a response status was not checked for in `fileclient.get_url`
- Enable eauth when running salt in batch mode
- Increase timeout in Boto Route53 module
- Fix bugs with Salt's ``tar'` module option parsing
- Fix parsing of NTP servers on Windows
- Fix issue with blockdev tuning not reporting changes correctly
- Update to the latest Salt bootstrap script
- Update Linode salt-cloud driver to use either `linode-python` or `apache-libcloud`
- Fix for `s3.query` function to return correct headers
- Fix for `s3.head` returning `None` for files that exist
- Fix the `disable` function in `win_service` module so that the service is disabled correctly
- Fix race condition between master and minion when making a directory when both daemons are on the same host

- Fix an issue where file.recurse would fail at the root of an svn repo when the repo has a mountpoint
- Fix an issue where file.recurse would fail at the root of an hgfs repo when the repo has a mountpoint
- Fix an issue where file.recurse would fail at the root of an gitfs repo when the repo has a mountpoint
- Add status.master capability for Windows.
- Various fixes to ssh\_known\_hosts
- Various fixes to states.network bonding for Debian
- The debian\_ip.get\_interfaces module no longer removes nameservers.
- Better integration between grains.virtual and systemd-detect-virt and virt-what
- Fix traceback in sysctl.present state output
- Fix for issue where mount.mounted would fail when superopts were not a part of mount.active (extended=True). Also mount.mounted various fixes for Solaris and FreeBSD.
- Fix error where datetimes were not correctly safeguarded before being passed into msgpack.
- Fix file.replace regressions. If the pattern is not found, and if dry run is False, and if *backup* is False, and if a pre-existing file exists with extension *.bak*, then that backup file will be overwritten. This backup behavior is a result of how *fileinput* works. Fixing it requires either passing through the file twice (the first time only to search for content and set a flag), or rewriting *file.replace* so it doesn't use *fileinput*
- VCS filereserver fixes/optimizations
- Catch fileserver configuration errors on master start
- Raise errors on invalid gitfs configurations
- set\_locale when locale file does not exist (Redhat family)
- Fix to correctly count active devices when created mdadm array with spares
- Fix to correctly target minions in batch mode
- Support ssh:// urls using the gitfs dulwich backend
- New fileserver runner
- Fix various bugs with argument parsing to the publish module.
- Fix disk.usage for Synology OS
- Fix issue with tags occurring twice with docker.pulled
- Fix incorrect key error in SMTP returner
- Fix condition which would remount loopback filesystems on every state run
- Remove requisites from listens after they are called in the state system
- Make system implementation of service.running aware of legacy service calls
- Fix issue where publish.publish would not handle duplicate responses gracefully.
- Accept Kali Linux for aptpkg salt execution module
- Fix bug where cmd.which could not handle a dirname as an argument
- Fix issue in ps.pgrep where exceptions were thrown on Windows.

Known issues:

- In multimaster mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting ``auth_timeout`` and ``auth_tries`` down to shorter periods.
- There are known issues with batch mode operating on the incorrect number of minions. This bug can be patched with the change in [Pull Request #22464](#).
- The *fun*, *state*, and *unless* keywords are missing from the state internals, which can cause problems running some states. This bug can be patched with the change in [Pull Request #22365](#).

### 35.2.18 Salt 2014.7.5 Release Notes

`release` 2015-04-16

Version 2014.7.5 is a bugfix release for 2014.7.0.

Changes:

- Fixed a key error bug in salt-cloud
- Updated man pages to better match documentation
- Fixed bug concerning high CPU usage with salt-ssh
- Fixed bugs with remounting cvfs and fuse filesystems
- Fixed bug with allowing requisite tracking of entire sls files
- Fixed bug with aptpkg.mod\_repo returning OK even if apt-add-repository fails
- Increased frequency of ssh terminal output checking
- Fixed malformed locale string in localmod module
- Fixed checking of available version of package when `accept_keywords` were changed
- Fixed bug to make `git.latest` work with empty repositories
- Added `**kwargs` to `service.mod_watch` which removes warnings about *enable* and `__reqs__` not being supported by the function
- Improved state comments to not grow so quickly on failed requisites
- Added `force` argument to `service` to trigger `force_reload`
- Fixed bug to andle `pkgrepo` keyids that have been converted to int
- Fixed `module.portage_config` bug with appending `accept_keywords`
- Fixed bug to correctly report disk usage on windows minion
- Added the ability to specify key prefix for S3 `ext_pillar`
- Fixed issues with batch mode operating on the incorrect number of minions
- Fixed a bug with the proxmox cloud provider stacktracing on disk definition
- Fixed a bug with the changes dictionary in the file state
- Fixed the TCP keep alive settings to work better with SREQ caching
- Fixed many bugs within the `iptables` state and module
- Fixed bug with states by adding *fun*, *state*, and *unless* to the state runtime internal keywords listing
- Added ability to eAuth against Active Directory
- Fixed some salt-ssh issues when running on Fedora 21

- Fixed grains.get\_or\_set\_hash to work with multiple entries under same key
- Added better explanations and more examples of how the Reactor calls functions to docs
- Fixed bug to not pass *ex\_config\_drive* to libcloud unless it's explicitly enabled
- Fixed bug with pip.install on windows
- Fixed bug where puppet.run always returns a 0 retcode
- Fixed race condition bug with minion scheduling via pillar
- Made efficiency improvements and bug fixes to the windows installer
- Updated environment variables to fix bug with pygit2 when running salt as non-root user
- Fixed cas behavior on data module -- data.cas was not saving changes
- Fixed GPG rendering error
- Fixed strace error in virt.query
- Fixed stacktrace when running chef-solo command
- Fixed possible bug wherein uncaught exceptions seem to make zmq3 tip over when threading is involved
- Fixed argument passing to the reactor
- Fixed glibc caching to prevent bug where salt-minion getaddrinfo in dns\_check() never got updated name-servers

Known issues:

- In multimaster mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting `'auth_timeout'` and `'auth_tries'` down to shorter periods.

### 35.2.19 Salt 2014.7.6 Release Notes

release 2015-05-18

Version 2014.7.6 is a bugfix release for 2014.7.0.

This release is a security release. A minor issue was found, as cited below:

- CVE-2015-4017 -- Certificates are not verified when connecting to server in the Aliyun and Proxmox modules

Only users of the Aliyun or Proxmox cloud modules are at risk. The vulnerability does not exist in the latest 2015.5.0 release of Salt.

Changes:

- salt.runners.cloud.action() has changed the *fun* keyword argument to *func*. Please update any calls to this function in the cloud runner.

Extended Changelog Courtesy of Todd Stansell (<https://github.com/tjstansell/salt-changelogs>):

- **PR #23810:** (*rallytime*) Backport #23757 to 2014.7 @ 2015-05-18T15:30:21Z
  - PR #23757: (*clan*) use abspath, do not eliminating symlinks | refs: #23810
  - aee00c8 Merge pull request #23810 from rallytime/bp-23757
  - fb32c32 use abspath, do not eliminating symlinks
- **PR #23809:** (*rallytime*) Fix virtualport section of virt.get\_nics loop @ 2015-05-18T15:30:09Z

- ISSUE #20198: (*jef tang*) virt.get\_graphics, virt.get\_nics are broken, in turn breaking other things | refs: #23809
- PR #21487: (*rallytime*) Backport #21469 to 2014.7 | refs: #23809
- PR #21469: (*vdesjardins*) fixes #20198: virt.get\_graphics and virt.get\_nics calls in module virt | refs: #21487
- 6b3352b Merge pull request #23809 from rallytime/virt\_get\_nics\_fix
- 0616fb7 Fix virtualport section of virt.get\_nics loop
- PR #23823: (*gtmanfred*) add link local for ipv6 @ 2015-05-17T12:48:25Z
  - 188f03f Merge pull request #23823 from gtmanfred/2014.7
  - 5ef006d add link local for ipv6
- PR #23802: (*gtmanfred*) if it is ipv6 ip\_to\_int will fail @ 2015-05-16T04:06:59Z
  - PR #23573: (*techhat*) Scan all available networks for public and private IPs | refs: #23802
  - f3ca682 Merge pull request #23802 from gtmanfred/2014.7
  - 2da98b5 if it is ipv6 ip\_to\_int will fail
- PR #23488: (*cellscape*) LXC cloud fixes @ 2015-05-15T18:09:35Z
  - ISSUE #16424: (*stanvit*) salt-run cloud.create fails with saltify
  - d9af0c3 Merge pull request #23488 from cellscape/lxc-cloud-fixes
  - 64250a6 Remove profile from opts after creating LXC container
  - c4047d2 Set destroy=True in opts when destroying cloud instance
  - 9e1311a Store instance names in opts when performing cloud action
  - 934bc57 Correctly pass custom env to lxc-attach
  - 7fb85f7 Preserve test=True option in cloud states
  - 9771b5a Fix detection of absent LXC container in cloud state
  - fb24f0c Report failure when failed to create/clone LXC container
  - 2d9aa2b Avoid shadowing variables in lxc module
  - 792e102 Allow to override profile options in lxc.cloud\_init\_interface
  - 42bd64b Return changes on successful lxc.create from salt-cloud
  - 4409eab Return correct result when creating cloud LXC container
  - 377015c Issue #16424: List all providers when creating salt-cloud instance without profile
- PR #23748: (*basepi*) [2014.7] Log salt-ssh roster render errors more assertively and verbosely @ 2015-05-14T22:38:10Z
  - ISSUE #22332: (*rallytime*) [salt-ssh] Add a check for host in /etc/salt/roster | refs: #23748
  - 808bbe1 Merge pull request #23748 from basepi/salt-ssh.roster.host.check
  - bc53e04 Log entire exception for render errors in roster
  - 753de6a Log render errors in roster to error level
  - e01a7a9 Always let the real YAML error through

- PR #23731: (*twangboy*) Fixes #22959: Trying to add a directory to an unmapped drive in windows @ 2015-05-14T21:59:14Z
  - ISSUE #22959: (*highlyunavailable*) Windows Salt hangs if file.directory is trying to write to a drive that doesn't exist
  - 72cf360 Merge pull request #23731 from twangboy/fix\_22959
  - 88e5495 Fixes #22959: Trying to add a directory to an unmapped drive in windows
- PR #23730: (*rallytime*) Backport #23729 to 2014.7 @ 2015-05-14T21:58:34Z
  - PR #23729: (*rallytime*) Partially merge #23437 (grains fix) | refs: #23730
  - PR #23437: (*cedwards*) Grains item patch | refs: #23729
  - 2610195 Merge pull request #23730 from rallytime/bp-23729
  - 1877cae adding support for nested grains to grains.item
- PR #23688: (*twangboy*) Added inet\_pton to utils/validate/net.py for ip.set\_static\_ip in windows @ 2015-05-14T16:15:56Z
  - 3e9df88 Merge pull request #23688 from twangboy/fix\_23415
  - 6a91169 Fixed unused-import pylint error
  - 5e25b3f fixed pylint errors
  - 1a96766 Added inet\_pton to utils/validate/net.py for ip.set\_static\_ip in windows
- PR #23680: (*cachedout*) Rename kwar in cloud runner @ 2015-05-13T19:44:02Z
  - ISSUE #23403: (*iamfil*) salt.runners.cloud.action fun parameter is replaced | refs: #23680
  - 1b86460 Merge pull request #23680 from cachedout/issue\_23403
  - d5986c2 Rename kwar in cloud runner
- PR #23674: (*cachedout*) Handle lists correctly in grains.list\_prsresent @ 2015-05-13T18:34:58Z
  - ISSUE #23548: (*kkaig*) grains.list\_present produces incorrect (?) output | refs: #23674
  - cd64af0 Merge pull request #23674 from cachedout/issue\_23548
  - da8a2f5 Handle lists correctly in grains.list\_prsresent
- PR #23672: (*twangboy*) Fix user present @ 2015-05-13T18:30:09Z
  - d322a19 Merge pull request #23672 from twangboy/fix\_user\_present
  - 731e7af Merge branch `2014.7' of <https://github.com/saltstack/salt> into fix\_user\_present
  - d6f70a4 Fixed user.present to create password in windows
- PR #23670: (*rallytime*) Backport #23607 to 2014.7 @ 2015-05-13T18:27:17Z
  - ISSUE #23604: (*Azidburn*) service.dead on systemd Minion create an Error Message | refs: #23607
  - PR #23607: (*Azidburn*) Fix for #23604. No error reporting. Exitcode !=0 are ok | refs: #23670
  - 43f7025 Merge pull request #23670 from rallytime/bp-23607
  - ed30dc4 Fix for #23604. No error reporting. Exitcode !=0 are ok
- PR #23661: (*rallytime*) Merge #23640 with whitespace fix @ 2015-05-13T15:47:30Z
  - ISSUE #22141: (*Deshke*) grains.get\_or\_set\_hash render error if hash begins with ``%" | refs: #23640
  - PR #23640: (*cachedout*) Add warning to get\_or\_set\_hash about reserved chars | refs: #23661

- 0f006ac Merge pull request #23661 from rallytime/merge-23640
- 4427f42 Whitespace fix
- dd91154 Add warning to get\_or\_set\_hash about reserved chars
- PR #23639: (*cachedout*) Handle exceptions raised by `__virtual__` @ 2015-05-13T15:11:12Z
  - ISSUE #23452: (*michaelforge*) minion crashed with empty grain | refs: #23639
  - 84e2ef8 Merge pull request #23639 from cachedout/issue\_23452
  - d418b49 Syntax error!
  - 45b4015 Handle exceptions raised by `__virtual__`
- PR #23637: (*cachedout*) Convert str master to list @ 2015-05-13T15:08:19Z
  - ISSUE #23611: (*hubez*) master\_type set to 'failover' but 'master' is not of type list but of type <type 'str'> | refs: #23637
  - bd9b94b Merge pull request #23637 from cachedout/issue\_23611
  - 56cb1f5 Fix typo
  - f6fcf19 Convert str master to list
- PR #23595: (*rallytime*) Backport #23549 to 2014.7 @ 2015-05-12T21:19:40Z
  - PR #23549: (*vr-jack*) Update `__init__.py` | refs: #23595
  - f20c0e4 Merge pull request #23595 from rallytime/bp-23549
  - 6efcac0 Update `__init__.py`
- PR #23594: (*rallytime*) Backport #23496 to 2014.7 @ 2015-05-12T21:19:34Z
  - ISSUE #23110: (*martinhoefling*) Copying files from gitfs in file.recurse state fails
  - PR #23496: (*martinhoefling*) Fix for issue #23110 | refs: #23594
  - 1acaf86 Merge pull request #23594 from rallytime/bp-23496
  - d5ae1d2 Fix for issue #23110 This resolves issues when the freshly created directory is removed by file-server.update.
- PR #23593: (*rallytime*) Backport #23442 to 2014.7 @ 2015-05-12T21:19:26Z
  - PR #23442: (*clan*) add directory itself to keep list | refs: #23593
  - 2c221c7 Merge pull request #23593 from rallytime/bp-23442
  - 39869a1 check w/ low['name'] only
  - 304cc49 another fix for file defined w/ id, but require name
  - 8814d41 add directory itself to keep list
- PR #23606: (*twangboy*) Fixed checkbox for starting service and actually starting it @ 2015-05-12T21:18:50Z
  - fadd1ef Merge pull request #23606 from twangboy/fix\_installer
  - 038331e Fixed checkbox for starting service and actually starting it
- PR #23592: (*rallytime*) Backport #23389 to 2014.7 @ 2015-05-12T16:44:42Z
  - ISSUE #22908: (*karanjad*) Add failhard option to salt orchestration | refs: #23389
  - PR #23389: (*cachedout*) Correct fail\_hard typo | refs: #23592
  - 10b3f0f Merge pull request #23592 from rallytime/bp-23389

- 734cc43 Correct fail\_hard typo
- PR #23573: (*techhat*) Scan all available networks for public and private IPs | refs: #23802 @ 2015-05-12T15:22:22Z
  - cd34b9b Merge pull request #23573 from techhat/novaquery
  - f92db5e Linting
  - 26e00d3 Scan all available networks for public and private IPs
- PR #23558: (*jfindlay*) reorder emerge command line @ 2015-05-12T15:17:46Z
  - ISSUE #23479: (*danielmorlock*) Typo in pkg.removed for Gentoo? | refs: #23558
  - 2a72cd7 Merge pull request #23558 from jfindlay/fix\_ebuild
  - 45404fb reorder emerge command line
- PR #23530: (*dr4Ke*) salt-ssh state: fix including all salt:// references @ 2015-05-12T15:13:43Z
  - ISSUE #23355: (*dr4Ke*) salt-ssh: `sources: salt://` files from `pkg` state are not included in salt\_state.tgz | refs: #23530
  - a664a3c Merge pull request #23530 from dr4Ke/fix\_salt-ssh\_to\_include\_pkg\_sources
  - 5df6a80 fix pylint warning
  - d0549e5 salt-ssh state: fix including all salt:// references
- PR #23433: (*twangboy*) Obtain all software from the registry @ 2015-05-11T22:47:52Z
  - ISSUE #23004: (*b18*) 2014.7.5 - Windows - pkg.list\_pkgs - ``nxlog`` never shows up in output. | refs: #23433
  - 55c3869 Merge pull request #23433 from twangboy/list\_pkgs\_fix
  - 8ab5b1b Fix pylint error
  - 2d11d65 Obtain all software from the registry
- PR #23554: (*jleroy*) Debian: Hostname always updated @ 2015-05-11T21:57:00Z
  - 755bed0 Merge pull request #23554 from jleroy/debian-hostname-fix
  - 5ff749e Debian: Hostname always updated
- PR #23551: (*dr4Ke*) grains.append unit tests, related to #23474 @ 2015-05-11T21:54:25Z
  - 6ec87ce Merge pull request #23551 from dr4Ke/grains.append\_unit\_tests
  - ebf9df fix pylint errors
  - c495404 unit tests for grains.append module function
  - 0c9a323 use MagickMock
  - c838a22 unit tests for grains.append module function
- PR #23474: (*dr4Ke*) Fix grains.append in nested dictionary grains #23411 @ 2015-05-11T18:00:21Z
  - ISSUE #23411: (*dr4Ke*) grains.append should work at any level of a grain | refs: #23440
  - PR #23440: (*dr4Ke*) fix grains.append in nested dictionary grains #23411 | refs: #23474
  - e96c5c5 Merge pull request #23474 from dr4Ke/fix\_grains.append\_nested
  - a01a5bb grains.get, parameter delimititer, versionadded: 2014.7.6
  - b39f504 remove debugging output

- b6e15e2 fix grains.append in nested dictionary grains #23411
- PR #23537: (t0rrant) Update changelog @ 2015-05-11T17:02:16Z
  - ab7e1ae Merge pull request #23537 from t0rrant/patch-1
  - 8e03cc9 Update changelog
- PR #23538: (cro) Update date in LICENSE file @ 2015-05-11T15:19:25Z
  - b79fed3 Merge pull request #23538 from cro/licupdate
  - 345efe2 Update date in LICENSE file
- PR #23505: (aneeshusa) Remove unused ssh config validator. Fixes #23159. @ 2015-05-09T13:24:15Z
  - ISSUE #23159: (aneeshusa) Unused validator
  - a123a36 Merge pull request #23505 from aneeshusa/remove-unused-ssh-config-validator
  - 90af167 Remove unused ssh config validator. Fixes #23159.
- PR #23467: (slinu3d) Added AWS v4 signature support @ 2015-05-08T14:36:19Z
  - ISSUE #20518: (ekle) module s3.get does not support eu-central-1 | refs: #23467
  - ca2c21a Merge pull request #23467 from slinu3d/2014.7
  - 0b4081d Fixed pylint error at line 363
  - 5be5eb5 Fixed pylink errors
  - e64f374 Fixed lint errors
  - b9d1ac4 Added AWS v4 signature support
- PR #23444: (techhat) Add create\_attach\_volume to nova driver @ 2015-05-07T19:51:32Z
  - e6f9eec Merge pull request #23444 from techhat/novacreateattach
  - ebdb7ea Add create\_attach\_volume to nova driver
- PR #23460: (s0undt3ch) [2014.7] Update to latest stable bootstrap script v2015.05.07 @ 2015-05-07T19:10:54Z
  - ISSUE #563: (chutz) pidfile support for minion and master daemons | refs: #23460
  - e331463 Merge pull request #23460 from s0undt3ch/hotfix/bootstrap-script-2014.7
  - edcd0c4 Update to latest stable bootstrap script v2015.05.07
- PR #23439: (techhat) Add wait\_for\_passwd\_maxtries variable @ 2015-05-07T07:28:56Z
  - 7a8ce1a Merge pull request #23439 from techhat/maxtries
  - 0ad3ff2 Add wait\_for\_passwd\_maxtries variable
- PR #23422: (cro) \$HOME should not be used, some shells don't set it. @ 2015-05-06T21:02:36Z
  - 644eb75 Merge pull request #23422 from cro/gce\_sh\_home
  - 4ef9e6b Don't use \$HOME to find user's directory, some shells don't set it
- PR #23425: (basepi) [2014.7] Fix typo in FunctionWrapper @ 2015-05-06T20:38:03Z
  - ef17ab4 Merge pull request #23425 from basepi/functionwrapper\_typo
  - c390737 Fix typo in FunctionWrapper
- PR #23385: (rallytime) Backport #23346 to 2014.7 @ 2015-05-06T20:12:29Z
  - PR #23346: (ericfode) Allow file\_map in salt-cloud to handle folders. | refs: #23385

- 1b13ec0 Merge pull request #23385 from rallytime/bp-23346
- 9efc13c more linting fixes
- cf131c9 cleaned up some pylint errors
- f981699 added logic to sftp\_file and file\_map to allow folder uploads using file\_map
- PR #23414: (*jfindlay*) 2015.2 -> 2015.5 @ 2015-05-06T20:04:02Z
  - f8c7a62 Merge pull request #23414 from jfindlay/update\_branch
  - 8074d16 2015.2 -> 2015.5
- PR #23404: (*hvnsweeting*) saltapi cherry-py: initialize var when POST body is empty @ 2015-05-06T17:35:56Z
  - 54b3bd4 Merge pull request #23404 from hvnsweeting/cherry-py-post-emptybody-fix
  - f85f8f9 initialize var when POST body is empty
- PR #23409: (*terminalmage*) Update Lithium docstrings in 2014.7 branch @ 2015-05-06T16:20:46Z
  - 160f703 Merge pull request #23409 from terminalmage/update-lithium-docstrings-2014.7
  - bc97d01 Fix sphinx typo
  - 20006b0 Update Lithium docstrings in 2014.7 branch
- PR #23397: (*jfindlay*) add more flexible whitespace to locale\_gen search @ 2015-05-06T03:44:11Z
  - ISSUE #17245: (*tomashavlas*) localemod does not generate locale for Arch | refs: #23307 #23397
  - aa5fb0a Merge pull request #23397 from jfindlay/fix\_locale\_gen
  - 0941fef add more flexible whitespace to locale\_gen search
- PR #23368: (*kaithar*) Backport #23367 to 2014.7 @ 2015-05-05T21:42:26Z
  - PR #23367: (*kaithar*) Put the sed insert statement back in to the output. | refs: #23368
  - PR #18368: (*basepi*) Merge forward from 2014.7 to develop | refs: #23367 #23368
  - 0c76dd4 Merge pull request #23368 from kaithar/bp-23367
  - 577f419 Pylint fix
  - 8d9acd1 Put the sed insert statement back in to the output.
- PR #23350: (*lorenegordon*) Append/prepend: search for full line @ 2015-05-05T21:42:11Z
  - ISSUE #23294: (*variia*) file.replace fails to append if repl string partially available | refs: #23350
  - 3493cc1 Merge pull request #23350 from lorenegordon/file.replace\_assume\_line
  - b60e224 Append/prepend: search for full line
- PR #23341: (*cachedout*) Fix syndic pid and logfile path @ 2015-05-05T21:29:10Z
  - ISSUE #23026: (*adelcast*) Incorrect salt-syndic logfile and pidfile locations | refs: #23341
  - 7be5c48 Merge pull request #23341 from cachedout/issue\_23026
  - e98e65e Fix tests
  - 6011b43 Fix syndic pid and logfile path
- PR #23272: (*basepi*) [2014.7] Allow salt-ssh minion config overrides via master config and roster | refs: #23347 @ \*\*
  - ISSUE #19114: (*pykler*) salt-ssh and gpg pillar renderer | refs: #23188 #23272 #23347

- PR #23188: (*basepi*) [2014.7] Work around bug in salt-ssh in config.get for gpg renderer | refs: #23272
- ea61abf Merge pull request #23272 from basepi/salt-ssh.minion.config.19114
- c223309 Add versionadded
- be7407f Lint
- c2c3375 Missing comma
- 8e3e8e0 Pass the minion\_opts through the FunctionWrapper
- cb69cd0 Match the master config template in the master config reference
- 87fc316 Add Salt-SSH section to master config template
- 91dd9dc Add ssh\_minion\_opts to master config ref
- c273ea1 Add minion config to salt-ssh doc
- a0b6b76 Add minion\_opts to roster docs
- 5212c35 Accept minion\_opts from the target information
- e2099b6 Process ssh\_minion\_opts from master config
- 3b64214 Revert ``Work around bug in salt-ssh in config.get for gpg renderer''
- 494953a Remove the strip (embracing multi-line YAML dump)
- fe87f0f Dump multi-line yaml into the SHIM
- b751a72 Inject local minion config into shim if available
- PR #23347: (*basepi*) [2014.7] Salt-SSH Backport FunctionWrapper.\_\_contains\_\_ @ 2015-05-05T14:13:21Z
  - ISSUE #19114: (*pykler*) salt-ssh and gpg pillar renderer | refs: #23188 #23272 #23347

  - PR #23188: (*basepi*) [2014.7] Work around bug in salt-ssh in config.get for gpg renderer | refs: #23272
  - 4f760dd Merge pull request #23347 from basepi/salt-ssh.functionwrapper.contains.19114
  - 30595e3 Backport FunctionWrapper.\_\_contains\_\_
- PR #23344: (*cachedout*) Explicitely set file\_client on master @ 2015-05-04T23:21:48Z
  - ISSUE #22742: (*hvnsweeting*) salt-master says: ``This master address: `salt' was previously resolvable but now fails to resolve!'' | refs: #23344
  - 02658b1 Merge pull request #23344 from cachedout/issue\_22742
  - 5adc96c Explicitely set file\_client on master
- PR #23318: (*cellscape*) Honor seed argument in LXC container initializaton @ 2015-05-04T20:58:12Z
  - PR #23311: (*cellscape*) Fix new container initialization in LXC runner | refs: #23318
  - ba7605d Merge pull request #23318 from cellscape/honor-seed-argument
  - 228b1be Honor seed argument in LXC container initializaton
- PR #23307: (*jfindlay*) check for /etc/locale.gen @ 2015-05-04T20:56:32Z
  - ISSUE #17245: (*tomashavlas*) localemod does not generate locale for Arch | refs: #23307 #23397
  - 4ac4509 Merge pull request #23307 from jfindlay/fix\_locale\_gen
  - 101199a check for /etc/locale.gen

- **PR #23324:** (*s0undt3ch*) [2014.7] Update to the latest stable release of the bootstrap script v2015.05.04 @ 2015-05-04T16:28:30Z
  - **ISSUE #580:** (*thatch45*) recursive watch not being caught | refs: #23324
  - **ISSUE #552:** (*jhutchins*) Support require and watch under the same state dec | refs: #23324
  - **PR #589:** (*epoelke*) add --quiet and --outfile options to saltkey | refs: #23324
  - **PR #567:** (*bastichelaar*) Added upstart module | refs: #23324
  - **PR #560:** (*UtahDave*) The runas feature that was added in 93423aa2e5e4b7de6452090b0039560d2b13... | refs: #23324
  - **PR #504:** (*SEJeff*) File state goodies | refs: #23324
  - f790f42 Merge pull request #23324 from s0undt3ch/hotfix/bootstrap-script-2014.7
  - 6643e47 Update to the latest stable release of the bootstrap script v2015.05.04
- **PR #23329:** (*cro*) Require requests to verify cert when talking to aliyun and proxmox cloud providers @ 2015-05-04T16:18:17Z
  - 5487367 Merge pull request #23329 from cro/cloud\_verify\_cert
  - 860d4b7 Turn on ssl verify for requests.
- **PR #23311:** (*cellscape*) Fix new container initialization in LXC runner | refs: #23318 @ 2015-05-04T09:55:29Z
  - ea20176 Merge pull request #23311 from cellscape/fix-salt-cloud-lxc-init
  - 76fbb34 Fix new container initialization in LXC runner
- **PR #23298:** (*chris-prince*) Fixed issue #18880 in 2014.7 branch @ 2015-05-03T15:49:41Z
  - **ISSUE #18880:** (*johtso*) npm installed breaks when a module is missing
  - c399b8f Merge pull request #23298 from chris-prince/2014.7
  - 0fa25db Fixed issue #18880 in 2014.7 branch
- **PR #23292:** (*rallytime*) Merge #23151 with pylint fixes @ 2015-05-02T03:54:12Z
  - **ISSUE #23148:** (*cr1st1p*) virt - error handling bogus if machine image location is wrong
  - **PR #23151:** (*cr1st1p*) Fixes #23148 | refs: #23292
  - 16ecefcd Merge pull request #23292 from rallytime/merge-23151
  - 8ff852a Merge #23151 with pylint fixes
  - 8ffa12e Fixes #23148
- **PR #23274:** (*basepi*) [2014.7] Reduce salt-ssh debug log verbosity @ 2015-05-01T20:19:23Z
  - ce24315 Merge pull request #23274 from basepi/salt-ssh.debug.verbosity
  - ecee6c6 Log stdout and stderr to trace
  - 08f54d7 Log stdout and stderr to trace as well
  - 9b9c30f Reduce salt-ssh debug log verbosity
- **PR #23261:** (*rallytime*) Fix tornado websocket event handler registration @ 2015-05-01T18:20:31Z
  - **ISSUE #22605:** (*mavenAtHouzz*) Tornado websockets event Handlers registration are incorrect | refs: #23261
  - 7b55e43 Merge pull request #23261 from rallytime/fix-22605

- 4950fbf Fix tornado websocket event handler registration
- PR #23258: (*teizz*) TCP keepalives on the ret side, Revisited. @ 2015-05-01T16:13:49Z
  - 83ef7cb Merge pull request #23258 from teizz/i»¿ret\_keepalive\_2014\_7\_5
  - 0b9fb6f The fixes by i»¿cachedout which were backported into 2015\_2 were missing a single parameter thus not setting up the TCP keepalive for the ZeroMQ Channel by default.
- PR #23241: (*techhat*) Move iptables log options after the jump @ 2015-05-01T01:31:59Z
  - ISSUE #23224: (*twellspring*) iptables.append --log parameters must be after --jump LOG | refs: #23241
  - 8de3c83 Merge pull request #23241 from techhat/issue23224
  - 87f7948 Move iptables log options after the jump
- PR #23228: (*rallytime*) Backport #23171 to 2014.7 @ 2015-04-30T21:09:45Z
  - PR #23171: (*skizunov*) Bugfix: `clean\_proc\_dir` is broken | refs: #23228
  - f20210e Merge pull request #23228 from rallytime/bp-23171
  - e670e99 Bugfix: `clean\_proc\_dir` is broken
- PR #23227: (*rallytime*) Backport #22808 to 2014.7 @ 2015-04-30T21:09:14Z
  - ISSUE #22703: (*Xiol*) salt-ssh does not work with list matcher | refs: #22808
  - PR #22808: (*basepi*) [2015.2] Add list targeting to salt-ssh flat roster | refs: #23227
  - 721cc28 Merge pull request #23227 from rallytime/bp-22808
  - d208a00 Dict, not list
  - a3f529e It's already been converted to a list
  - dd57f2d Add list targeting to salt-ssh flat roster
- PR #22823: (*hvnsweeting*) 22822 file directory clean @ 2015-04-30T15:25:51Z
  - 82c22af Merge pull request #22823 from hvnsweeting/22822-file-directory-clean
  - c749c27 fix lint - remove unnecessary parenthesis
  - cb3dfee refactor
  - 8924b5a refactor: use relpath instead of do it manually
  - d3060a5 refactor
  - 5759a0e bugfix: fix file.directory clean=True when it require parent dir
- PR #22977: (*bersace*) Fix fileserver backends \_\_opts\_\_ overwritten by \_pillar @ 2015-04-30T15:24:56Z
  - ISSUE #22941: (*bersace*) \_pillar func breaks fileserver globals | refs: #22977 #22942
  - PR #22942: (*bersace*) Fix fileserver backends global overwritten by \_pillar | refs: #22977
  - f6c0728 Merge pull request #22977 from bersace/fix-fileserver-backends-pillar-side-effect
  - 5f451f6 Fix fileserver backends \_\_opts\_\_ overwritten by \_pillar
- PR #23180: (*jfindlay*) fix typos from 36841bdd in masterapi.py @ 2015-04-30T15:22:41Z
  - ISSUE #23166: (*claudiuopescu*) ``Error in function \_minion\_event" resulting in modules not loaded | refs: #23180
  - 34206f7 Merge pull request #23180 from jfindlay/remote\_event
  - 72066e1 fix typos from 36841bdd in masterapi.py

- **PR #23176:** (*jfindlay*) copy standard cmd.run\* kwargs into cmd.run\_chroot @ 2015-04-30T15:22:12Z
  - **ISSUE #23153:** (*cr1st1p*) cmdmod : run\_chroot - broken in 2014.7.5 - missing kwargs | refs: #23176
  - b6b8216 Merge pull request #23176 from jfindlay/run\_chroot
  - 7dc3417 copy standard cmd.run\* kwargs into cmd.run\_chroot
- **PR #23193:** (*joejulian*) supervisord.mod\_watch should accept sfun @ 2015-04-30T04:34:21Z
  - **ISSUE #23192:** (*joejulian*) supervisord mod\_watch does not accept sfun | refs: #23193
  - effache Merge pull request #23193 from joejulian/2014.7\_supervisord\_accept\_sfun
  - efb59f9 supervisord.mod\_watch should accept sfun
- **PR #23188:** (*basepi*) [2014.7] Work around bug in salt-ssh in config.get for gpg renderer | refs: #23272 @ 2015-04-30T04:34:10Z
  - **ISSUE #19114:** (*pykler*) salt-ssh and gpg pillar renderer | refs: #23188 #23272 #23347
  - 72fe88e Merge pull request #23188 from basepi/salt-ssh.function.wrapper.gpg.19114
  - d73979e Work around bug in salt-ssh in config.get for gpg renderer
- **PR #23154:** (*cachedout*) Re-establish channel on interruption in fileclient @ 2015-04-29T16:18:59Z
  - **ISSUE #21480:** (*msciciel*) TypeError: string indices must be integers, not str | refs: #23154
  - 168508e Merge pull request #23154 from cachedout/refresh\_channel
  - 9f8dd80 Re-establish channel on interruption in fileclient
- **PR #23146:** (*rallytime*) Backport #20779 to 2014.7 @ 2015-04-28T20:45:06Z
  - **ISSUE #20647:** (*ryan-lane*) file.serialize fails to serialize due to ordered dicts | refs: #20779
  - **PR #20779:** (*cachedout*) Use declared yaml options | refs: #23146
  - 3b53e04 Merge pull request #23146 from rallytime/bp-20779
  - ffd1849 compare OrderedDicts in serializer unit test
  - a221706 Just change serialize
  - a111798 Use declared yaml options
- **PR #23145:** (*rallytime*) Backport #23089 to 2014.7 @ 2015-04-28T20:44:56Z
  - **PR #23089:** (*cachedout*) Stringify version number before lstrip | refs: #23145
  - 8bb4664 Merge pull request #23145 from rallytime/bp-23089
  - 93c41af Stringify version number before lstrip
- **PR #23144:** (*rallytime*) Backport #23124 to 2014.7 @ 2015-04-28T20:44:46Z
  - **ISSUE #16188:** (*drawks*) salt.modules.parted has various functions with bogus input validation. | refs: #23124
  - **PR #23124:** (*ether42*) fix parsing the output of parted in parted.list\_() | refs: #23144
  - c85d36f Merge pull request #23144 from rallytime/bp-23124-2014-7
  - 6b64da7 fix parsing the output of parted
- **PR #23120:** (*terminalmage*) Don't run os.path.relpath() if repo doesn't have a ``root'' param set @ 2015-04-28T15:46:54Z
  - a27b158 Merge pull request #23120 from terminalmage/fix-gitfs-relpath

- 1860fff Don't run os.path.relpath() if repo doesn't have a ``root" param set
- PR #23132: (*clinta*) Backport b27c176 @ 2015-04-28T15:00:30Z
  - fcb607 Merge pull request #23132 from clinta/patch-2
  - a824d72 Backport b27c176
- PR #23114: (*rallytime*) Adjust ZeroMQ 4 docs to reflect changes to Ubuntu 12 packages @ 2015-04-28T03:59:24Z
  - ISSUE #18476: (*Auha*) Upgrading salt on my master caused dependency issues | refs: #23114 #18610
  - PR #18610: (*rallytime*) Make ZMQ 4 installation docs for ubuntu more clear | refs: #23114
  - b0f4b28 Merge pull request #23114 from rallytime/remove\_ubuntu\_zmq4\_docs
  - f6cc7c8 Adjust ZeroMQ 4 docs to reflect changes to Ubuntu 12 packages
- PR #23108: (*rallytime*) Backport #23097 to 2014.7 @ 2015-04-28T03:58:05Z
  - ISSUE #23085: (*xenophonf*) Use ``s3fs" (not ``s3") in filesaver\_roots | refs: #23097
  - PR #23097: (*rallytime*) Change s3 to s3fs in filesaver\_roots docs example | refs: #23108
  - 399857f Merge pull request #23108 from rallytime/bp-23097
  - fa88984 Change s3 to s3fs in filesaver\_roots docs example
- PR #23112: (*basepi*) [2014.7] Backport #22199 to fix mysql returner save\_load errors @ 2015-04-28T03:55:44Z
  - ISSUE #22171: (*basepi*) We should only call returner.save\_load once per jid | refs: #22199
  - PR #22199: (*basepi*) [2015.2] Put a bandaid on the save\_load duplicate issue (mysql returner) | refs: #23112
  - 5541537 Merge pull request #23112 from basepi/mysql\_returner\_save\_load
  - 0127012 Put a bandaid on the save\_load duplicate issue
- PR #23113: (*rallytime*) Revert ``Backport #22895 to 2014.7" @ 2015-04-28T03:27:29Z
  - PR #22925: (*rallytime*) Backport #22895 to 2014.7 | refs: #23113
  - PR #22895: (*aletourneau*) pam\_tally counter was not reset to 0 after a succesfull login | refs: #22925
  - dfe2066 Merge pull request #23113 from saltstack/revert-22925-bp-22895
  - b957ea8 Revert ``Backport #22895 to 2014.7"
- PR #23094: (*terminalmage*) pygit2: disable cleaning of stale refs for authenticated remotes @ 2015-04-27T20:51:28Z
  - ISSUE #23013: (*markusr815*) gitfs regression with authenticated repos | refs: #23094
  - 21515f3 Merge pull request #23094 from terminalmage/issue23013
  - aaf7b04 pygit2: disable cleaning of stale refs for authenticated remotes
- PR #23048: (*jfindlay*) py-2.6 compat for utils/boto.py ElementTree exception @ 2015-04-25T16:56:45Z
  - d45aa21 Merge pull request #23048 from jfindlay/ET\_error
  - 64c42cc py-2.6 compat for utils/boto.py ElementTree exception
- PR #23025: (*jfindlay*) catch exceptions on bad system locales/encodings @ 2015-04-25T16:56:30Z
  - ISSUE #22981: (*syphehl*) Locale state throwing traceback when generating not (yet) existing locale | refs: #23025
  - d25a5c1 Merge pull request #23025 from jfindlay/fix\_sys\_locale
  - 9c4d62b catch exceptions on bad system locales/encodings

- **PR #22932:** (*hvnsweeting*) bugfix: also manipulate `dir_mode` when source not defined @ 2015-04-25T16:54:58Z
  - 5e44b59 Merge pull request #22932 from hvnsweeting/file-append-bugfix
  - 3f368de do not use `assert` in execution module
  - 9d4fd4a bugfix: also manipulate `dir_mode` when source not defined
- **PR #23055:** (*jfindlay*) prevent `ps` module errors on accessing dead procs @ 2015-04-24T22:39:49Z
  - **ISSUE #23021:** (*ether42*) `ps.pgrep` raises `NoSuchProcess` | refs: #23055
  - c2416a4 Merge pull request #23055 from jfindlay/fix\_ps
  - c2dc7ad prevent `ps` module errors on accessing dead procs
- **PR #23031:** (*jfindlay*) convert exception `e.message` to just `e` @ 2015-04-24T18:38:13Z
  - bfd9158 Merge pull request #23031 from jfindlay/exception
  - 856bad1 convert exception `e.message` to just `e`
- **PR #23015:** (*hvnsweeting*) if status of service is stop, there is not an error with it @ 2015-04-24T14:35:10Z
  - 7747f33 Merge pull request #23015 from hvnsweeting/set-non-error-lvl-for-service-status-log
  - 92ea163 if status of service is stop, there is not an error with it
- **PR #23000:** (*jfindlay*) set `systemd` service `killMode` to process for minion @ 2015-04-24T03:42:39Z
  - **ISSUE #22993:** (*jetpak*) salt-minion restart causes all spawned daemons to die on centos7 (systemd) | refs: #23000
  - 2e09789 Merge pull request #23000 from jfindlay/systemd\_kill
  - 3d575e2 set `systemd` service `killMode` to process for minion
- **PR #22999:** (*jtand*) Added `retry_dns` to minion doc. @ 2015-04-24T03:30:24Z
  - **ISSUE #22707:** (*arthurlogilab*) `retry_dns` of master configuration is missing from the documentation | refs: #22999
  - b5c059a Merge pull request #22999 from jtand/fix\_22707
  - 8486e17 Added `retry_dns` to minion doc.
- **PR #22990:** (*techhat*) Use the proper cloud conf variable @ 2015-04-23T17:48:07Z
  - 27dc877 Merge pull request #22990 from techhat/2014.7
  - d33bcbc Use the proper cloud conf variable
- **PR #22976:** (*multani*) Improve `state_output` documentation @ 2015-04-23T12:24:22Z
  - 13dff65 Merge pull request #22976 from multani/fix/state-output-doc
  - 19efd41 Improve `state_output` documentation
- **PR #22955:** (*terminalmage*) Fix regression introduced yesterday in `dockerio` module @ 2015-04-22T18:56:39Z
  - 89fa185 Merge pull request #22955 from terminalmage/dockerio-run-fix
  - b4472ad Fix regression introduced yesterday in `dockerio` module
- **PR #22954:** (*rallytime*) Backport #22909 to 2014.7 @ 2015-04-22T18:56:20Z
  - **PR #22909:** (*mguegan*) Fix compatibility with `pkgin > 0.7` | refs: #22954
  - 46ef227 Merge pull request #22954 from rallytime/bp-22909
  - 70c1cd3 Fix compatibility with `pkgin > 0.7`

- **PR #22856:** (*jfindlay*) increase timeout and decrease tries for route53 records @ 2015-04-22T16:47:01Z
  - **ISSUE #18720:** (*Reiner030*) timeouts when setting Route53 records | refs: #22856
  - c9ae593 Merge pull request #22856 from jfindlay/route53\_timeout
  - ba4a786 add route53 record sync wait, default=False
  - ea2fd50 increase timeout and tries for route53 records
- **PR #22946:** (*s0undt3ch*) Test with a more recent pip version to avoid a traceback @ 2015-04-22T16:25:17Z
  - a178d44 Merge pull request #22946 from s0undt3ch/2014.7
  - bc87749 Test with a more recent pip version to avoid a traceback
- **PR #22945:** (*garethgreenaway*) Fixes to scheduler @ 2015-04-22T16:25:00Z
  - **ISSUE #22571:** (*BoomerB*) same error message as on issue #18504 | refs: #22945
  - de339be Merge pull request #22945 from garethgreenaway/22571\_2014\_7\_schedule\_pillar\_refresh\_seconds\_exceptions
  - bfa6d25 Fixing a reported issue when using a scheduled job from pillar with splay. \_seconds element that acted as a backup of the actual seconds was being removed when pillar was refreshed and causing exceptions. This fix moves some splay related code out of the if else condition so it's checked whether the job is in the job queue or not.
- **PR #22887:** (*hvnsweeting*) fix #18843 @ 2015-04-22T15:47:05Z
  - **ISSUE #18843:** (*calvinhp*) State user.present will fail to create home if user exists and homedir doesn't
  - 12d2b91 Merge pull request #22887 from hvnsweeting/18843-fix-user-present-home
  - 7fe7b08 run user.chhome once to avoid any side-effect when run it twice
  - 19de995 clarify the usage of home arg
  - d6dc09a enhance doc, as usermod on ubuntu 12.04 will not CREATE home
  - 0ce4d7f refactor: force to use boolean
  - 849d19e log debug the creating dir process
  - c4e95b9 fix #18843: usermod won't create a dir if old home does not exist
- **PR #22930:** (*jfindlay*) localemod.gen\_locale now always returns a boolean @ 2015-04-22T15:37:39Z
  - **ISSUE #21140:** (*holms*) locale.present state executed successfully, although originally fails | refs: #22930 #22829
  - **ISSUE #2417:** (*ffa*) Module standards | refs: #22829
  - **PR #22829:** (*F30*) Always return a boolean in gen\_locale() | refs: #22930
  - b7de7bd Merge pull request #22930 from jfindlay/localegen\_bool
  - 399399f localemod.gen\_locale now always returns a boolean
- **PR #22933:** (*hvnsweeting*) add test for #18843 @ 2015-04-22T15:27:18Z
  - **ISSUE #18843:** (*calvinhp*) State user.present will fail to create home if user exists and homedir doesn't
  - 11bcf14 Merge pull request #22933 from hvnsweeting/18843-test
  - b13db32 add test for #18843
- **PR #22925:** (*rallytime*) Backport #22895 to 2014.7 | refs: #23113 @ 2015-04-22T02:30:26Z
  - **PR #22895:** (*aletourneau*) pam\_tally counter was not reset to 0 after a succesfull login | refs: #22925

- 6890752 Merge pull request #22925 from rallytime/bp-22895
- 3852d96 Pylint fix
- 90f7829 Fixed pylint issues
- 5ebf159 Cleaned up pull request
- a08ac47 pam\_tally counter was not reset to 0 after a succesfull login
- PR #22914: (*cachedout*) Call proper returner function in jobs.list\_jobs @ 2015-04-22T00:49:01Z
  - ISSUE #22790: (*whiteinge*) jobs.list\_jobs runner tracebacks on `missing` argument | refs: #22914
  - eca37eb Merge pull request #22914 from cachedout/issue\_22790
  - d828d6f Call proper returner function in jobs.list\_jobs
- PR #22918: (*JaseFace*) Add a note to the git\_pillar docs stating that GitPython is the only currently supported provider @ 2015-04-22T00:48:26Z
  - 44f3409 Merge pull request #22918 from JaseFace/git-pillar-provider-doc-note
  - 0aee5c2 Add a note to the git\_pillar docs stating that GitPython is the only currently supported provider
- PR #22907: (*techhat*) Properly merge cloud configs to create profiles @ 2015-04-21T22:02:44Z
  - 31c461f Merge pull request #22907 from techhat/cloudconfig
  - 3bf4e66 Properly merge cloud configs to create profiles
- PR #22894: (*0xf10e*) Fix issue #22782 @ 2015-04-21T18:55:18Z
  - f093975 Merge pull request #22894 from 0xf10e/2014.7
  - 58fa24c Clarify doc on kwarg `roles` for user\_present().
  - f0ae2eb Improve readability by renaming tenant\_role
- PR #22902: (*rallytime*) Change state example to use proper kwarg @ 2015-04-21T18:50:47Z
  - ISSUE #12003: (*MarkusMuellerAU*) [state.dockerio] docker.run TypeError: run() argument after \*\* must be a mapping, not str | refs: #22902
  - c802ba7 Merge pull request #22902 from rallytime/docker\_doc\_fix
  - 8f70346 Change state example to use proper kwarg
- PR #22898: (*terminalmage*) dockerio: better error message for native exec driver @ 2015-04-21T18:02:58Z
  - 81771a7 Merge pull request #22898 from terminalmage/issue12003
  - c375309 dockerio: better error message for native exec driver
- PR #22897: (*rallytime*) Add param documentation for file.replace state @ 2015-04-21T17:31:04Z
  - ISSUE #22825: (*paolodina*) Issue using file.replace in state file | refs: #22897
  - e2ec4ec Merge pull request #22897 from rallytime/fix-22825
  - 9c51630 Add param documentation for file.replace state
- PR #22850: (*bersace*) Fix pillar and salt fileserver mixed @ 2015-04-21T17:04:33Z
  - ISSUE #22844: (*bersace*) LocalClient file cache confuse pillar and state files | refs: #22850
  - fd53889 Merge pull request #22850 from bersace/fix-pillar-salt-mixed
  - 31b98e7 Initialize state file client after pillar loading
  - f6bebb7 Use saltenv

- **PR #22818:** (*twangboy*) Added documentation regarding pip in windows @ 2015-04-21T03:58:59Z
  - 1380fec Merge pull request #22818 from twangboy/upd\_pip\_docs
  - cb999c7 Update pip.py
  - 3cc5c97 Added documentation regarding pip in windows
- **PR #22872:** (*rallytime*) Prevent stacktrace on os.path.exists in hosts module @ 2015-04-21T02:54:40Z
  - b2bf17f Merge pull request #22872 from rallytime/fix\_hosts\_stacktrace
  - c88a1ea Prevent stacktrace on os.path.exists in hosts module
- **PR #22853:** (*s0undt3ch*) Don't assume package installation order. @ 2015-04-21T02:42:41Z
  - 03af523 Merge pull request #22853 from s0undt3ch/2014.7
  - b62df62 Don't assume package installation order.
- **PR #22877:** (*s0undt3ch*) Don't fail on *make clean* just because the directory does not exist @ 2015-04-21T02:40:47Z
  - 9211e36 Merge pull request #22877 from s0undt3ch/hotfix/clean-docs-fix
  - 95d6887 Don't fail on *make clean* just because the directory does not exist
- **PR #22873:** (*thatch45*) Type check the version since it will often be numeric @ 2015-04-21T02:38:11Z
  - 5bdbd08 Merge pull request #22873 from thatch45/type\_check
  - 53b8376 Type check the version since it will often be numeric
- **PR #22870:** (*twangboy*) Added ability to send a version with a space in it @ 2015-04-20T23:18:28Z
  - c965b0a Merge pull request #22870 from twangboy/fix\_installer\_again
  - 3f180cf Added ability to send a version with a space in it
- **PR #22863:** (*rallytime*) Backport #20974 to 2014.7 @ 2015-04-20T19:29:37Z
  - **PR #20974:** (*JohannesEbke*) Fix expr\_match usage in salt.utils.check\_whitelist\_blacklist | refs: #22863
  - 2973eb1 Merge pull request #22863 from rallytime/bp-20974
  - 14913a4 Fix expr\_match usage in salt.utils.check\_whitelist\_blacklist
- **PR #22578:** (*hvnsweeting*) gracefully handle when salt-minion cannot decrypt key @ 2015-04-20T15:24:45Z
  - c45b92b Merge pull request #22578 from hvnsweeting/2014-7-fix-compile-pillar
  - f75b24a gracefully handle when salt-minion cannot decrypt key
- **PR #22800:** (*terminalmage*) Improve error logging for pygit2 SSH-based remotes @ 2015-04-18T17:18:55Z
  - **ISSUE #21979:** (*yrdevops*) gitfs: error message not descriptive enough when libgit2 was compiled without libssh2 | refs: #22800
  - 900c7a5 Merge pull request #22800 from terminalmage/issue21979
  - 8f1c008 Clarify that for pygit2, receiving 0 objects means repo is up-to-date
  - 98885f7 Add information about libssh2 requirement for pygit2 ssh auth
  - 09468d2 Fix incorrect log message
  - 2093bf8 Adjust loglevels for gitfs errors
  - 9d394df Improve error logging for pygit2 SSH-based remotes
- **PR #22813:** (*twangboy*) Updated instructions for building salt @ 2015-04-18T04:10:07Z

- e99f2fd Merge pull request #22813 from twangboy/win\_doc\_fix
- adc421a Fixed some formatting issues
- 8901b3b Updated instructions for building salt
- PR #22810: (*basepi*) [2014.7] More msgpack gating for salt-ssh @ 2015-04-17T22:28:24Z
  - ISSUE #22708: (*Bilge*) salt-ssh file.accumulated error: NameError: global name `msgpack' is not defined | refs: #22810
  - fe1de89 Merge pull request #22810 from basepi/salt-ssh.more.msgpack.gating
  - d4da8e6 Gate msgpack in salt/modules/saltutil.py
  - 02303b2 Gate msgpack in salt/modules/data.py
  - d7e8741 Gate salt.states.file.py msgpack
- PR #22803: (*rallytime*) Allow map file to work with softlayer @ 2015-04-17T20:34:42Z
  - ISSUE #17144: (*xpender*) salt-cloud -m fails with softlayer | refs: #22803
  - 11df71e Merge pull request #22803 from rallytime/fix-17144
  - ce88b6a Allow map file to work with softlayer
- PR #22807: (*rallytime*) Add 2014.7.5 links to windows installation docs @ 2015-04-17T20:32:13Z
  - cd43a95 Merge pull request #22807 from rallytime/windows\_docs\_update
  - 5931a58 Replace all 4s with 5s
  - eadaead Add 2014.7.5 links to windows installation docs
- PR #22795: (*rallytime*) Added release note for 2014.7.5 release @ 2015-04-17T18:05:36Z
  - 0b295e2 Merge pull request #22795 from rallytime/release\_notes
  - fde1fee Remove extra line
  - b19b95d Added release note for 2014.7.5 release
- PR #22759: (*twangboy*) Final edits to the batch files for running salt @ 2015-04-17T04:31:15Z
  - ISSUE #22740: (*lorenegordon*) New Windows installer assumes salt is installed to the current directory | refs: #22759
  - PR #22754: (*twangboy*) Removed redundant \ and " | refs: #22759
  - 3c91459 Merge pull request #22759 from twangboy/fix\_bat\_one\_last\_time
  - 075f82e Final edits to the batch files for running salt
- PR #22760: (*thatch45*) Fix issues with the syndic @ 2015-04-17T04:30:48Z
  - 20d3f2b Merge pull request #22760 from thatch45/syndic\_fix
  - e2db624 Fix issues with the syndic not resolving the master when the interface is set
- PR #22762: (*twangboy*) Fixed version not showing in Add/Remove Programs @ 2015-04-17T04:29:46Z
  - 54c4584 Merge pull request #22762 from twangboy/fix\_installer
  - 4d25af8 Fixed version not showing in Add/Remove Programs

## 35.2.20 Salt 2014.7.8 Release Notes

### Changes for v2014.7.7..v2014.7.8

Extended changelog courtesy of Todd Stansell (<https://github.com/tjstansell/salt-changelogs>):

Generated at: 2016-03-11T21:18:48Z

Statistics:

- Total Merges: 7
- Total Issue references: 3
- Total PR references: 10

Changes:

- **PR #28839:** (*cachedout*) Revert #28740 @ 2015-11-12T22:54:28Z
  - **PR #28740:** (*MasterNayru*) Add missing S3 module import | refs: #28777
  - 4b8bdd0 Merge pull request #28839 from cachedout/revert\_28740
  - 215b26c Revert #28740
- **PR #28777:** (*rallytime*) Back-port #28740 to 2014.7 @ 2015-11-11T18:00:00Z
  - **PR #28740:** (*MasterNayru*) Add missing S3 module import | refs: #28777
  - 76e69b4 Merge pull request #28777 from rallytime/bp-28740-2014.7
  - da5fac2 Back-port #28740 to 2014.7
- **PR #28716:** (*rallytime*) Back-port #28705 to 2014.7 @ 2015-11-10T16:15:03Z
  - **PR #28705:** (*cachedout*) Account for new headers class in tornado 4.3 | refs: #28716
  - 45c73eb Merge pull request #28716 from rallytime/bp-28705
  - 32e7bd3 Account for new headers class in tornado 4.3
- **PR #28717:** (*cachedout*) Add note about recommended umask @ 2015-11-09T23:26:20Z
  - **ISSUE #28199:** (*felskrone*) Non-standard umasks might break the master | refs: #28717
  - f4fe921 Merge pull request #28717 from cachedout/umask\_note
  - 1874300 Add note about recommended umask
- **PR #28461:** (*cachedout*) Wrap all cache calls in state.sls in correct umask @ 2015-11-02T17:11:02Z
  - **ISSUE #28455:** (*zmalone*) highstate.cache is world readable, and contains secrets | refs: #28461
  - 4bf56ca Merge pull request #28461 from cachedout/issue\_28455
  - 097838e Wrap all cache calls in state.sls in correct umask
- **PR #28407:** (*DmitryKuzmenko*) Don't request creds if auth with key. @ 2015-10-29T16:12:30Z
  - **ISSUE #24910:** (*bocig*) -T, --make-token flag does NOT work- LDAP Groups | refs: #28407
  - f3e61db Merge pull request #28407 from DSRCCompany/issues/24910\_token\_auth\_fix\_2014
  - b7b5bec Don't request creds if auth with key.
- **PR #27390:** (*JaseFace*) Ensure we pass on the enable setting if present, or use the default of True if not in build\_schedule\_item() @ 2015-10-05T18:09:33Z
  - d284eb1 Merge pull request #27390 from JaseFace/schedule-missing-enabled

- 563db71 Ensure we pass on the enable setting if present, or use the default of True if not in `build_schedule_item()` Prior to this, when `schedule.present` compares the existing schedule to the one crafted by this function, enabled will actually be removed at each run. `schedule.present` sees a modification needs to be made, and invokes `schedule.modify`, which does so with `enabled: True`, creating and endless loop of an `'enabled'` removal and addition.

### 35.2.21 Salt 2014.7.9 Release Notes

#### Changes for v2014.7.8..v2014.7.9

Extended changelog courtesy of Todd Stansell (<https://github.com/tjstansell/salt-changelogs>):

Generated at: 2016-03-11T20:58:58Z

  - 85aa70a Merge pull request #29392 from jacobhammons/2014.7
  - d7f0db1 updated version number to not reference a specific build from the latest branch
- PR #29296: (*douardda*) Use process KillMode on Debian systems also @ 2015-12-01T16:00:16Z
  - ISSUE #29295: (*douardda*) systemd's service file should use the `'process'` KillMode option on Debian also | refs: #29296
  - d2fb210 Merge pull request #29296 from douardda/patch-3
  - d288539 Use process KillMode on Debian systems also

### 35.2.22 Salt 2014.1.0 Release Notes - Codename Hydrogen

---

**Note:** Due to a change in master to minion communication, 2014.1.0 minions are not compatible with older-version masters. Please upgrade masters first. More info on backwards-compatibility policy [here](#), under the `''Upgrading Salt''` subheading.

---

**Note:** A change in the grammar in the state compiler makes `module.run` in requisites illegal syntax. Its use is replaced simply with the word `module`. In other words you will need to change requisites like this:

```
require:
  module.run: some_module_name
```

to:

```
require:  
  module: some_module_name
```

This is a breaking change. We apologize for the inconvenience, we needed to do this to remove some ambiguity in parsing requisites.

---

#### release 2014-02-24

The 2014.1.0 release of Salt is a major release which not only increases stability but also brings new capabilities in virtualization, cloud integration, and more. This release brings a great focus on the expansion of testing making roughly double the coverage in the Salt tests, and comes with many new features.

2014.1.0 is the first release to follow the new date-based release naming system. See the `version numbers` page for more details.

## Major Features

### Salt Cloud Merged into Salt

Salt Cloud is a tool for provisioning salted minions across various cloud providers. Prior to this release, Salt Cloud was a separate project but this marks its full integration with the Salt distribution. A Getting Started guide and additional documentation for Salt Cloud can be found [here](#):

### Google Compute Engine

Alongside Salt Cloud comes new support for the Google Compute Engine. Salt Stack can now deploy and control GCE virtual machines and the application stacks that they run.

For more information on Salt Stack and GCE, please see [this blog post](#).

Documentation for Salt and GCE can be found [here](#).

### Salt Virt

Salt Virt is a cloud controller that supports virtual machine deployment, inspection, migration, and integration with many aspects of Salt.

Salt Virt has undergone a major overhaul with this release and now supports many more features and includes a number of critical improvements.

### Docker Integration

Salt now ships with `states` and an `execution module` to manage Docker containers.

### Substantial Testing Expansion

Salt continues to increase its unit/regression test coverage. This release includes over 300 new tests.

### BSD Package Management

BSD package management has been entirely rewritten. FreeBSD 9 and older now default to using `pkg_add`, while FreeBSD 10 and newer will use `pkgng`. FreeBSD 9 can be forced to use `pkgng`, however, by specifying the following option in the minion config file:

```
providers:
  pkg: pkgng
```

In addition, support for installing software from the ports tree has been added. See the documentation for the `ports` *state* and *execution module* for more information.

### Network Management for Debian/Ubuntu

Initial support for management of network interfaces on Debian-based distros has been added. See the documentation for the *network state* and the *debian\_ip* for more information.

### IPv6 Support for iptables State/Module

The iptables *state* and *module* now have IPv6 support. A new parameter `family` has been added to the states and execution functions, to distinguish between IPv4 and IPv6. The default value for this parameter is `ipv4`, specifying `ipv6` will use `ip6tables` to manage firewall rules.

### GitFS Improvements

Several performance improvements have been made to the *Git fileserver backend*. Additionally, file states can now use any any SHA1 commit hash as a fileserver environment:

```
/etc/httpd/httpd.conf:
  file.managed:
    - source: salt://webserver/files/httpd.conf
    - saltenv: 45af879
```

This applies to the functions in the *cp module* as well:

```
salt '*' cp.get_file salt://readme.txt /tmp/readme.txt saltenv=45af879
```

### MinionFS

This new fileserver backend allows files which have been pushed from the minion to the master (using *cp.push*) to be served up from the salt fileserver. The path for these files takes the following format:

```
salt://minion-id/path/to/file
```

`minion-id` is the id of the ``source'' minion, the one from which the files were pushed to the master. `/path/to/file` is the full path of the file.

The [MinionFS Walkthrough](#) contains a more thorough example of how to use this backend.

## saltenv

To distinguish between fileservers environments and execution functions which deal with environment variables, file-server environments are now specified using the `saltenv` parameter. `env` will continue to work, but is deprecated and will be removed in a future release.

## Grains Caching

A caching layer has been added to the Grains system, which can help speed up minion startup. Disabled by default, it can be enabled by setting the minion config option `grains_cache`:

```
grains_cache: True

# Seconds before grains cache is considered to be stale.
grains_cache_expiration: 300
```

If set to `True`, the grains loader will read from/write to a msgpack-serialized file containing the grains data.

Additional command-line parameters have been added to salt-call, mainly for testing purposes:

- `--skip-grains` will completely bypass the grains loader when salt-call is invoked.
- `--refresh-grains-cache` will force the grains loader to bypass the grains cache and refresh the grains, writing a new grains cache file.

## Improved Command Logging Control

When using the `cmd` *module*, either on the CLI or when developing Salt execution modules, a new keyword argument `output_loglevel` allows for greater control over how (or even if) the command and its output are logged. For example:

```
salt '*' cmd.run 'tail /var/log/messages' output_loglevel=debug
```

The package management modules (`apt`, `yumpkg`, etc.) have been updated to log the copious output generated from these commands at loglevel debug.

---

**Note:** To keep a command from being logged, `output_loglevel=quiet` can be used.

Prior to this release, this could be done using `quiet=True`. This argument is still supported, but will be removed in a future Salt release.

---

## PagerDuty Support

Initial support for firing events via `PagerDuty` has been added. See the documentation for the `pagerduty` module.

## Virtual Terminal

Sometimes the subprocess module is not good enough, and, in fact, not even `askpass` is. This virtual terminal is still in it's infant childhood, needs quite some love, and was originally created to replace `askpass`, but, while developing it, it immediately proved that it could do so much more. It's currently used by salt-cloud when bootstrapping salt on clouds which require the use of a password.

## Proxy Minions

Initial basic support for Proxy Minions is in this release. Documentation can be found [here](#).

Proxy minions are a developing feature in Salt that enables control of devices that cannot run a minion. Examples include network gear like switches and routers that run a proprietary OS but offer an API, or "dumb" devices that just don't have the horsepower or ability to handle a Python VM.

Proxy minions can be difficult to write, so a simple REST-based example proxy is included. A Python bottle-based webserver can be found at <https://github.com/cro/salt-proxy-rest> as an endpoint for this proxy.

This is an ALPHA-quality feature. There are a number of issues with it currently, mostly centering around process control, logging, and inability to work in a masterless configuration.

## Additional Bugfixes (Release Candidate Period)

Below are many of the fixes that were implemented in salt during the release candidate phase.

- Fix mount.mounted leaving conflicting entries in fstab ([issue 7079](#))
- Fix mysql returner serialization to use json ([issue 9590](#))
- Fix ZMQError: Operation cannot be accomplished in current state errors ([issue 6306](#))
- Rbenv and ruby improvements
- Fix quoting issues with mysql port ([issue 9568](#))
- Update mount module/state to support multiple swap partitions ([issue 9520](#))
- Fix archive state to work with bsdtar
- Clarify logs for minion ID caching
- Add numeric revision support to git state ([issue 9718](#))
- Update master\_uri with master\_ip ([issue 9694](#))
- Add comment to Debian mod\_repo ([issue 9923](#))
- Fix potential undefined loop variable in rabbitmq state ([issue 8703](#))
- Fix for salt-virt runner to delete key on VM deletion
- Fix for salt-run -d to limit results to specific runner or function ([issue 9975](#))
- Add tracebacks to jinja renderer when applicable ([issue 10010](#))
- Fix parsing in monit module ([issue 10041](#))
- Fix highstate output from syndic minions ([issue 9732](#))
- Quiet logging when dealing with passwords/hashes ([issue 10000](#))
- Fix for multiple remotes in git\_pillar ([issue 9932](#))
- Fix npm installed command ([issue 10109](#))
- Add safeguards for utf8 errors in zcbuildout module
- Fix compound commands ([issue 9746](#))
- Add systemd notification when master is started
- Many doc improvements

### 35.2.23 Salt 2014.1.1 Release Notes

**release** 2014-03-18

Version 2014.1.1 is a bugfix release for 2014.1.0. The changes include:

- Various doc fixes, including up-to-date Salt Cloud installation documentation.
- Renamed state.sls runner to state.orchestrate, to reduce confusion with the *state.sls* execution function
- Fix various bugs in the *dig* module (issue 10367)
- Add retry for query on certain EC2 status codes (issue 10154)
- Fix various bugs in *mongodb\_user* state module (issue 10430)
- Fix permissions on *~/ .salt\_token* (issue 10422)
- Add PyObjects support
- Fix *launchctl* module crash with missing files
- Fix *saltutil.find\_job* for Windows (issue 10581)
- Fix OS detection for OpenSolaris (issue 10601)
- Fix broken salt-ssh *key\_deploy*
- Add support for multiline cron comments (issue 10721)
- Fix *timezone* module for Arch (issue 10789)
- Fix symlink support for *file.recurse* (issue 10809)
- Fix multi-master bugs (issue 10732 and issue 10969)
- Fix *file.patch* to error when source file is unavailable (issue 10380)
- Fix *pkg* to handle packages set as *purge* in *pkg.installed* (issue 10719)
- Add *zmqversion* grain
- Fix *highstate* summary for masterless minions (issue 10945)
- Fix *saltutil.find\_job* for 2014.1 masters talking to 0.17 minions (issue 11020)
- Fix *file.recurse* states with trailing slashes in source (issue 11002)
- Fix *pkg.states* to allow *pkgname.x86\_64* (issue 7306)
- Make *iptables.states* set a default table for *flush* (issue 11037)
- Added *iptables --reject-with* after final *iptables* call in *iptables.states* (issue:10757)
- Fix improper passing of “family” in *iptables.states* (issue 10774)
- Fix traceback in *iptables.insert* states (issue 10988)
- Fix zombie processes (issue 10867 and others)
- Fix batch mode to obey *--return* settings (issue 9146)
- Fix localclient issue that was causing batch mode breakage (issue 11094, issue 10470, and others)
- Multiple salt-ssh fixes
- FreeBSD: look in */usr/local/etc/salt* for configuration by default, if installed using *pip --editable*.
- Add a *skip\_suggestions* parameter to *pkg.installed* states which allows pre-flight check to be skipped (issue 11106)

- Fixed tag-based gitfs fileservers environments regression ([issue 10956](#))
- Yum: fix cache of available pkgs not cleared when repos are changed ([issue 11001](#))
- Yum: fix for plugin-provided repositories (i.e. RHN/Spacewalk) ([issue 11145](#))
- Fix regression in *chocolatey.bootstrap* ([issue 10541](#))
- Fix fail on unknown target in *jobs runner* ([issue 11151](#))
- Don't log errors for commands which are expected to sometimes exit with non-zero exit status ([issue 11154](#), [issue 11090](#))
- Fix `test=True` CLI override of config option ([issue 10877](#))
- Log `sysctl` key listing at loglevel TRACE ([issue 10931](#))

### 35.2.24 Salt 2014.1.10 Release Notes

release 2014-08-01

---

**Note:** Version 2014.1.9 contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. This version contains the version detection fix, but is otherwise identical to 2014.1.9.

---

Version 2014.1.10 is another bugfix release for 2014.1.0. Changes include:

- Ensure salt-ssh will not continue if permissions on a temporary directory are not correct.
- Use the bootstrap script distributed with Salt instead of relying on an external resource
- Remove unused testing code
- Ensure salt states are placed into the `.salt` directory in salt-ssh
- Use a randomized path for temporary files in a salt-cloud deployment
- Clean any stale directories to ensure a fresh copy of salt-ssh during a deployment

Salt 2014.1.10 fixes security issues documented by CVE-2014-3563: "Insecure tmp-file creation in seed.py, salt-ssh, and salt-cloud." Upgrading is recommended.

### 35.2.25 Salt 2014.1.11 Release Notes

release 2014-08-29

Version 2014.1.11 is another bugfix release for 2014.1.0. Changes include:

- Fix for `minion_id` with byte-order mark (BOM) ([issue 12296](#))
- Fix `runas` deprecation in `at` module
- Fix trailing slash behavior for `file.makedirs_` ([issue 14019](#))
- Fix chocolatey path ([issue 13870](#))
- Fix `git_pillar` infinite loop issues ([issue 14671](#))
- Fix json outputter `null` case
- Fix for minion error if one of multiple masters are down ([issue 14099](#))

### 35.2.26 Salt 2014.1.12 Release Notes

`release` 2014-10-08

Version 2014.1.12 is another bugfix release for 2014.1.0. Changes include:

- Fix `scp_file` always failing (which broke salt-cloud) (issue 16437)
- Fix regression in pillar in masterless (issue 16210, issue 16416, issue 16428)

### 35.2.27 Salt 2014.1.13 Release Notes

`release` 2014-10-14

Version 2014.1.13 is another bugfix release for 2014.1.0. Changes include:

- Fix `sftp_file` by checking the exit status code of scp (which broke salt-cloud) (issue 16599)

### 35.2.28 Salt 2014.1.2 Release Notes

`release` 2014-04-15

Version 2014.1.2 is another bugfix release for 2014.1.0. The changes include:

- Fix username detection when su'ed to root on FreeBSD (issue 11628)
- Fix minionfs backend for file.recurse states
- Fix 32-bit packages of different arches than the CPU arch, on 32-bit RHEL/CentOS (issue 11822)
- Fix bug with specifying alternate home dir on user creation (FreeBSD) (issue 11790)
- Don't reload `site` module on module refresh for MacOS
- Fix regression with running execution functions in Pillar SLS (issue 11453)
- Fix some modules missing from Windows installer
- Don't log an error for yum commands that return nonzero exit status on non-failure (issue 11645)
- Fix bug in rabbitmq state (issue 8703)
- Fix missing ssh config options (issue 10604)
- Fix top.sls ordering (issue 10810 and issue 11691)
- Fix `salt-key --list all` (issue 10982)
- Fix `win_servermanager` install/remove function (issue 11038)
- Fix interaction with tokens when running commands as root (issue 11223)
- Fix overstate bug with `find_job` and `**kwargs` (issue 10503)
- Fix saltenv for `aptpkg.mod_repo` from `pkgrepo` state
- Fix environment issue causing file caching problems (issue 11189)
- Fix bug in `__parse_key` in registry state (issue 11408)
- Add minion auth retry on rejection (issue 10763)
- Fix `publish_session` updating the encryption key (issue 11493)
- Fix for bad `AssertionError` raised by GitPython (issue 11473)

- Fix `debian_ip` to allow disabling and enabling networking on Ubuntu ([issue 11164](#))
- Fix potential memory leak caused by saved (and unused) events ([issue 11582](#))
- Fix exception handling in the MySQL module ([issue 11616](#))
- Fix environment-related error ([issue 11534](#))
- Include `psutil` on Windows
- Add `file.replace` and `file.search` to Windows ([issue 11471](#))
- Add additional `file` module helpers to Windows ([issue 11235](#))
- Add `pid` to `netstat` output on Windows ([issue 10782](#))
- Fix Windows not caching new versions of installers in `winrepo` ([issue 10597](#))
- Fix hardcoded md5 hashing
- Fix `kwargs` in `salt-ssh` ([issue 11609](#))
- Fix file backup timestamps ([issue 11745](#))
- Fix `stacktrace` on `sys.doc` with invalid `eauth` ([issue 11293](#))
- Fix `git.latest` with `test=True` ([issue 11595](#))
- Fix `file.check_perms` hardcoded `follow_symlinks` ([issue 11387](#))
- Fix certain `pkg` states for RHEL5/Cent5 machines ([issue 11719](#))

### 35.2.29 Salt 2014.1.3 Release Notes

`release` 2014-04-15

Version 2014.1.3 is another bugfix release for 2014.1.0. It was created as a hotfix for a regression found in 2014.1.2, which was not distributed. The only change made was as follows:

- Fix regression that caused `saltutil.find_job` to fail, causing premature terminations of salt CLI commands.

Changes in the not-distributed 2014.1.2, also included in 2014.1.3:

- Fix username detection when `su`'ed to root on FreeBSD ([issue 11628](#))
- Fix `minionfs` backend for `file.recurse` states
- Fix 32-bit packages of different arches than the CPU arch, on 32-bit RHEL/CentOS ([issue 11822](#))
- Fix bug with specifying alternate home dir on user creation (FreeBSD) ([issue 11790](#))
- Don't reload `site` module on module refresh for MacOS
- Fix regression with running execution functions in Pillar SLS ([issue 11453](#))
- Fix some modules missing from Windows installer
- Don't log an error for `yum` commands that return nonzero exit status on non-failure ([issue 11645](#))
- Fix bug in `rabbitmq` state ([issue 8703](#))
- Fix missing `ssh` config options ([issue 10604](#))
- Fix `top.sls` ordering ([issue 10810](#) and [issue 11691](#))
- Fix `salt-key --list all` ([issue 10982](#))
- Fix `win_servermanager` install/remove function ([issue 11038](#))

- Fix interaction with tokens when running commands as root ([issue 11223](#))
- Fix overstate bug with `find_job` and `**kwargs` ([issue 10503](#))
- Fix `saltenv` for `aptpkg.mod_repo` from `pkgrepo` state
- Fix environment issue causing file caching problems ([issue 11189](#))
- Fix bug in `__parse_key` in registry state ([issue 11408](#))
- Add minion auth retry on rejection ([issue 10763](#))
- Fix `publish_session` updating the encryption key ([issue 11493](#))
- Fix for bad `AssertionError` raised by `GitPython` ([issue 11473](#))
- Fix `debian_ip` to allow disabling and enabling networking on Ubuntu ([issue 11164](#))
- Fix potential memory leak caused by saved (and unused) events ([issue 11582](#))
- Fix exception handling in the MySQL module ([issue 11616](#))
- Fix environment-related error ([issue 11534](#))
- Include `psutil` on Windows
- Add `file.replace` and `file.search` to Windows ([issue 11471](#))
- Add additional `file` module helpers to Windows ([issue 11235](#))
- Add `pid` to `netstat` output on Windows ([issue 10782](#))
- Fix Windows not caching new versions of installers in `winrepo` ([issue 10597](#))
- Fix hardcoded md5 hashing
- Fix `kwargs` in `salt-ssh` ([issue 11609](#))
- Fix file backup timestamps ([issue 11745](#))
- Fix `stacktrace` on `sys.doc` with invalid `eauth` ([issue 11293](#))
- Fix `git.latest` with `test=True` ([issue 11595](#))
- Fix `file.check_perms` hardcoded `follow_symlinks` ([issue 11387](#))
- Fix certain `pkg` states for RHEL5/Cent5 machines ([issue 11719](#))

### 35.2.30 Salt 2014.1.4 Release Notes

`release` 2014-05-05

Version 2014.1.4 is another bugfix release for 2014.1.0. Changes include:

- Fix `setup.py` dependency issue ([issue 12031](#))
- Fix handling for `IOErrors` under certain circumstances ([issue 11783](#) and [issue 11853](#))
- Fix fatal exception when `/proc/1/cgroup` is not readable ([issue 11619](#))
- Fix `os` grains for OpenSolaris ([issue 11907](#))
- Fix `lvs.zero` module argument pass-through ([issue 9001](#))
- Fix bug in `debian_ip` interaction with `network.system` state ([issue 11164](#))
- Remove bad binary package verification code ([issue 12177](#))
- Fix traceback in solaris package installation ([issue 12237](#))

- Fix `file.directory` state symlink handling (issue 12209)
- Remove `external_ip` grain
- Fix `file.managed` makedirs issues (issue 10446)
- Fix hang on non-existent Windows drive letter for `file` module (issue 9880)
- Fix salt minion caching all users on the server (issue 9743)
- Add strftime formatting for `ps.boot_time` (issue 12428)

### 35.2.31 Salt 2014.1.5 Release Notes

release 2014-06-11

Version 2014.1.5 is another bugfix release for 2014.1.0. Changes include:

- Add function for finding cached job on the minion
- Fix iptables save file location for Debian (issue 11730)
- Fix for minion caching jobs when master is down
- Bump default `syndic_wait` to 5 to fix syndic-related problems (issue 12262)
- Add OpenBSD, FreeBSD, and NetBSD support for `network.netstat` (issue 12121)
- Fix false positive error in logs for `makeconf` state (issue 9762)
- Fix for yum `fromrepo` package installs when repo is disabled by default (issue 12466)
- Fix for extra blank lines in `file.blockreplace` (issue 12422)
- Fix grain detection for OpenVZ guests (issue 11877)
- Fix `get_dns_servers` function for Windows `win_dns_client`
- Use system locale for ports package installations
- Use correct stop/restart procedure for Debian networking in `debian_ip` (issue 12614)
- Fix for `cmd_iter/cmd_iter_no_block` blocking issues (issue 12617)
- Fix traceback when syncing custom types (issue 12883)
- Fix cleaning directory symlinks in `file.directory`
- Add performance optimizations for `saltutil.sync_all` and `state.highstate`
- Fix possible error in `saltutil.running`
- Fix for `kmod` modules with dashes (issue 13239)
- Fix possible race condition for Windows minions in state module reloading (issue 12370)
- Fix bug with roster for `passwd` option that is loaded as a non-string object (issue 13249)
- Keep duplicate version numbers from showing up in `pkg.list_pkgs` output
- Fixes for Jinja renderer, timezone `module/state` (issue 12724)
- Fix `timedatectl` parsing for `systemd>=210` (issue 12728)
- Fix `saltenv` being written to YUM repo config files (issue 12887)
- Removed the deprecated external nodes classifier (originally accessible by setting a value for `external_nodes` in the master configuration file). Note that this functionality has been marked deprecated for some time and was replaced by the more general `master tops` system.

- More robust escaping of ldap filter strings.
- Fix trailing slash in `gitfs_root` causing files not to be available ([issue 13185](#))

### 35.2.32 Salt 2014.1.6 Release Notes

`release` 2014-07-08

Version 2014.1.6 is another bugfix release for 2014.1.0. Changes include:

- Fix extra `iptables --help` output (Sorry!) ([issue 13648](#), [issue 13507](#), [issue 13527](#), [issue 13607](#))
- Fix `mount.active` for Solaris
- Fix support for `allow-hotplug` statement in `debian_ip` network module
- Add `sqlite3` to esky builds
- Fix `jobs.active` output ([issue 9526](#))
- Fix the `virtual` grain for Xen ([issue 13534](#))
- Fix `eauth` for batch mode ([issue 9605](#))
- Fix force-related issues with `tomcat` support ([issue 12889](#))
- Fix `KeyError` when cloud mapping
- Fix salt-minion restart loop in Windows ([issue 12086](#))
- Fix detection of `service` virtual module on Fedora minions
- Fix traceback with missing `ipv4` grain ([issue 13838](#))
- Fix issue in roots backend with invalid data in `mtime_map` ([issue 13836](#))
- Fix traceback in `jobs.active` ([issue 11151](#))
- Fix `master_tops` and `_ext_nodes` issue ([issue 13535](#), [issue 13673](#))

### 35.2.33 Salt 2014.1.7 Release Notes

`release` 2014-07-09

Version 2014.1.7 is another bugfix release for 2014.1.0. Changes include:

- Fix batch mode regression ([issue 14046](#))

This release was a hotfix release for the regression listed above which was present in the 2014.1.6 release. The changes included in 2014.1.6 are listed below:

- Fix extra `iptables --help` output (Sorry!) ([issue 13648](#), [issue 13507](#), [issue 13527](#), [issue 13607](#))
- Fix `mount.active` for Solaris
- Fix support for `allow-hotplug` statement in `debian_ip` network module
- Add `sqlite3` to esky builds
- Fix `jobs.active` output ([issue 9526](#))
- Fix the `virtual` grain for Xen ([issue 13534](#))
- Fix `eauth` for batch mode ([issue 9605](#))
- Fix force-related issues with `tomcat` support ([issue 12889](#))

- Fix `KeyError` when cloud mapping
- Fix salt-minion restart loop in Windows ([issue 12086](#))
- Fix detection of `service` virtual module on Fedora minions
- Fix traceback with missing `ipv4` grain ([issue 13838](#))
- Fix issue in roots backend with invalid data in `mtime_map` ([issue 13836](#))
- Fix traceback in `jobs.active` ([issue 11151](#))
- Fix `master_tops` and `_ext_nodes` issue ([issue 13535](#), [issue 13673](#))

### 35.2.34 Salt 2014.1.8 Release Notes

release 2014-07-30

---

**Note:** This release contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. Please use version 2014.1.10 instead.

---

Version 2014.1.8 is another bugfix release for 2014.1.0. Changes include:

- Ensure salt-ssh will not continue if permissions on a temporary directory are not correct.
- Use the bootstrap script distributed with Salt instead of relying on an external resource
- Remove unused testing code
- Ensure salt states are placed into the `.salt` directory in salt-ssh
- Use a randomized path for temporary files in a salt-cloud deployment
- Clean any stale directories to ensure a fresh copy of salt-ssh during a deployment

### 35.2.35 Salt 2014.1.9 Release Notes

release 2014-07-31

---

**Note:** This release contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. Please use version 2014.1.10 instead.

---

**Note:** Version 2014.1.8 contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. This version contains the version detection fix, but is otherwise identical to 2014.1.8.

---

Version 2014.1.9 is another bugfix release for 2014.1.0. Changes include:

- Ensure salt-ssh will not continue if permissions on a temporary directory are not correct.
- Use the bootstrap script distributed with Salt instead of relying on an external resource
- Remove unused testing code
- Ensure salt states are placed into the `.salt` directory in salt-ssh
- Use a randomized path for temporary files in a salt-cloud deployment
- Clean any stale directories to ensure a fresh copy of salt-ssh during a deployment

### 35.2.36 Salt 0.10.0 Release Notes

release 2012-06-16

0.10.0 has arrived! This release comes with MANY bug fixes, and new capabilities which greatly enhance performance and reliability. This release is primarily a bug fix release with many new tests and many repaired bugs. This release also introduces a few new key features which were brought in primarily to repair bugs and some limitations found in some of the components of the original architecture.

#### Major Features

##### Event System

The Salt Master now comes equipped with a new event system. This event system has replaced some of the back end of the Salt client and offers the beginning of a system which will make plugging external applications into Salt. The event system relies on a local ZeroMQ publish socket and other processes can connect to this socket and listen for events. The new events can be easily managed via Salt's event library.

##### Unprivileged User Updates

Some enhancements have been added to Salt for running as a user other than root. These new additions should make switching the user that the Salt Master is running as very painless, simply change the `user` option in the master configuration and restart the master, Salt will take care of all of the particulars for you.

##### Peer Runner Execution

Salt has long had the peer communication system used to allow minions to send commands via the salt master. 0.10.0 adds a new capability here, now the master can be configured to allow for minions to execute Salt runners via the `peer_run` option in the salt master configuration.

##### YAML Parsing Updates

In the past the YAML parser for sls files would return the incorrect numbers when the file mode was set with a preceding 0. The YAML parser used in Salt has been modified to no longer convert these number into octal but to keep them as the correct value so that sls files can be a little cleaner to write.

##### State Call Data Files

It was requested that the minion keep a local cache of the most recent executed state run. This has been added and now with state runs the data is stored in a msgpack file in the minion's cachedir.

##### Turning Off the Job Cache

A new option has been added to the master configuration file. In previous releases the Salt client would look over the Salt job cache to read in the minion return data. With the addition of the event system the Salt client can now watch for events directly from the master worker processes.

This means that the job cache is no longer a hard requirement. Keep in mind though, that turning off the job cache means that historic job execution data cannot be retrieved.

## Test Updates

### Minion Swarms Are Faster

To continue our efforts with testing Salt's ability to scale the minionswarm script has been updated. The minionswarm can now start up minions much faster than it could before and comes with a new feature allowing modules to be disabled, thus lowering the minion's footprint when making a swarm. These new updates have allows us to test

```
# python minionswarm.py -m 20 --master salt-master
```

## Many Fixes

To get a good idea for the number of bugfixes this release offers take a look at the closed tickets for 0.10.0, this is a very substantial update:

<https://github.com/saltstack/salt/issues?milestone=12&state=closed>

### Master and Minion Stability Fixes

As Salt deployments grow new ways to break Salt are discovered. 0.10.0 comes with a number of fixes for the minions and master greatly improving Salt stability.

## 35.2.37 Salt 0.10.1 Release Notes

release 2012-06-19

## 35.2.38 Salt 0.10.2 Release Notes

release 2012-07-30

0.10.2 is out! This release comes with enhancements to the pillar interface, cleaner ways to access the salt-call capabilities in the API, minion data caching and the event system has been added to salt minions.

There have also been updates to the ZeroMQ functions, many more tests (thanks to sponsors, the code sprint and many contributors) and a swath of bug fixes.

## Major Features

### Ext Pillar Modules

The ranks of available Salt modules directories sees a new member in 0.10.2. With the popularity of pillar a higher demand has arisen for `ext_pillar` interfaces to be more like regular Salt module additions. Now `ext_pillar` interfaces can be added in the same way as other modules, just drop it into the pillar directory in the salt source.

### Minion Events

In 0.10.0 an event system was added to the Salt master. 0.10.2 adds the event system to the minions as well. Now event can be published on a local minion as well.

The minions can also send events back up to the master. This means that Salt is able to communicate individual events from the minions back up to the Master which are not associated with command.

### Minion Data Caching

When pillar was introduced the landscape for available data was greatly enhanced. The minion's began sending grain data back to the master on a regular basis.

The new config option on the master called `minion_data_cache` instructs the Salt master to maintain a cache of the minion's grains and pillar data in the `cachedir`. This option is turned off by default to avoid hitting the disk more, but when enabled the cache is used to make grain matching from the salt command more powerful, since the minions that will match can be predetermined.

### Backup Files

By default all files replaced by the `file.managed` and `file.recurse` states we simply deleted. 0.10.2 adds a new option. By setting the `backup` option to `minion` the files are backed up before they are replaced.

The backed up files are located in the `cachedir` under the `file_backup` directory. On a default system this will be at: `/var/cache/salt/file_backup`

### Configuration files

`salt-master` and `salt-minion` automatically load additional configuration files from `master.d/*.conf` respective `minion.d/*.conf` where `master.d/minion.d` is a directory in the same directory as the main configuration file.

### Salt Key Verification

A number of users complained that they had inadvertently deleted the wrong salt authentication keys. 0.10.2 now displays what keys are going to be deleted and verifies that they are the keys that are intended for deletion.

### Key auto-signing

If `autosign_file` is specified in the configuration file incoming keys will be compared to the list of keynames in `autosign_file`. Regular expressions as well as globbing is supported.

The file must only be writable by the user otherwise the file will be ignored. To relax the permission and allow group write access set the `permissive_pki_access` option.

### Module changes

**Improved OpenBSD support** New modules for managing services and packages were provided by Joshua Elsasser to further improve the support for OpenBSD.

Existing modules like the `disk` module were also improved to support OpenBSD.

**SQL Modules** The MySQL and PostgreSQL modules have both received a number of additions thanks to the work of Avi Marcus and Roman Imankulov.

**ZFS Support on FreeBSD** A new ZFS module has been added by Kurtis Velarde for FreeBSD supporting various ZFS operations like creating, extending or removing zpools.

**Augeas** A new Augeas module by Ulrich Dangel for editing and verifying config files.

**Native Debian Service module** The support for the Debian was further improved with an new service module for Debian by Ahmad Khayyat supporting *disable* and *enable*.

**Cassandra** Cassandra support has been added by Adam Garside. Currently only status and diagnostic information are supported.

**Networking** The networking support for *RHEL* has been improved and supports bonding support as well as zero-conf configuration.

**Monit** Basic monit support by Kurtis Velarde to control services via monit.

**nzbget** Basic support for controlling nzbget by Joseph Hall

**Bluetooth** Basic bluez support for managing and controlling Bluetooth devices. Supports scanning as well as pairing/unpairing by Joseph Hall.

## Test Updates

### Consistency Testing

Another testing script has been added. A bug was found in pillar when many minions generated pillar data at the same time. The new `consistent.py` script in the `tests` directory was created to reproduce bugs where data should always be consistent.

### Many Fixes

To get a good idea for the number of bugfixes this release offers take a look at the closed tickets for 0.10.2, this is a very substantial update:

<https://github.com/saltstack/salt/issues?milestone=24&page=1&state=closed>

### Master and Minion Stability Fixes

As Salt deployments grow new ways to break Salt are discovered. 0.10.2 comes with a number of fixes for the minions and master greatly improving Salt stability.

### 35.2.39 Salt 0.10.3 Release Notes

**release** 2012-09-30

The latest taste of Salt has come, this release has many fixes and feature additions. Modifications have been made to make ZeroMQ connections more reliable, the beginning of the ACL system is in place, a new command line parsing system has been added, dynamic module distribution has become more environment aware, the new *master\_finger* option and many more!

#### Major Features

##### ACL System

The new ACL system has been introduced. The ACL system allows for system users other than root to execute salt commands. Users can be allowed to execute specific commands in the same way that minions are opened up to the peer system.

The configuration value to open up the ACL system is called `client_acl` and is configured like so:

```
client_acl:
  fred:
    - test.*
    - pkg.list_pkgs
```

Where *fred* is allowed access to functions in the test module and to the `pkg.list_pkgs` function.

##### Master Finger Option

The *master\_finger* option has been added to improve the security of minion provisioning. The *master\_finger* option allows for the fingerprint of the master public key to be set in the configuration file to double verify that the master is valid. This option was added in response to a motivation to pre-authenticate the master when provisioning new minions to help prevent man in the middle attacks in some situations.

##### Salt Key Fingerprint Generation

The ability to generate fingerprints of keys used by Salt has been added to `salt-key`. The new option *finger* accepts the name of the key to generate and display a fingerprint for.

```
salt-key -F master
```

Will display the fingerprints for the master public and private keys.

##### Parsing System

Pedro Algavio, aka s0undt3ch, has added a substantial update to the command line parsing system that makes the help message output much cleaner and easier to search through. Salt parsers now have `--versions-report` besides usual `--version` info which you can provide when reporting any issues found.

## Key Generation

We have reduced the requirements needed for *salt-key* to generate minion keys. You're no longer required to have salt configured and it's common directories created just to generate keys. This might prove useful if you're batch creating keys to pre-load on minions.

## Startup States

A few configuration options have been added which allow for states to be run when the minion daemon starts. This can be a great advantage when deploying with Salt because the minion can apply states right when it first runs. To use startup states set the `startup_states` configuration option on the minion to *highstate*.

## New Exclude Declaration

Some users have asked about adding the ability to ensure that other sls files or ids are excluded from a state run. The exclude statement will delete all of the data loaded from the specified sls file or will delete the specified id:

```
exclude:
  - sls: http
  - id: /etc/vimrc
```

## Max Open Files

While we're currently unable to properly handle ZeroMQ's abort signals when the max open files is reached, due to the way that's handled on ZeroMQ's, we have minimized the chances of this happening without at least warning the user.

## More State Output Options

Some major changes have been made to the state output system. In the past state return data was printed in a very verbose fashion and only states that failed or made changes were printed by default. Now two options can be passed to the master and minion configuration files to change the behavior of the state output. State output can be set to verbose (default) or non-verbose with the `state_verbose` option:

```
state_verbose: False
```

It is noteworthy that the `state_verbose` option used to be set to *False* by default but has been changed to *True* by default in 0.10.3 due to many requests for the change.

The next option to be aware of new and called `state_output`. This option allows for the state output to be set to *full* (default) or *terse*.

The *full* output is the standard state output, but the new *terse* output will print only one line per state making the output much easier to follow when executing a large state system.

```
state_output: terse
```

### *state.file.append* Improvements

The salt state *file.append()* tries *not* to append existing text. Previously the matching check was being made line by line. While this kind of check might be enough for most cases, if the text being appended was multi-line, the check would not work properly. This issue is now properly handled, the match is done as a whole ignoring any white space addition or removal except inside commas. For those thinking that, in order to properly match over multiple lines, salt will load the whole file into memory, that's not true. For most cases this is not important but an erroneous order to read a 4GB file, if not properly handled, like salt does, could make salt chew that amount of memory. Salt has a buffered file reader which will keep in memory a maximum of 256KB and iterates over the file in chunks of 32KB to test for the match, more than enough, if not, explain your usage on a ticket. With this change, also *salt.modules.file.contains()*, *salt.modules.file.contains\_regex()*, *salt.modules.file.contains\_glob()* and *salt.utils.find* now do the searching and/or matching using the buffered chunks approach explained above.

Two new keyword arguments were also added, *makedirs*, and *source*. The first, *makedirs* will create the necessary directories in order to append to the specified file, of course, it only applies if we're trying to append to a non-existing file on a non-existing directory:

```
/tmp/salttest/file-append-makedirs:
  file.append:
    text: foo
    makedirs: True
```

The second, *source*, allows one to append the contents of a file instead of specifying the text.

```
/tmp/salttest/file-append-source:
file.append:
  - source: salt://testfile
```

### Security Fix

A timing vulnerability was uncovered in the code which decrypts the AES messages sent over the network. This has been fixed and upgrading is strongly recommended.

## 35.2.40 Salt 0.10.4 Release Notes

release 2012-10-23

Salt 0.10.4 is a monumental release for the Salt team, with two new module systems, many additions to allow granular access to Salt, improved platform support and much more.

This release is also exciting because we have been able to shorten the release cycle back to under a month. We are working hard to keep up the aggressive pace and look forward to having releases happen more frequently!

This release also includes a serious security fix and all users are very strongly recommended to upgrade. As usual, upgrade the master first, and then the minion to ensure that the process is smooth.

### Major Features

#### External Authentication System

The new external authentication system allows for Salt to pass through authentication to any authentication system to determine if a user has permission to execute a Salt command. The Unix PAM system is the first supported system

with more to come!

The external authentication system allows for specific users to be granted access to execute specific functions on specific minions. Access is configured in the master configuration file, and uses the new access control system:

```
external_auth:
  pam:
    thatch:
      - 'web*':
        - test.*
        - network.*
```

The configuration above allows the user *thatch* to execute functions in the test and network modules on minions that match the *web\** target.

### Access Control System

All Salt systems can now be configured to grant access to non-administrative users in a granular way. The old configuration continues to work. Specific functions can be opened up to specific minions from specific users in the case of external auth and client ACLs, and for specific minions in the case of the peer system.

Access controls are configured like this:

```
client_acl:
  fred:
    - web\*:
      - pkg.list_pkgs
      - test.*
      - apache.*
```

### Target by Network

A new matcher has been added to the system which allows for minions to be targeted by network. This new matcher can be called with the *-S* flag on the command line and is available in all places that the matcher system is available. Using it is simple:

```
$ salt -S '192.168.1.0/24' test.ping
$ salt -S '192.168.1.100' test.ping
```

### Nodegroup Nesting

Previously a nodegroup was limited by not being able to include another nodegroup, this restraint has been lifted and now nodegroups will be expanded within other nodegroups with the *N@* classifier.

### Salt Key Delete by Glob

The ability to delete minion keys by glob has been added to *salt-key*. To delete all minion keys whose minion name starts with *'web'*:

```
$ salt-key -d 'web*'
```

### Master Tops System

The *external\_nodes* system has been upgraded to allow for modular subsystems to be used to generate the top file data for a highstate run.

The *external\_nodes* option still works but will be deprecated in the future in favor of the new *master\_tops* option.

Example of using *master\_tops*:

```
master_tops:  
  ext_nodes: cobbler-external-nodes
```

### Next Level Solaris Support

A lot of work has been put into improved Solaris support by Romeo Theriault. Packaging modules (*pkgadd/pkgrm* and *pkgutil*) and states, cron support and user and group management have all been added and improved upon. These additions along with SMF (Service Management Facility) service support and improved Solaris grain detection in 0.10.3 add up to Salt becoming a great tool to manage Solaris servers with.

### Security

A vulnerability in the security handshake was found and has been repaired, old minions should be able to connect to a new master, so as usual, the master should be updated first and then the minions.

### Pillar Updates

The pillar communication has been updated to add some extra levels of verification so that the intended minion is the only one allowed to gather the data. Once all minions and the master are updated to salt 0.10.4 please activate pillar 2 by changing the *pillar\_version* in the master config to 2. This will be set to 2 by default in a future release.

## 35.2.41 Salt 0.10.5 Release Notes

**release** 2012-11-15

Salt 0.10.5 is ready, and comes with some great new features. A few more interfaces have been modularized, like the outputter system. The job cache system has been made more powerful and can now store and retrieve jobs archived in external databases. The returner system has been extended to allow minions to easily retrieve data from a returner interface.

As usual, this is an exciting release, with many noteworthy additions!

## Major Features

### External Job Cache

The external job cache is a system which allows for a returner interface to also act as a job cache. This system is intended to allow users to store job information in a central location for longer periods of time and to make the act of looking up information from jobs executed on other minions easier.

Currently the external job cache is supported via the mongo and redis returners:

```
ext_job_cache: redis
redis.host: salt
```

Once the external job cache is turned on the new *ret* module can be used on the minions to retrieve return information from the job cache. This can be a great way for minions to respond and react to other minions.

### OpenStack Additions

OpenStack integration with Salt has been moving forward at a blistering pace. The new *nova*, *glance*, and *keystone* modules represent the beginning of ongoing OpenStack integration.

The Salt team has had many conversations with core OpenStack developers and is working on linking to OpenStack in powerful new ways.

### Wheel System

A new API was added to the Salt Master which allows the master to be managed via an external API. This new system allows Salt API to easily hook into the Salt Master and manage configs, modify the state tree, manage the pillar and more. The main motivation for the wheel system is to enable features needed in the upcoming web UI so users can manage the master just as easily as they manage minions.

The wheel system has also been hooked into the external auth system. This allows specific users to have granular access to manage components of the Salt Master.

### Render Pipes

Jack Kuan has added a substantial new feature. The render pipes system allows Salt to treat the render system like unix pipes. This new system enables sls files to be passed through specific render engines. While the default renderer is still recommended, different engines can now be more easily merged. So to pipe the output of Mako used in YAML use this shebang line:

```
#!/mako|yaml
```

### Salt Key Overhaul

The Salt Key system was originally developed as only a CLI interface, but as time went on it was pressed into becoming a clumsy API. This release marks a complete overhaul of Salt Key. Salt Key has been rewritten to function purely from an API and to use the outputter system. The benefit here is that the outputter system works much more cleanly with Salt Key now, and the internals of Salt Key can be used much more cleanly.

## Modular Outputters

The outputter system is now loaded in a modular way. This means that output systems can be more easily added by dropping a python file down on the master that contains the function *output*.

## Gzip from Fileserver

Gzip compression has been added as an option to the `cp.get_file` and `cp.get_dir` commands. This will make file transfers more efficient and faster, especially over slower network links.

## Unified Module Configuration

In past releases of Salt, the minions needed to be configured for certain modules to function. This was difficult because it required pre-configuring the minions. 0.10.5 changes this by making all module configs on minions search the master config file for values.

Now if a single database server is needed, then it can be defined in the master config and all minions will become aware of the configuration value.

## Salt Call Enhancements

The `salt-call` command has been updated in a few ways. Now, `salt-call` can take the `--return` option to send the data to a returner. Also, `salt-call` now reports executions in the minion proc system, this allows the master to be aware of the operation `salt-call` is running.

## Death to `pub_refresh` and `sub_timeout`

The old configuration values `pub_refresh` and `sub_timeout` have been removed. These options were in place to alleviate problems found in earlier versions of ZeroMQ which have since been fixed. The continued use of these options has proven to cause problems with message passing and have been completely removed.

## Git Revision Versions

When running Salt directly from git (for testing or development, of course) it has been difficult to know exactly what code is being executed. The new versioning system will detect the git revision when building and how many commits have been made since the last release. A release from git will look like this:

```
0.10.4-736-gec74d69
```

## Svn Module Addition

Anthony Cornehl (twinshadow) contributed a module that adds Subversion support to Salt. This great addition helps round out Salt's VCS support.

## Noteworthy Changes

### Arch Linux Defaults to Systemd

Arch Linux recently changed to use systemd by default and discontinued support for init scripts. Salt has followed suit and defaults to systemd now for managing services in Arch.

### Salt, Salt Cloud and Openstack

With the releases of Salt 0.10.5 and Salt Cloud 0.8.2, OpenStack becomes the first (non-OS) piece of software to include support both on the user level (with Salt Cloud) and the admin level (with Salt). We are excited to continue to extend support of other platforms at this level.

## 35.2.42 Salt 0.11.0 Release Notes

**release** 2012-12-14

Salt 0.11.0 is here, with some highly sought after and exciting features. These features include the new overstate system, the reactor system, a new state run scope component called `__context__`, the beginning of the search system (still needs a great deal of work), multiple package states, the MySQL returner and a better system to arbitrarily reference outputters.

It is also noteworthy that we are changing how we mark release numbers. For the life of the project we have been pushing every release with features and fixes as point releases. We will now be releasing point releases for only bug fixes on a more regular basis and major feature releases on a slightly less regular basis. This means that the next release will be a bugfix only release with a version number of 0.11.1. The next feature release will be named 0.12.0 and will mark the end of life for the 0.11 series.

### Major Features

#### OverState

The overstate system is a simple way to manage rolling state executions across many minions. The overstate allows for a state to depend on the successful completion of another state.

#### Reactor System

The new reactor system allows for a reactive logic engine to be created which can respond to events within a salted environment. The reactor system uses sls files to match events fired on the master with actions, enabling Salt to react to problems in an infrastructure.

Your load-balanced group of webservers is under extra load? Spin up a new VM and add it to the group. Your fileserver is filling up? Send a notification to your sysadmin on call. The possibilities are endless!

#### Module Context

A new component has been added to the module loader system. The module context is a data structure that can hold objects for a given scope within the module.

This allows for components that are initialized to be stored in a persistent context which can greatly speed up ongoing connections. Right now the best example can be found in the `cp` execution module.

## Multiple Package Management

A long desired feature has been added to package management. By definition Salt States have always installed packages one at a time. On most platforms this is not the fastest way to install packages. Erik Johnson, aka terminalmage, has modified the package modules for many providers and added new capabilities to install groups of packages. These package groups can be defined as a list of packages available in repository servers:

```
python_pkgs:
  pkg.installed:
    - pkgs:
      - python-mako
      - whoosh
      - python-git
```

or specify based on the location of specific packages:

```
python_pkgs:
  pkg.installed:
    - sources:
      - python-mako: http://some-rpms.org/python-mako.rpm
      - whoosh: salt://whoosh/whoosh.rpm
      - python-git: ftp://companyserver.net/python-git.rpm
```

## Search System

The bones to the search system have been added. This is a very basic interface that allows for search backends to be added as search modules. The first supported search module is the whoosh search backend. Right now only the basic paths for the search system are in place, making this very experimental. Further development will involve improving the search routines and index routines for whoosh and other search backends.

The search system has been made to allow for searching through all of the state and pillar files, configuration files and all return data from minion executions.

## Notable Changes

All previous versions of Salt have shared many directories between the master and minion. The default locations for keys, cached data and sockets has been shared by master and minion. This has created serious problems with running a master and a minion on the same systems. 0.11.0 changes the defaults to be separate directories. Salt will also attempt to migrate all of the old key data into the correct new directories, but if it is not successful it may need to be done manually. If your keys exhibit issues after updating make sure that they have been moved from `/etc/salt/pki` to `/etc/salt/pki/{master,minion}`.

The old setup will look like this:

```
/etc/salt/pki
|-- master.pem
|-- master.pub
|-- minions
|   |-- ragnarok.saltstack.net
|-- minions_pre
|-- minion.pem
|-- minion.pub
```

```
|-- minion_master.pub
|-- minions_pre
`-- minions_rejected
```

With the accepted minion keys in `/etc/salt/pki/minions`, the new setup places the accepted minion keys in `/etc/salt/pki/master/minions`.

```
/etc/salt/pki
|-- master
|   |-- master.pem
|   |-- master.pub
|   |-- minions
|   |   `-- ragnarok.saltstack.net
|   |-- minions_pre
|   `-- minions_rejected
|-- minion
|   |-- minion.pem
|   |-- minion.pub
|   `-- minion_master.pub
```

### 35.2.43 Salt 0.11.1 Release Notes

release 2012-12-19

### 35.2.44 Salt 0.12.0 Release Notes

release 2013-01-15

Another feature release of Salt is here! Some exciting additions are included with more ways to make salt modular and even easier management of the salt file server.

#### Major Features

##### Modular Fileserver Backend

The new modular fileserver backend allows for any external system to be used as a salt file server. The main benefit here is that it is now possible to tell the master to directly use a git remote location, or many git remote locations, automatically mapping git branches and tags to salt environments.

##### Windows is First Class!

A new Salt Windows installer is now available! Much work has been put in to improve Windows support. With this much easier method of getting Salt on your Windows machines, we hope even more development and progress will occur. Please file bug reports on the Salt GitHub repo issue tracker so we can continue improving.

One thing that is missing on Windows that Salt uses extensively is a software package manager and a software package repository. The Salt pkg state allows sys admins to install software across their infrastructure and across operating systems. Software on Windows can now be managed in the same way. The SaltStack team built a package

manager that interfaces with the standard Salt pkg module to allow for installing and removing software on Windows. In addition, a software package repository has been built on top of the Salt fileserver. A small YAML file provides the information necessary for the package manager to install and remove software.

An interesting feature of the new Salt Windows software package repository is that one or more remote git repositories can supplement the master's local repository. The repository can point to software on the master's fileserver or on an HTTP, HTTPS, or ftp server.

### New Default Outputter

Salt displays data to the terminal via the outputter system. For a long time the default outputter for Salt has been the python pretty print library. While this has been a generally reasonable outputter, it did have many failings. The new default outputter is called ``nested'', it recursively scans return data structures and prints them out cleanly.

If the result of the new nested outputter is not desired any other outputter can be used via the `--out` option, or the `output` option can be set in the master and minion configs to change the default outputter.

### Internal Scheduler

The internal Salt scheduler is a new capability which allows for functions to be executed at given intervals on the minion, and for runners to be executed at given intervals on the master. The scheduler allows for sequences such as executing state runs (locally on the minion or remotely via an overstate) or continually gathering system data to be run at given intervals.

The configuration is simple, add the `schedule` option to the master or minion config and specify jobs to run, this in the master config will execute the `state.over` runner every 60 minutes:

```
schedule:
  overstate:
    function: state.over
    minutes: 60
```

This example for the minion configuration will execute a `highstate` every 30 minutes:

```
schedule:
  highstate:
    function: state.highstate
    minutes: 30
```

### Optional DSL for SLS Formulas

Jack Kuan, our renderer expert, has created something that is astonishing. Salt, now comes with an optional Python based DSL, this is a very powerful interface that makes writing SLS files in pure python easier than it was with the raw py renderer. As usual this can be used with the `renderer shebang` line, so a single sls can be written with the DSL if pure python power is needed while keeping other sls files simple with YAML.

### Set Grains Remotely

A new execution function and state module have been added that allows for grains to be set on the minion. Now grains can be set via a remote execution or via states. Use the `grains.present` state or the `grains.setval` execution functions.

## Gentoo Additions

Major additions to Gentoo specific components have been made. The encompasses executions modules and states ranging from supporting the make.conf file to tools like layman.

### 35.2.45 Salt 0.12.1 Release Notes

release 2013-01-21

### 35.2.46 Salt 0.13.0 Release Notes

release 2013-02-12

The lucky number 13 has turned the corner! From CLI notifications when quitting a salt command, to substantial improvements on Windows, Salt 0.13.0 has arrived!

## Major Features

### Improved file.recurse Performance

The file.recurse system has been deployed and used in a vast array of situations. Fixes to the file state and module have led towards opening up new ways of running file.recurse to make it faster. Now the file.recurse state will download fewer files and will run substantially faster.

### Windows Improvements

Minion stability on Windows has improved. Many file operations, including file.recurse, have been fixed and improved. The network module works better, to include network.interfaces. Both 32bit and 64bit installers are now available.

### Nodegroup Targeting in Peer System

In the past, nodegroups were not available for targeting via the peer system. This has been fixed, allowing the new nodegroup `expr_form` argument for the `publish.publish` function:

```
salt-call publish.publish group1 test.ping expr_form=nodegroup
```

### Blacklist Additions

Additions allowing more granular blacklisting are available in 0.13.0. The ability to blacklist users and functions in `client_acl` have been added, as well as the ability to exclude state formulas from the command line.

### Command Line Pillar Embedding

Pillar data can now be embedded on the command line when calling `state.sls` and `state.highstate`. This allows for on the fly changes or settings to pillar and makes parameterizing state formulas even easier. This is done via the `keyword` argument:

```
salt '*' state.highstate pillar='{"cheese": "spam"}'
```

The above example will extend the existing pillar to hold the cheese key with a value of spam. If the cheese key is already specified in the minion's pillar then it will be overwritten.

### CLI Notifications

In the past hitting ctrl-C and quitting from the salt command would just drop to a shell prompt, this caused confusion with users who expected the remote executions to also quit. Now a message is displayed showing what command can be used to track the execution and what the job id is for the execution.

### Version Specification in Multiple-Package States

Versions can now be specified within multiple-package *pkg.installed* states. An example can be found below:

```
mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: 1.2.3-4
      - baz
```

### Noteworthy Changes

The configuration subsystem in Salt has been overhauled to make the `opts` dict used by Salt applications more portable, the problem is that this is an incompatible change with salt-cloud, and salt-cloud will need to be updated to the latest git to work with Salt 0.13.0. Salt Cloud 0.8.5 will also require Salt 0.13.0 or later to function.

The SaltStack team is sorry for the inconvenience here, we work hard to make sure these sorts of things do not happen, but sometimes hard changes get in.

#### 35.2.47 Salt 0.13.1 Release Notes

release 2013-02-15

#### 35.2.48 Salt 0.13.2 Release Notes

release 2013-03-13

#### 35.2.49 Salt 0.13.3 Release Notes

release 2013-03-18

## 35.2.50 Salt 0.14.0 Release Notes

release 2013-03-23

Salt 0.14.0 is here! This release was held up primarily by PyCon, Scale, and illness, but has arrived! 0.14.0 comes with many new features and is breaking ground for Salt in the area of cloud management with the introduction of Salt providing basic cloud controller functionality.

### Major Features

#### Salt - As a Cloud Controller

This is the first primitive inroad to using Salt as a cloud controller is available in 0.14.0. Be advised that this is alpha, only tested in a few very small environments.

The cloud controller is built using kvm and libvirt for the hypervisors. Hypervisors are autodetected as minions and only need to have libvirt running and kvm installed to function. The features of the Salt cloud controller are as follows:

- Basic vm discovery and reporting
- Creation of new virtual machines
- Seeding virtual machines with Salt via qemu-nbd or libguestfs
- Live migration (shared and non shared storage)
- Delete existing VMs

It is noteworthy that this feature is still Alpha, meaning that all rights are reserved to change the interface if needs be in future releases!

#### Libvirt State

One of the problems with libvirt is management of certificates needed for live migration and cross communication between hypervisors. The new `libvirt` state makes the Salt Master hold a CA and manage the signing and distribution of keys onto hypervisors, just add a call to the libvirt state in the sls formulas used to set up a hypervisor:

```
libvirt_keys:
  libvirt.keys
```

#### New get Functions

An easier way to manage data has been introduced. The pillar, grains, and config execution modules have been extended with the new `get` function. This function works much in the same way as the `get` method in a python dict, but with an enhancement, nested dict components can be extracted using a `:` delimiter.

If a structure like this is in pillar:

```
foo:
  bar:
    baz: quo
```

Extracting it from the raw pillar in an sls formula or file template is done this way:

```
{{ pillar['foo']['bar']['baz'] }}
```

Now with the new get function the data can be safely gathered and a default can be set allowing the template to fall back if the value is not available:

```
{{ salt['pillar.get']('foo:bar:baz', 'qux') }}
```

This makes handling nested structures much easier, and defaults can be cleanly set. This new function is being used extensively in the new formulae repository of salt sls formulas.

### 35.2.51 Salt 0.14.1 Release Notes

release 2013-04-13

### 35.2.52 Salt 0.15.0 Release Notes

release 2013-05-03

The many new features of Salt 0.15.0 have arrived! Salt 0.15.0 comes with many smaller features and a few larger ones.

These features range from better debugging tools to the new Salt Mine system.

#### Major Features

##### The Salt Mine

First there was the peer system, allowing for commands to be executed from a minion to other minions to gather data live. Then there was the external job cache for storing and accessing long term data. Now the middle ground is being filled in with the Salt Mine. The Salt Mine is a system used to execute functions on a regular basis on minions and then store only the most recent data from the functions on the master, then the data is looked up via targets.

The mine caches data that is public to all minions, so when a minion posts data to the mine all other minions can see it.

##### IPV6 Support

0.13.0 saw the addition of initial IPV6 support but errors were encountered and it needed to be stripped out. This time the code covers more cases and must be explicitly enabled. But the support is much more extensive than before.

##### Copy Files From Minions to the Master

Minions have long been able to copy files down from the master file server, but until now files could not be easily copied from the minion up to the master.

A new function called `cp.push` can push files from the minions up to the master server. The uploaded files are then cached on the master in the master cachedir for each minion.

### Better Template Debugging

Template errors have long been a burden when writing states and pillar. 0.15.0 will now send the compiled template data to the debug log, this makes tracking down the intermittent stage templates much easier. So running `state.sls` or `state.highstate` with `-l debug` will now print out the rendered templates in the debug information.

### State Event Firing

The state system is now more closely tied to the master's event bus. Now when a state fails the failure will be fired on the master event bus so that the reactor can respond to it.

### Major Syndic Updates

The Syndic system has been basically re-written. Now it runs in a completely asynchronous way and functions primarily as an event broker. This means that the events fired on the syndic are now pushed up to the higher level master instead of the old method used which waited for the client libraries to return.

This makes the syndic much more accurate and powerful, it also means that all events fired on the syndic master make it up the pipe as well making a reactor on the higher level master able to react to minions further downstream.

### Peer System Updates

The Peer System has been updated to run using the client libraries instead of firing directly over the publish bus. This makes the peer system much more consistent and reliable.

### Minion Key Revocation

In the past when a minion was decommissioned the key needed to be manually deleted on the master, but now a function on the minion can be used to revoke the calling minion's key:

```
$ salt-call saltutil.revoke_auth
```

### Function Return Codes

Functions can now be assigned numeric return codes to determine if the function executed successfully. While not all functions have been given return codes, many have and it is an ongoing effort to fill out all functions that might return a non-zero return code.

### Functions in Overstate

The overstate system was originally created to just manage the execution of states, but with the addition of return codes to functions, requisite logic can now be used with respect to the overstate. This means that an overstate stage can now run single functions instead of just state executions.

### Pillar Error Reporting

Previously if errors surfaced in pillar, then the pillar would consist of only an empty dict. Now all data that was successfully rendered stays in pillar and the render error is also made available. If errors are found in the pillar, states will refuse to run.

### Using Cached State Data

Sometimes states are executed purely to maintain a specific state rather than to update states with new configs. This is grounds for the new cached state system. By adding `cache=True` to a state call the state will not be generated fresh from the master but the last state data to be generated will be used. If no previous state data is available then fresh data will be generated.

### Monitoring States

The new monitoring states system has been started. This is very young but allows for states to be used to configure monitoring routines. So far only one monitoring state is available, the `disk.status` state. As more capabilities are added to Salt UI the monitoring capabilities of Salt will continue to be expanded.

## 35.2.53 Salt 0.15.1 Release Notes

**release** 2013-05-08

The 0.15.1 release has been posted, this release includes fixes to a number of bugs in 0.15.1 and a three security patches.

### Security Updates

A number of security issues have been resolved via the 0.15.1 release.

#### Path Injection in Minion IDs

Salt masters did not properly validate the id of a connecting minion. This can lead to an attacker uploading files to the master in arbitrary locations. In particular this can be used to bypass the manual validation of new unknown minions. Exploiting this vulnerability does not require authentication.

This issue affects all known versions of Salt.

This issue was reported by Ronald Volgers.

**Patch** The issue is fixed in Salt 0.15.1. Updated packages are available in the usual locations.

Specific commits:

<https://github.com/saltstack/salt/commit/5427b9438e452a5a8910d9128c6aafb45d8fd5d3>

<https://github.com/saltstack/salt/commit/7560908ee62351769c3cd43b03d74c1ca772cc52>

<https://github.com/saltstack/salt/commit/e200b8a7ff53780124e08d2bdefde7587e52bfca>

### RSA Key Generation Fault

RSA key generation was done incorrectly, leading to very insecure keys. It is recommended to regenerate all RSA keys.

This issue can be used to impersonate Salt masters or minions, or decrypt any transferred data.

This issue can only be exploited by attackers who are able to observe or modify traffic between Salt minions and the legitimate Salt master.

A tool was included in 0.15.1 to assist in mass key regeneration, the `manage.regen_keys` runner.

This issue affects all known versions of Salt.

This issue was reported by Ronald Volgers.

**Patch** The issue is fixed in Salt 0.15.1. Updated packages are available in the usual locations.

Specific commits:

<https://github.com/saltstack/salt/commit/5dd304276ba5745ec21fc1e6686a0b28da29e6fc>

### Command Injection Via `ext_pillar`

Arbitrary shell commands could be executed on the master by an authenticated minion through options passed when requesting a pillar.

Ext pillar options have been restricted to only allow safe external pillars to be called when prompted by the minion.

This issue affects Salt versions from 0.14.0 to 0.15.0.

This issue was reported by Ronald Volgers.

**Patch** The issue is fixed in Salt 0.15.1. Updated packages are available in the usual locations.

Specific commits:

<https://github.com/saltstack/salt/commit/43d8c16bd26159d827d1a945c83ac28159ec5865>

## 35.2.54 Salt 0.15.2 Release Notes

release 2013-05-29

## 35.2.55 Salt 0.15.3 Release Notes

release 2013-06-01

## 35.2.56 Salt 0.16.0 Release Notes

release 2013-07-01

The 0.16.0 release is an exciting one, with new features in master redundancy, and a new, powerful requisite.

## Major Features

### Multi-Master

This new capability allows for a minion to be actively connected to multiple salt masters at the same time. This allows for multiple masters to send out commands to minions and for minions to automatically reconnect to masters that have gone down. A tutorial is available to help get started here:

[Multi Master Tutorial](#)

### Prereq, the New Requisite

The new *prereq* requisite is very powerful! It allows for states to execute based on a state that is expected to make changes in the future. This allows for a change on the system to be preempted by another execution. A good example is needing to shut down a service before modifying files associated with it, allowing, for instance, a webserver to be shut down allowing a load balancer to stop sending requests while server side code is updated. In this case, the *prereq* will only run if changes are expected to happen in the prerequired state, and the prerequired state will always run after the *prereq* state and only if the *prereq* state succeeds.

### Peer System Improvements

The peer system has been revamped to make it more reliable, faster, and like the rest of Salt, async. The peer calls when an updated minion and master are used together will be much faster!

### Relative Includes

The ability to include an sls relative to the defined sls has been added, the new syntax id documented here:

[Includes](#)

### More State Output Options

The `state_output` option in the past only supported *full* and *terse*, 0.16.0 add the *mixed* and *changes* modes further refining how states are sent to users' eyes.

### Improved Windows Support

Support for Salt on Windows continues to improve. Software management on Windows has become more seamless with Linux/UNIX/BSD software management. Installed software is now recognized by the short names defined in the [repository SLS](#). This makes it possible to run `salt '*' pkg.version firefox` and get back results from Windows and non-Windows minions alike.

When templating files on Windows, Salt will now correctly use Windows appropriate line endings. This makes it much easier to edit and consume files on Windows.

When using the `cmd` state the `shell` option now allows for specifying Windows Powershell as an alternate shell to execute `cmd.run` and `cmd.script`. This opens up Salt to all the power of Windows Powershell and its advanced Windows management capabilities.

Several fixes and optimizations were added for the Windows networking modules, especially when working with IPv6.

A system module was added that makes it easy to restart and shutdown Windows minions.

The Salt Minion will now look for its config file in `c:\salt\conf` by default. This means that it's no longer necessary to specify the `-c` option to specify the location of the config file when starting the Salt Minion on Windows in a terminal.

#### Multiple Targets for `pkg.removed`, `pkg.purged` States

Both `pkg.removed` and `pkg.purged` now support the `pkgs` argument, which allow for multiple packages to be targeted in a single state. This, as in `pkg.installed`, helps speed up these states by reducing the number of times that the package management tools (`apt`, `yum`, etc.) need to be run.

#### Random Times in Cron States

The temporal parameters in `cron.present` states (`minute`, `hour`, etc.) can now be randomized by using `random` instead of a specific value. For example, by using the `random` keyword in the `minute` parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.

```
/path/to/cron/script:
cron.present:
  - user: root
  - minute: random
  - hour: 2
```

Since Salt assumes a value of `*` for unspecified temporal parameters, adding a parameter to the state and setting it to `random` will change that value from `*` to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the `random` keyword will not modify it.

#### Confirmation Prompt on Key Acceptance

When accepting new keys with `salt-key -a minion-id` or `salt-key -A`, there is now a prompt that will show the affected keys and ask for confirmation before proceeding. This prompt can be bypassed using the `-y` or `--yes` command line argument, as with other `salt-key` commands.

#### Support for Setting Password Hashes on BSD Minions

FreeBSD, NetBSD, and OpenBSD all now support setting passwords in `user.present` states.

### 35.2.57 Salt 0.16.1 Release Notes

release 2013-07-29

### 35.2.58 Salt 0.16.2 Release Notes

release 2013-08-01

Version 0.16.2 is a bugfix release for 0.16.0, and contains a number of fixes.

## Windows

- Only allow Administrator's group and SYSTEM user access to C:\salt. This eliminates a race condition where a non-admin user could modify a template or managed file before it is executed by the minion (which is running as an elevated user), thus avoiding a potential escalation of privileges. ([issue 6361](#))

## Grains

- Fixed detection of `virtual` grain on OpenVZ hardware nodes
- Gracefully handle `lsb_release` data when it is enclosed in quotes
- LSB grains are now prefixed with `lsb_distrib_` instead of simply `lsb_`. The old naming is not preserved, so SLS may be affected.
- Improved grains detection on MacOS

## Pillar

- Don't try to load `git_pillar` if not enabled in master config ([issue 6052](#))
- Functions `pillar.item` and `pillar.items` added for parity with `grains.item/grains.items`. The old function `pillar.data` is preserved for backwards compatibility.
- Fixed minion traceback when Pillar SLS is malformed ([issue 5910](#))

## Peer Publishing

- More gracefully handle improperly quoted publish commands ([issue 5958](#))
- Fixed traceback when timeout specified via the CLI fo `publish.publish`, `publish.full_data` ([issue 5959](#))
- Fixed unintended change in output of `publish.publish` ([issue 5928](#))

## Minion

- Fixed salt-key usage in minionswarm script
- Quieted warning about `SALT_MINION_CONFIG` environment variable on minion startup and for CLI commands run via `salt-call` ([issue 5956](#))
- Added minion config parameter `random_reauth_delay` to stagger re-auth attempts when the minion is waiting for the master to approve its public key. This helps prevent SYN flooding in larger environments.

## User/Group Management

- Implement previously-ignored `unique` option for `user.present` states in FreeBSD
- Report in state output when a `group.present` state attempts to use a gid in use by another group
- Fixed regression that prevents a `user.present` state to set the password hash to the system default (i.e. an unset password)
- Fixed multiple `group.present` states with the same group ([issue 6439](#))

## File Management

- Fixed file.mkdir setting incorrect permissions (issue 6033)
- Fixed cleanup of source files for templates when /tmp is in file\_roots (issue 6118)
- Fixed caching of zero-byte files when a non-empty file was previously cached at the same path
- Added HTTP authentication support to the cp module (issue 5641)
- Diffs are now suppressed when binary files are changed

## Package/Repository Management

- Fixed traceback when there is only one target for *pkg.latest* states
- Fixed regression in detection of virtual packages (apt)
- Limit number of pkg database refreshes to once per *state.sls/state.highstate*
- YUM: Allow 32-bit packages with arches other than i686 to be managed on 64-bit systems (issue 6299)
- Fixed incorrect reporting in pkgrepo.managed states (issue 5517)
- Fixed 32-bit binary package installs on 64-bit RHEL-based distros, and added proper support for 32-bit packages on 64-bit Debian-based distros (issue 6303)
- Fixed issue where requisites were inadvertently being put into YUM repo files (issue 6471)

## Service Management

- Fixed inaccurate reporting of results in *service.running* states when the service fails to start (issue 5894)
- Fixed handling of custom initscripts in RHEL-based distros so that they are immediately available, negating the need for a second state run to manage the service that the initscript controls

## Networking

- Function network.hwaddr renamed to *network.hw\_addr* to match *network.ip\_addrs* and *network.ip\_addrs6*. All three functions also now work without the underscore in the name, as well.
- Fixed traceback in *bridge.show* when interface is not present (issue 6326)

## SSH

- Fixed incorrect result reporting for some *ssh\_known\_hosts.present* states
- Fixed inaccurate reporting when *ssh\_auth.present* states are run with `test=True`, when `rsa/dss` is used for the `enc` param instead of `ssh-rsa/ssh-dss` (issue 5374)

## pip

- Properly handle `-f` lines in pip freeze output
- Fixed regression in pip.installed states with specifying a requirements file (issue 6003)
- Fixed use of `editable` argument in pip.installed states (issue 6025)

- Deprecated `runas` parameter in execution function calls, in favor of `user`

## MySQL

- Allow specification of MySQL connection arguments via the CLI, overriding/bypassing minion config params
- Allow `mysql_user.present` states to set a passwordless login (issue 5550)
- Fixed endless loop when `mysql.processlist` is run (issue 6297)

## PostgreSQL

- Fixed traceback in `postgres.user_list` (issue 6352)

## Miscellaneous

- Don't allow `npm` states to be used if `npm` module is not available
- Fixed `alternatives.install` states for which the target is a symlink (issue 6162)
- Fixed traceback in `sysbench` module (issue 6175)
- Fixed traceback in job cache
- Fixed tempfile cleanup for windows
- Fixed issue where SLS files using the `pydsl` renderer were not being run
- Fixed issue where returners were being passed incorrect information (issue 5518)
- Fixed traceback when numeric args are passed to `cmd.script` states
- Fixed bug causing `cp.get_dir` to return more directories than expected (issue 6048)
- Fixed traceback when `supervisord.running` states are run with `test=True` (issue 6053)
- Fixed tracebacks when Salt encounters problems running `rbenv` (issue 5888)
- Only make the `monit` module available if `monit` binary is present (issue 5871)
- Fixed incorrect behavior of `img.mount_image`
- Fixed traceback in `tomcat.deploy_war` in Windows
- Don't re-write `/etc/fstab` if mount fails
- Fixed tracebacks when Salt encounters problems running `gem` (issue 5886)
- Fixed incorrect behavior of `selinux.boolean` states (issue 5912)
- RabbitMQ: Quote passwords to avoid symbols being interpolated by the shell (issue 6338)
- Fixed tracebacks in `extfs.mkfs` and `extfs.tune` (issue 6462)
- Fixed a regression with the `module.run` state where the `m_name` and `m_fun` arguments were being ignored (issue 6464)

### 35.2.59 Salt 0.16.3 Release Notes

release 2013-08-09

Version 0.16.3 is another bugfix release for 0.16.0. The changes include:

- Various documentation fixes
- Fix proc directory regression (issue 6502)
- Properly detect Linaro Linux (issue 6496)
- Fix regressions in `mount.mounted` (issue 6522, issue 6545)
- Skip malformed state requisites (issue 6521)
- Fix regression in gitfs from bad import
- Fix for watching prereq states (including recursive requisite error) (issue 6057)
- Fix `mod_watch` not overriding prereq (issue 6520)
- Don't allow functions which compile states to be called within states (issue 5623)
- Return error for malformed top.sls (issue 6544)
- Fix traceback in `mysql.query`
- Fix regression in binary package installation for 64-bit packages on Debian-based Linux distros (issue 6563)
- Fix traceback caused by running `cp.push` without having set `file_recv` in the master config file
- Fix scheduler configuration in pillar (issue 6201)

### 35.2.60 Salt 0.16.4 Release Notes

release 2013-09-07

Version 0.16.4 is another bugfix release for 0.16.0, likely to be the last before 0.17.0 is released. The changes include:

- Multiple documentation improvements/additions
- Added the `osfinger` and `osarch` grains
- Properly handle 32-bit packages for `debian32` on `x86_64` (issue 6607)
- Fix regression in yum package installation in CentOS 5 (issue 6677)
- Fix bug in `hg.latest` state that would erroneously delete directories (issue 6661)
- Fix bug related to pid not existing for `ps.top` (issue 6679)
- Fix regression in `MySQL_returner` (issue 6695)
- Fix IP addresses grains (`ip4` and `ip6`) to include all addresses (issue 6656)
- Fix regression preventing authenticated FTP (issue 6733)
- Fix setting password for windows users (issue 6824)
- Fix `file.contains` on values YAML parses as non-string (issue 6817)
- Fix `file.get_gid`, `file.get_uid`, and `file.chown` for broken symlinks (issue 6826)
- Fix comment for service reloads in service state (issue 6851)

### 35.2.61 Salt 0.17.0 Release Notes

**release** 2013-09-26

The 0.17.0 release is a very exciting release of Salt, this brings to Salt some very powerful new features and advances. The advances range from the state system to the test suite, covering new transport capabilities and making states easier and more powerful, to extending Salt Virt and much more!

The 0.17.0 release will also be the last release of Salt to follow the old 0.XX.X numbering system, the next release of Salt will change the numbering to be date based following this format:

<Year>.<Month>.<Minor>

So if the release happens in November of 2013 the number will be 13.11.0, the first bugfix release will be 13.11.1 and so forth.

#### Major Features

##### Halite

The new Halite web GUI is now available on PyPI. A great deal of work has been put into Halite to make it fully event driven and amazingly fast. The Halite UI can be started from within the Salt Master (after being installed from PyPI), or standalone, and does not require an external database to run. It is very lightweight!

This initial release of Halite is primarily the framework for the UI and the communication systems, making it easy to extend and build the UI up. It presently supports watching the event bus and firing commands over Salt.

At this time, Halite is not available as a package, but installation documentation is available at: <http://docs.saltstack.com/topics/tutorials/halite.html>

Halite is, like the rest of Salt, Open Source!

Much more will be coming in the future of Halite!

##### Salt SSH

The new `salt-ssh` command has been added to Salt. This system allows for remote execution and states to be run over ssh. The benefit here being, that salt can run relying only on the ssh agent, rather than requiring a minion to be deployed.

The `salt-ssh` system runs states in a compatible way as Salt and states created and run with salt-ssh can be moved over to a standard salt deployment without modification.

Since this is the initial release of salt-ssh, there is plenty of room for improvement, but it is fully operational, not just a bootstrap tool.

##### Rosters

Salt is designed to have the minions be aware of the master and the master does not need to be aware of the location of the minions. The new salt roster system was created and designed to facilitate listing the targets for salt-ssh.

The roster system, like most of Salt, is a plugin system, allowing for the list of systems to target to be derived from any pluggable backend. The rosters shipping with 0.17.0 are flat and scan. Flat is a file which is read in via the salt render system and the scan roster does simple network scanning to discover ssh servers.

### State Auto Order

This is a major change in how states are evaluated in Salt. State Auto Order is a new feature that makes states get evaluated and executed in the order in which they are defined in the sls file. This feature makes it very easy to see the finite order in which things will be executed, making Salt now, fully imperative AND fully declarative.

The requisite system still takes precedence over the order in which states are defined, so no existing states should break with this change. But this new feature can be turned off by setting `state_auto_order: False` in the master config, thus reverting to the old lexicographical order.

### state.sls Runner

The `state.sls` runner has been created to allow for a more powerful system for orchestrating state runs and function calls across the salt minions. This new system uses the state system for organizing executions.

This allows for states to be defined that are executed on the master to call states on minions via `salt-run state.sls`.

### Salt Thin

Salt Thin is an exciting new component of Salt, this is the ability to execute Salt routines without any transport mechanisms installed, it is a pure python subset of Salt.

Salt Thin does not have any networking capability, but can be dropped into any system with Python installed and then `salt-call` can be called directly. The Salt Thin system, is used by the `salt-ssh` command, but can still be used to just drop salt somewhere for easy use.

### Event Namespacing

Events have been updated to be much more flexible. The tags in events have all been namespaced allowing easier tracking of event names.

### Mercurial Fileserver Backend

The popular git fileserver backend has been joined by the mercurial fileserver backend, allowing the state tree to be managed entirely via mercurial.

### External Logging Handlers

The external logging handler system allows for Salt to directly hook into any external logging system. Currently supported are sentry and logstash.

### Jenkins Testing

The testing systems in Salt have been greatly enhanced, tests for salt are now executed, via `jenkins.saltstack.com`, across many supported platforms. Jenkins calls out to salt-cloud to create virtual machines on Rackspace, then the minion on the virtual machine checks into the master running on Jenkins where a state run is executed that sets up the minion to run tests and executes the test suite.

This now automates the sequence of running platform tests and allows for continuous destructive tests to be run.

### Salt Testing Project

The testing libraries for salt have been moved out of the main salt code base and into a standalone codebase. This has been done to ease the use of the testing systems being used in salt based projects other than Salt itself.

### StormPath External Authentication

The external auth system now supports the fantastic Stormpath cloud based authentication system.

### LXC Support

Extensive additions have been added to Salt for LXC support. This included the backend libs for managing LXC containers. Addition into the salt-virt system is still in the works.

### Mac OS X User/Group Support

Salt is now able to manage users and groups on Minions running Mac OS X. However, at this time user passwords cannot be managed.

### Django ORM External Pillar

Pillar data can now be derived from Django managed databases.

### Fixes from RC to release

- Multiple documentation fixes
- Add multiple source files + templating for *file.append* (issue 6905)
- Support sysctl configuration files in systemd $\geq$ 207 (issue 7351)
- Add *file.search* and *file.replace*
- Fix cross-calling execution functions in provider overrides
- Fix locale override for postgres (issue 4543)
- Fix Raspbian identification for service/pkg support (issue 7371)
- Fix *cp.push* file corruption (issue 6495)
- Fix ALT Linux password hash specification (issue 3474)
- Multiple salt-ssh-related fixes and improvements

## 35.2.62 Salt 0.17.1 Release Notes

release 2013-10-17

---

**Note:** THIS RELEASE IS NOT COMPATIBLE WITH PREVIOUS VERSIONS. If you update your master to 0.17.1, you must update your minions as well. Sorry for the inconvenience -- this is a result of one of the security fixes listed below.

---

The 0.17.1 release comes with a number of improvements to salt-ssh, many bugfixes, and a number of security updates.

Salt SSH has been improved to be faster, more featureful and more secure. Since the original release of Salt SSH was primarily a proof of concept, it has been very exciting to see its rapid adoption. We appreciate the willingness of security experts to review Salt SSH and help discover oversights and ensure that security issues only exist for such a tiny window of time.

### SSH Enhancements

#### Shell Improvements

Improvements to Salt SSH's communication have been added that improve routine execution regardless of the target system's login shell.

#### Performance

Deployment of routines is now faster and takes fewer commands to execute.

### Security Updates

Be advised that these security issues all apply to a small subset of Salt users and mostly apply to Salt SSH.

#### Insufficient Argument Validation

This issue allowed for a user with limited privileges to embed executions inside of routines to execute routines that should be restricted. This applies to users using external auth or client ACL and opening up specific routines.

Be advised that these patches address the direct issue. Additional commits have been applied to help mitigate this issue from resurfacing.

CVE CVE-2013-4435

#### Affected Versions

0.15.0 - 0.17.0

**Patches** <https://github.com/saltstack/salt/commit/6d8ef68b605fd63c36bb8ed96122a75ad2e80269>

**Found By** Feth Arezki, of Majerti

### MITM SSH attack in salt-ssh

SSH host keys were being accepted by default and not enforced on future SSH connections. These patches set SSH host key checking by default and can be overridden by passing the `-i` flag to `salt-ssh`.

CVE CVE-2013-4436

**Affected Versions** 0.17.0

**Found By** Michael Scherer, Red Hat

### Insecure Usage of /tmp in salt-ssh

The initial release of salt-ssh used the `/tmp` directory in an insecure way. These patches not only secure usage of files under `/tmp` in salt-ssh, but also add checksum validation for all packages sent into the now secure locations on target systems.

CVE CVE-2013-4438

**Affected Versions** 0.17.0

**Patches** <https://github.com/saltstack/salt/commit/aa4bb77ef230758cad84381dde0ec660d2dc340a>

**Found By** Michael Scherer, Red Hat

### YAML Calling Unsafe Loading Routine

It has been argued that this is not a valid security issue, as the YAML loading that was happening was only being called after an initial gateway filter in Salt has already safely loaded the YAML and would fail if non-safe routines were embedded. Nonetheless, the CVE was filed and patches applied.

CVE CVE-2013-4438

### Patches

<https://github.com/saltstack/salt/commit/339b0a51befae6b6b218ebcb55daa9cd3329a1c5>

**Found By** Michael Scherer, Red Hat

### Failure to Drop Supplementary Group on Salt Master

If a salt master was started as a non-root user by the root user, root's groups would still be applied to the running process. This fix changes the process to have only the groups of the running user.

CVE CVE not considered necessary by submitter.

**Affected Versions** 0.11.0 - 0.17.0

**Patches** <https://github.com/saltstack/salt/commit/b89fa9135822d029795ab1eecd68cce2d1ced715>

**Found By** Michael Scherer, Red Hat

### Failure to Validate Minions Posting Data

This issue allowed a minion to pose as another authorized minion when posting data such as the mine data. All minions now pass through the id challenge before posting such data.

CVE CVE-2013-4439

**Affected Versions** 0.15.0 - 0.17.0

### Patches

<https://github.com/saltstack/salt/commit/7b850ff3d07ef6782888914ac4556c01e8a1c482>  
<https://github.com/saltstack/salt/commit/151759b2a1e1c6ce29277aa81b054219147f80fd>

**Found By** David Anderson

### Fix Reference

Version 0.17.1 is the first bugfix release for 0.17.0. The changes include:

- Fix symbolic links in thin.tgz (issue 7482)
- Pass env through to file.patch state (issue 7452)
- Service provider fixes and reporting improvements (issue 7361)
- Add `--priv` option for specifying salt-ssh private key
- Fix salt-thin's salt-call on setup tools installations (issue 7516)
- Fix salt-ssh to support passwords with spaces (issue 7480)
- Fix regression in wildcard includes (issue 7455)
- Fix salt-call outputter regression (issue 7456)
- Fix custom returner support for startup states (issue 7540)
- Fix value handling in augeas (issue 7605)

- Fix regression in apt (issue 7624)
- Fix minion ID guessing to use `socket.getfqdn()` first (issue 7558)
- Add minion ID caching (issue 7558)
- Fix salt-key race condition (issue 7304)
- Add `--include-all` flag to salt-key (issue 7399)
- Fix custom grains in pillar (part of issue 5716, issue 6083)
- Fix race condition in salt-key (issue 7304)
- Fix regression in minion ID guessing, prioritize `socket.getfqdn()` (issue 7558)
- Cache minion ID on first guess (issue 7558)
- Allow trailing slash in `file.directory` state
- Fix reporting of `file_roots` in pillar return (issue 5449 and issue 5951)
- Remove pillar matching for `mine.get` (issue 7197)
- Sanitize args for multiple execution modules
- Fix `yumpkg mod_repo` functions to filter hidden args (issue 7656)
- Fix conflicting IDs in state includes (issue 7526)
- Fix `mysql_grants.absent` string formatting issue (issue 7827)
- Fix `postgres.version` so it won't return None (issue 7695)
- Fix for trailing slashes in `mount.mounted` state
- Fix rogue `AttributErrors` in the outputter system (issue 7845)
- Fix for incorrect ssh key encodings resulting in incorrect key added (issue 7718)
- Fix for pillar/grains naming regression in python renderer (issue 7693)
- Fix args/kwargs handling in the scheduler (issue 7422)
- Fix logfile handling for `file://`, `tcp://`, and `udp://` (issue 7754)
- Fix error handling in config file parsing (issue 6714)
- Fix RVM using sudo when running as non-root user (issue 2193)
- Fix client ACL and underlying logging bugs (issue 7706)
- Fix scheduler bug with returner (issue 7367)
- Fix user management bug related to default groups (issue 7690)
- Fix various salt-ssh bugs (issue 7528)
- Many various documentation fixes

### 35.2.63 Salt 0.17.2 Release Notes

release 2013-11-14

Version 0.17.2 is another bugfix release for 0.17.0. The changes include:

- Add ability to delete key with `grains.delval` (issue 7872)
- Fix possible state compiler stack trace (issue 5767)

- Fix architecture regression in yumpkg (issue 7813)
- Use correct ps on Debian to prevent truncating (issue 5646)
- Fix grains targeting for new grains (issue 5737)
- Fix bug with merging in git\_pillar (issue 6992)
- Fix print\_jobs duplicate results
- Fix apt version specification for pkg.install
- Fix possible KeyError from ext\_job\_cache missing option
- Fix auto\_order for - names states (issue 7649)
- Fix regression in new gitfs installs (directory not found error)
- Fix escape pipe issue on Windows for file.recurse (issue 7967)
- Fix fileclient in case of master restart (issue 7987)
- Try to output warning if CLI command malformed (issue 6538)
- Fix --out=quiet to actually be quiet (issue 8000)
- Fix for state.sls in salt-ssh (issue 7991)
- Fix for MySQL grants ordering issue (issue 5817)
- Fix traceback for certain missing CLI args (issue 8016)
- Add ability to disable lspci queries on master (issue 4906)
- Fail if sls defined in topfile does not exist (issue 5998)
- Add ability to downgrade MySQL grants (issue 6606)
- Fix ssh\_auth.absent traceback (issue 8043)
- Add upstart detection for Debian/Raspbian (issue 8039)
- Fix ID-related issues (issue 8052, issue 8050, and others)
- Fix for jinja rendering issues (issue 8066 and issue 8079)
- Fix argument parsing in salt-ssh (issue 7928)
- Fix some GPU detection instances (issue 6945)
- Fix bug preventing includes from other environments in SLS files
- Fix for kwargs with dashes (issue 8102)
- Fix salt.utils.which for windows '.exe' (issue 7904)
- Fix apache.adduser without apachectl (issue 8123)
- Fix issue with evaluating test kwarg in states (issue 7788)
- Fix regression in salt.client.Caller() (issue 8078)
- Fix apt-key silent failure
- Fix bug where cmd.script would try to run even if caching failed (issue 7601)
- Fix apt pkg.latest regression (issue 8067)
- Fix for mine data not being updated (issue 8144)
- Fix for noarch packages in yum

- Fix a Xen detection edge case ([issue 7839](#))
- Fix windows `__opts__` dictionary persistence ([issue 7714](#))
- Fix version generation for when it's part of another git repo ([issue 8090](#))
- Fix `_handle_iorder` stacktrace so that the real syntax error is shown ([issue 8114](#) and [issue 7905](#))
- Fix `git.latest` state when a commit SHA is used ([issue 8163](#))
- Fix various small bugs in `yumpkg.py` ([issue 8201](#))
- Fix for specifying identify file in `git.latest` ([issue 8094](#))
- Fix for `--output-file` CLI arg ([issue 8205](#))
- Add ability to specify shutdown time for `system.shutdown` ([issue 7833](#))
- Fix for salt version using non-salt git repo info ([issue 8266](#))
- Add additional hints at impact of `pkgrepo` states when `test=True` ([issue 8247](#))
- Fix for salt-ssh files not being owned by root ([issue 8216](#))
- Fix retry logic and error handling in `filesrv` (related to [issue 7755](#))
- Fix `file.replace` with `test=True` ([issue 8279](#))
- Add flag for limiting file traversal in `filesrv` ([issue 6928](#))
- Fix for extra mine processes ([issue 5729](#))
- Fix for unloading custom modules ([issue 7691](#))
- Fix for salt-ssh `opts` ([issue 8005](#) and [issue 8271](#))
- Fix compound matcher for `grains` ([issue 7944](#))
- Improve error reporting in `ebuild` module (related to [issue 5393](#))
- Add `dir_mode` to `file.managed` ([issue 7860](#))
- Improve traceroute support for FreeBSD and OS X ([issue 4927](#))
- Fix for matching minions under `syndics` ([issue 7671](#))
- Improve exception handling for missing ID ([issue 8259](#))
- Fix grain mismatch for `ScientificLinux` ([issue 8338](#))
- Add configuration option for `minion_id_caching`
- Fix open mode auth errors ([issue 8402](#))

### 35.2.64 Salt 0.17.3 Release Notes

release 2013-12-08

---

**Note:** 0.17.3 had some regressions which were promptly fixed in the 0.17.4 release. Please use 0.17.4 instead.

---

Version 0.17.3 is another bugfix release for 0.17.0. The changes include:

- Fix some jinja render errors ([issue 8418](#))
- Fix `file.replace` state changing file ownership ([issue 8399](#))
- Fix state ordering with the PyDSL renderer ([issue 8446](#))

- Fix for new npm version ([issue 8517](#))
- Fix for pip state requiring name even with requirements file ([issue 8519](#))
- Fix yum logging to open terminals ([issue 3855](#))
- Add sane maxrunning defaults for scheduler ([issue 8563](#))
- Fix states duplicate key detection ([issue 8053](#))
- Fix SUSE patch level reporting ([issue 8428](#))
- Fix managed file creation umask ([issue 8590](#))
- Fix logstash exception ([issue 8635](#))
- Improve argument exception handling for salt command ([issue 8016](#))
- Fix pecl success reporting ([issue 8750](#))
- Fix launchctl module exceptions ([issue 8759](#))
- Fix argument order in pw\_user module
- Add warnings for failing grains ([issue 8690](#))
- Fix hgfs problems caused by connections left open ([issue 8811](#) and [issue 8810](#))
- Add Debian iptables default for iptables-persistent package ([issue 8889](#))
- Fix installation of packages with dots in pkg name ([issue 8614](#))
- Fix noarch package installation on CentOS 6 ([issue 8945](#))
- Fix portage\_config.enforce\_nice\_config ([issue 8252](#))
- Fix salt.util.copyfile umask usage ([issue 8590](#))
- Fix rescheduling of failed jobs ([issue 8941](#))
- Fix pkg on Amazon Linux (uses yumpkg5 now) ([issue 8226](#))
- Fix conflicting options in postgres module ([issue 8717](#))
- Fix ps modules for psutil >= 0.3.0 ([issue 7432](#))
- Fix postgres module to return False on failure ([issue 8778](#))
- Fix argument passing for args with pound signs ([issue 8585](#))
- Fix pid of salt CLI command showing in status.pid output ([issue 8720](#))
- Fix rvm to run gem as the correct user ([issue 8951](#))
- Fix namespace issue in win\_file module ([issue 9060](#))
- Fix masterless state paths on windows ([issue 9021](#))
- Fix timeout option in master config ([issue 9040](#))

### 35.2.65 Salt 0.17.4 Release Notes

release 2013-12-10

Version 0.17.4 is another bugfix release for 0.17.0. The changes include:

- Fix file.replace bug when replacement str is numeric ([issue 9101](#))
- Fix regression in file.managed ([issue 9131](#))

- Prevent traceback when job is None. (issue 9145)

### 35.2.66 Salt 0.17.5 Release Notes

**release** 2014-01-27

Version 0.17.5 is another bugfix release for 0.17.0. The changes include:

- Fix `user.present` states with non-string fullname (issue 9085)
- Fix `virt.init` return value on failure (issue 6870)
- Fix reporting of `file.blockreplace` state when `test=True`
- Fix `network.interfaces` when used in cron (issue 7990)
- Fix bug in `pkgrepo` when switching to/from mirrorlist-based repo def (issue 9121)
- Fix infinite recursion when cache file is corrupted
- Add checking for rev and mirror/bare args in `git.latest` (issue 9107)
- Add `cmd.watch` alias (points to `cmd.wait`) (issue 8612)
- Fix stacktrace when prereq is not formed as a list (issue 8235)
- Fix stdin issue with `lvdisplay` command (issue 9128)
- Add pre-check function for range matcher (issue 9236)
- Add exception handling for `psutil` for processes that go missing (issue 9274)
- Allow `_in` requisites to match both on ID and name (issue 9061)
- Fix multiple client timeout issues (issue 7157 and issue 9302, probably others)
- Fix `ZMQError: Operation cannot be accomplished in current state errors` (issue 6306)
- Multiple optimization in minion auth routines
- Clarify logs for minion ID caching

### 35.2.67 Salt 0.6.0 release notes

The Salt remote execution manager has reached initial functionality! Salt is a management application which can be used to execute commands on remote sets of servers.

The whole idea behind Salt is to create a system where a group of servers can be remotely controlled from a single master, not only can commands be executed on remote systems, but salt can also be used to gather information about your server environment.

Unlike similar systems, like Func and MCollective, Salt is extremely simple to setup and use, the entire application is contained in a single package, and the master and minion daemons require no running dependencies in the way that Func requires Certmaster and MCollective requires activeMQ.

Salt also manages authentication and encryption. Rather than using SSL for encryption, salt manages encryption on a payload level, so the data sent across the network is encrypted with fast AES encryption, and authentication uses RSA keys. This means that Salt is fast, secure, and very efficient.

Messaging in Salt is executed with ZeroMQ, so the message passing interface is built into salt and does not require an external ZeroMQ server. This also adds speed to Salt since there is no additional bloat on the networking layer, and ZeroMQ has already proven itself as a very fast networking system.

The remote execution in Salt is "Lazy Execution", in that once the command is sent the requesting network connection is closed. This makes it easier to detach the execution from the calling process on the master, it also means that replies are cached, so that information gathered from historic commands can be queried in the future.

Salt also allows users to make execution modules in Python. Writers of these modules should also be pleased to know that they have access to the impressive information gathered from PuppetLabs' Facter application, making Salt module more flexible. In the future I hope to also allow Salt to group servers based on Facter information as well.

All in all Salt is fast, efficient, and clean, can be used from a simple command line client or through an API, uses message queue technology to make network execution extremely fast, and encryption is handled in a very fast and efficient manner. Salt is also VERY easy to use and VERY easy to extend.

You can find the source code for Salt on my GitHub page, I have also set up a few wiki pages explaining how to use and set up Salt. If you are using Arch Linux there is a package available in the Arch Linux AUR.

Salt 0.6.0 Source: <https://cloud.github.com/downloads/saltstack/salt/salt-0.6.0.tar.gz>

GitHub page: <https://github.com/saltstack/salt>

Wiki: <https://github.com/saltstack/salt/wiki>

Arch Linux Package: <https://aur.archlinux.org/packages/salt-git/>

I am very open to contributions, for instance I need packages for more Linux distributions as well as BSD packages and testers.

Give Salt a try, this is the initial release and is not a 1.0 quality release, but it has been working well for me! I am eager to get your feedback!

### 35.2.68 Salt 0.7.0 release notes

I am pleased to announce the release of Salt 0.7.0!

This release marks what is the first stable release of salt, 0.7.0 should be suitable for general use.

0.7.0 Brings the following new features to Salt:

- Integration with Facter data from puppet labs
- Allow for matching minions from the salt client via Facter information
- Minion job threading, many jobs can be executed from the master at once
- Preview of master clustering support - Still experimental
- Introduce new minion modules for stats, virtualization, service management and more
- Add extensive logging to the master and minion daemons
- Add `sys.reload_functions` for dynamic function reloading
- Greatly improve authentication
- Introduce the `saltkey` command for managing public keys
- Begin backend development preparatory to introducing butter
- Addition of man pages for the core commands
- Extended and cleaned configuration

0.7.0 Fixes the following major bugs:

- Fix crash in minions when matching failed

- Fix configuration file lookups for the local client
- Repair communication bugs in encryption
- Numerous fixes in the minion modules

The next release of Salt should see the following features:

- Stabilize the cluster support
- Introduce a remote client for salt command tiers
- salt-ftp system for distributed file copies
- Initial support for ``butter''

Coming up next is a higher level management framework for salt called Butter. I want salt to stay as a simple and effective communication framework, and allow for more complicated executions to be managed via Butter.

Right now Butter is being developed to act as a cloud controller using salt as the communication layer, but features like system monitoring and advanced configuration control (a puppet manager) are also in the pipe.

Special thanks to Joseph Hall for the status and network modules, and thanks to Matthias Teege for tracking down some configuration bugs!

Salt can be downloaded from the following locations;

Source Tarball:

<https://cloud.github.com/downloads/saltstack/salt/salt-0.7.0.tar.gz>

Arch Linux Package:

<https://aur.archlinux.org/packages/salt-git/>

Please enjoy the latest Salt release!

### 35.2.69 Salt 0.8.0 release notes

Salt 0.8.0 is ready for general consumption! The source tarball is available on GitHub for download:

<https://cloud.github.com/downloads/saltstack/salt/salt-0.8.0.tar.gz>

A lot of work has gone into salt since the last release just 2 weeks ago, and salt has improved a great deal. A swath of new features are here along with performance and threading improvements!

The main new features of salt 0.8.0 are:

Salt-cp

Cython minion modules

Dynamic returners

Faster return handling

Lowered required Python version to 2.6

Advanced minion threading

Configurable minion modules

## Salt-cp

The salt-cp command introduces the ability to copy simple files via salt to targeted servers. Using salt-cp is very simple, just call salt-cp with a target specification, the source file(s) and where to copy the files on the minions. For instance:

```
# salt-cp '*' /etc/hosts /etc/hosts
```

Will copy the local /etc/hosts file to all of the minions.

Salt-cp is very young, in the future more advanced features will be added, and the functionality will much more closely resemble the cp command.

## Cython minion modules

Cython is an amazing tool used to compile Python modules down to c. This is arguably the fastest way to run Python code, and since pyzmq requires cython, adding support to salt for cython adds no new dependencies.

Cython minion modules allow minion modules to be written in cython and therefore executed in compiled c. Simply write the salt module in cython and use the file extension “.pyx” and the minion module will be compiled when the minion is started. An example cython module is included in the main distribution called cytest.pyx:

<https://github.com/saltstack/salt/blob/develop/salt/modules/cytest.pyx>

## Dynamic Returners

By default salt returns command data back to the salt master, but now salt can return command data to any system. This is enabled via the new returners modules feature for salt. The returners modules take the return data and sends it to a specific module. The returner modules work like minion modules, so any returner can be added to the minions.

This means that a custom data returner can be added to communicate the return data so anything from MySQL, Redis, MongoDB, and more!

There are 2 simple stock returners in the returners directory:

<https://github.com/saltstack/salt/blob/develop/salt/returners>

The documentation on writing returners will be added to the wiki shortly, and returners can be written in pure Python, or in cython.

## Configurable Minion Modules

Minion modules may need to be configured, now the options passed to the minion configuration file can be accessed inside of the minion modules via the `__opt__` dict.

Information on how to use this simple addition has been added to the wiki: [Writing modules](#)

The test module has an example of using the `__opts__` dict, and how to set default options:

<https://github.com/saltstack/salt/blob/develop/salt/modules/test.py>

## Advanced Minion Threading

In 0.7.0 the minion would block after receiving a command from the master, now the minion will spawn a thread or multiprocessing. By default Python threads are used because for general use they have proved to be faster, but the minion can now be configured to use the Python multiprocessing module instead. Using multiprocessing will cause executions that are CPU bound or would otherwise exploit the negative aspects of the Python GIL to run faster and

more reliably, but simple calls will still be faster with Python threading. The configuration option can be found in the minion configuration file:

<https://github.com/saltstack/salt/blob/develop/conf/minion>

### Lowered Supported Python to 2.6

The requirement for Python 2.7 has been removed to support Python 2.6. I have received requests to take the minimum Python version back to 2.4, but unfortunately this will not be possible, since the ZeroMQ Python bindings do not support Python 2.4.

Salt 0.8.0 is a very major update, it also changes the network protocol slightly which makes communication with older salt daemons impossible, your master and minions need to be upgraded together!

I could use some help bringing salt to the people! Right now I only have packages for Arch Linux, Fedora 14 and Gentoo. We need packages for Debian and people willing to help test on more platforms. We also need help writing more minion modules and returner modules. If you want to contribute to salt please hop on the mailing list and send in patches, make a fork on GitHub and send in pull requests! If you want to help but are not sure where you can, please email me directly or post to the mailing list!

I hope you enjoy salt, while it is not yet 1.0 salt is completely viable and usable!

-Thomas S. Hatch

### 35.2.70 Salt 0.8.7 release notes

It has been a month since salt 0.8.0, and it has been a long month! But Salt is still coming along strong. 0.8.7 has a lot of changes and a lot of updates. This update makes Salt's ZeroMQ back end better, strips Factor from the dependencies, and introduces interfaces to handle more capabilities.

Many of the major updates are in the background, but the changes should shine through to the surface. A number of the new features are still a little thin, but the back end to support expansion is in place.

I also recently gave a presentation to the Utah Python users group in Salt Lake City, the slides from this presentation are available here: <https://cloud.github.com/downloads/saltstack/salt/Salt.pdf>

The video from this presentation will be available shortly.

The major new features and changes in Salt 0.8.7 are:

- Revamp ZeroMQ topology on the master for better scalability
- State enforcement
- Dynamic state enforcement managers
- Extract the module loader into salt.loader
- Make Job ids more granular
- Replace Factor functionality with the new salt grains interface
- Support for “virtual” salt modules
- Introduce the salt-call command
- Better debugging for minion modules

The new ZeroMQ topology allows for better scalability, this will be required by the need to execute massive file transfers to multiple machines in parallel and state management. The new ZeroMQ topology is available in the aforementioned presentation.

0.8.7 introduces the capability to declare states, this is similar to the capabilities of Puppet. States in salt are declared via state data structures. This system is very young, but the core feature set is available. Salt states work around rendering files which represent Salt high data. More on the Salt state system will be documented in the near future.

The system for loading salt modules has been pulled out of the minion class to be a standalone module, this has enabled more dynamic loading of Salt modules and enables many of the updates in 0.8.7 –

<https://github.com/saltstack/salt/blob/develop/salt/loader.py>

Salt Job ids are now microsecond precise, this was needed to repair a race condition unveiled by the speed improvements in the new ZeroMQ topology.

The new grains interface replaces the functionality of Facter, the idea behind grains differs from Facter in that the grains are only used for static system data, dynamic data needs to be derived from a call to a salt module. This makes grains much faster to use, since the grains data is generated when the minion starts.

Virtual salt modules allows for a salt module to be presented as something other than its module name. The idea here is that based on information from the minion decisions about which module should be presented can be made. The best example is the pacman module. The pacman module will only load on Arch Linux minions, and will be called pkg. Similarly the yum module will be presented as pkg when the minion starts on a Fedora/RedHat system.

The new salt-call command allows for minion modules to be executed from the minion. This means that on the minion a salt module can be executed, this is a great tool for testing Salt modules. The salt-call command can also be used to view the grains data.

In previous releases when a minion module threw an exception very little data was returned to the master. Now the stack trace from the failure is returned making debugging of minion modules MUCH easier.

Salt is nearing the goal of 1.0, where the core feature set and capability is complete!

Salt 0.8.7 can be downloaded from GitHub here: <https://cloud.github.com/downloads/saltstack/salt/salt-0.8.7.tar.gz>

-Thomas S Hatch

### 35.2.71 Salt 0.8.8 release notes

Salt 0.8.8 is here! This release adds a great deal of code and some serious new features. The latest release can be downloaded here: <https://cloud.github.com/downloads/saltstack/salt/salt-0.8.8.tar.gz>

Improved Documentation has been set up for salt using sphinx thanks to the efforts of Seth House. This new documentation system will act as the back end to the salt website which is still under heavy development. The new sphinx documentation system has also been used to greatly clean up the salt manpages. The salt 7 manpage in particular now contains extensive information which was previously only in the wiki. The new documentation can be found at: <http://docs.saltstack.com/> We still have a lot to add, and when the domain is set up I will post another announcement.

More additions have been made to the ZeroMQ setup, particularly in the realm of file transfers. Salt 0.8.8 introduces a built in, stateless, encrypted file server which allows salt minions to download files from the salt master using the same encryption system used for all other salt communications. The main motivation for the salt file server has been to facilitate the new salt state system.

Much of the salt code has been cleaned up and a new cleaner logging system has been introduced thanks to the efforts of Pedro Algarvio. These additions will allow for much more flexible logging to be executed by salt, and fixed a great deal of my poor spelling in the salt docstrings! Pedro Algarvio has also cleaned up the API, making it easier to embed salt into another application.

The biggest addition to salt found in 0.8.8 is the new state system. The salt module system has received a new front end which allows salt to be used as a configuration management system. The configuration management system allows for system configuration to be defined in data structures. The configuration management system, or as it is called in salt, the “salt state system” supports many of the features found in other configuration managers, but

allows for system states to be written in a far simpler format, executes at blazing speeds, and operates via the salt minion matching system. The state system also operates within the normal scope of salt, and requires no additional configuration to use.

The salt state system can enforce the following states with many more to come: Packages Files Services Executing commands Hosts

The system used to define the salt states is based on a data structure, the data structure used to define the salt states has been made to be as easy to use as possible. The data structure is defined by default using a YAML file rendered via a Jinja template. This means that the state definition language supports all of the data structures that YAML supports, and all of the programming constructs and logic that Jinja supports. If the user does not like YAML or Jinja the states can be defined in yamll-mako, json-jinja, or json-mako. The system used to render the states is completely dynamic, and any rendering system can be added to the capabilities of Salt, this means that a rendering system that renders XML data in a cheetah template, or whatever you can imagine, can be easily added to the capabilities of salt.

The salt state system also supports isolated environments, as well as matching code from several environments to a single salt minion.

The feature base for Salt has grown quite a bit since my last serious documentation push. As we approach 0.9.0 the goals are becoming very clear, and the documentation needs a lot of work. The main goals for 0.9.0 are to further refine the state system, fix any bugs we find, get Salt running on as many platforms as we can, and get the documentation filled out. There is a lot more to come as Salt moves forward to encapsulate a much larger scope, while maintaining supreme usability and simplicity.

If you would like a more complete overview of Salt please watch the Salt presentation: Slides: <https://cloud.github.com/downloads/saltstack/salt/Salt.pdf>

-Thomas S Hatch

### 35.2.72 Salt 0.8.9 Release Notes

Salt 0.8.9 has finally arrived! Unfortunately this is much later than I had hoped to release 0.8.9, life has been very crazy over the last month. But despite challenges, Salt has moved forward!

This release, as expected, adds few new features and many refinements. One of the most exciting aspect of this release is that the development community for salt has grown a great deal and much of the code is from contributors.

Also, I have filled out the documentation a great deal. So information on States is properly documented, and much of the documentation that was out of date has been filled in.

#### Download!

The Salt source can be downloaded from the salt GitHub site:

<https://cloud.github.com/downloads/saltstack/salt/salt-0.8.9.tar.gz>

Or from PyPI:

<https://pypi.python.org/packages/source/s/salt/salt-0.8.9.tar.gz>

Here s the md5sum:

7d5aca4633bc22f59045f59e82f43b56

For instructions on how to set up Salt please see the *Installation* instructions.

## New Features

### Salt Run

A big feature is the addition of Salt run, the `salt-run` command allows for master side execution modules to be made that gather specific information or execute custom routines from the master.

Documentation for salt-run can be found [here](#)

### Refined Outputters

One problem often complained about in salt was the fact that the output was so messy. Thanks to help from Jeff Schroeder a cleaner interface for the command output for the Salt CLI has been made. This new interface makes adding new printout formats easy and additions to the capabilities of minion modules makes it possible to set the printout mode or `outputter` for functions in minion modules.

### Cross Calling Salt Modules

Salt modules can now call each other, the `__salt__` dict has been added to the predefined references in minion modules. This new feature is documented in the [modules documentation](#).

### Watch Option Added to Salt State System

Now in Salt states you can set the watch option, this will allow watch enabled states to change based on a change in the other defined states. This is similar to subscribe and notify statements in puppet.

### Root Dir Option

Travis Cline has added the ability to define the option `root_dir` which allows the salt minion to operate in a subdir. This is a strong move in supporting the minion running as an unprivileged user

### Config Files Defined in Variables

Thanks again to Travis Cline, the master and minion configuration file locations can be defined in environment variables now.

## New Modules

Quite a few new modules, states, returners, and runners have been made.

### New Minion Modules

**apt** Support for apt-get has been added, this adds greatly improved Debian and Ubuntu support to Salt!

**useradd and groupadd** Support for manipulating users and groups on Unix-like systems.

**moosefs** Initial support for reporting on aspects of the distributed file system, MooseFS. For more information on MooseFS please see: <http://www.moosefs.org>

Thanks to Joseph Hall for his work on MooseFS support.

**mount** Manage mounts and the fstab.

**puppet** Execute puppet on remote systems.

**shadow** Manipulate and manage the user password file.

**ssh** Interact with ssh keys.

#### New States

**user and group** Support for managing users and groups in Salt States.

**mount** Enforce mounts and the fstab.

#### New Returners

**mongo\_return** Send the return information to a MongoDB server.

#### New Runners

**manage** Display minions that are up or down.

### 35.2.73 Salt 0.9.0 Release Notes

**release** 2011-08-27

Salt 0.9.0 is here. This is an exciting release, 0.9.0 includes the new network topology features allowing peer salt commands and masters of masters via the syndic interface.

0.9.0 also introduces many more modules, improvements to the API and improvements to the ZeroMQ systems.

#### Download!

The Salt source can be downloaded from the salt GitHub site:

<https://cloud.github.com/downloads/saltstack/salt/salt-0.9.0.tar.gz>

Or from PyPI:

<https://pypi.python.org/packages/source/s/salt/salt-0.9.0.tar.gz>

Here is the md5sum:

9a925da04981e65a0f237f2e77ddab37

For instructions on how to set up Salt please see the *Installation* instructions.

## New Features

### Salt Syndic

The new *Syndic interface* allows a master to be commanded via another higher level salt master. This is a powerful solution allowing a master control structure to exist, allowing salt to scale to much larger levels than before.

### Peer Communication

0.9.0 introduces the capability for a minion to call a publication on the master and receive the return from another set of minions. This allows salt to act as a communication channel between minions and as a general infrastructure message bus.

Peer communication is turned off by default but can be enabled via the `peer` option in the master configuration file. Documentation on the new *Peer interface*.

### Easily Extensible API

The minion and master classes have been redesigned to allow for specialized minion and master servers to be easily created. An example on how this is done for the master can be found in the `master.py` salt module:

<https://github.com/saltstack/salt/blob/develop/salt/master.py>

The `Master` class extends the `SMaster` class and set up the main master server.

The minion functions can now also be easily added to another application via the `SMinion` class, this class can be found in the `minion.py` module:

<https://github.com/saltstack/salt/blob/develop/salt/minion.py>

### Cleaner Key Management

This release changes some of the key naming to allow for multiple master keys to be held based on the type of minion gathering the master key.

The `-d` option has also been added to the `salt-key` command allowing for easy removal of accepted public keys.

The `--gen-keys` option is now available as well for `salt-key`, this allows for a salt specific RSA key pair to be easily generated from the command line.

### Improved 0MQ Master Workers

The 0MQ worker system has been further refined to be faster and more robust. This new system has been able to handle a much larger load than the previous setup. The new system uses the IPC protocol in 0MQ instead of TCP.

## New Modules

Quite a few new modules have been made.

### New Minion Modules

**apache** Work directly with apache servers, great for managing balanced web servers

**cron** Read out the contents of a systems crontabs

**mdadm** Module to manage raid devices in Linux, appears as the `raid` module

**mysql** Gather simple data from MySQL databases

**ps** Extensive utilities for managing processes

**publish** Used by the peer interface to allow minions to make publications

### 35.2.74 Salt 0.9.1 Release Notes

**release** 2011-08-29

### 35.2.75 Salt 0.9.2 Release Notes

**release** 2011-09-17

Salt 0.9.2 has arrived! 0.9.2 is primarily a bugfix release, the exciting component in 0.9.2 is greatly improved support for salt states. All of the salt states interfaces have been more thoroughly tested and the new salt-states git repo is growing with example of how to use states.

This release introduces salt states for early developers and testers to start helping us clean up the states interface and make it ready for the world!

0.9.2 also fixes a number of bugs found on Python 2.6.

#### Download!

The Salt source can be downloaded from the salt GitHub site:

<https://cloud.github.com/downloads/saltstack/salt/salt-0.9.2.tar.gz>

Or from PyPI:

<https://pypi.python.org/packages/source/s/salt/salt-0.9.2.tar.gz>

For instructions on how to set up Salt please see the *Installation* instructions.

#### New Features

##### Salt-Call Additions

The salt-call command has received an overhaul, it now hooks into the outputter system so command output looks clean, and the logging system has been hooked into salt-call, so the `-l` option allows the logging output from salt minion functions to be displayed.

The end result is that the salt-call command can execute the state system and return clean output:

```
# salt-call state.highstate
```

### State System Fixes

The state system has been tested and better refined. As of this release the state system is ready for early testers to start playing with. If you are interested in working with the state system please check out the (still very small) salt-states GitHub repo:

<https://github.com/saltstack/salt-states>

This git repo is the active development branch for determining how a clean salt-state database should look and act. Since the salt state system is still very young a lot of help is still needed here. Please fork the salt-states repo and help us develop a truly large and scalable system for configuration management!

### Notable Bug Fixes

#### Python 2.6 String Formatting

Python 2.6 does not support format strings without an index identifier, all of them have been repaired.

#### Cython Loading Disabled by Default

Cython loading requires a development tool chain to be installed on the minion, requiring this by default can cause problems for most Salt deployments. If Cython auto loading is desired it will need to be turned on in the minion config.

## 35.2.76 Salt 0.9.3 Release Notes

release 2011-11-05

Salt 0.9.3 is finally arrived. This is another big step forward for Salt, new features range from proper FreeBSD support to fixing issues seen when attaching a minion to a master over the Internet.

The biggest improvements in 0.9.3 though can be found in the state system, it has progressed from something ready for early testers to a system ready to compete with platforms such as Puppet and Chef. The backbone of the state system has been greatly refined and many new features are available.

### Download!

The Salt source can be downloaded from the salt GitHub site:

<https://cloud.github.com/downloads/saltstack/salt/salt-0.9.3.tar.gz>

Or from PyPI:

<https://pypi.python.org/packages/source/s/salt/salt-0.9.3.tar.gz>

For instructions on how to set up Salt please see the *Installation* instructions.

### New Features

#### WAN Support

Recently more people have been testing Salt minions connecting to Salt Masters over the Internet. It was found that Minions would commonly loose their connection to the master when working over the internet. The minions

can now detect if the connection has been lost and reconnect to the master, making WAN connections much more reliable.

### State System Fixes

Substantial testing has gone into the state system and it is ready for real world usage. A great deal has been added to the documentation for states and the modules and functions available to states have been cleanly documented.

A number of State System bugs have also been founds and repaired, the output from the state system has also been refined to be extremely clear and concise.

Error reporting has also been introduced, issues found in sls files will now be clearly reported when executing Salt States.

### Extend Declaration

The Salt States have also gained the `extend` declaration. This declaration allows for states to be cleanly modified in a post environment. Simply said, if there is an `apache.sls` file that declares the `apache` service, then another `sls` can include `apache` and then extend it:

```
include:
  - apache

extend:
  apache:
    service:
      - require:
        - pkg: mod_python

mod_python:
  pkg:
    - installed
```

The notable behavior with the `extend` functionality is that it literally extends or overwrites a declaration set up in another `sls` module. This means that Salt will behave as though the modifications were made directly to the `apache.sls`. This ensures that the `apache` service in this example is directly tied to all requirements.

### Highstate Structure Specification

This release comes with a clear specification of the Highstate data structure that is used to declare Salt States. This specification explains everything that can be declared in the Salt SLS modules.

The specification is extremely simple, and illustrates how Salt has been able to fulfill the requirements of a central configuration manager within a simple and easy to understand format and specification.

### SheBang Renderer Switch

It came to our attention that having many renderers means that there may be a situation where more than one State Renderer should be available within a single State Tree.

The method chosen to accomplish this was something already familiar to developers and systems administrators, a SheBang. The Python State Renderer displays this new capability.

### Python State Renderer

Until now Salt States could only be declared in yaml or json using Jinja or Mako. A new, very powerful, renderer has been added, making it possible to write Salt States in pure Python:

```
#!/py
def run():
    '''
    Install the python-mako package
    '''
    return {'include': ['python'],
            'python-mako': {'pkg': ['installed']}}
```

This renderer is used by making a run function that returns the Highstate data structure. Any capabilities of Python can be used in pure Python sls modules.

This example of a pure Python sls module is the same as this example in yaml:

```
include:
  - python

python-mako:
  pkg:
    - installed
```

### FreeBSD Support

Additional support has been added for FreeBSD, this is Salt's first branch out of the Linux world and proves the viability of Salt on non-Linux platforms.

Salt remote execution already worked on FreeBSD, and should work without issue on any Unix-like platform. But this support comes in the form of package management and user support, so Salt States also work on FreeBSD now.

The new `freebsd_pkg` module provides package management support for FreeBSD and the new `pw_user` and `pw_group` provide user and group management.

### Module and State Additions

#### Cron Support

Support for managing the system crontab has been added, declaring a cron state can be done easily:

```
date > /tmp/datestamp:
cron:
  - present
  - user: fred
  - minute: 5
  - hour: 3
```

## File State Additions

The file state has been given a number of new features, primarily the directory, recurse, symlink, and absent functions.

**file.directory** Make sure that a directory exists and has the right permissions.

```
/srv/foo:
  file:
    - directory
    - user: root
    - group: root
    - mode: 1755
```

**file.symlink** Make a symlink.

```
/var/lib/www:
  file:
    - symlink
    - target: /srv/www
    - force: True
```

**file.recurse** The recurse state function will recursively download a directory on the master file server and place it on the minion. Any change in the files on the master will be pushed to the minion. The recurse function is very powerful and has been tested by pushing out the full Linux kernel source.

```
/opt/code:
  file:
    - recurse
    - source: salt://linux
```

**file.absent** Make sure that the file is not on the system, recursively deletes directories, files, and symlinks.

```
/etc/httpd/conf.d/somebogusfile.conf:
  file:
    - absent
```

## Sysctl Module and State

The sysctl module and state allows for sysctl components in the kernel to be managed easily. the sysctl module contains the following functions:

**sysctl.show** Return a list of sysctl parameters for this minion

**sysctl.get** Return a single sysctl parameter for this minion

**sysctl.assign** Assign a single sysctl parameter for this minion

**sysctl.persist** Assign and persist a simple sysctl parameter for this minion

The sysctl state allows for sysctl parameters to be assigned:

```
vm.swappiness:
  sysctl:
    - present
    - value: 20
```

## Kernel Module Management

A module for managing Linux kernel modules has been added. The new functions are as follows:

**kmod.available** Return a list of all available kernel modules

**kmod.check\_available** Check to see if the specified kernel module is available

**kmod.lsm** Return a dict containing information about currently loaded modules

**kmod.load** Load the specified kernel module

**kmod.remove** Unload the specified kernel module

The kmod state can enforce modules be either present or absent:

```
kvm_intel:
  kmod:
    - present
```

## Ssh Authorized Keys

The ssh\_auth state can distribute ssh authorized keys out to minions. Ssh authorized keys can be present or absent.

```
AAAAB3NzaC1kc3MAAACBAL0sQ9fJ5bYTEyYvLRBsJdD0o49CNfhLWHWXQRqul6rwL4KIuPrhY7hBw0tV7UNC7J9IZRN04iGod9C+
  ssh_auth:
    - present
    - user: frank
    - enc: dsa
    - comment: 'Frank's key'
```

## 35.2.77 Salt 0.9.4 Release Notes

**release** 2011-11-27

Salt 0.9.4 has arrived. This is a critical update that repairs a number of key bugs found in 0.9.3. But this update is not without feature additions as well! 0.9.4 adds support for Gentoo portage to the pkg module and state system. Also there are 2 major new state additions, the failhard option and the ability to set up finite state ordering with the order option.

This release also sees our largest increase in community contributions. These contributors have and continue to be the life blood of the Salt project, and the team continues to grow. I want to put out a big thanks to our new and existing contributors.

### Download!

The Salt source can be downloaded from the salt GitHub site:

<https://cloud.github.com/downloads/saltstack/salt/salt-0.9.4.tar.gz>

Or from PyPI:

<https://pypi.python.org/packages/source/s/salt/salt-0.9.4.tar.gz>

For instructions on how to set up Salt please see the *Installation* instructions.

## New Features

### Failhard State Option

Normally, when a state fails Salt continues to execute the remainder of the defined states and will only refuse to execute states that require the failed state.

But the situation may exist, where you would want all state execution to stop if a single state execution fails. The capability to do this is called `failing hard`.

**State Level Failhard** A single state can have a failhard set, this means that if this individual state fails that all state execution will immediately stop. This is a great thing to do if there is a state that sets up a critical config file and setting a require for each state that reads the config would be cumbersome. A good example of this would be setting up a package manager early on:

```
/etc/yum.repos.d/company.repo:
file:
  - managed
  - source: salt://company/yumrepo.conf
  - user: root
  - group: root
  - mode: 644
  - order: 1
  - failhard: True
```

In this situation, the yum repo is going to be configured before other states, and if it fails to lay down the config file, than no other states will be executed.

**Global Failhard** It may be desired to have failhard be applied to every state that is executed, if this is the case, then failhard can be set in the master configuration file. Setting failhard in the master configuration file will result in failing hard when any minion gathering states from the master have a state fail.

This is NOT the default behavior, normally Salt will only fail states that require a failed state.

Using the global failhard is generally not recommended, since it can result in states not being executed or even checked. It can also be confusing to see states failhard if an admin is not actively aware that the failhard has been set.

To use the global failhard set `failhard: True` in the master configuration

### Finite Ordering of State Execution

When creating salt sls files, it is often important to ensure that they run in a specific order. While states will always execute in the same order, that order is not necessarily defined the way you want it.

A few tools exist in Salt to set up the correct state ordering, these tools consist of requisite declarations and order options.

**The Order Option** Before using the order option, remember that the majority of state ordering should be done with requisite statements, and that a requisite statement will override an order option.

The order option is used by adding an order number to a state declaration with the option `order`:

```
vim:
  pkg:
    - installed
    - order: 1
```

By adding the order option to `1` this ensures that the vim package will be installed in tandem with any other state declaration set to the order `1`.

Any state declared without an order option will be executed after all states with order options are executed.

But this construct can only handle ordering states from the beginning. Sometimes you may want to send a state to the end of the line, to do this set the order to last:

```
vim:
  pkg:
    - installed
    - order: last
```

Substantial testing has gone into the state system and it is ready for real world usage. A great deal has been added to the documentation for states and the modules and functions available to states have been cleanly documented.

A number of State System bugs have also been founds and repaired, the output from the state system has also been refined to be extremely clear and concise.

Error reporting has also been introduced, issues found in sls files will now be clearly reported when executing Salt States.

### Gentoo Support

Additional experimental support has been added for Gentoo. This is found in the contribution from Doug Renn, aka nestegg.

## 35.2.78 Salt 0.9.5 Release Notes

**release** 2012-01-15

Salt 0.9.5 is one of the largest steps forward in the development of Salt.

0.9.5 comes with many milestones, this release has seen the community of developers grow out to an international team of 46 code contributors and has many feature additions, feature enhancements, bug fixes and speed improvements.

**Warning:** Be sure to *read the upgrade instructions* about the switch to msgpack before upgrading!

### Community

Nothing has proven to have more value to the development of Salt than the outstanding community that has been growing at such a great pace around Salt. This has proven not only that Salt has great value, but also the expandability of Salt is as exponential as I originally intended.

0.9.5 has received over 600 additional commits since 0.9.4 with a swath of new committers. The following individuals have contributed to the development of 0.9.5:

- Aaron Bull Schaefer

- Antti Kaihola
- Bas Tichelaar
- Brad Barden
- Brian Wagner
- Byron Clark
- Chris Scheller
- Christer Edwards
- Clint Savage
- Corey Quinn
- David Boucha
- Eivind Uggedal
- Eric Poelke
- Evan Borgstrom
- Jed Glazner
- Jeff Schroeder
- Jeffrey C. Ollie
- Jonas Buckner
- Kent Tenney
- Martin Schnabel
- Maxim Burgerhout
- Mitch Anderson
- Nathaniel Whiteinge
- Seth House
- Thomas S Hatch
- Thomas Schreiber
- Tor Hveem
- lzyeval
- syphernl

This makes 21 new developers since 0.9.4 was released!

To keep up with the growing community follow Salt on Ohloh (<http://www.ohloh.net/p/salt>), to join the Salt development community, fork Salt on Github, and get coding (<https://github.com/saltstack/salt>)!

## Major Features

### SPEED! Pickle to msgpack

For a few months now we have been talking about moving away from Python pickles for network serialization, but a preferred serialization format had not yet been found. After an extensive performance testing period involving

everything from JSON to protocol buffers, a clear winner emerged. Message Pack (<http://msgpack.org/>) proved to not only be the fastest and most compact, but also the most ``salt like''. Message Pack is simple, and the code involved is very small. The msgpack library for Python has been added directly to Salt.

This move introduces a few changes to Salt. First off, Salt is no longer a ``noarch'' package, since the msgpack lib is written in C. Salt 0.9.5 will also have compatibility issues with 0.9.4 with the default configuration.

We have gone through great lengths to avoid backwards compatibility issues with Salt, but changing the serialization medium was going to create issues regardless. Salt 0.9.5 is somewhat backwards compatible with earlier minions. A 0.9.5 master can command older minions, but only if the `serial` config value in the master is set to `pickle`. This will tell the master to publish messages in pickle format and will allow the master to receive messages in both msgpack and pickle formats.

Therefore **the suggested methods for upgrading** are either to just upgrade everything at once, or:

1. Upgrade the master to 0.9.5
2. Set `serial` to `pickle` in the master config
3. Upgrade the minions
4. Remove the `serial` option from the master config

Since pickles can be used as a security exploit the ability for a master to accept pickles from minions at all will be removed in a future release.

### C Bindings for YAML

All of the YAML rendering is now done with the YAML C bindings. This speeds up all of the sls files when running states.

### Experimental Windows Support

David Boucha has worked tirelessly to bring initial support to Salt for Microsoft Windows operating systems. Right now the Salt Minion can run as a native Windows service and accept commands.

In the weeks and months to come Windows will receive the full treatment and will have support for Salt States and more robust support for managing Windows systems. This is a big step forward for Salt to move entirely outside of the Unix world, and proves Salt is a viable cross platform solution. Big Thanks to Dave for his contribution here!

### Dynamic Module Distribution

Many Salt users have expressed the desire to have Salt distribute in-house modules, states, renderers, returners, and grains. This support has been added in a number of ways:

**Modules via States** Now when salt modules are deployed to a minion via the state system as a file, then the modules will be automatically loaded into the active running minion - no restart required - and into the active running state. So custom state modules can be deployed and used in the same state run.

**Modules via Module Environment Directories** Under the `file_roots` each environment can now have directories that are used to deploy large groups of modules. These directories sync modules at the beginning of a state run on the minion, or can be manually synced via the Salt module `salt.modules.saltutil.sync_all`.

The directories are named:

- `_modules`
- `_states`
- `_grains`
- `_renderers`
- `_returners`

The modules are pushed to their respective scopes on the minions.

### Module Reloading

Modules can now be reloaded without restarting the minion, this is done by calling the `salt.modules.sys.reload_modules` function.

But wait, there's more! Now when a salt module of any type is added via states the modules will be automatically reloaded, allowing for modules to be laid down with states and then immediately used.

Finally, all modules are reloaded when modules are dynamically distributed from the salt master.

### Enable / Disable Added to Service

A great deal of demand has existed for adding the capability to set services to be started at boot in the service module. This feature also comes with an overhaul of the service modules and initial systemd support.

This means that the `service state` can now accept `- enable: True` to make sure a service is enabled at boot, and `- enable: False` to make sure it is disabled.

### Compound Target

A new target type has been added to the lineup, the compound target. In previous versions the desired minions could only be targeted via a single specific target type, but now many target specifications can be declared.

These targets can also be separated by and/or operators, so certain properties can be used to omit a node:

```
salt -C 'webserv* and G@os:Debian or E@db.*' test.ping
```

will match all minions with ids starting with `webserv` via a glob and minions matching the `os:Debian` grain. Or minions that match the `db.*` regular expression.

### Node Groups

Often the convenience of having a predefined group of minions to execute targets on is desired. This can be accomplished with the new nodegroups feature. Nodegroups allow for predefined compound targets to be declared in the master configuration file:

```
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com and bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
```

And then used via the `-N` option:

```
salt -N group1 test.ping
```

### Minion Side Data Store

The data module introduces the initial approach into storing persistent data on the minions, specific to the minions. This allows for data to be stored on minions that can be accessed from the master or from the minion.

The Minion datastore is young, and will eventually provide an interface similar to a more mature key/value pair server.

### Major Grains Improvement

The Salt grains have been overhauled to include a massive amount of extra data. this includes hardware data, os data and salt specific data.

### Salt -Q is Useful Now

In the past the salt query system, which would display the data from recent executions would be displayed in pure Python, and it was unreadable.

0.9.5 has added the outputter system to the -Q option, thus enabling the salt query system to return readable output.

### Packaging Updates

Huge strides have been made in packaging Salt for distributions. These additions are thanks to our wonderful community where the work to set up packages has proceeded tirelessly.

### FreeBSD

Salt on FreeBSD? There a port for that:

<http://svnweb.freebsd.org/ports/head/sysutils/py-salt/>

This port was developed and added by Christer Edwards. This also marks the first time Salt has been included in an upstream packaging system!

### Fedora and Red Hat Enterprise

Salt packages have been prepared for inclusion in the Fedora Project and in EPEL for Red Hat Enterprise 5 and 6. These packages are the result of the efforts made by Clint Savage (herlo).

### Debian/Ubuntu

A team of many contributors have assisted in developing packages for Debian and Ubuntu. Salt is still actively seeking inclusion in upstream Debian and Ubuntu and the package data that has been prepared is being pushed through the needed channels for inclusion.

These packages have been prepared with the help of:

- Corey
- Aaron Toponce
- and`

### More to Come

We are actively seeking inclusion in more distributions. Primarily getting Salt into Gentoo, SUSE, OpenBSD, and preparing Solaris support are all turning into higher priorities.

### Refinement

Salt continues to be refined into a faster, more stable and more usable application. 0.9.5 comes with more debug logging, more bug fixes and more complete support.

### More Testing, More BugFixes

0.9.5 comes with more bugfixes due to more testing than any previous release. The growing community and the introduction a a dedicated QA environment have unearthed many issues that were hiding under the covers. This has further refined and cleaned the state interface, taking care of things from minor visual issues to repairing misleading data.

### Custom Exceptions

A custom exception module has been added to throw salt specific exceptions. This allows Salt to give much more granular error information.

### New Modules

**data** The new data module manages a persistent datastore on the minion. Big thanks to bastichelaar for his help refining this module

**frebsdckmod** FreeBSD kernel modules can now be managed in the same way Salt handles Linux kernel modules. This module was contributed thanks to the efforts of Christer Edwards

**gentoo\_service** Support has been added for managing services in Gentoo. Now Gentoo services can be started, stopped, restarted, enabled, disabled, and viewed.

**pip** The pip module introduces management for pip installed applications. Thanks goes to whitinge for the addition of the pip module

**rh\_service** The rh\_service module enables Red Hat and Fedora specific service management. Now Red Hat like systems come with extensive management of the classic init system used by Red Hat

**saltutil** The saltutil module has been added as a place to hold functions used in the maintenance and management of salt itself. Saltutil is used to salt the salt minion. The saltutil module is presently used only to sync extension modules from the master server.

**systemd** Systemd support has been added to Salt, now systems using this next generation init system are supported on systems running systemd.

**virtualenv** The virtualenv module has been added to allow salt to create virtual Python environments. Thanks goes to whitinge for the addition of the virtualenv module

**win\_disk** Support for gathering disk information on Microsoft Windows minions The windows modules come courtesy of Utah\_Dave

**win\_service** The win\_service module adds service support to Salt for Microsoft Windows services

**win\_useradd** Salt can now manage local users on Microsoft Windows Systems

**yumpkg5** The yumpkg module introduces in 0.9.4 uses the yum API to interact with the yum package manager. Unfortunately, on Red Hat 5 systems salt does not have access to the yum API because the yum API is running under Python 2.4 and Salt needs to run under Python 2.6.

The yumpkg5 module bypasses this issue by shelling out to yum on systems where the yum API is not available.

#### New States

**mysql\_database** The new mysql\_database state adds the ability to systems running a mysql server to manage the existence of mysql databases.

The mysql states are thanks to syphernl

**mysql\_user** The mysql\_user state enables mysql user management.

**virtualenv** The virtualenv state can manage the state of Python virtual environments. Thanks to Whitinge for the virtualenv state

#### New Returners

**cassandra\_returner** A returner allowing Salt to send data to a cassandra server. Thanks to Byron Clark for contributing this returner

### 35.2.79 Salt 0.9.6 Release Notes

release 2012-01-21

Salt 0.9.6 is a release targeting a few bugs and changes. This is primarily targeting an issue found in the names declaration in the state system. But a few other bugs were also repaired, like missing support for grains in extmods.

Due to a conflict in distribution packaging msgpack will no longer be bundled with Salt, and is required as a dependency.

## New Features

### HTTP and ftp support in files.managed

Now under the source option in the file.managed state a HTTP or ftp address can be used instead of a file located on the salt master.

### Allow Multiple Returners

Now the returner interface can define multiple returners, and will also return data back to the master, making the process less ambiguous.

### Minion Memory Improvements

A number of modules have been taken out of the minion if the underlying systems required by said modules are not present on the minion system. A number of other modules need to be stripped out in this same way which should continue to make the minion more efficient.

### Minions Can Locally Cache Return Data

A new option, cache\_jobs, has been added to the minion to allow for all of the historically run jobs to cache on the minion, allowing for looking up historic returns. By default cache\_jobs is set to False.

### Pure Python Template Support For file.managed

Templates in the file.managed state can now be defined in a Python script. This script needs to have a run function that returns the string that needs to be in the named file.

## 35.2.80 Salt 0.9.7 Release Notes

**release** 2012-02-15

Salt 0.9.7 is here! The latest iteration of Salt brings more features and many fixes. This release is a great refinement over 0.9.6, adding many conveniences under the hood, as well as some features that make working with Salt much better.

A few highlights include the new Job system, refinements to the requisite system in states, the `mod_init` interface for states, external node classification, search path to managed files in the file state, and refinements and additions to dynamic module loading.

0.9.7 also introduces the long developed (and oft changed) unit test framework and the initial unit tests.

## Major Features

### Salt Jobs Interface

The new jobs interface makes the management of running executions much cleaner and more transparent. Building on the existing execution framework the jobs system allows clear introspection into the active running state of the running Salt interface.

The Jobs interface is centered in the new minion side proc system. The minions now store msgpack serialized files under `/var/cache/salt/proc`. These files keep track of the active state of processes on the minion.

**Functions in the saltutil Module** A number of functions have been added to the saltutil module to manage and view the jobs:

`running` - Returns the data of all running jobs that are found in the proc directory.

`find_job` - Returns specific data about a certain job based on job id.

`signal_job` - Allows for a given jid to be sent a signal.

`term_job` - Sends a termination signal (SIGTERM, 15) to the process controlling the specified job.

`kill_job` Sends a kill signal (SIGKILL, 9) to the process controlling the specified job.

### The jobs Runner

A convenience runner front end and reporting system has been added as well. The jobs runner contains functions to make viewing data easier and cleaner.

The jobs runner contains a number of functions...

**active** The active function runs `saltutil.running` on all minions and formats the return data about all running jobs in a much more usable and compact format. The active function will also compare jobs that have returned and jobs that are still running, making it easier to see what systems have completed a job and what systems are still being waited on.

**lookup\_jid** When jobs are executed the return data is sent back to the master and cached. By default is is cached for 24 hours, but this can be configured via the `keep_jobs` option in the master configuration.

Using the `lookup_jid` runner will display the same return data that the initial job invocation with the salt command would display.

**list\_jobs** Before finding a historic job, it may be required to find the job id. `list_jobs` will parse the cached execution data and display all of the job data for jobs that have already, or partially returned.

### External Node Classification

Salt can now use external node classifiers like Cobbler's `cobbler-ext-nodes`.

Salt uses specific data from the external node classifier. In particular the `classes` value denotes which sls modules to run, and the `environment` value sets to another environment.

An external node classification can be set in the master configuration file via the `external_nodes` option: <http://salt.readthedocs.org/en/latest/ref/configuration/master.html#external-nodes>

External nodes are loaded in addition to the top files. If it is intended to only use external nodes, do not deploy any top files.

### State Mod Init System

An issue arose with the `pkg` state. Every time a package was run Salt would need to refresh the package database. This made systems with slower package metadata refresh speeds much slower to work with. To alleviate this issue the `mod_init` interface has been added to salt states.

The `mod_init` interface is a function that can be added to a state file. This function is called with the first state called. In the case of the `pkg` state, the `mod_init` function sets up a tag which makes the package database only refresh on the first attempt to install a package.

In a nutshell, the `mod_init` interface allows a state to run any command that only needs to be run once, or can be used to set up an environment for working with the state.

### Source File Search Path

The file state continues to be refined, adding speed and capabilities. This release adds the ability to pass a list to the source option. This list is then iterated over until the source file is found, and the first found file is used.

The new syntax looks like this:

```
/etc/httpd/conf/httpd.conf:
  file:
    - managed
    - source:
      - salt://httpd/httpd.conf
      - http://myserver/httpd.conf: md5=8c1fe119e6f1fd96bc06614473509bf1
```

The source option can take sources in the list from the salt file server as well as an arbitrary web source. If using an arbitrary web source the checksum needs to be passed as well for file verification.

### Refinements to the Requisite System

A few discrepancies were still lingering in the requisite system, in particular, it was not possible to have a `require` and a `watch` requisite declared in the same state declaration.

This issue has been alleviated, as well as making the requisite system run more quickly.

### Initial Unit Testing Framework

Because of the module system, and the need to test real scenarios, the development of a viable unit testing system has been difficult, but unit testing has finally arrived. Only a small amount of unit testing coverage has been developed, much more coverage will be in place soon.

A huge thanks goes out to those who have helped with unit testing, and the contributions that have been made to get us where we are. Without these contributions unit tests would still be in the dark.

### Compound Targets Expanded

Originally only support for `and` and `or` were available in the compound target. 0.9.7 adds the capability to negate compound targets with `not`.

## Nodegroups in the Top File

Previously the nodegroups defined in the master configuration file could not be used to match nodes for states. The nodegroups support has been expanded and the nodegroups defined in the master configuration can now be used to match minions in the top file.

## 35.2.81 Salt 0.9.8 Release Notes

release 2012-03-21

Salt 0.9.8 is a big step forward, with many additions and enhancements, as well as a number of precursors to advanced future developments.

This version of Salt adds much more power to the command line, making the old hard timeout issues a thing of the past and adds keyword argument support. These additions are also available in the salt client API, making the available API tools much more powerful.

The new pillar system allows for data to be stored on the master and assigned to minions in a granular way similar to the state system. It also allows flexibility for users who want to keep data out of their state tree similar to 'external lookup' functionality in other tools.

A new way to extend requisites was added, the ``requisite in" statement. This makes adding requires or watch statements to external state decs much easier.

Additions to requisites making them much more powerful have been added as well as improved error checking for sls files in the state system. A new provider system has been added to allow for redirecting what modules run in the background for individual states.

Support for OpenSUSE has been added and support for Solaris has begun serious development. Windows support has been significantly enhanced as well.

The matcher and target systems have received a great deal of attention. The default behavior of grain matching has changed slightly to reflect the rest of salt and the compound matcher system has been refined.

A number of impressive features with keyword arguments have been added to both the CLI and to the state system. This makes states much more powerful and flexible while maintaining the simple configuration everyone loves.

The new batch size capability allows for executions to be rolled through a group of targeted minions a percentage or specific number at a time. This was added to prevent the ``thundering herd" problem when targeting large numbers of minions for things like service restarts or file downloads.

## Upgrade Considerations

### Upgrade Issues

There was a previously missed oversight which could cause a newer minion to crash an older master. That oversight has been resolved so the version incompatibility issue will no longer occur. When upgrading to 0.9.8 make sure to upgrade the master first, followed by the minions.

### Debian/Ubuntu Packages

The original Debian/Ubuntu packages were called salt and included all salt applications. New packages in the ppa are split by function. If an old salt package is installed then it should be manually removed and the new split packages need to be freshly installed.

On the master:

```
# apt-get purge salt
# apt-get install salt-{master,minion}
```

On the minions:

```
# apt-get purge salt
# apt-get install salt-minion
```

And on any Syndics:

```
# apt-get install salt-syndic
```

The official Salt PPA for Ubuntu is located at: <https://launchpad.net/~saltstack/+archive/salt>

## Major Features

### Pillar

Pillar offers an interface to declare variable data on the master that is then assigned to the minions. The pillar data is made available to all modules, states, sls files etc. It is compiled on the master and is declared using the existing renderer system. This means that learning pillar should be fairly trivial to those already familiar with salt states.

### CLI Additions

The `salt` command has received a serious overhaul and is more powerful than ever. Data is returned to the terminal as it is received, and the `salt` command will now wait for all running minions to return data before stopping. This makes adding very large `--timeout` arguments completely unnecessary and gets rid of long running operations returning empty `{}` when the timeout is exceeded.

When calling salt via `sudo`, the user originally running salt is saved to the log for auditing purposes. This makes it easy to see who ran what by just looking through the minion logs.

The `salt-key` command gained the `-D` and `--delete-all` arguments for removing all keys. Be careful with this one!

### Running States Without a Master

The addition of running states without a salt-master has been added to 0.9.8. This feature allows for the unmodified salt state tree to be read locally from a minion. The result is that the UNMODIFIED state tree has just become portable, allowing minions to have a local copy of states or to manage states without a master entirely.

This is accomplished via the new file client interface in Salt that allows for the `salt://` URI to be redirected to custom interfaces. This means that there are now two interfaces for the salt file server, calling the master or looking in a local, minion defined `file_roots`.

This new feature can be used by modifying the minion config to point to a local `file_roots` and setting the `file_client` option to `local`.

### Keyword Arguments and States

State modules now accept the `**kwargs` argument. This results in all data in a `sls` file assigned to a state being made available to the state function.

This passes data in a transparent way back to the modules executing the logic. In particular, this allows adding arguments to the `pkg.install` module that enable more advanced and granular controls with respect to what the state is capable of.

An example of this along with the new `debconf` module for installing `ldap` client packages on Debian:

```
ldap-client-packages:
  pkg:
    - debconf: salt://debconf/ldap-client.ans
    - installed
    - names:
      - nslcd
      - libpam-ldapd
      - libnss-ldapd
```

### Keyword Arguments and the CLI

In the past it was required that all arguments be passed in the proper order to the `salt` and `salt-call` commands. As of 0.9.8, keyword arguments can be passed in the form of `kwarg=argument`.

```
# salt -G 'type:dev' git.clone \
  repository=https://github.com/saltstack/salt.git cwd=/tmp/salt user=jeff
```

### Matcher Refinements and Changes

A number of fixes and changes have been applied to the Matcher system. The most noteworthy is the change in the grain matcher. The grain matcher used to use a regular expression to match the passed data to a grain, but now defaults to a shell glob like the majority of match interfaces in Salt. A new option is available that still uses the old style regex matching to grain data called `grain-pcre`. To use regex matching in compound matches use the letter `P`.

For example, this would match any ArchLinux or Fedora minions:

```
# salt --grain-pcre 'os:(Arch:Fed).*' test.ping
```

And the associated compound matcher suitable for `top.sls` is `P`:

```
P@os: (Arch|Fed) . *
```

**NOTE:** Changing the grains matcher from `pcre` to `glob` is backwards incompatible.

Support has been added for matching minions with Yahoo's range library. This is handled by passing range syntax with `-R` or `--range` arguments to `salt`.

More information at: <https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec>

## Requisite ``in``

A new means to updating requisite statements has been added to make adding watchers and requires to external states easier. Before 0.9.8 the only way to extend the states that were watched by a state outside of the sls was to use an extend statement:

```
include:
  - http
extend:
  apache:
    service:
      - watch:
        - pkg: tomcat
tomcat:
  pkg:
    - installed
```

But the new `Requisite in` statement allows for easier extends for requisites:

```
include:
  - http
tomcat:
  pkg:
    - installed
    - watch_in:
      - service: apache
```

Requisite `in` is part of the extend system, so still remember to always include the sls that is being extended!

## Providers

Salt predetermines what modules should be mapped to what uses based on the properties of a system. These determinations are generally made for modules that provide things like package and service management. The `apt` module maps to `pkg` on Debian and the `yum` module maps to `pkg` on Fedora for instance.

Sometimes in states, it may be necessary for a non-default module to be used for the desired functionality. For instance, an Arch Linux system may have been set up with `systemd` support. Instead of using the default service module detected for Arch Linux, the `systemd` module can be used:

```
http:
  service:
    - running
    - enable: True
    - provider: systemd
```

Default providers can also be defined in the minion config file:

```
providers:
  service: systemd
```

When default providers are passed in the minion config, then those providers will be applied to all functionality in Salt, this means that the functions called by the minion will use these modules, as well as states.

### Requisite Glob Matching

Requisites can now be defined with glob expansion. This means that if there are many requisites, they can be defined on a single line.

To watch all files in a directory:

```
http:
  service:
    - running
    - enable: True
    - watch:
      - file: /etc/http/conf.d/*
```

This example will watch all defined files that match the glob `/etc/http/conf.d/*`

### Batch Size

The new batch size option allows commands to be executed while maintaining that only so many hosts are executing the command at one time. This option can take a percentage or a finite number:

```
salt '*' -b 10 test.ping

salt -G 'os:RedHat' --batch-size 25% apache.signal restart
```

This will only run `test.ping` on 10 of the targeted minions at a time and then restart `apache` on 25% of the minions matching `os:RedHat` at a time and work through them all until the task is complete. This makes jobs like rolling web server restarts behind a load balancer or doing maintenance on BSD firewalls using `carp` much easier with salt.

### Module Updates

This is a list of notable, but non-exhaustive updates with new and existing modules.

Windows support has seen a flurry of support this release cycle. We've gained all new `file`, `network`, and `shadow` modules. Please note that these are still a work in progress.

For our ruby users, new `rvm` and `gem` modules have been added along with the `associated states`

The `virt` module gained basic Xen support.

The `yum` module gained Scientific Linux support.

The `pkg` module on Debian, Ubuntu, and derivatives force `apt` to run in a non-interactive mode. This prevents issues when package installation waits for confirmation.

A `pkg` module for OpenSUSE's `zypper` was added.

The `service` module on Ubuntu natively supports `upstart`.

A new `debconf` module was contributed by our community for more advanced control over `deb` package deployments on Debian based distributions.

The `mysql.user` state and `mysql` module gained a `password_hash` argument.

The `cmd` module and state gained a `shell` keyword argument for specifying a shell other than `/bin/sh` on Linux / Unix systems.

New `git` and `mercurial` modules have been added for fans of distributed version control.

## In Progress Development

### Master Side State Compiling

While we feel strongly that the advantages gained with minion side state compiling are very critical, it does prevent certain features that may be desired. 0.9.8 has support for initial master side state compiling, but many more components still need to be developed, it is hoped that these can be finished for 0.9.9.

The goal is that states can be compiled on both the master and the minion allowing for compilation to be split between master and minion. Why will this be great? It will allow storing sensitive data on the master and sending it to some minions without all minions having access to it. This will be good for handling ssl certificates on front-end web servers for instance.

### Solaris Support

Salt 0.9.8 sees the introduction of basic Solaris support. The daemon runs well, but grains and more of the modules need updating and testing.

### Windows Support

Salt states on windows are now much more viable thanks to contributions from our community! States for file, service, local user, and local group management are more fully fleshed out along with network and disk modules. Windows users can also now manage registry entries using the new `reg` module.

## 35.2.82 Salt 0.9.9 Release Notes

**release** 2012-04-27

0.9.9 is out and comes with some serious bug fixes and even more serious features. This release is the last major feature release before 1.0.0 and could be considered the 1.0.0 release candidate.

A few updates include more advanced kwargs support, the ability for salt states to more safely configure a running salt minion, better job directory management and the new state test interface.

Many new tests have been added as well, including the new minion swarm test that allows for easier testing of Salt working with large groups of minions. This means that if you have experienced stability issues with Salt before, particularly in larger deployments, that these bugs have been tested for, found, and killed.

### Major Features

#### State Test Interface

Until 0.9.9 the only option when running states to see what was going to be changed was to print out the highstate with `state.show_highstate` and manually look it over. But now states can be run to discover what is going to be changed.

Passing the option `test=True` to many of the state functions will now cause the salt state system to only check for what is going to be changed and report on those changes.

```
salt '*' state.highstate test=True
```

Now states that would have made changes report them back in yellow.

### State Syntax Update

A shorthand syntax has been added to sls files, and it will be the default syntax in documentation going forward. The old syntax is still fully supported and will not be deprecated, but it is recommended to move to the new syntax in the future. This change moves the state function up into the state name using a dot notation. This is in-line with how state functions are generally referred to as well:

The new way:

```
/etc/sudoers:
  file.present:
    - source: salt://sudo/sudoers
    - user: root
    - mode: 400
```

### Use and Use\_in Requisites

Two new requisite statements are available in 0.9.9. The use and use\_in requisite and requisite-in allow for the transparent duplication of data between states. When a state ``uses" another state it copies the other state's arguments as defaults. This was created in direct response to the new network state, and allows for many network interfaces to be configured in the same way easily. A simple example:

```
root_file:
  file.absent:
    - name: /tmp/nothing
    - user: root
    - mode: 644
    - group: root
    - use_in:
      - file: /etc/vimrc

fred_file:
  file.absent:
    - name: /tmp/nothing
    - user: fred
    - group: marketing
    - mode: 660

/files/marketing/district7.rst:
  file.present:
    - source: salt://marketing/district7.rst
    - template: jinja
    - use:
      - file: fred_file

/etc/vimrc:
  file.present:
    - source: salt://edit/vimrc
```

This makes the 2 lower state decs inherit the options from their respectively ``used" state decs.

## Network State

The new network state allows for the configuration of network devices via salt states and the ip salt module. This addition has been given to the project by Jeff Hutchins and Bret Palsson from Jive Communications.

Currently the only network configuration backend available is for Red Hat based systems, like Red Hat Enterprise, CentOS, and Fedora.

## Exponential Jobs

Originally the jobs executed were stored on the master in the format: `<cachedir>/jobs/jid/{minion ids}` But this format restricted the number of jobs in the cache to the number of subdirectories allowed on the filesystem. Ext3 for instance limits subdirectories to 32000. To combat this the new format for 0.9.9 is: `<cachedir>/jobs/jid_hash[:2]/jid_hash[2:]/{minion ids}` So that now the number of maximum jobs that can be run before the cleanup cycle hits the job directory is substantially higher.

## ssh\_auth Additions

The original ssh\_auth state was limited to accepting only arguments to apply to a public key, and the key itself. This was restrictive due to the way the we learned that many people were using the state, so the key section has been expanded to accept options and arguments to the key that over ride arguments passed in the state. This gives substantial power to using ssh\_auth with names:

```
sshkeys:
  ssh_auth:
    - present
    - user: backup
    - enc: ssh-dss
    - options:
      - option1="value1"
      - option2="value2 flag2"
    - comment: backup
    - names:
      - AAAAB3NzaC1yc2EAAAABIWAAAQEAlY26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd05ochiLoz8aSi
      - AAAAB3NzaC1yc2EAAAABIWAAAQEAlY26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd05ochiLoz8aSi
      - ssh-rsa AAAAB3NzaC1yc2EAAAABIWAAAQEAlY26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd05ochi
      - ssh-rsa AAAAB3NzaC1yc2EAAAABIWAAAQEAlY26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd05ochi
      - option3="value3",option4="value4 flag4" ssh-rsa AAAAB3NzaC1yc2EAAAABIWAAAQEAlY26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASf
      - option3="value3" ssh-rsa AAAAB3NzaC1yc2EAAAABIWAAAQEAlY26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASf
```

## LocalClient Additions

To follow up the recent additions in 0.9.8 of additional kwargs support, 0.9.9 also adds the capability to send kwargs into commands via a dict. This addition to the LocalClient api can be used like so:

```
import salt.client

client = salt.client.LocalClient('/etc/salt/master')
ret = client.cmd('*', 'cmd.run', ['ls -l'], kwarg={'cwd': '/etc'})
```

This update has been added to all cmd methods in the LocalClient class.

### Better Self Salting

One problem faced with running Salt states, is that it has been difficult to manage the Salt minion via states, this is due to the fact that if the minion is called to restart while a state run is happening then the state run would be killed. 0.9.9 slightly changes the process scope of the state runs, so now when salt is executing states it can safely restart the salt-minion daemon.

In addition to daemonizing the state run, the apt module also daemonizes. This update makes it possible to cleanly update the salt-minion package on Debian/Ubuntu systems without leaving apt in an inconsistent state or killing the active minion process mid-execution.

### Wildcards for SLS Modules

Now, when including sls modules in include statements or in the top file, shell globs can be used. This can greatly simplify listing matched sls modules in the top file and include statements:

```
base:
  '*':
    - files*
    - core*
```

```
include:
  - users.dev.*
  - apache.ser*
```

### External Pillar

Since the pillar data is just, data, it does not need to come expressly from the pillar interface. The external pillar system allows for hooks to be added making it possible to extract pillar data from any arbitrary external interface. The external pillar interface is configured via the `ext_pillar` option. Currently interfaces exist to gather external pillar data via hiera or via a shell command that sends yaml data to the terminal:

```
ext_pillar:
  - cmd_yaml: cat /etc/salt/ext.yaml
  - hiera: /etc/hiera.yaml
```

The initial external pillar interfaces and extra interfaces can be added to the file `salt/pillar.py`, it is planned to add more external pillar interfaces. If the need arises a new module loader interface will be created in the future to manage external pillar interfaces.

### Single State Executions

The new `state.single` function allows for single states to be cleanly executed. This is a great tool for setting up a small group of states on a system or for testing out the behavior of single states:

```
salt '*' state.single user.present name=wade uid=2000
```

The test interface functions here as well, so changes can also be tested against as:

```
salt '*' state.single user.present name=wade uid=2000 test=True
```

## New Tests

A few exciting new test interfaces have been added, the minion swarm allows not only testing of larger loads, but also allows users to see how Salt behaves with large groups of minions without having to create a large deployment.

## Minion Swarm

The minion swarm test system allows for large groups of minions to be tested against easily without requiring large numbers of servers or virtual machines. The minion swarm creates as many minions as a system can handle and roots them in the /tmp directory and connects them to a master.

The benefit here is that we were able to replicate issues that happen only when there are large numbers of minions. A number of elusive bugs which were causing stability issues in masters and minions have since been hunted down. Bugs that used to take careful watch by users over several days can now be reliably replicated in minutes, and fixed in minutes.

Using the swarm is easy, make sure a master is up for the swarm to connect to, and then use the minionswarm.py script in the tests directory to spin up as many minions as you want. Remember, this is a fork bomb, don't spin up more than your hardware can handle!

```
python minionswarm.py -m 20 --master salt-master
```

## Shell Tests

The new Shell testing system allows us to test the behavior of commands executed from a high level. This allows for the high level testing of salt runners and commands like salt-key.

## Client Tests

Tests have been added to test the aspects of the client APIs and ensure that the client calls work, and that they manage passed data, in a desirable way.

---

## Salt Based Projects

---

A number of unofficial open source projects, based on Salt, or written to enhance Salt have been created.

### 36.1 Salt Sandbox

Created by Aaron Bull Schaefer, aka ``elasticdog".

<https://github.com/elasticdog/salt-sandbox>

Salt Sandbox is a multi-VM Vagrant-based Salt development environment used for creating and testing new Salt state modules outside of your production environment. It's also a great way to learn firsthand about Salt and its remote execution capabilities.

Salt Sandbox will set up three separate virtual machines:

- salt.example.com - the Salt master server
- minion1.example.com - the first Salt minion machine
- minion2.example.com - the second Salt minion machine

These VMs can be used in conjunction to segregate and test your modules based on node groups, top file environments, grain values, etc. You can even test modules on different Linux distributions or release versions to better match your production infrastructure.

-----END PGP PUBLIC KEY BLOCK-----
```

The SaltStack Security Team is available at [security@saltstack.com](mailto:security@saltstack.com) for security-related bug reports or questions.

We request the disclosure of any security-related bugs or issues be reported non-publicly until such time as the issue can be resolved and a security-fix release can be prepared. At that time we will release the fix and make a public announcement with upgrade instructions and download locations.

## 37.1 Security response procedure

SaltStack takes security and the trust of our customers and users very seriously. Our disclosure policy is intended to resolve security issues as quickly and safely as is possible.

1. A security report sent to [security@saltstack.com](mailto:security@saltstack.com) is assigned to a team member. This person is the primary contact for questions and will coordinate the fix, release, and announcement.
2. The reported issue is reproduced and confirmed. A list of affected projects and releases is made.
3. Fixes are implemented for all affected projects and releases that are actively supported. Back-ports of the fix are made to any old releases that are actively supported.
4. Packagers are notified via the [salt-packagers](#) mailing list that an issue was reported and resolved, and that an announcement is incoming.
5. A new release is created and pushed to all affected repositories. The release documentation provides a full description of the issue, plus any upgrade instructions or other relevant details.
6. An announcement is made to the [salt-users](#) and [salt-announce](#) mailing lists. The announcement contains a description of the issue and a link to the full release documentation and download locations.

## 37.2 Receiving security announcements

The fastest place to receive security announcements is via the [salt-announce](#) mailing list. This list is low-traffic.

---

### FAQ

- *Frequently Asked Questions*
  - *Is Salt open-core?*
  - *What ports should I open on my firewall?*
  - *I'm seeing weird behavior (including but not limited to packages not installing their users properly)*
  - *My script runs every time I run a state.apply. Why?*
  - *When I run test.ping, why don't the Minions that aren't responding return anything? Returning False would be helpful.*
  - *How does Salt determine the Minion's id?*
  - *I'm trying to manage packages/services but I get an error saying that the state is not available. Why?*
  - *I'm using gitfs and my custom modules/states/etc are not syncing. Why?*
  - *Why aren't my custom modules/states/etc. available on my Minions?*
  - *Module X isn't available, even though the shell command it uses is installed. Why?*
  - *Can I run different versions of Salt on my Master and Minion?*
  - *Does Salt support backing up managed files?*
  - *What is the best way to restart a Salt daemon using Salt?*
    - \* *Linux/Unix*
    - \* *Windows*
  - *Salting the Salt Master*
  - *Is Targeting using Grain Data Secure?*

### 38.1 Is Salt open-core?

No. Salt is 100% committed to being open-source, including all of our APIs and the `Halite` web interface which was introduced in version 0.17.0. It is developed under the `Apache 2.0` license, allowing it to be used in both open and proprietary projects.

### 38.2 What ports should I open on my firewall?

Minions need to be able to connect to the Master on TCP ports 4505 and 4506. Minions do not need any inbound ports open. More detailed information on firewall settings can be found [here](#).

### 38.3 I'm seeing weird behavior (including but not limited to packages not installing their users properly)

This is often caused by SELinux. Try disabling SELinux or putting it in permissive mode and see if the weird behavior goes away.

### 38.4 My script runs every time I run a `state.apply`. Why?

You are probably using `cmd.run` rather than `cmd.wait`. A `cmd.wait` state will only run when there has been a change in a state that it is watching.

A `cmd.run` state will run the corresponding command *every time* (unless it is prevented from running by the `unless` or `onlyif` arguments).

More details can be found in the documentation for the `cmd` states.

### 38.5 When I run `test.ping`, why don't the Minions that aren't responding return anything? Returning `False` would be helpful.

When you run `test.ping` the Master tells Minions to run commands/functions, and listens for the return data, printing it to the screen when it is received. If it doesn't receive anything back, it doesn't have anything to display for that Minion.

There are a couple options for getting information on Minions that are not responding. One is to use the verbose (`-v`) option when you run salt commands, as it will display ``Minion did not return" for any Minions which time out.

```
salt -v '*' pkg.install zsh
```

Another option is to use the `manage.down` runner:

```
salt-run manage.down
```

Also, if the Master is under heavy load, it is possible that the CLI will exit without displaying return data for all targeted Minions. However, this doesn't mean that the Minions did not return; this only means that the Salt CLI timed out waiting for a response. Minions will still send their return data back to the Master once the job completes. If any expected Minions are missing from the CLI output, the `jobs.list_jobs` runner can be used to show the job IDs of the jobs that have been run, and the `jobs.lookup_jid` runner can be used to get the return data for that job.

```
salt-run jobs.list_jobs
salt-run jobs.lookup_jid 20130916125524463507
```

If you find that you are often missing Minion return data on the CLI, only to find it with the jobs runners, then this may be a sign that the `worker_threads` value may need to be increased in the master config file. Additionally, running your Salt CLI commands with the `-t` option will make Salt wait longer for the return data before the CLI command exits. For instance, the below command will wait up to 60 seconds for the Minions to return:

```
salt -t 60 '*' test.ping
```

## 38.6 How does Salt determine the Minion's id?

If the Minion id is not configured explicitly (using the *id* parameter), Salt will determine the id based on the host-name. Exactly how this is determined varies a little between operating systems and is described in detail [here](#).

## 38.7 I'm trying to manage packages/services but I get an error saying that the state is not available. Why?

Salt detects the Minion's operating system and assigns the correct package or service management module based on what is detected. However, for certain custom spins and OS derivatives this detection fails. In cases like this, an issue should be opened on our [tracker](#), with the following information:

1. The output of the following command:

```
salt <minion_id> grains.items | grep os
```

2. The contents of `/etc/lsb-release`, if present on the Minion.

## 38.8 I'm using gitfs and my custom modules/states/etc are not syncing. Why?

In versions of Salt 0.16.3 or older, there is a bug in `gitfs` which can affect the syncing of custom types. Upgrading to 0.16.4 or newer will fix this.

## 38.9 Why aren't my custom modules/states/etc. available on my Minions?

Custom modules are only synced to Minions when `state.apply`, `saltutil.sync_modules`, or `saltutil.sync_all` is run. Similarly, custom states are only synced to Minions when `state.apply`, `saltutil.sync_states`, or `saltutil.sync_all` is run.

Other custom types (renderers, outputters, etc.) have similar behavior, see the documentation for the `saltutil` module for more information.

## 38.10 Module X isn't available, even though the shell command it uses is installed. Why?

This is most likely a PATH issue. Did you custom-compile the software which the module requires? RHEL/CentOS/etc. in particular override the root user's path in `/etc/init.d/functions`, setting it to `/sbin:/usr/sbin:/bin:/usr/bin`, making software installed into `/usr/local/bin` unavailable to Salt when the Minion is started using the initscript. In version 2014.1.0, Salt will have a better solution for these sort of PATH-related issues, but recompiling the software to install it into a location within the PATH should resolve the issue in the meantime. Alternatively, you can create a symbolic link within the PATH using a `file.symlink` state.

```
/usr/bin/foo:
  file.symlink:
    - target: /usr/local/bin/foo
```

## 38.11 Can I run different versions of Salt on my Master and Minion?

This depends on the versions. In general, it is recommended that Master and Minion versions match.

When upgrading Salt, the master(s) should always be upgraded first. Backwards compatibility for minions running newer versions of salt than their masters is not guaranteed.

Whenever possible, backwards compatibility between new masters and old minions will be preserved. Generally, the only exception to this policy is in case of a security vulnerability.

Recent examples of backwards compatibility breakage include the 0.17.1 release (where all backwards compatibility was broken due to a security fix), and the 2014.1.0 release (which retained compatibility between 2014.1.0 masters and 0.17 minions, but broke compatibility for 2014.1.0 minions and older masters).

## 38.12 Does Salt support backing up managed files?

Yes. Salt provides an easy to use addition to your file.managed states that allow you to back up files via `backup_mode`, `backup_mode` can be configured on a per state basis, or in the minion config (note that if set in the minion config this would simply be the default method to use, you still need to specify that the file should be backed up!).

## 38.13 What is the best way to restart a Salt daemon using Salt?

Updating the salt-minion package requires a restart of the salt-minion service. But restarting the service while in the middle of a state run interrupts the process of the minion running states and sending results back to the master. It's a tricky problem to solve, and we're working on it, but in the meantime one way of handling this (on Linux and UNIX-based operating systems) is to use `at` (a job scheduler which predates cron) to schedule a restart of the service. `at` is not installed by default on most distros, and requires a service to be running (usually called `atd`) in order to schedule jobs. Here's an example of how to upgrade the salt-minion package at the end of a Salt run, and schedule a service restart for one minute after the package update completes.

### 38.13.1 Linux/Unix

```
salt-minion:
  pkg.installed:
    - name: salt-minion
    - version: 2014.1.7-3.el6
    - order: last
  service.running:
    - name: salt-minion
    - require:
      - pkg: salt-minion
  cmd.wait:
    - name: echo service salt-minion restart | at now + 1 minute
```

```
- watch:
  - pkg: salt-minion
```

To ensure that `at` is installed and `atd` is running, the following states can be used (be sure to double-check the package name and service name for the distro the minion is running, in case they differ from the example below).

```
at:
  pkg.installed:
    - name: at
  service.running:
    - name: atd
    - enable: True
```

An alternative to using the `atd` daemon is to fork and disown the process.

```
restart_minion:
  cmd.run:
    - name: |
      nohup /bin/sh -c 'sleep 10 && salt-call --local service.restart salt-minion'
    - python_shell: True
    - order: last
```

### 38.13.2 Windows

For Windows machines, restarting the minion `at` can be accomplished by adding the following state:

```
schedule-start:
  cmd.run:
    - name: 'start powershell "Restart-Service -Name salt-minion"'
    - order: last
```

or running immediately from the command line:

```
salt -G kernel:Windows cmd.run 'start powershell "Restart-Service -Name salt-minion"'
```

## 38.14 Salting the Salt Master

In order to configure a master server via states, the Salt master can also be "salted" in order to enforce state on the Salt master as well as the Salt minions. Salting the Salt master requires a Salt minion to be installed on the same machine as the Salt master. Once the Salt minion is installed, the minion configuration file must be pointed to the local Salt master:

```
master: 127.0.0.1
```

Once the Salt master has been "salted" with a Salt minion, it can be targeted just like any other minion. If the minion on the salted master is running, the minion can be targeted via any usual `salt` command. Additionally, the `salt-call` command can execute operations to enforce state on the salted master without requiring the minion to be running.

More information about salting the Salt master can be found in the `salt-formula` for `salt` itself:

<https://github.com/saltstack-formulas/salt-formula>

## 38.15 Is Targeting using Grain Data Secure?

Because grains can be set by users that have access to the minion configuration files on the local system, grains are considered less secure than other identifiers in Salt. Use caution when targeting sensitive operations or setting pillar values based on grain data.

When possible, you should target sensitive operations and data using the Minion ID. If the Minion ID of a system changes, the Salt Minion's public key must be re-accepted by an administrator on the Salt Master, making it less vulnerable to impersonation attacks.

---

## Glossary

---

**Auto-Order** The evaluation of states in the order that they are defined in a SLS file. *See also: [ordering](#).*

**Bootstrap** A stand-alone Salt project which can download and install a Salt master and/or a Salt minion onto a host. *See also: [salt-bootstrap](#).*

**Compound Matcher** A combination of many target definitions that can be combined with boolean operators. *See also: [targeting](#).*

**EAuth** Shorthand for 'external authentication'. A system for calling to a system outside of Salt in order to authenticate users and determine if they are allowed to issue particular commands to Salt. *See also: [external auth](#).*

**Environment** A directory tree containing state files which can be applied to minions. *See also: [top file](#).*

**Execution Module** A Python module that contains execution functions which directly perform various system-management tasks on a server. Salt ships with a number of execution modules but users can also write their own execution modules to perform specialized tasks. *See also: [the list of execution modules](#).*

**Execution Function** A Python function inside an Execution Module that may take arguments and performs specific system-management tasks. *See also: [the list of execution modules](#).*

**External Job Cache** An external data-store that can archive information about jobs that have been run. A default returner. *See also: [ext\\_job\\_cache](#), [the list of returners](#).*

**External Pillar** A module that accepts arbitrary arguments and returns a dictionary. The dictionary is automatically added to a pillar for a minion.

**Event** A notice emitted onto an event bus. Events are often driven by requests for actions to occur on a minion or master and the results of those actions. *See also: [Salt Reactor](#).*

**File Server** A local or remote location for storing both Salt-specific files such as top files or SLS files as well as files that can be distributed to minions, such as system configuration files. *See also: [Salt's file server](#).*

**Grain** A key-value pair which contains a fact about a system, such as its hostname, network addresses. *See also: [targeting with grains](#).*

**Halite** The Salt GUI. *See also: [Halite](#).*

**Jinja** A templating language which allows variables and simple logic to be dynamically inserted into static text files when they are rendered. *See also: [Salt's Jinja documentation](#).*

**Job** The complete set of tasks to be performed by the execution of a Salt command are a single job. *See also: [jobs runner](#).*

**Job Cache** A storage location for job results, which may then be queried by a salt runner or an external system. May be local to a salt master or stored externally.

- Job ID** A unique identifier to represent a given *job*.
- Highdata** The data structure in a SLS file that represents a set of state declarations. *See also: state layers.*
- Highstate** The collection of states to be applied to a system. *See also: state layers.*
- Low State** The collection of processed states after requisites and order are evaluated. *See also: state layers.*
- Master** A central Salt daemon from which commands can be issued to listening minions.
- Masterless** A minion which does not require a Salt master to operate. All configuration is local. *See also: file\_client.*
- Master Tops** A system for the master that allows hooks into external systems to generate top file data.
- Mine** A facility to collect arbitrary data from minions and store that data on the master. This data is then available to all other minions. [Sometimes referred to as Salt Mine.] *See also: Salt Mine.*
- Minion** A server running a Salt minion daemon which can listen to commands from a master and perform the requested tasks. Generally, minions are servers which are to be controlled using Salt.
- Minion ID** A globally unique identifier for a minion. *See also: id.*
- Multi-Master** The ability for a minion to be actively connected to multiple Salt masters at the same time in high-availability environments.
- Node Group** A pre-defined group of minions declared in the master configuration file. *See also: targeting.*
- Outputter** A formatter for defining the characteristics of output data from a Salt command. *See also: list of outputters.*
- Overstate** A system by which a Master can issue function calls to minions in a deterministic order. *See also: overstate.*
- Peer Communication** The ability for minions to communicate directly with other minions instead of brokering commands through the Salt master. *See also: peer communication.*
- Pillar** A simple key-value store for user-defined data to be made available to a minion. Often used to store and distribute sensitive data to minions. *See also: Pillar, list of Pillar modules.*
- Proxy Minion** A minion which can control devices that are unable to run a Salt minion locally, such as routers and switches.
- PyDSL** A Pythonic domain-specific-language used as a Salt renderer. PyDSL can be used in cases where adding pure Python into SLS files is beneficial. *See also: PyDSL.*
- Reactor** An interface for listening to events and defining actions that Salt should take upon receipt of given events. *See also: Reactor.*
- Render Pipe** Allows SLS files to be rendered by multiple renderers, with each renderer receiving the output of the previous. *See also: composing renderers.*
- Renderer** Responsible for translating a given data serialization format such as YAML or JSON into a Python data structure that can be consumed by Salt. *See also: list of renderers.*
- Returner** Allows for the results of a Salt command to be sent to a given data-store such as a database or log file for archival. *See also: list of returners.*
- Roster** A flat-file list of target hosts. (Currently only used by salt-ssh.)
- Runner Module** A module containing a set of runner functions. *See also: list of runner modules.*
- Runner Function** A function which is called by the **salt-run** command and executes on the master instead of on a minion. *See also: Runner Module.*
- Salt Cloud** A suite of tools used to create and deploy systems on many hosted cloud providers. *See also: salt-cloud.*

**Salt SSH** A configuration management and remote orchestration system that does not require that any software besides SSH be installed on systems to be controlled.

**Salt Thin** A subset of the normal Salt distribution that does not include any transport routines. A Salt Thin bundle can be dropped onto a host and used directly without any requirement that the host be connected to a network. Used by Salt SSH. *See also: [thin runner](#).*

**Salt Virt** Used to manage the creation and deployment of virtual machines onto a set of host machines. Often used to create and deploy private clouds. *See also: [virt runner](#).*

**SLS Module** Contains a set of *state declarations*.

**State Declaration** A data structure which contains a unique ID and describes one or more states of a system such as ensuring that a package is installed or a user is defined. *See also: [highstate structure](#).*

**State Module** A module which contains a set of state functions. *See also: [list of state modules](#).*

**State Function** A function contained inside a *state module* which can manages the application of a particular state to a system. State functions frequently call out to one or more *execution modules* to perform a given task.

**State Run** The application of a set of states on a set of systems.

**State Compiler** Translates *highdata* into lowdata.

**Syndic** A forwarder which can relay messages between tiered masters. **See also:** *Syndic*.

**Target** Minion(s) to which a given salt command will apply. *See also: [targeting](#).*

**Top File** Determines which SLS files should be applied to various systems and organizes those groups of systems into environments. *See also: [top file](#), [list of master top modules](#).*

**Worker** A master process which can send notices and receive replies from minions. *See also: [worker\\_threads](#).*

**\_\_virtual\_\_** A function in a module that is called on module load to determine whether or not the module should be available to a minion. This function commonly contains logic to determine if all requirements for a module are available, such as external libraries.
